Many of the HEIs works and services departments prepare maintenance budget based on the previous year's budget plus a percentage increase. Some use forecasting, and some use the prevailing prices of materials in the market. However, the best practice is for the HEIs works and services departments to carry out reconnaissance survey of the built environments use the data derived to prepare annual maintenance budget for the built environments. Such budgets are realistic; hence they are derived from accurate and reliable data.

Sustainable Programmes

Most HEIs in Nigeria are characterised with irregularities, such as: epileptic supply of electricity; poor drinkable water supply; poor waste collection, treatment, and disposal system; poor drainage system; poor maintenance budgeting system, and poor maintenance method. In spite of the erratic supply of electricity, majority of them use direct current (use of generating plants), only that poor budgeting system and the delay in releasing maintenance cash hinder the efforts.

Project Quality Control

The researchers recommend the establishment of a Quality Control Unit within each works and services department. Such a unit could be manned by seasoned professionals from the works and services departments plus seasoned professionals from the designing consulting firm. The duties of this unit is: to monitor, control, and supervise the quality of project materials, workmanship, and ensure compliance with all regulatory requirements, advise the production team on issues relating to: cost overrun, and timely delivery of projects. All these could help projects deliveries to time, projects run to budgets, without compromising quality.

i. It is a good practice that each HEI to prepare and operate with maintenance budget. Such maintenance budget could be prepared from data derived from the reconnaissance survey, and letters of complaint from the facilities users. This type of budget could be adequate and reliable.
ii. Each HEI could attach maintenance control toolkit with the budget proposal to the HEI management for approval and prompt release of maintenance cash. Such control toolkit include: Maintenance schedule; Maintenance program me; Jobs specification; Facility register; Maintenance records; and history record of the assets.
iii. Each HEI works and services department could prepare and use sustainable programme for its built environment. Such a programme could include three integrated principal factors, such as: environmental, economic and social. Such a sustainable programme could include: regular supply of electricity; drinkable water; regular waste collection; waste treatment, and waste disposal system; self-cleansing drainage system; preparation and use of maintenance budget; and maintenance method. The existing teaching and learning facilities could be improved upon.
iv. Authorities of each HEI could design a staff developmental programme to train works and services department technical staff. Such staff developmental programme could enable them to perform their official duties satisfactorily.

v. Each HEI works and services department could create a "Project Quality Control Unit" within. The membership of such unit could be drawn from seasoned professionals from among the designing consultants and the seasoned in-house technical staff. In all, the unit could ensure total compliance to all ISO policies on quality of materials and workmanship.
vi. Each HEI could improve on the quality and quantity of facilities being provided to staff offices and Lecture rooms regularly. This could be achieved by carrying out reconnaissance surveys, and letters of complaint from the facilities users.

ABSTRACT

Rework is defined as the non-required effort of redoing a process or activity that was faultily executed at the first time resulting in unsatisfactory completed project subject to cost and time overrun. The susceptibility of building elements to rework in selected higher educational buildings in Nigeria is evaluated using primary and secondary data of 30 educational building projects in the study area adopting the elemental groupings of building component for data collection. Descriptive and inferential statistics were employed in the data analysis using the SPSS version 20 at 95% confidence interval. The Chi-square analysis indicates shortage of materials, poor coordination between design team and members, and poor communication with the design team as leading causes of rework in educational buildings respectively. The Kruskal-Wallis Rank Sum Test shows that all the building elements are significantly susceptible to rework. However the level of susceptibility of individual building elements was found to be between 26% and 40%. It is believed that there is an urgent need to evolve strategies to bring rework to an abysmal level by ensuring the proper implementation of the due process policy and its tenets and the need for the professionals involved on such projects especially the in-house professionals (client's representatives) to do their due diligence in ensuring proper communication of the client's need to the design team to reduce rework to a considerable extent thereby minimizing the financial loss due rework.

INTRODUCTION

Construction industry occupies a focal point in the economy of any nation. It is the driver of every form of development since no sector of the economy can progress without quality and adequate infrastructure which only the construction industry provides. The Construction industry in Nigeria is of great importance as it generates employment opportunity which is second only to Agriculture (Oladinrin, Ogunsemi, and Aje, 2012). Adeagbo (2014) affirmed the capacity of the construction industry to lead the economic growth of the country. The Nigerian Union of Civil Engineering Carpentry, Formwork workers (NUCEFWW)(2015) lamented the huge infrastructural deficit in Nigeria despite the 5.1% contribution of the construction industry to the Gross Domestic Product (GDP) in 2010. This persistent infrastructural shortage in the country is as a result of the many challenges confronting the construction industry prominent of which are time and cost overrun. Others are poor quality construction output resulting from defects, poor quality workmanship and poor quality material to mention a few.

Rework are activities that have to be done more than once or in which work previously executed as part of the project is removed due to error of omission or commission. Rework is a significant factor that does not only affect the construction process but directly leads to client dissatisfaction, reduces profitability and in extreme conditions leads to acrimonious relationship between participants which can either be settled through a recourse to law court or arbitration. According to Love and Smith (2006), it is a major contributor to cost and time overruns in project delivery process. It was also identified as the largest contributor to waste

Ade-Ojo, O. C.; Adewumi, B. O. & Akinola, J. A. (2016). Susceptibility of Building Elements to Rework in Selected Higher Educational Buildings in Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1145-1150

on construction projects (Adewuyi & Otali, 2013). It may occur in any conceived construction project at both the design and construction stages and it may be in the form of variation, non-variation, design error or omission which can be occur directly and indirectly.

LITERATURE REVIEW

Rework in Construction Projects

Construction industry is largely project based with various complexities inherent in the construction process such as dealing with diverse interests of multiple stakeholders and resultant changes. Nandhakumar and Ranjith(2015) rported that in India,30% of construction works are subject to rework with 40-60% underutilization of the labour firce. The study carried out by Ade-Ojo and Babalola (2013) on educational building projects revealed that despite the Due Process Policy in place, cost and time overrun were 18% and 108% respectively. Other studies by Fayek, Dissanayake, and Campero, (2003) proposed a methodology for measuring and classifying rework in construction projects while Palaneeswaras (2006) developed a model for the management of rework in a bid to improve construction project performance. Oyewobi and Ogunsemi (2010), assessing the factors that influence rework occurrence observed that despite the contribution of rework to cost and time overrun, it has not been given adequate consideration. The duo identified technical, quality and human as contributory factors to rework. From these studies it obvious that rework is a phenomenon that has stayed with the industry for long without any serious attention given to its existence. From the foregoing, it can be inferred that rework has been a silent killer afflicting the construction industry all over. However, if it cannot be removed, it can be minimized and its effect on the construction output adequately mitigated. It is in line with the latter that this paper seeks to assess the causes of rework and the level of susceptibility of the various building elements to rework using educational buildings in Ondo and Ekiti State. Construction projects in this sector are wholly financed by the Federal government hence there is full compliance with the procurement regulations. As public institutions funded by the public fund, cost data and contract documentation are easier to access than in other sectors most especially the private sector.

Educational buildings

Educational buildings are buildings designed for various activities in primary, secondary or higher education systems which often include living area for students such as: lecture halls, laboratories, workshop, departmental faculties, offices and many others. The gross building and infrastructural deficit in the Nigerian higher educational institutions has been a thing of concern in recent years. The federal government in November, 2012 set up a Committee on Need Assessment of Nigerian Universities (CNANU) to carry out a detail appraisal of the physical facilities for teaching and learning to determine their capacity and functionality. According to the CNANU (2012) Physical facilities for teaching and learning in the public universities were inadequate, dilapidated, over-stretched and improvised. The committee report noted that one of the major challenges facing university education is the unsatisfactory state of facilities for research and teaching in most Nigerian universities (International organization for Migration - IOM, 2014). Since rework has been identified as a common occurrence in construction project and identified as one of the factors that can degrade construction project performance, its effect on the quantity and quality of building projects in our higher institutions cannot be overemphasized.

METHODOLOGY

A qualitative research approach was adopted for the study. A random sampling of building construction projects within the selected higher educational institutions within Ondo and

Ekiti states was carried out to assess the causes of rework and determine the susceptibility of the building elements to rework. A total number of six and eight higher educational institutions were identified in Ondo and Ekiti States respectively with a total number of five questionnaires administered to the client's representative in each institution under the study.

Stratified random sampling was adopted in the process of data collection. A structured questionnaire with two sections was administered on the respondents. The section A was used to collect secondary data in relation to the project's details while section B was used in assessing information on causes of rework and the susceptibility of building elements to rework. The building element classification according to Seeley (1996) was also adapted for the data collection. Respondents were asked to rank the causes and the level of susceptibility of each building element on an ordinal scale of 1-5. The Likert's scale of 1-5 for least susceptible to most susceptible was used for the purpose of data collection. The importance index rating *(IIR)* was used to determine the level of susceptibility of building elements to rework. The susceptibility rate was then established in percentages from the (*IIR)* (Sambasivan et al., 2007). The chi-square test was carried out to determine the level of significance of the various causes of rework while the Kruskawallis test of significance was applied to establish the susceptibility of the different building at 0.05 significance level.

Causes of Rework in Educational Building

The chi- square analysis in table 1 showed the significance values of the various causes of rework in educational buildings in Ekiti and Ondo states under four different groups. Eleven out of the 23 factors were found to be significant at 95% confidence interval. Lack of fund and poor workmanship were significant under the contractor related causes with 0.015 and 0.020 respectively. Shortage of materials (0.02), poor coordination between design team and members (0.023), and poor communication with the design team were significant causes of rework in educational buildings respectively. The use of poor quality materials was most significant at 0.035 under the subcontractor and contractor related causes. This agrees with Josephson et al (2003) who suggested that poor/faulty manufacturing of material was a main contribution to rework. However in table 2, the design related causes is ranked first with a

mean item score *(MIS)* of 3.78 followed by client related causes, 3.66 *(MIS)*, subcontractor related causes and contractor related causes ranked 3rd and fourth with *(MIS)* of .53 and 3.19 respectively. The implication of this is that rework problems are mostly the result of errors in the design of the project which could be due to omission or commission.

Susceptibility of building elements to rework in Educational Building

Table 4.3 shows the susceptibility index of building elements to rework. From the findings, fittings have the highest rate of rework of 40.27, followed by super structure; 37.75%, substructure;36.73%, external works;35.65%, internal finishes; 35.28 and services,; 33.94% for the group of elements. However the level of susceptibility of building elements is between 26% (site works), lowest and 40% (fittings and furnishings) highest for individual elements. Under superstructure, roof is the most susceptible to rework with 43.81% rate while frames is the least with 29.66%. Communication installations have the highest rate of susceptibility under service with 40% while electrical installation is least with 29.39%. Kruskal-Wallis Rank Sum Test shows that all the building elements are significantly susceptible to rework at 95% confidence interval.

CONCLUSION

In assessing the susceptibility of the building elements to rework in educational institutions, results from the data analysis showed that lack of fund and poor workmanship on the part of the contractor are quite significant in giving rise to rework. Poor coordination between the design team and poor communication with design consultants are also significant causes of rework in higher educational buildings in Ondo and Ekiti States in Nigeria. The study also showed that building elements are quite susceptible to rework with most of the elemental components having up to 40% rate of susceptibility. Considering the huge amount of fund required for building project development and the susceptibility rate of the building elements, it implies that between 26-43% of money invested in these projects are wasted as a result of works that needed to be reworked. The high level of susceptibility of the different building elements to rework should be a thing of concern to all stakeholders in the higher educational building project. In lieu of the foregoing and considering the shortage of quality building and infrastructural development in higher educational institutions in Nigeria, there is an urgent need to evolve strategies to bring rework to an abysmal level by ensuring the proper implementation of the due process policy and its tenets, there is also the need for the professionals especially the in-house professional who serve as clients representative on such projects to do their due diligence in ensuring proper communication of the clients need to the design team. These, if taken into consideration will reduce rework to a considerable extent thereby minimizing the financial loss due rework.

Pedagogic Experience of Spreadsheet Applications to Contemporary Valuation of Property Investments: Perspective of the Federal Polytechnic, Idah

[1*]*Ataguba, J. O. & [1]Ogungbenro, M. T.*

[1]*Department of Estate Management and Valuation, School of Environmental Studies, the Federal Polytechnic Idah, Kogi State, Nigeria*
[*]*josephtgb81@gmail.com*

ABSTRACT

Recent studies have indicated preference for the application of computers in the teaching and learning of property investment valuation. With recourse to the department of estate management and valuation of the Federal Polytechnic Idah, appropriate pedagogies for the application of spreadsheet to contemporary techniques of property investment valuation were identified. Using a combination of narratives and explanatory case study, it was found that demonstrations and case studies are appropriate pedagogies for the delivery of the practical content of the subject matter, while multi-media presentations, lecture-based instruction, tutorials, practical exercises and case studies were found to be appropriate in the delivery of its theoretical content. 57% of students who attempted the compulsory question on spreadsheet application scored below 6 marks in 2013/2014 compared to 63% of students in the 2007/2008 session. Results further indicate a significant improvement in mean score of students who attempted the compulsory question on spreadsheet application to contemporary technique of property investment valuation in 2013/2014 ($p > 0.05$) compared to those who attempted similar question in the 2007/2008 session. The marginal improvement in students' performance in 2013/2014 was attributed to the combination of these pedagogies, availability of adequate teaching resources and personal efforts of students.

Keywords: Contemporary techniques, Pedagogy, Property investment valuation, Spreadsheet, The Federal Polytechnic Idah

INTRODUCTION

Lecturers of property valuation courses have contributed immensely towards teaching their students the rudiments of contemporary property valuation techniques. In view of this, studies relating to estate management education and the changes required for sustained teaching of property investment valuation in the 21st century have been documented (Ali & Alias, 2006; Czarnecka, Sobolewska, Mikulska et al., 2007; Gustafsson & Lundström, 2008; Udoekanem, Adoga, & Kuma, 2013). Furthermore, most higher education institutions offering degree/diploma programmes in real estate/land management across the globe have incorporated courses in computer applications to real estate/property as pre-requisites for graduation (Ali & Alias, 2006; Callanan & McCarthy, 2003; Kampamba, Nkwae, & Tembo, 2015). Specifically Udoekanem et al. (2013), emphasized that the teaching of property investment valuation should be complemented with computer-aided practical. In view of these studies, it is acknowledged that the teaching of spreadsheet applications for contemporary valuation of property investment is indeed a requisite skill for the 21st century valuer in Nigeria. Notwithstanding its being an efficient dimension to the teaching of contemporary techniques of property investment valuation, there is a knowledge gap regarding pedagogic experience of valuation lecturers in that context. The question is: What pedagogies are relevant to spreadsheet applications for contemporary techniques of property investment valuation? This research problem shall be addressed with recourse to the experience of the authors and the impact of these pedagogies and learning resources on the academic performance of students in this context.

Specific objectives of this research include to:

i. examine the curriculum for teaching of spreadsheet skills in valuation;

Ataguba, J. O. & Ogungbenro, M. T. (2016). Pedagogic Experience of Spreadsheet Applications to Contemporary Valuation of Property Investments: Perspective of the Federal Polytechnic, Idah. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1151-1162

ii. identify the required teaching and learning resources;
iii. examine teaching styles deployed by the lecturers; and
iv. evaluate performance of student in the examination.

This study is significant to lecturers teaching property investment valuation and/or computer application to real estate because it unravels innovative ways of course delivery aimed at a successful student-centered learning. The cross breed of ideas and learning process captured in this research would be beneficial to lecturers, students and practicing valuers within Nigeria and other emerging economies of the world as they strive to bridge the digital divide that has plagued the application of computing technologies to property investment valuation.

LITERATURE REVIEW

Estate Management and Valuation Programmes at the Federal Polytechnic Idah

Academic programmes leading to the award of National- and Higher National Diploma in Estate Management and Valuation are offered in the Department of Estate Management and Valuation of the Federal Polytechnic, Idah in Kogi State, Nigeria. Domiciled within the School of Environmental Studies (SES), the department which originally commenced academic activities in the year 2001 is supported by five cognate academic departments comprising Architecture, Building, Surveying and Geo-Informatics, Quantity surveying, and Urban and Regional Planning from where students offer ancillary courses as pre-requisites for graduation.

Both the National- and Higher National Diploma programmes last for a minimum duration of 2 years (The Federal Polytechnic Idah, 2010). In addition, it is required that holders of National Diploma (ND) acquire a minimum of 1-year industrial experience before enrolling for the Higher National Diploma (HND) programme. All programmes in the department have enjoyed sustained accreditation in 2008 and 2014 by the accreditation panel of the National Board for technical Education - NBTE. The department is endowed with vibrant academic staff with postgraduate qualifications, four of whom are registered Estate Surveyors and Valuers.

The Place of Property Valuation as a Subject

Notwithstanding the variation in country contexts for the training of property valuers across the world, there is a consensus that the subject of valuation is central to academic programmes in the property domain (Ali & Alias, 2006; Ashaolu, 2012; Czarnecka et al., 2007; Kampamba et al., 2015). Specifically, the emerging general practice surveyor is taught valuation as a subject and a tool for decision-making with respect to management of property assets, viability appraisal of property development, purchase and sales decisions, property taxation and rating, mortgage and project funding techniques among others. In other words, it may not be out of place to say that valuation is a subject that facilitates understanding of the decisions of stakeholders in the property market.

At the HND level, students are taught a range of intermediate and advanced topics in property investment valuation including the rationale behind property as an investment class which compares with other investments like equities, bonds, and derivative financial assets. It is this fundamental knowledge that drives the use of investment method of valuation which is indeed a specialized body of knowledge within the valuation discipline. With an emphasis on property investment valuation, Udoekanem et al. (2013) recommended the development of a curriculum with practical bias and computer applications for the teaching of contemporary techniques at the university level. This paper addresses the pedagogies necessary to close the gaps in the use of spreadsheets to contemporary techniques of property investment valuation at the HND level in the polytechnic.

Overview of Contemporary Value Models

According to Baum, Mackmin, and Nunnington (1997), all models of property investment valuation are anchored on income capitalization. Differences however emerge in the application of these models such that real cash flows are valued using real discount rates while nominal cash flows are valued using nominal discount (Brown & Matysiak, 2000). Specifically, contemporary techniques of property investment valuation were developed in response to the emergence of the reverse yield gap, which is phenomenon where bond yields are higher than initial yield of property investments (Baum & Crosby, 2007). Figure 1 presents an unambiguous picture of the variants of contemporary techniques and their link with the body of knowledge of investment method of valuation. These techniques evolved from the growth explicit discounted cash flow (DCF), which was originally used for capital budgeting decisions on the basis of net present value (NPV) criterion. Thereafter came the rational model otherwise called the short-cut DCF technique which determines capital value of an interest in property as the sum of term (nominal) rent discounted at the equated yield and the value of reversionary rent which has been adjusted using a growth rate (McIntosh, 1983; Sykes, 1981).

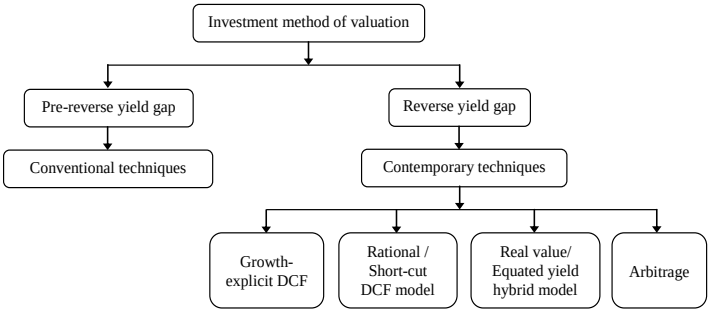

Figure 1: The four major contemporary techniques of property investment valuation

Third in the timeline of contemporary techniques is the real value/equated yield hybrid model (Baum & Crosby, 2007; Crosby, 1983, 1986a, 1986b), which was developed to simplify Dr. Earnest Wood's PhD thesis on real value techniques in 1972. Just like the short-cut DCF technique, the real value/equated yield hybrid model values the term rent of a property using the equated yield, however, the reversionary rent is valued using a proxy of the all risks yield which comprises a 3-in-1 Years' Purchase (YP) formula incorporating the nominal rate of interest (equated yield), period to the next rent review, and real return (Baum & Crosby, 2007).

Informing the development of the arbitrage technique is the notion that tranches of property cash inflows should be discounted in comparison with investments exhibiting similar risk profile (French & Ward, 1995, 1996; Wyatt, 2007). This technique still adopts the convention of term and reversion. Just like the real value model, the term income in the arbitrage technique is discounted using the equated yield, while the reversionary income could be implicitly discounted using a combination of all risks yield and deferred capital yield (real rate of return) (Crosby, 1996; Crosby, French, & Ward, 1997). Alternatively, the implied rental growth can be used to project the deferred capital yield if an explicit valuation of reversionary income is required (Wyatt, 2007).

Valuations produced from these four contemporary techniques have been found to reconcile irrespective of their conceptual variation and input parameters (Crosby et al., 1997). The rationale for such phenomenon is the interrelationship and synergy among input parameters for these techniques.

Except for property investment valuation scholars in Nigeria who might be conversant with the arbitrage technique, it would not come as a surprise that majority of practicing valuers in the country are ignorant of its existence even after nearly two decades since it was developed for the purpose of property valuation. Similarly, the HND curriculum for Advanced Valuation insists on the teaching of contemporary techniques (NBTE, 2002), it was however silent on the treatment of arbitrage. Notwithstanding, the curriculum prepared by the NBTE is only a minimum standard. Hence, valuation lecturers can go beyond that standard in the interest of students.

The Complementary Role of Computer Application Course

Over the years, valuers have utilized computers to handle analytical content of valuations (Dixon, 1986; Dixon, Hargitay, & Bevan, 1991). Specifically, valuers with the requisite computing skills tend to use specific software packages to increase the efficiency of their valuations and analysis. Notwithstanding, Oni (2013) found that the knowledge of ICT application by general practice surveyors in Nigeria stills ranks low when compared to their counterparts in developed countries. While one of the rationales for this digital divide can be traced to the daunting cost of specialist software acquisition and upgrade, it would be appropriate if the emerging valuer is taught how to customize simple spreadsheets to handle tasks in a similar fashion as these proprietary software packages. Hence the pedestal for this ingenious stride is the complementary role of computer application courses offered in connection with degree or diploma programmes in estate management and valuation. Through the incorporation of a course on Computer applications to Real Estate, the curriculum of Estate Management and Valuation programmes in the Federal Polytechnic Idah has been re-designed to avail students with these skills.

Students at the HND level offer EST 418 - Computer Application to Real Estate in the 2nd year of the programme (NBTE, 2002). Goals of this course is to avail students with requisite training on how to deploy computer software packages to address dynamic issues of modern professional practice (valuation, property and facilities management, project management/property development, land administration, and estate agency); and to enhance their employability in organizations with a high taste for office automation. The content of this course include classifications of computer; components of a microcomputer; Meaning and types of software; the use of packaged application software of relevance in real estate; Programming using BASIC; Geographic- and Land Information Systems for Real Estate Practice; and Information and communication technology (ICT) in Real Estate practice. Drawn from the array of topics is an exposition of methods and tools used to teach the application of spreadsheets to contemporary property investment valuations. The essence of this sub-topic under the computer application course is to complement learning outcomes of their advanced valuation courses.

Pedagogies for Contemporary Valuation Models

According to the 6th Edition of the Oxford Advanced learner's Dictionary of the English Language, pedagogy is defined as a study of teaching methods. It is not out of place to say that the teaching of property valuation is appropriately anchored on social constructivism. As a school of thought, social constructivism connotes the combination of teacher-guided and student-centred learning aimed at meeting the competence needs of potential problem-solvers (Westbrook, Durrani, Brown et al., 2013). Problem-solvers in this context comprise a body of professionals (Estate Surveyors and Valuers) who exhibit similar competence, and are bound by the same ethics.

Common pedagogies that are appropriate to the teaching of contemporary techniques of property investment valuation include presentation, group work, and collaboration

(Westbrook et al., 2013); lecture-based instruction, tutorials or challenge-based instruction (Osborne, Miller, & Farabee-Siers, 2008), where training is directed towards solving valuation exercises; physical/video/virtual demonstrations (Raman, 2013; Westbrook et al., 2013); practical exercises and case studies directed towards solving real live valuation problems (Udoekanem et al., 2013), including the use of computers/spreadsheets applications; and field trips to relevant organizations where they can experience the practical applications of classroom activities (Ali & Alias, 2006). Furthermore, pedagogies that facilitate professional practice include apprenticeship and role-playing. While the former is driven by experiential learning of the student, the latter can be organized by the lecturer or tutor to assess readiness of the student to practice what has been learnt in the course of the degree or diploma programme. In order to obtain desired results from the application of these pedagogies, studies have shown that optimal class size and adequate infrastructure for teaching and learning must be put in place otherwise the purpose of teaching and learning would be defeated (Atchoarena & Gasperini, 2003; Westbrook et al., 2013). This underscores why proprietors of educational institutions are expected to avail such institutions with the requisite atmosphere and infrastructure that can drive innovation and scholarship.

Emphasis on Spreadsheet Applications

The layout of contemporary property investment valuations in term and reversion makes it possible to applying computerized spreadsheets. Within the context of computer applications, spreadsheets are software designed to handle the analysis of alphanumeric data arranged in rows and columns (Morley & Parker, 2011), an example of which is Microsoft® Excel® (Dixon, 2007; Harvey, 2006). While teaching spreadsheet applications to contemporary techniques of property valuation, the lecturer assumes that all enrolled students are beginners in the use of Excel®. Prior to handling advanced operations in Excel®, students are taught basic steps of launching the program, data entry and editing, and saving of worksheets.

CONCEPTUAL FRAMEWORK

The conceptual framework for this study is captured in Figure 2, which is essentially a social constructivism of student-centred learning (Westbrook et al., 2013). According to Ball (2002), institutions of higher learning confer reputation for competence on students while imparting knowledge. With the application of appropriate pedagogies, a student would be able to develop sound conceptual skills. Within this context, conceptual skill implies the creative ability of the student to use and manipulate data that applies to specific model of contemporary property investment valuation.

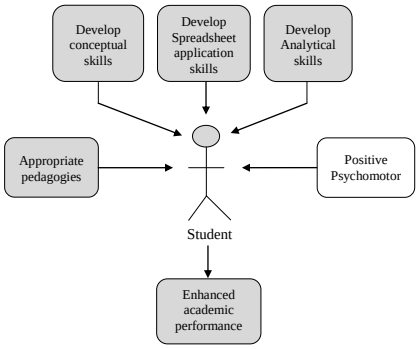

Figure 2: Conceptual representation of the study

Secondly, Figure 2 further underscores the need for the student to develop analytical skills in order to successfully solve problems on the use of contemporary models of property investment valuation. This conception aligns with findings from a related study which emphasized the teaching and learning of quantitative aspects of property investment valuation

(Udoekanem et al., 2013). While Advanced Valuation courses might emphasize manual analysis of data and determination of capital values, appropriate pedagogies for the computer application course would develop spreadsheet application skills of the student in that regard.

Although outside the scope of this study, psychomotor (emotional and mental wellbeing) of a student exerts impact on his/her ability to derive benefits from learning activities and must be accounted for. Given that student-centred learning would avail the student with deep understanding of a topic (Entwistle, Skinner, Entwistle et al., 2000; Postareff, Lindblom-Ylänne, & Nevgi, 2007; Trigwell, Prosser, & Waterhouse, 1999), it is envisaged that when all these concepts are articulated in a student-centred learning, the end product would include sound knowledge of the application of spreadsheet to property investment valuations and an enhanced academic performance of the student.

METHODOLOGY

This study adopts a mixed methodology comprising narratives and the explanatory case study. Narratives essentially imply the use of stories as basis for data collection and analysis (Golsteijn & Wright, 2013). Within the context of this study, the stories were drawn from experience of the lecturer for the course: EST 418- Computer application to real estate as well as inputs from the co-author who taught the same students the rudiments of contemporary techniques of property investment valuation. Secondly, the explanatory case study seeks to examine the relationship among variables (Creswell, 2003; Singh, 2006). The variables in this context are the elements of the conceptual framework identified in Figure 2. Data for this study include the examinations questions on the subject for the 2007/2008- and the 2013/2014 academic sessions respectively; as well as students' scores in those questions.

Students who enrolled for EST 418 in the 2013/2014 class were availed the advantage of using the sufficient departmental computing facilities compared to their colleagues who enrolled for the same course in 2007/2008 (seven years earlier). Currently, the available teaching resources for the course includes magic board, projector screen, multimedia projector, the departmental computer laboratory (which is fully equipped with micro computers), and copies of manual of spreadsheet exercises made available to students. Students were mainly taught how to use Excel® to value property investments with recourse to the Rational/Short-cut DCF-, and the Real value/ Equated yield hybrid models respectively. Prominent among the pedagogies adopted include multimedia presentations, lecture-based instruction, tutorials and case studies. Through demonstrations, the course lecturer further encourages student-centred learning whereby the student independently avails himself/herself the opportunity to try out and master the various computerized exercises in the practical manual.

The total assessment score for EST 418 is 100%, out of which the examination attracts 70%; active participation in computer practical (including spreadsheet exercises) attracts 20%; and a short essay test constituting 10%. Notwithstanding, a compulsory examination question is designed to test the students understanding of the theory and practice of spreadsheet application to contemporary property investment valuation. Data analysis in this paper (measures of central tendency, dispersion, and t-test for difference in mean score) focuses on the compulsory question in the examination, and compares students' performance in the subject during 2007/2008- and the 2013/2014 academic sessions respectively.

FINDINGS AND DISCUSSIONS

Impact of the Pedagogies on Students' Academic Performance

For both the 2007/2008- and the 2013/2014 academic sessions, examination questions in Excel® formula audits were designed to test students' knowledge of spreadsheet applications

to Real value/ Equated yield hybrid- and Rational/Short-cut DCF models of property investment valuation (Figures 3A and 4A). In addition, Figures 3B and 4B are the solutions to the exercises in Figures 3A and 4B respectively.

2007/2008 FIRST SEMESTER EXAMINATION

Study the spreadsheet-extract below for the valuation of a leasehold interest and use it to calculate the variables attributed to each formula in the cell. Thereafter, reproduce a complete spreadsheet for the valuation. [11 marks]

FIGURE 4B: SOLUTION TO SPREADSHEET APPLICATION TO SHORT-CUT DCF TECHNIQUE

Besides the difference in these questions, manual worksheets were distributed to students who sat for the examination in 2013/2014 session contrary to the 2007/2008 session. Questions in Figures 3A and 4A were allotted a total of 11 marks respectively.

Table 1 is the frequency distribution of scores earned by students who enrolled for the course and attempted the questions on spreadsheet applications to contemporary techniques of property investment valuation. During the 2013/2014 session, 57% of students who attempted the question in Figure 4A scored below 6 marks, compared to 63% of students who attempted cognate question in the 2007/2008 session (Figure 3A). This implies that over 50% of students in both cases still have problems grasping and tackling valuation exercises in contemporary techniques notwithstanding improvements in teaching and learning aid. However, 6 out of 71 students scored the maximum of 11 marks allotted to the compulsory question in 2013/2014 session compared to 1 out of 46 students in the 2007/2008 session.

Table 1. Frequency distribution of students' scores for the questions

Band of score	2007/2008		2013/2014	
	Frequency	Percentage (%)	Frequency	Percentage (%)
11	1	2	6	8.5
10.0 -10.5	2	4	3	4
9.0 - 9.5	3	7	3	4
8.0 - 8.5	1	2	5	7
7.0 - 7.5	3	7	8	11
6.0 - 6.5	7	15	6	8.5
5.0 - 5.5	7	15	2	3
4.0 - 4.5	4	9	9	13
3.0 - 3.5	7	15	8	11
2.0 - 2.5	3	7	8	11
1.0 - 1.5	7	15	9	13
< 1.0	1	2	4	6
Total	**46**	**100.0**	**71**	**100.0**

Students' performances in these examination questions were evaluated using measures of central tendency and dispersion (Table 2). Compared to the 2007/2008 session for which the mean score for the question in Figure 3A stood at 4.88 ± 0.41; there was an improvement in 2013/2014 session with mean score of 5.10 ± 0.39. With reference to the 2007/2008 session, the 95% confidence interval of mean score for 2013/2014 session increased marginally by 0.25 and 0.18 for the lower and upper bounds respectively.

Table 2. Descriptive statistics of students performance

Variables	Session	
	2007/2008	2013/2014
Observation	46	71
Mean	4.88	5.10
Median	5.00	4.00
Mode	5.00	4.00
Standard deviation	2.79	3.32
Standard error of mean	0.41	0.39
Minimum score	0	0
Maximum score	11	11
95% confidence interval (lower limit)	4.03	4.28
95% confidence interval (Upper limit)	5.73	5.91

It can be narrated that as at 2007/2008 session when the department was confronted with dearth of useful learning resources, students' overall performance in EST 418 was adversely affected compared to the 2013/2014 session which witnessed an improvement in average score of students in the compulsory question where students were expected to deploy spreadsheet theory to solve simple problems in contemporary property investment valuation.

Besides the application of pedagogies (comprising multimedia presentations, lecture-based instruction, tutorials), the provision of self-study manual of spreadsheet exercises and a fully equipped micro computer laboratory prior to academic activities in 2013/2014 might have contributed immensely to foster student-centred learning and a fairly thorough understanding of spreadsheet application to contemporary valuation of property investment among these students compared to the 2007/2008 session when the department was confronted with dearth of these resources.

Result of the t-test for difference in mean score for both sessions indicated $p > 0.05$, implying a marginal improvement in students' performance in 2013/2014. This result aligns with similar studies conducted by Entwistle et al. (2000) and Trigwell et al. (1999) on the use of student-centred learning; as well as the positive impact of available resources to support teaching and learning (Westbrook et al., 2013). In spite of this marginal improvement, more efforts are desired to ensure that over 60% of prospective students that enrolled for the computer application course (EST 418) are given the ample opportunity to study hard with a view to grasp the concept, theory, and practice of spreadsheet applications to contemporary techniques of property investment valuation.

DISCUSSION OF RESULTS

This section examines the extent to which each research objective has been addressed within the context of the results. In consonance with the first objective, the curriculum for teaching of spreadsheet skills in valuation was found to be embedded in the second year HND course tagged "EST 418" with title designated as "Computer Applications to Real Estate". Specifically, the teaching of spreadsheet applications to contemporary techniques of property investment valuation was drawn from the topic pertaining to the use of packaged application software of relevance in real estate. This current practice within the department aligns with the curriculum of other higher educational institutions offering similar programmes leading to academic qualifications in general practice surveying across the globe (Ali & Alias, 2006; Callanan & McCarthy, 2003; Kampamba et al., 2015).

Secondly, the success of teaching and learning of spreadsheet applications to contemporary techniques of property investment valuation was found to be facilitated by classroom facilities comprising magic board, projector screen, and multimedia projector. Aligning with the norm that the teaching of property investment valuation should be complemented with computer-aided practical (Udoekanem et al., 2013), the study has shown that the successful exercise of relevant pedagogies in this context was anchored on adequately equipped computer laboratory designed to facilitate student-computer interaction, thereby availing students the opportunity to try out and master the various computerized exercises in the practical manual. The implication of this in practice is that the emerging graduate would have been imparted the requisite skill to help bridge the knowledge gap in the application of spreadsheets to contemporary techniques of property investment valuation. Notwithstanding, expereicne shows that majority of the HND students in the department do not have the means to own a low-priced laptop; implication of which is the tendency to lose grip of frequent practice of what they had been taught in the computer application course when access to the computer laboratory become restricted upon their graduation from the polytechnic.

Thirdly, pedagogies within the context of this study predominantly revolves around student-centred learning, which is a social constructivism of how the student can make concerted effort to use available resources to develop conceptual- and analytical skills; and above all, develop spreadsheet application skills for contemporary valuation of property investments (See Figure 2). In consonance with related studies on pedagogies for student-centred learning comprising Westbrook et al. (2013), Raman (2013) and Udoekanem et al. (2013), it was

found that lecturers teaching the course - EST 418 have deployed demonstrations and case studies to deliver the practical content of the curriculum with the intent of encouraging students to independently attempt and master the various computerized exercises in the practical manual. On the other hand, these lecturers have used multi-media presentations, lecture-based instruction, tutorials, practical exercises and case studies to deliver the theoretical content of the curriculum in line with pedagogic practices outlined in related studies credited to Osborne et al. (2008) and Raman (2013). The combination of these pedagogies provides a balance in the teaching of practical- and theoretical content of spreadsheet application to contemporary techniques of property investment valuation.

Pursuant to the deployment of a combination of these pedagogies outlined above, data analysis was concluded with a comparison of students' performance in the compulsory examination question designed to test their knowledge of the concept, theory, and practice of spreadsheet applications to contemporary techniques of property investment valuation. Results indicate a significant improvement in mean score of students who attempted the compulsory question on the subject matter in 2013/2014 ($p > 0.05$) compared to those who attempted similar question in the 2007/2008 session. This finding generally underscores the positive impact which the availability of educational resources could exert on students' academic performance (Westbrook et al., 2013). Notwithstanding the improvement in teaching and learning aids in 2013/2014, over 50% of students (who scores below the average mark) were found to have a weak grasp of the solution to the compulsory question - a phenomenon which might be attributed to weak efforts and poor learning habits.

RECOMMENDATIONS

The following recommendations are put forward in connection with the results discussed above:

i. It is expedient that lecturers of valuation and computer application to real estate at all levels of higher education in Nigeria should adopt these appropriate pedagogies with the intent of stimulating and sustaining the interest of their students towards learning how to apply spreadsheets to contemporary techniques of property investment valuation; and
ii. Proprietors of educational institutions should take a cue from the experience narrated in this study and sustain the provision of nascent academic resources that would enhance the teaching and learning of computer-aided valuation of property investments.

CONCLUSION

Motivating this study was the knowledge gaps of valuation lecturers in Nigeria pertaining to the relevant pedagogies for the application of spreadsheets to contemporary techniques of property investment valuation. With emphasis on the experience of the authors in the teaching of spreadsheet applications in this aspect of valuation, it has been discovered that multimedia presentations, lecture-based instruction, demonstrations, tutorials, and independent learning are important pedagogies capable of enhancing the academic performance of students in this context. For the study area, the marginal improvement in students' scores within this context might be sustained through a synergy of these pedagogies with student's mental and physical effort towards applying spreadsheets to contemporary techniques of property investment valuation.

Drawing Pre-knowledge and Design: A Case Study of Year Two Undergraduate Architecture Students of Ahmadu Bello University

Ohambele, C. C.[1*]; Maina, J. J.[2]; Stephen, H.[3] & Okafor, C. A.[4]

[1-4] Department of Architecture, Ahmadu Bello University Zaria, Nigeria
[*] ohambel@yahoo.com

ABSTRACT

Pre-knowledge is the potential skill acquired before entering school or before its relevance is put to use, which aids, enhances or augments education. Drawing is an inevitable aspect of the architectural education and design and the ability to graphically present cognitive design proposals to physical entities is an essential skill for all architects. This research assesses the drawing pre-knowledge of 53 year two undergraduate students in Ahmadu Bello University. The survey provided information on the students' ability to convey cognitive and physical realities on paper via drawing. A relationship was also sought between grades in design related courses/tasks, preferred techniques for graphical representation as well as demographic data through questionnaire responses. Study findings reveal that many students are yet to achieve mastery in free-hand drawing as a technique for representation. No relationship was observed between their semester grades in design related courses/tasks to their inherent ability to draw. It was also observed that, although some of the students didn't find free-hand drawing as the most suitable technique for representation, they engage in it because it is required of them by the curriculum. The implication of these findings on architecture education and design is that the sample set of students surveyed lack satisfactory drawing pre-knowledge prior to entering the School of Architecture. The paper recommends that Schools of Architecture need to emphasize the need of free-hand drawing exercises as part of admission entry requirements and in early formative years of training in order to improve the cognitive design skills requisite for quality architecture education of future architects.

Keywords: Drawing, pre-knowledge, architecture education

INTRODUCTION

Foreknowledge/Pre-knowledge "is the awareness of something before it happens or exists." (Oxford English Dictionary, 2003). In architecture, having foreknowledge of the profession means to have burgeoning understanding of the design ideas, representation techniques and artistic inclinations that would supplement the formal education to be received in the classroom. In the case of prospective architecture students, it is adequate that such, has a synoptic idea on the rudimentary knowledge of the course and the architectural skills that may aid in the pursuit of his/her professional career.

The core course in an architectural curriculum is design (Cikis, 2009). If any student be unsuccessful in this course, both peers and educators may perceive he/she as being architecturally blunt. Both students and educators perceive this as the central aim of being in the professional course (Adedapo, 2012). The essential method of designing is drawing, either in virtual reality or on crude surfaces.

Bhzad (2013) explains that, the extent of ingenuity expressed by any student, depends partly on the student's ability to conceive a new idea or approach to solving a problem and not necessarily produce a wholly creative one. (Yi-Do & Gross, 1996) says design requires reasoning, expressing ideas, making decisions, evaluating and verifying proposals and finally proving decisions, a similitude in all problem-solving activities. Because architectural education depends greatly on ideas, the backbone for the interpretation of these ideas are usually visual representations and verbal expressions, which the former takes preeminence. In addition, Adedapo (2012) explains that, the various elements of architecture within their local

Ohambele, C. C.; Maina, J. J.; Stephen, H. & Okafor, C. A. (2016). Drawing Pre-knowledge and Design: A Case Study of Year Two Undergraduate Architecture Students of Ahmadu Bello University. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1163-1174

environment would most likely creep into their own design performance and expression unconsciously.

Rationale

Other literature have tried to ascertain the role of drawing; by highlighting the cognitive complex development of the students' mind and their relationship with individuals gender, Cherney (2006). While others have discussed on the characteristics associated with drawings (and other media), and it's figures' relationship in relation to its designers socio-cultural environment. Others have investigated the effect of pre-knowledge and their enthusiasm in graphical representations and the total architectural education (Nazan Kirci, 2013). It is however not clear the extent pre-knowledge of drawing skills play in architectural design output of students.

Purpose of the Study

This research would try to highlight an important architectural representational skill: free-hand drawing, which is essential to succeed for an architecture student in his/her pursuit. This research aims to assess and establish the impact of foreknown drawing skills on individual architecture students of the Department of Architecture, Ahmadu Bello University Zaria as a case study.

Research Questions

So this research would try to answer:

i. What relationships exist between the cognitive realities perceived in the mind, the physical realities, and the drawing capabilities of architecture students?
ii. What roles drawing foreknowledge have on graphically oriented architectural courses of undergraduate architecture students?
iii. What other factors could affect the architectural design of students?

Research Objectives

i. Determining the possible relationships that drawing foreknowledge and architectural design and graphics may share and;
ii. Determining the relationships that may exist between the architectural cognitive realities, architectural physical realities and its influence/s on students drawing capacity.
iii. Investigating any other factor that could influence architectural design.

LITERATURE REVIEW

Pre-knowledge

The term Pre-knowledge a synonym for fore-knowledge has a generic meaning. It isn't a technical term in architecture nor does it have any direct relationship to architecture. (Oxford English Dictionary, 2003) explains foreknowledge as, "the awareness of something before it happens or exists". This meaning only delineates foreknowledge as an aforehand premonition of an event prior to its occurrence.

In architecture, for a student to be considered as being trained in this honourable profession, design is inevitable. Architecture student's design is defined by (Schneider et al, 2013), as "architects putting themselves in the perspective of a buildings future users to predict the likely patterns of use in these buildings, concurrently generating shapes and forms that corresponds to the expected users' needs." This definition highlights the property of an architect: that is, one's ability to dabble with one's imagination; an ability to create a virtual imagery of his/her creative reality and exist in it, while juxtaposing the users convenience in such virtual reality. This quality of an architect; if found in any student, gives such an

upperhand over others. This argument is also supported by (fallingwater, 2015), defining architecural design as, "necessary step to take in designing any structure… been able to imagine such structure in the mind before transmitting it to paper…". Not to deviate, Cahtarevic (2008) describes representation as '…the act of producing virtual reality and involving the spectator into the pictorial space (…) Providing some kind of psychological involvement and transfer of the spectator into the space in the picture.'. Likewise (Yee) says; architectural "renderings" (representation) are the composition of various linear elements of a building to provide an imagery that could better relate to the three dimensional environment that is appreciated by everyone. To support this; while discussing on the necessary tools necessary for future professional architects, (Alagbe, 2014) says,"…they must have adequate hands-on experience on manual drafting to enhance their design creativity…".

Architectural Design

Adedapo (2012) says within the architectural educational curriculum, architecture students' design is given paramount importance; that's why it is a major form of assessment by jury. This is often because, design is a major course taken by students, which exhausts most of the lecture hours of the student.". Graphical/Visual representation, (Yi-Do & Gross, 1996) explains that, its role in design problem solving is of paramount importance. Representations are the fruits of perception. In order for raw data to be shaped into a coherent whole, they must go through the process of filtering and organization, yielding a structured representation that can be used by the mind for any number of purposes (David J. Chalmers, 1991).

Graphical Representation

Sketching is still the quickest and the most direct means to produce visual representation of ideas" (Ellen, 1996). This aspect of the architectural training is so important as it was also part of a questionnaire set in a somewhat similar study, which asked first year architecture students if they had pre-knowledge of any representation technique prior to entering the university? 78% responded in negation to this p.620 (Nazan Kirci, 2013). This caused the researcher conclude that, "the language of architectural practice is a little known subject among architecture students prior to studying architecture" pp.620-621 (Nazan Kirci, 2013). We would in this study focus on sketching as a means of representation.

Grading drawings

It is a norm to find grading of artworks like drawings impossible. No wonder (Linda, 2008)says 'Many have assumed its judgement to be subjective, because the different drawings are produced by unique individuals with a personal understanding in their perception of art'. Because the educators themselves are human, they follow different rubrics in judging artworks. Stating also that,certain sundry efforts have been made to ascertain and lay down certain paradigms for grading drawings, by assessing the qualities of the work such as:

i. Choice of subject .
ii. Handling of media
iii. And control of the composition

But one bane that (Cikis & Cil, 2009.) says pertaining assessment by numerous mentors is the use of "a particular conceptual framework", and any deviation from the stipulated criteria is often poorly rewarded. Likewise, the framework may be ambigiuos, giving room for hidden criteria to operate during assessment, discouraging ideas outside this framework. So for the case of this research, the method of assessing drawings would be chosen from one below;

i. *Limitless members of jury*: where decision is based on arbitrary choice from a sample of public opinion. No particular rubric is provided as a guideline, except the quality observed by the viewers in response to personal choice (bias).
ii. *Sole jury:* this is observed in single classroom settings, where a particular educator is assigned to a number of students to educate them in a particular subject or subjects; where such is left with the sole responsibility of grading, assessing and assigning tasks to them.

METHODOLOGY

Sample selection

Students of architecture department Ahmadu Bello University, Zaria are the case study for this research. The following criteria for sample selection was considered to achieve the best stock,

i. Offered a graphical course either in the university or before coming to the university.
ii. Seen one or more of their semester results on architectural design or graphics.
iii. Current drawing skill from their pre-university education.
iv. The lowest influence in design by their school of architecture.

The only category of students to have fit into these criteria was the second year undergraduate (200 level) students. They were the only category of students who had surface alterations in their design concepts or understanding, compared to their immediate juniors who were, as is in line with the department's curriculum still taking majorly science related courses. Their senior colleagues were doubtful a choice because, their years of consistent mentoring with the architectural precepts would have permeated them.

Questionnaire

A questionnaire was the medium of survey that was used to obtain information of the respondents' level in school, age, and graphical subjects taken while in secondary school; if it was technical drawing or fine art. Also, information concerning the respondents' present level of familiarity with architectural software. It also obtained what method of representation they may prefer, either free hand or technical drawing, sculpting out in 3-Dimensional forms or painting/drawing in 2D forms, likewise previous grades on architecture design and graphical oriented courses were obtained. The respondents were asked to draw a realistic perspective of their observed space and an abstract façade, in order to relate both results. To support this, another practical example was given: they were asked to assume most accurately the height of the researcher and the headroom of the space they were in, in the familiar measurement: which is millimeters. To verify what aspect of design they were passionate about, they were asked if they preferred working drawing to presentation drawing. All these was taken to assess their inclination to generic aesthetical graphics, and note if any coherence existed between their ability to relate proportionally reality viewed on to surfaces. For other subsidiary factors to be considered, they were required to indicate if they were right-handed or left-handed. Other questions include, their personal preference to what aspect of the design process seemed most difficult. Understanding user functions within space and implementation in their designs; adopting an abstract concept and implementing it into design was also enquired. Similarly, it enquired if they (the students) were satisfied personally with their present level of design creativity and those of their colleagues; and if the school of architecture was making the design process easier for them to express themselves using the graphical skill they found most familiar with.

Grading drawings

The questionnaire required assuming the physical height of the researcher, so the researcher stood at a conspicuous position in front of the class. In addition, the researcher was hands on

to collect the filled questionnaires and answer any other questions they may have concerning filling it. Only 53 respondents were assessable. Seven senior colleagues within the department were chosen to grade the respondents' drawings on a scale of ten, because of their obvious exposure to architectural precepts over the sample population, guided by its obedience to proportionality; balance; graphical prowess and ability to emphasis depth, height and contrast as well as to follow the principles of drawing/design.

Analyzing Questionnaire

The questionnaires were analyzed and converted into information. The collected information was collated, produced and represented using figures and tables showing a brief summary of the entire provided data. These information were interpreted aided by literature to support or negate the provided study's assertion.

FINDINGS

Sample Population

As we have stated above, based on the criteria given, our choice of sample population was obvious. The second year undergraduate class---that is the 200 level students---based on reliable information from statutory personnel of the department, as at the time of this research stood at 86 students. Nevertheless, as is a norm: the amount of questionnaires given do not usually come back perfectly assessable. The overall acceptable and assessable questionnaires that were returned stood at 53, which is 61.6% of the 86 questionnaires handed out.

Results

It was obtained that 77% of the students had undertaken a graphical course; based on this study: fine art or technical drawing which could better enhance their graphical capacity. Thus, a high probability for the students to have a good foundation in graphics representation, which makes graphical courses easier for students to engage in. So it was observed that 54% of the students, were satisfied or had gained mastery with the technique of representation that they had taken as a course in their pre-university education. In essence, they were satisfied with their pre-university graphical exposure. It is also observed that 23% of the students were not interested or had not attained mastery in the graphical technique they took as courses while in Secondary School. Meaning: the graphical technique they preferred to engage in were not the same graphical subjects they were taught back in Secondary School. For example, a student who took fine art as the only graphical subject in secondary school would prefer to use technical methods rather than an arbitrary method such as a free hand drawing to illustrate their cognitive ideas or representations. Also results showed that 45% of the students partook in the drawing exercise, highlighting the fact that not all the students who are free hand artist are always ready to draw when the need arises. Another observation was that, among these students that partook in the drawing exercise, only 20% of these students who received fine art training partook in this exercise: an anomaly. Meaning that 80% of these students were available to draw even though it may not be their strong points. This finding reinforce formerly iterated literature that, free-hand drawings still maintains its basic role as the fastest and easiest way to relate realities on surfaces.

It was observed that 60% of the students that took part in the drawing exercise would most likely draw with free hand when availed the opportunity, contrary to the technical courses they undertook while in Secondary School. This implies that, since drawing by free hand is of public demand, the school of architecture should imbibe fine art or its relative as prerequisite for admission. Further information revealed that despite the students' inadequacy in free hand graphics, they are getting trendy with application software that are useful for graphical representations.

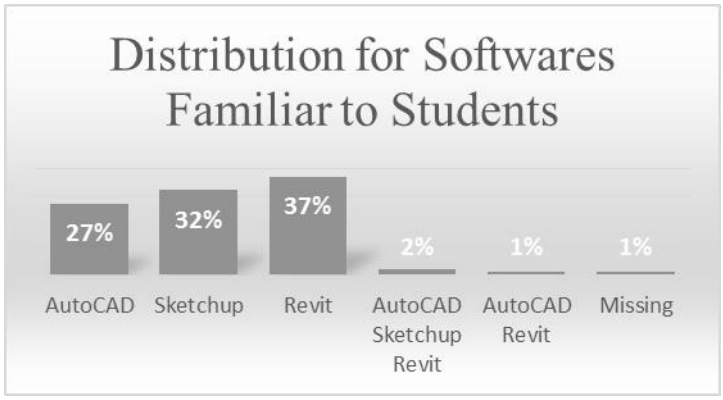

Figure 1. Distribution for Software Familiar to Students

Results revealed that at 96% of the total number of students have gained some level of familiarity with at least an architecturally inclined software. This further proves that, although their capacity to adopt the fastest way of representation, which is drawing, they have sought to adopt other modes of representation that appeals to them. From both instances, they seem to have fallen short of expectations.

As shown in Figure 1. Average scores obtained by students' interior perspective was 2.08 and in building's façade was 2.72.

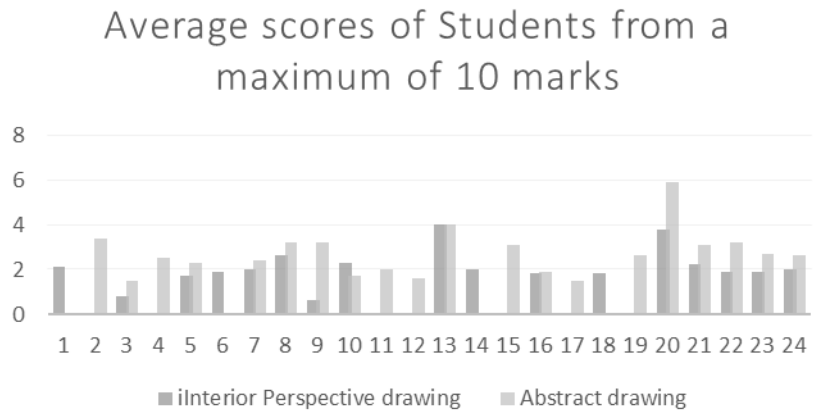

Figure 2. Distribution illustrating students' average scores in drawing task

This insinuates that, the students would have a greater edge in drawing cognitive abstract views rather representing visual realities unto paper. Implying that, any of the students from this sample population if picked at random, cannot fully represent architecturally or otherwise, realities either in the cognitive or real on to surface for others to appreciate its full context. So, this particular set of students inclined to free hand and those that claim mastery in this skill are not impressive drawers as they claim to be. From research it was also observed as shown in Figure 2. That in their curricular course; architectural design, almost all the students of this class are averagely good, while in architectural graphics, there are two extreme divisions of students: those that pass it with distinction and those that fail it woefully. If this result is compared to former results, there seems to be a correlation. Implying that the grading method adopted by this school of architecture at present is dependable when compared to the other methods of grading drawings.

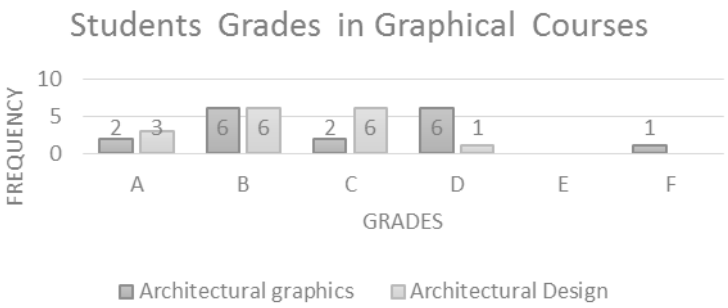

Figure 3. Distribution of frequency for Students' grades in architectural courses requiring graphical representation

The students indicated that they preferred presentation drawings than working drawings, given a consistency in their average scores in the drawing exercise. The students maintained a neutral stand when asked what their capacity to relate physical realities on to paper was; implementing abstract concepts in to their design and appropriating the users' need within the design.

Other results showed that the students were able to determine proportionately what dimensions their physical realities were, but unable to represent this dimensions relative to other elements of the physical reality on to surfaces through sketches.

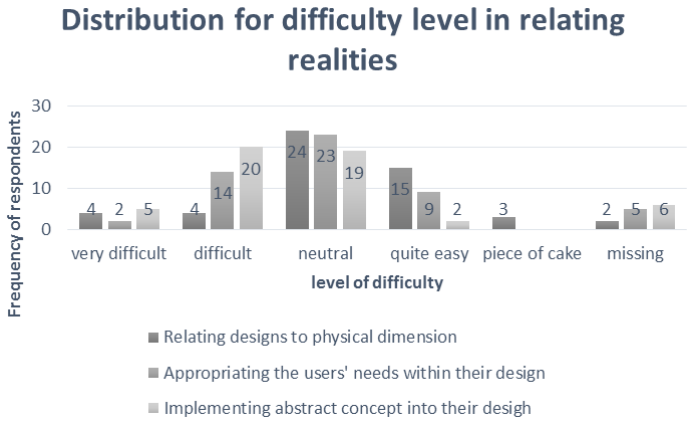

Figure 4. Distribution for difficulty levels in relating realities

Also, their ability to assume proportionately the sizes of animate and inanimate elements within their physical environment was tested and it provided the results Figure 5. It revealed that a larger sample of the class would assume almost exactly the dimension of an animate element than the other.

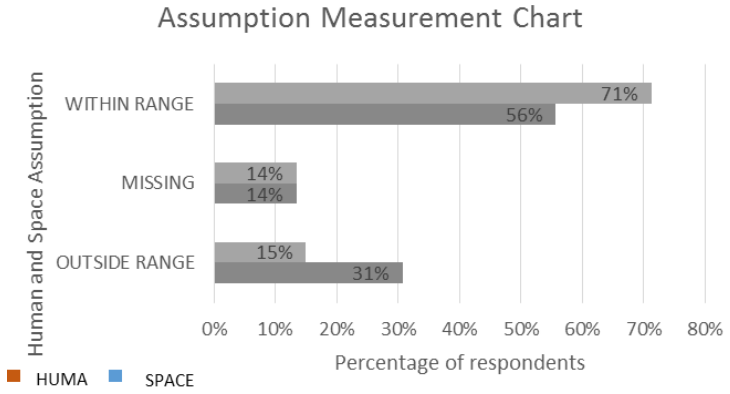

Figure 5. Assumption Chart

An awesome fact obtained from the research indicates that left handed students preferred presentation drawings and were able to relate elements within their physical realities proportionately. But data for right-handed students did not give a particular assessable pattern.

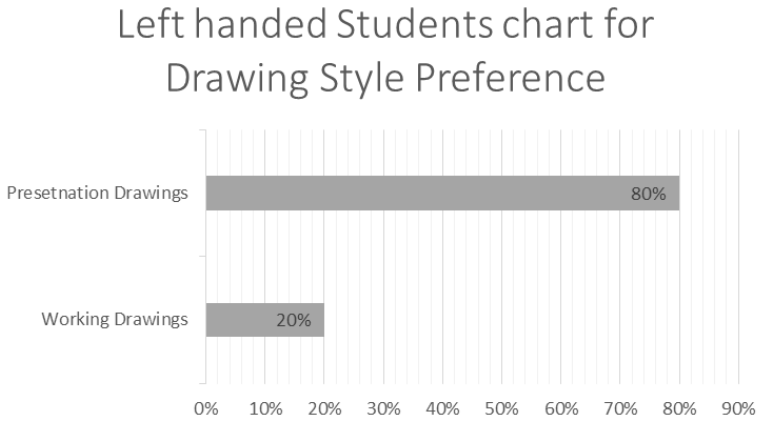

Figure 6. Left-handed Students Chart for Drawing Style Preference

The students were asked to state their level of satisfaction pertaining their state of creativity. Their response as shown in figure 7. Their classmate's level of creativity and the level of freedom to express themselves architecturally, their response was that of dissatisfaction and satisfaction: which I wish to denote as a state of confusion.

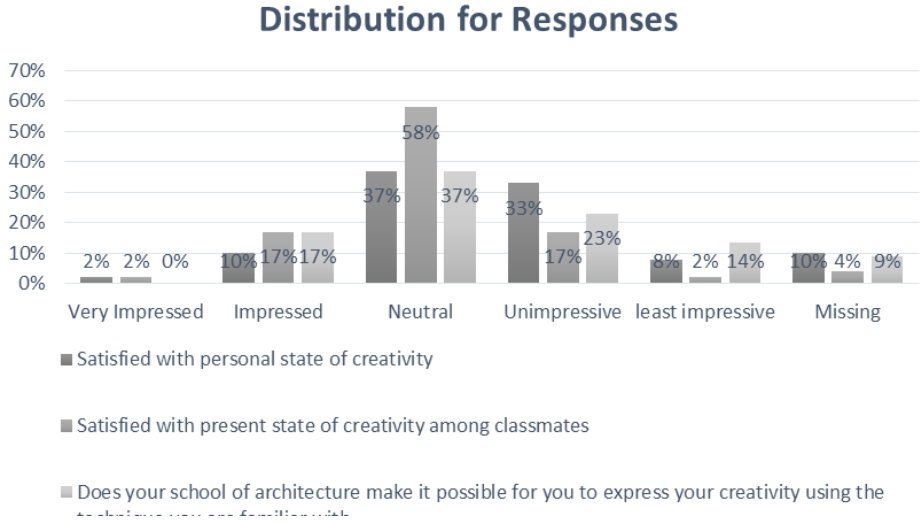

Figure 7. Distribution for Responses

Therefore, in relation to the objectives we set out with from the beginning; we could see that drawing as a pre-knowledge for entering an architecture school is integral and the students know this. But in its relation to the two graphically oriented courses: architectural graphics and design, their individual grades seem not to follow any pattern when collated and analyzed with their drawing capacity. Likewise, the research showed that students were unable to relate their physical realities on to surfaces through drawings but had good *photometric* capabilities. When posed with an opportunity to express their thoughts or physical environment graphically, they will find it difficult.

CONCLUSION

From the onset, we sought to answer questions as regards students drawing pre-knowledge and one of these was "what relationships exist between the cognitive realities perceived in the

mind, the physical realities and the drawing capabilities of architecture students?" The research showed that the students found it difficult to translate cognitive or physical realities on to paper, and were well aware of this fact. This was observed in the students' defiance to perform a sketch, although, quite a number of the students claimed to have attained mastery in a particular representation technique. The study showed that a number of students that had taken a graphical subject while in secondary school were unwilling to adopt the learnt technique in tackling any drawing exercise. The research also highlighted the fact that the students were able to presume dimensions by sight, but were incapable of representing these perceived dimensions on to paper proportionally. Regarding the research question that seeks to determine "what roles drawing foreknowledge has on graphically oriented architectural courses of undergraduate architecture students?" From study, we noticed that students were well below average in architectural representations in relation to commendable graphics and design, but felt they were twice as good in these courses. Approximately 80% of the students claimed to have obtained some form of formal training in at least Fine Arts or Technical Drawing, thus enforcing the role that any technique for representation would play in augmenting the received architectural education. Likewise, other factors that could affect the architectural design of students within this research, was that students would very well prefer arbitrary graphical works than they would architecturally essential working drawings. Thus, students would prefer an uncoordinated format for representing their drawings than the stiffened method for architectural representation. And it was observed that left-handed students preferred free-hand graphically oriented tasks than coordinated technical drawings.

Alternate Interpretations

The population used in this study were only a sample of the many levels of the undergraduate students. If this research were to be carried out on other levels of architecture within the institution, we may obtain a contrary result or confirmation. Talk more of other sample students within the global architecture schools. Criteria such as socio, cultural, religious or educational backgrounds may play very strong roles in determining the end results of the research.

The results provided may yield quite different results, if aspects of the questionnaire such as the drawing were graded by other persons within the society who had little or no affiliations to the architecture field and perception. Their unconscious individual bias for standards in accepting a drawing as obeying proportionality; balance; graphical prowess and ability to emphasis depth, height; and this ability is dependent on the individuals understanding of these terminologies.

Based on the method of assessment chosen to analyze the provided data within respondents questions, like the drawings made by the students. The grades supplied by the graders could be challenged on several fronts such as; drawings have no standard rubric to be followed during grading.

Also, the students may have misinterpreted the need for the questions contained in the questionnaire. The provided information may have been flawed by the respondents due to misinterpretation of the entire purpose of the research. Students may have filled the questionnaire through public/peer choice or in a bid to impress or downplay the research process, thereby reducing the potency of the entire purpose of the research.

Likewise the students' predisposition to presentation drawings than working drawings may not suggest their inclination to engage in the former than the latter. As it is not everything that a person admires that such can engage in.

Study Limitations and Recommendations

There seemed to be scarce literature to support in direct terms most of my terminologies in relation to architecture. As little has been done in this field. During the process of dispensing questionnaires, a few of the students were initially unwilling to fill my questionnaires. Likewise, some of the students found engaging in a drawing exercise quite rigorous. Therefore, unless the drawing exercise is extremely relevant, do not proffer it in a questionnaire survey. In terms of analyzing the data, I had difficulty getting appropriate personnel that would grade my questionnaire drawings. As most lecturers whom I first reached out to, declined involving in giving grades to enhance the instrument of grading. When undertaking a survey, guarantee the commitment of personnel that would grade the drawings prior to handing out the questionnaire.

ABSTRACT

A school is an environment where knowledge is acquired at various levels. The buildings or environment where this knowledge is acquired is as important as the knowledge itself. With the prevalence of secondary schools established often within residential quarters to cater to the needs of the Nigerian populace, it has become imperative that research explores the impact of building typology/environments on academic performance of students. This study evaluates this relationship within two schools in Sabon Gari Zaria; First Baptist High School and Top Spring School. A survey of 232 senior secondary school students as well as physical measurements/documentation of both schools was used to obtain the students' view of their school building, how it affects them and if their school building was built for school purposes or not. Interviews were also conducted to get more information from the students on the subject matter. The data was analyzed using IBM SPSS® 21 for descriptive statistics from questionnaire responses. Study findings reveal that performance of students would improve with the provision of adequate and conducive school environment with emphasis on facilities such as classrooms and toilets. It further revealed that good indoor air quality, good visual comfort and sufficient space within and outside learning spaces are factors that affect performance of students amongst others. The implication of these findings to designers is that the building typology (be it originally residential or institutional) plays a significant role in the overall academic performance of students in the study area.

Keywords: School environment, Academic Performance, Building Typology, Senior Secondary School Students

INTRODUCTION

With the increase in the population of Nigerians there is high demand on infrastructure, social amenities, housing needs, schools, jobs etc. to cater for the growing population. The educational sector being one of the many sectors in economic development of a nation has evidently felt a lot of pressure in seeing to it that education is served to all (Olaniyi nd). Secondary schools being an intermediate institution as a point of emphasis have increased overtime from the past and presently we have more than 11000 secondary schools as at 2013 in the country with a greater percentage been private schools (Federal Ministry Of Education, 2014). Overtime research has explored the maintenance of the facilities within school buildings like classrooms, libraries, laboratories, workshops, assembly halls, toilets, sickbay etc. and how their deterioration affect the students and have identified problems such as inadequate funding, inadequate facilities, low staff morale, poor supervision of schools, frequent changes in policies, environment etc. as major factors that affects students' performance (Timilehin, 2010 and Matthew, 2013). Little has been done to ascertain the number of schools that are properly designed and have the minimum facilities required in a secondary school let alone its maintenance and policies to evade its deterioration.

In a bid to meet the educational needs of the people most school buildings are not really designed for institutional purposes and often times residential buildings are converted to schools as is the practice in Zaria. The main situation is that such building clearly lacks some of the basic facilities needed for proper learning which affects the performance of the users. In schools it is agreeable that the greater percentage of its users are the students but scarcely are their opinion sought on matters of this sort that affects them directly like how comfortable they are, what could be done better to help improve their performance etc. Winston Churchill

Okafor, C. A.; Maina, J. J.; Stephen, H. & Ohambele, C. C. (2016). Impact of School Environments on Academic Performance: Feedback from Senior Secondary School Students. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1175-1182

once said "we shape our building therefore our building shapes us". The school environment is shaped by designers and as such how comfortable and conducive the environment is, directly leaves an imprint on the performance of its users (Arong & Ogbadu, 2010 and Chukwuemeka, 2013).

Research questions posed by this study are:

i. What spaces and architectural design considerations would influence students' performance?
ii. Is there a difference in performance level of students from both schools with different building typology?

The paper is organized in six parts after the introduction. Section 2 reviews literature on spaces /facilities required in a secondary school building and design principles that would enhance comfort and improve students' performance. Section 3, 4 and 5 describes the methodology, findings/discussions and conclusion from the survey. References are contained in section 6.

SCHOOL BUILDING TYPOLOGY

School building typology refers to the type of school buildings obtainable in architecture. This could be classified either based on the evolution/period of construction or based of stages of education which is primary, secondary and tertiary either ways the needs, scales and sizes are different depending on the number of users. According to the Salford Centre for Research and Innovation (SCRI) report, it laid emphasis that school building typology explored three basic things: the plan and envelope of the building, the design principles for school buildings and the spaces required (Peter, & Yufan, 2009).

Plan and envelope

The plan and envelope of a school building describes the design of the building, its surrounding and the measures taken to ensure that the school is conducive for learning which enhances the academic performance of the students. Building envelope is a very important component which affects heat gain and transfer within a building and also the general comfort level in the building. The building envelope separates the internal and the external environment and serves as an outer shell to protect the indoor environment from adverse weather conditions. Mohammed (2010) emphasized that various design elements which includes wall colors, window surfaces, interior common spaces, courtyards etc. contributes to the aesthetics of the school environment which in turn creates a comfortable environment for the students and improves academic performance.

Space requirement of school buildings

Spaces in a school building refer to the usable space required for academic and extra curricula activities to function properly. The required spaces in school buildings are basically three they are instructional spaces, recreational spaces and facilities (Changu & Maida, 2005; Isaac & Musibau, 2009; Peter & Yufan, 2009). Instructional spaces are spaces where formal learning and training takes place; they are organized for that purpose and have special requirements for their design. They include classrooms, library, laboratory, school farm, workshop etc. recreational spaces involves spaces that allow for exercise, play, relaxation, extra curricula activities etc. they include well landscaped outdoor space, assembly hall etc. facilities are spaces that ensure that students are at ease in school this involves toilet, sickbay, canteen etc. all these spaces affects the users, as the need for a person to be well physically, psychologically and socially cannot be over emphasized.

Design principles for school buildings

Design principles for school buildings are considerations, fundamental sources and basis that guide the conceptual design and construction of school buildings in such a way that it (the building) achieves the following criteria; supports the users in terms of indoor/outdoor environmental comfort and ease of use of the facility, fits into the environment and supports the environment and finally promote economic growth in the intended vicinity. Peter, Yufan, Fay & Lucinda, 2015 proffered three principles to be considered in the design of school buildings they are; naturalness, individualization and level of stimulation.

Naturalness is associated with factors that affect the health, emotions and mood, visual, acoustic and thermal comfort of people within a space. Individualization involves factors that affect student's safety, privacy, free space, ease of use of spaces and satisfaction with their learning environment. Level of stimulation encompasses the factors that affect how the school environment supports its users by the serenity, balance, fitness, beauty and information it gives.

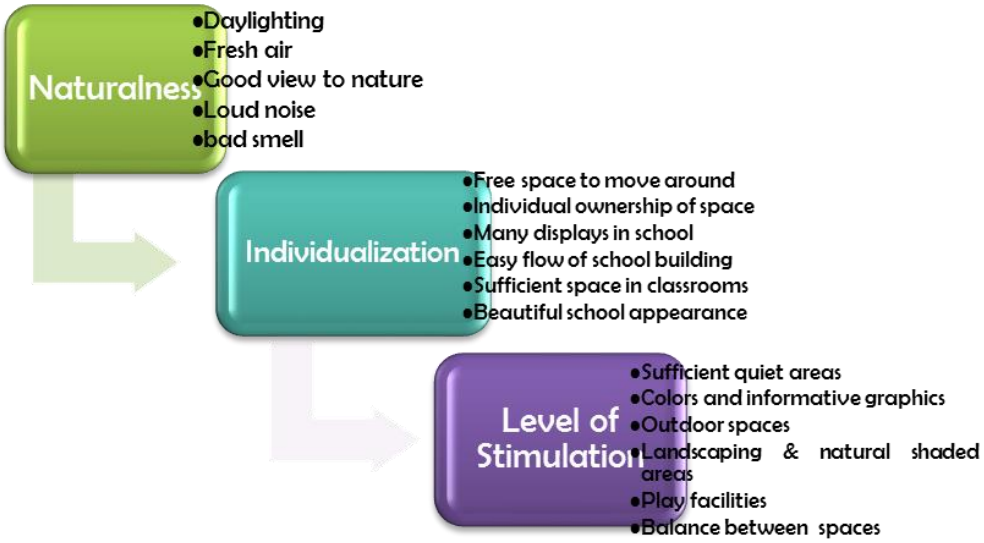

Fig 1 Principles to be considered in the design of school buildings source: Peter, Yufan, Fay & Lucinda, 2015.

Academic performance of students in secondary schools

The decline in the academic performance of secondary school students is on the increase (Arong & Ogbadu, 2010 and Moradeyo & Babatunde 2011), a lot has been put in research wise, on tackling the provision of good teachers, maintenance of provided facilities but so little has been put into enquires on the availability of the facilities and how its absence affects the performance of the students. Research in Nigeria is gaining a lot of recognition but it is quiet disturbing that student especially secondary school students are scarcely involved in the research process when it is done and eventually their grades and generally level of performance suffer. A great percentage of schools in Zaria are usually not designed for institutional purposes and the environment do not encourage academic success due to a number of reasons; absence of essential school facilities, absence of well-designed environment, change of use of building which in most cases do not have the facilities to cater for its users and schools situated in residential quarters.

METHODOLOGY

Case Studies and Study Population

The selected case studies are Top Spring School (TSS) and First Baptist High School (FBHS) located at Army Road and Benin Street respectively in Sabon Gari Zaria. They were selected on the following criteria; Sabon Gari is one of the largest residential areas in Zaria and the

research aimed at comparing performance level in a converted building and a designed institutional building which led to the choice of schools with Top Spring School a residential building from the onset and First Baptist High School an institutional building from the onset. The study population included all students from the senior secondary section of both schools classes I and II (equivalent to grade 10 and 11 in USA). A total of 255 respondents participated with 105 from TSS and 140 from FBHS.

Research Instrument

For the success of this research the following instruments were used: questionnaire, interview, physical measurement and for statistical analysis the IBM software SPSS® V 21 and Microsoft Excel were used.

Questionnaire

Well-structured questionnaires were administered to collect data relating to what degree the spaces and design factors would influence student performance and the type of building the school was using. These were based on previous school based research in USA and Nigeria by (Peter and Yufan) and (Isaac and Masibau) respectively. 255 questionnaires were issued with all retrieved and 232 analyzed. The questionnaires consisted of both open and closed ended questions with four sections. Section A with socio-demographics of the participants. Section B the degree of influence of required spaces on students' performance. Section C the degree of influence of design factors on students' performance. Sections B and C were designed according to Likert scale. Finally Section D explored information on the type of building used for school purposes either institutional or residential.

The principals and selected students were interviewed to further solidify the results. Also physical measurements of spaces like classrooms were done to get a grasp of the sizes of the spaces within the schools.

Statistical Analysis

Data from completed questionnaire were analyzed using IBM Software SPSS® v. 21. For means and frequencies which were achieved by running analysis of variance (ANOVA). Microsoft Excel was used to input data in tubular and graphical format. For research question 1 first the percentages of level of influence of spaces on performance were graphically represented and the RMI for the category of spaces and design considerations were computed for instructional, recreational and facility spaces and naturalness, indiviualisation and level of stimulation respectively. The RMI was obtained as a ratio of the sum of actual agreement scores (ASS_{ac}) and maximum possible agreement score (AS_{max}) on a five point Likert scale that each respondent would give for each question. (Ibem, Opoko, Adeboye and Amole, 2013). Mathematically, this is expressed as:

$$RMI = \frac{\sum ASSac}{\sum ASmax}$$

For research question 2 first different means of the various categories of both spaces and design considerations were computed. Next a test for normality was done as the means were observed to be different then nonparametric test Kolmogrov-Smirnov tests were done which showed that the distribution was normal, poisson and uniform. Finally Friedman's ANOVA was employed to statistically test the hypothesis that all the distributions of means for each category are equal.

Result and Discussion

Result From Questionnaire Survey (Research Question 1)

Results from the survey reveals that both schools participated in the survey and age range for senior secondary school students is from 12-19 with a greater percentage of the students from

SS1 in both schools. It also reveals that there are more male than females and had more classes with over 35 students.

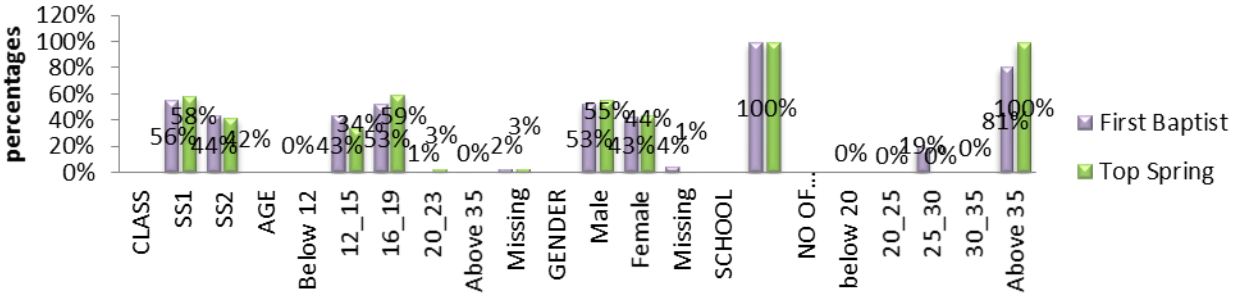

Fig 2: Demographics: Class, Age, Gender, School and Number of students

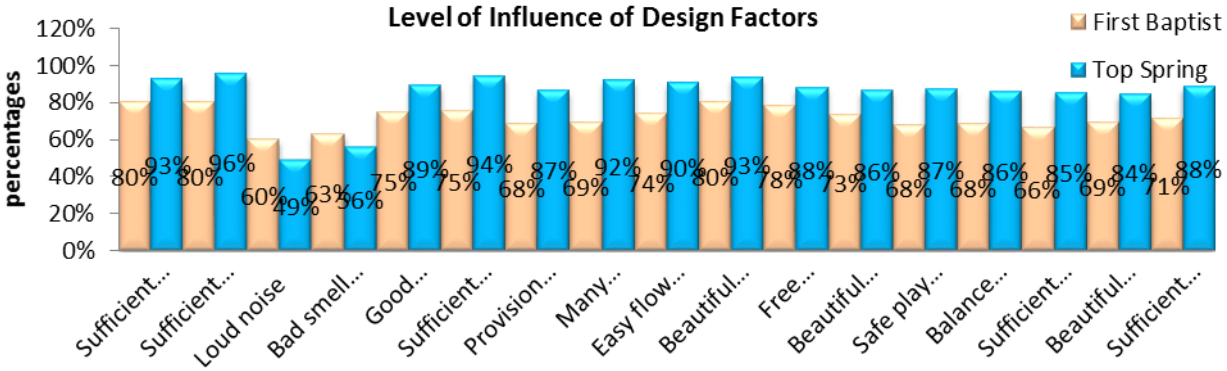

Fig 3: Influence of Design Principles on Academic Performance

Results from user perception on the influence of design principles on their academic performance as seen in Fig 3 shows that they attest to the influence of design considerations on their academic performance with more emphasis on indoor air quality, visual comfort, sufficient and ease of flow of spaces and aesthetics in the school environment as they ranked highest with fresh air having 96% and 80%, daylighting having 93% and 80%, sufficient space in class 94% and 75%, easy flow of building 90% and 74% and beautiful school appearance 93% and 80% for both schools. Results also show that the design consideration that would least affect their academic performance are noise and bad smell as they ranked least with loud noise having 60% and 49% and bad smell in school having 63% and 56%.

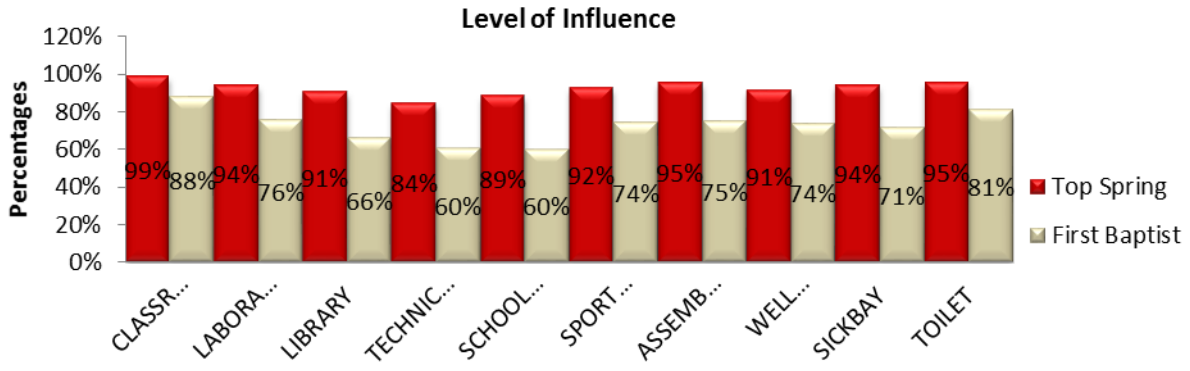

Fig 4 Influence of Spaces on Academic Performance

The results on the influence of available spaces on the academic performance of the respondents also shows that all the spaces will positively affect their academic performance with classroom having 99% and 88%, toilet 95% and 81%, assembly hall 95% and 75%, laboratory 94% and 76% and sickbay 94% and 71% ranking highest. The result also shows

that technical workshop with 84% and 60% will least affect their performance. This shows that due to the absence of some important spaces like technical workshop, library etc. the students did not know how important these are for their academic performance.

Table 1: RMI and ranking for categories of spaces from survey responses*

Spaces	Instructional spaces 1st					Recreational spaces 2nd			Facilities 3rd	
Question	1	2	3	4	5	6	7	8	9	10
$ASSac_{FB}$	597	514	448	410	408	505	507	500	486	549
RMI_Q1sf_{FB}	0.88	0.76	0.66	0.60	0.60	0.74	0.75	0.74	0.71	0.81
$ASSac_{TS}$	473	451	436	404	425	443	458	438	452	458
RMI_Q1sf_{TS}	0.99	0.94	0.91	0.84	0.89	0.92	0.95	0.91	0.94	0.95
$RMI^*_{FB,TS}$	3.496 , 4.561 **(1)**					2.224, 2.79 **(2)**			1.522, 1.896 **(3)**	

Table 2: RMI and ranking for categories of design principles from survey responses*

Design Factors	Naturalness 3rd					Individualization 1st						Level of Stimulation 2nd					
Question	1	2	3	4	5	6	7	8	9	10	11	12	13	14	15	16	17
$ASSac_{FB}$	547	544	409	428	508	512	464	468	503	546	531	496	461	465	452	469	483
RMI_Q1sf_{FB}	0.80	0.80	0.60	0.62	0.75	0.75	0.68	0.69	0.74	0.80	0.78	0.73	0.68	0.68	0.67	0.69	0.71
$ASSac_{TS}$	444	449	234	269	429	451	416	441	434	448	421	414	419	411	409	404	424
RMI_Q1sf_{TS}	0.93	0.96	0.49	0.56	0.89	0.94	0.87	0.92	0.90	0.93	0.88	0.86	0.87	0.86	0.85	0.84	0.88
$RMI^*_{FB,TS}$	3.581 , 3.895**(3)**					4.447 , 5.44**(1)**						4.156 , 4.837**(2)**					

The result above based on user responses reveals that, the category of spaces that would most influence their performance are instructional spaces such as: classrooms, library, laboratory etc. with RMI^* 3.496 and 4.561 followed by recreational spaces and then facilities. And the category of design principles that would most affect their academic performance are individualization such as sufficient space in class, easy flow of building, individual ownership of space etc. with RMI* 4.447 and 5.44 followed by level of stimulation and then naturalness. This depicts that both schools are relatively small and the students are overpopulated within small spaces it also shows the necessity for users to have a sense of privacy, safety and organization in their environment (Table 1 and 2). The need for proper design consideration and provision of adequate spaces in schools cannot be overemphasized as this rests on the shoulders of the design professionals such as architects, landscape architects etc. to ensure that the built environment supports its users.

Result From Statistical Analysis (Research Question 2)

From the statistical analysis below for space category the means are ranked with facilities with 4.17 as the space with the greatest influence recreational spaces with 4.14 and instructional spaces with 3.97 the least mean. And for the design factors category individualization ranked highest with 4.12 followed by level of stimulation with 3.87 and then naturalness with 3.71 as seen in Table 3. The mean result depicts that all the categories would influence performance as they are well above 3 the neutral level of influence.

Table 3 Ranking of variables (with means all above 3, the neutral level of influence)

Variables	Mean	Rank
Spaces: Facilities	4.17	1
Recreational	4.14	2
Instructional	3.97	3
Design Factors: Individualization	4.12	1
Level of stimulation	3.87	2
Naturalness	3.71	3

Due to the different in the means there was a need to run other tests to proof statistically that the variables above would affect the respondents performance. A Friedman test was carried

out and the result seen in Table 4 shows that there was no statistically significant difference between the mean ranks of both spaces and design factors suggesting that the variable would influence performance of the respondents with the Chi-Square value and degree of freedom (df) expressed as $X^2(9) = 200.471$ and significant level of difference $p = 0.000$. Further more Robust test of equality of means, ANOVA, Test of Homogeneity of Variance using Levene statistic, Friedman two way analysis of variance and Kolmogorov-Smirnov tests were all carried out they all confirmed that the means have no significant difference.

Table 4 Test Statistics [a]

N	213
Chi-Square	200.471
df	9
Asymp. Sig.	.000

a. Friedman Test

Table 5 (a): Independent Samples Test (Levene's Test and T-test)

		Levene's Test for Equality of Variances		t-test for Equality of Means			
		F	Sig.	t	df	Sig.	Mean Difference
INSTRUCTIONAL SPACES	Equal variances assumed	77.994	.000	6.68	228	.000	1.098
	Equal variances not assumed			7.27	204.55	.000	1.098
RECREATIONAL SPACES	Equal variances assumed	62.320	.000	5.77	227	.000	.895
	Equal variances not assumed			6.37	206.25	.000	.895
FACILITIES	Equal variances assumed	60.67	.000	5.74	229	.000	.894
	Equal variances not assumed			6.34	207.55	.000	.894

Levene's test for equality of variances, Table 5: shows that the result was significant (F=77.994, 62.320, 60.67, p=0.000) for each space category. Results from the T test, confirmed means were not significantly different (N=232, t = 6.68, 5.77, 5.74, p=0.000).

Results from Interview and Physical measurements of spaces

From the interview with principals of both schools it was found that the spaces visibly present in the schools are as follows for First Baptist High School: conveniences, playground, laboratory, staffrooms and classrooms. While Top Spring School had: classrooms, staffrooms, playground and conveniences. About 15 students from both schools were interviewed on how their building has influenced their performance and their response was centered on factors that cause discomforts which were noise from the road and surrounding buildings, bad smell from homes and toilets, absence of important instructional, recreational and facility spaces like well-equipped library, laboratory, technical workshop etc. and thermal comfort. During the course of the survey measurements of the classrooms were taken for FBHS the classes were within the range of $18m^2$-$24m^2$ with 2.55 headroom housing 29- 41 students. For TSS the classes were two with $17m^2$ and $31m^2$ housing 50 and 63 students respectively. Furthermore, the classrooms especially in TSS appeared to be overcrowded (50–60 students per class) based on a Nigerian policy guideline an occupancy of ≤36 in six rows of six students in a floor area ≥19.4m with ≥2 m between the teacher and front row and have only one door.

DISCUSSION CONCLUSION AND AREAS OF FURTHER RESEARCH

The paper aimed at finding out if there is a relationship between school building typology and academic performance of students by engaging the students who are the major users and

beneficiaries of the institution. The major finding from this research is that students would study better and perform better once the conditions that would enhance comfort and serenity are provided. The above result revealed that both schools are operating at almost the same level relating to available spaces and infrastructure even though First Baptist High School was designed for school purposes and Top spring school was a residential building from the onset. It is also seen that availability of adequate and sufficient space is also a big problem as the classrooms were overpopulated in both schools. The result finally revealed that availability of spaces and proper design considering functionality, aesthetics, thermal, visual, acoustic comfort, indoor air quality, landscaping etc. all affect the users performance and should not be neglected in design. This therefore establishes a relationship between the building typology and academic performance of the students. It is important to note that change of use building is allowed but without proper considerations and the right authorities not consulted the building may be used in such a way that it affects it users negatively. Invariably this goes to say that with improperly designed school buildings and unsupervised changed use of building the expected level of comfort is likely to be the same which will not support the performance of users. It is therefore highly recommended that design professionals such as architects, landscape architects, planners etc. should pay closer attention to proper design of school buildings especially secondary schools as it has serious effects on the users' performance and authorities responsible for the permission to change the use of a building should be notified and advice given by the authorities adhered to. This research should be done on a larger scale as this was limited to two schools.

User Perception of Comfort in Offices: A Case Study of Architecture and Quantity Surveying Departments, Ahmadu Bello University

Stephen, H.[1]*; Maina, J. J.[1]; Chinonso, A. O. [1] & Ohambele, C. C.[1]

[1]Department of Architecture, Ahmadu Bello University, Zaria-Nigeria
[*] stephen.haggai@yahoo.com

ABSTRACT

The concept of user comfort is very important to the office user. It affects the user's health and well being. Much work has been done in addressing the individual factors of comfort notably thermal comfort especially in residential buildings. Comparatively, little research exists addressing comfort in the new office structures of TETFund, using post occupancy evaluation, investigating how comfortable office users find offices. This study examines user comfort in offices by comparing office comfort levels through a survey of 36 staff of Architecture and Quantity Surveying Departments at Ahmadu Bello University, Zaria, Nigeria as well as physical surveys of both buildings. Questionnaire responses elicited information on how users felt about their office environment and what factors contributed to high comfort in offices of both departments. Results were analyzed using 〖IBM SPSS〗^® v. 21 and Microsoft Excel. Study results reveal that the ability of users to control the indoor environmental quality of their office is a strong variable in determining comfort in offices. Also, it was found out that offices in both departments are acoustically comfortable. However, user comfort overall is reduced by thermal comfort. This study recommends that policy makers, architects and other design professionals pay particular attention to the provision of more private (single user) spaces, building orientation and zoning away from public facilities, when designing future offices especially within academic environments.

INTRODUCTION

Each year, large funds are being spent on office structures in tertiary institutions. In 2014, the Tertiary Education Trust Fund (TETFund) allocated ₦912million to each public university in Nigeria up from ₦303million in 2010, ₦661million to public polytechnics in 2014 up from ₦180million in 2010 while public colleges of education received ₦581million in 2014 up from ₦157million in 2010. These figures were presented by the then Minister of Education, Mallam Ibrahim Shekarau at a public presentation, 'Consolidating the Transformation in the Education Sector: A Strategy – July, 2014 – May, 2015' (Oyedele, 2014). These figures tell that the Federal Government of Nigeria is in a bid to improving the standard of education in tertiary institutions and large funds are spent to erect new office structures and learning environments. However, there is little feedback, using post occupancy evaluation (POE), investigating how comfortable office users find these new offices.

According to research, office users not exempted, people spend up to 90% of their time indoors in the developed parts of the world (Klepeis, et al., 2001). Studies have also shown that conducive working environments impact on health and well being. When the conditions that make the working environment conducive or comfortable work are absent, the morale, productivity and performance of employees can deteriorate (Emuze, Mashili, & Botha, 2013). Office occupants, while carrying out tasks assigned to them, are often disrupted by the thermal, visual and acoustic conditions within the workplace (Simons, Koranteng, & Adinyira, 2014). Results include delay in undertaking tasks assigned to them, absenteeism, tardiness and complaints amongst others. In academic environments, the results mentioned above impact on academic performance. According to Ajayi, Awosusi, Arogundade, & Ekundayo (2011), lecturers absent themselves and rush lectures when exams are near and students complain of delay in exam results.

Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1183-1193

Much work has been done in addressing the individual factors of comfort especially in residential buildings, these include; Acoustic comfort (Navai & Veitch, 2003), air quality (Wargocki, Wyon, Nielson, & Fanger, 2002), thermal comfort (Monteiro da Silva & Guedes de Almeida, 2010), visual comfort (Galasiu & Veitch, 2006). However, little research exists addressing comfort in the new office structures of TETFund, using POE, investigating how comfortable office users find their new offices.

This study aims to examine user comfort in offices based on user perception of indoor environmental conditions using offices of the Departments of Architecture and Quantity Surveying, ABU Zaria as case studies and thereafter, proffer solutions based on problems identified so that similar future buildings can be improved upon in terms of indoor environmental quality (IEQ). The study presents two research questions. First, is there any difference between user perceptions of comfort variables from the sample? Second, is there any difference between general comfort levels across the two departments?

This paper is outlined in 8 sections; abstract, introduction, literature review, methodology, results and discussion, conclusion, recommendations and references pertinent to the study.

LITERATURE REVIEW

User Comfort

Comfort is a very subjective topic. Abbaszadeh, Zagreus, Lehrer, & Huizenga (2006) suggest that comfort in the office is achieved through satisfaction of the indoor environmental quality. However, this research is restricted only to acoustic, thermal and visual comfort, indoor air quality and office cleanliness, as outlined by the Green Building Council of Australia (released as an innovative challenge in August, 2013).

Thermal Comfort

This is the condition of mind which expresses satisfaction with the thermal environment (ISO 7730, 1984). It means that an employee wearing a normal amount of clothing feels neither too cold nor too warm (Elaiab, 2014). An environment achieves reasonable thermal comfort when at least 80% of its occupants are thermally comfortable (Abodunrin, 2014). Indoor thermal comfort is affected by physical and environmental factors. Thermal comfort improves happiness and productivity, health and well-being and reduces the energy demands of a building (Autodesk Sustainability Workshop, 2011). One of the best ways of determining whether a group of people are comfortable is by asking them. The simple (seven-point) scale below is often used in laboratory experiments, to the integration of techniques into questionnaires for practical surveys as well as behavioural measures.

Table 1. Scales of Warmth Sensation. Source: (ASHRAE, 1966; Bedford, 1936)

Bedford comfort scale		ASHRAE sensation scale	
Much too warm	7	Hot	7
Too warm	6	Warm	6
Comfortably warm	5	Slightly warm	5
Comfortable	4	Neutral	4
Comfortably cool	3	Slightly cool	3
Too cool	2	Cool	2
Much too cool	1	Cold	1

Acoustic Comfort

Acoustic comfort means having the right level and quality of noise to use the space as intended (Autodesk Sustainability Workshop, 2011). Noise in office buildings could be as a result of too much noise outside the building or from adjacent spaces and lack of sound control in the space. Designers are obliged to design buildings that include acoustic materials, in order to minimise noise in the office and/or other building environments (Emuze, Mashili,

& Botha, 2013). Paradis (2014) states that acoustic comfort can be achieved by good site selection, proper glazing and sound masking. Also, the ABC rule (Absorb, Block & Cover) is a principal method used by acoustic professionals to achieve effective acoustics. Acoustic comfort increases concentration of the mind on work, reduces headaches and improves health and well-being.

Visual Comfort

Means ensuring that people have enough light for their activities, the light has the right quality and balance, and people have good views (Autodesk Sustainability Workshop, 2011). It can be associated to the absence of glare caused by the presence of excessive luminance in the field of view. Most design professionals fail to include lighting requirements at the initial stage, forgetting the fact that this oversight will affect productivity in the workplace if lighting requirements are not met (De Carli & De Giuli, 2009). According to Laforgue, Souyri, Fontoynont and Achard, Glare can be categorized into: The uncomfortable glare and the disturbing glare, both reduce visual performance. The availability of daylight is an important requirement, especially for office buildings. Poor quality of lighting in the workplace causes eyestrain, which leads to dizziness and stress. Occupants become disgruntled because of their dissatisfaction with the lights in the building, which will result in reduced productivity as occupants will start spending long periods away from work to consult a medical expert for treatment of their eyes and/or vision problems (Samani, 2011). Also, one of the main source of dissatisfaction in offices is lack of the physical connection with the outside: the contact with the natural environment is important because it brings dynamism to the indoor and a sense of relax for people (De Carli, De Giuli, & Zecchin, 2008).

Indoor air quality (IAQ)

IAQ deals with how well the indoor air satisfies the occupants of the building. Inadequate ventilation increases indoor pollutants by not allowing sufficient outdoor air to dilute the emissions from indoor sources (Emuze, Mashili, & Botha, 2013). Environmental Protection Agency (EPA) and others show that indoor environments sometimes can have levels of pollutants that are actually higher than levels found outside. These Pollutants increase the risk of illness, making people uncomfortable, unproductive, and unhappy. Fresh air helps people to be alert and productive. The factors that affect air quality in the indoor environment result from the interaction of the site, climate, building system, potential contaminant sources (e.g., furnishings, moisture sources, work processes/activities, and out- door pollutants), and building occupants (OAR, 1997). Also, these symptoms of poor IAQ may cause health problems such as irritations of the eyes, mental fatigue and headaches. Constant failure to regularly evaluate the building's performance leads to poor indoor environmental quality (IEQ), which may negatively affect the quality of life of the occupants, who will ultimately have to resort to medical treatment (Cho & Lee , 2010).

Office Cleaning

A comfortable office environment is a building or room in which workers can generate their work properly as it is clean (Parveen, Sohail, Naeem, Azhar, & Khan, 2012). Research has shown that there is indeed a direct connection between a clean and healthy work environment and worker productivity levels. The results of an unclean office include headaches, lethargy, eye, nose and throat problems. Dirt and dust in an office also pollute the air, this polluted air when inhaled by the office worker makes the worker vulnerable to respiratory problems. Also, the linkage of sick building syndrome to poor IAQ creates a more critical need for a clean indoor office environment (Wargocki, 2000).

Tertiary Education Trust Fund (TETFund)

The Tertiary Education Trust Fund (TETFUND) was established by an Act of the National Assembly in June 2011 which replaced the Education Tax Fund Act Cap. E4 laws of the Federation of Nigeria 2004 and Education Tax Fund (Amendment) Act No 17, 2003. The Fund was set up to administer and disburse education tax collections to the Federal and State tertiary educational institutions in Nigeria. The main source of income available to the Fund is the 2% education tax paid from the assessable profit of companies registered in Nigeria. The levies are collected by the Federal Inland Revenue Service (FIRS) (TETFUND, 2014). TETFund intervenes through: provision of essential physical infrastructure for teaching and learning, provision of Instructional materials and equipment, research, book evelopment and publication, academic staff training and development, and any other need, which in the opinion of the Board of Trustees is critical and essential for the improvement of quality and maintenance of standards in the educational institutions.

The Board of Trustees (BOT) of the Fund is statutorily charged with the responsibility of administering, managing and disbursements of these funds to beneficiaries in the public tertiary educational institutions under established guidelines (TETFUND, 2014).

TETFund Interventions Categories can be categorized as follows:

i. normal (Regular) Interventions
ii. special intervention
iii. special high impact intervention

The Normal Intervention is yearly for all beneficiaries of TETFund. The Special Intervention is usually at the discretion of the Board of Trustees. The Special High Impact Intervention however seeks to massively inject funds into selected tertiary institutions to achieve a major turnaround through programme upgrade and improvement in the teaching and learning environment. (TETFUND, 2014)

Table 2. Performance Of Beneficiaries In Access To Funds For Normal Intervention Projects; 2007-2011. Source: (Abu, 2012)

Sector	Total Allocation	Total Disbursement	% Access	Balance Outstanding
Universities	34,577,700,000.00	11,551,508,000.00	33.41%	23,023,192,000.00
Polytechnics	20,136,660,000.00	7,656,511,400.00	38.2%	12,480,148,600.00
Colleges of Education	21,132,860,000.00	8,481,841,100.00	40.14%	12,651,018,900.00

Post Occupancy Evaluation (POE)

POE is a general term for a broad range of activities aimed at understanding how buildings perform once they are built, and the level of satisfaction of building users with the environment thus created (Hewitt, Higgins, Heatherly, & Turner, 2005). POE is vital, as it reminds corporate executives of the needs of employees that affect their productivity (Kooymans & Haylock, 2006), such needs are not limited to privacy, lighting, storage and thermal comfort. Providing feedback through POE can also assist the organisation when new ideas and knowledge are put forward for continuous improvement purposes (Lackney & Zajfen, 2005). A POE study conducted at the new location of a 174-person Architectural firm in Boston, USA by Sheply, Zimmerman, & Boggess, (2009) revealed that occupants were more satisfied with a new building when compared with an older building, although concerns were raised about the impact on indoor air quality, thermal comfort, lighting, noise and office layout. POE therefore is an evaluation tool that is perceived as a subprocess of building performance evaluation and can be defined as the act of evaluating buildings in a systematic manner after they have been built and occupied for some time (Preiser & Vischer, 2005). The benefits of POE include; Identification of and finding solutions to problems in buildings,

response to user needs, improved space utilisation based on feedback from use, understanding of implications on buildings of change whether it is budget cuts or working context, Informed decision making. There however seems to be a gap or lacking of literature as it concerns POE studies of TETFund buildings in Nigerian tertiary institutions.

METHODOLOGY

Case Study

Two buildings were selected for this research; the Departments of Architecture and Quantity Surveying (Q/S), ABU Zaria. Both are multi-use buildings with functional office spaces spread across all floors. Also, one aim was to compare comfort levels in both departments, the criteria was to select a building that was recently built through TETFund intervention (Q/S) and an old building (Architecture). The Dept. of Architecture building has 3 floors and a pent floor with 32 office spaces that spread across the entire building while the Dept. of Q/S building has 3 floors with 26 office spaces also spreading across the entire building. From a visual survey, it is noted that there is a conscious effort to make offices comfortable, buildings are oriented in the north/south direction, use of shading devices, use of a courtyard (Q/S), zoning of offices away from noise sources, use of mechanical cooling units, window blinds, and furniture arrangement.

Plate 1: Dept. of Architecture

Plate 2: Dept. of Quantity Surveying

Questionnaire Survey

Use of Questionnaires for this research was influenced by literature, POE studies seen in literature review that made use of questionnaires, physically issued to individuals generated great feedback. These include POE studies by Emuze, Mashili, & Botha (2013) and Sheply, Zimmerman, & Boggess (2009). Questionnaires were therefore issued to staff of both Departments and were retrieved over a period of one week. A total of 47 questionnaires were distributed, 36 (77%) were retrieved and analyzed. Confidentiality & honesty was enhanced by keeping participants anonymous throughout the study. Questionnaire responses elicited information on how users felt about their office environment and was designed in 5 sections;

Section 1 with demographics (providing information on age, gender, work description etc.), section 2 was designed according to the Likert scale to help evaluate satisfaction with the buildings IEQ. It addressed IEQ in the selected buildings with respect to whether the air in the building was fresh, stale, and stuffy or had any odour, control of ventilation, temperature, noise, artificial lighting and the rate of air circulation. Section 3 questions demanded a yes or no answer, they provided information on whether occupants offices had certain features that contributed to comfort of their offices including artificial lights and artificial means of cooling/heating. Section 4 was based on the ASHRAE comfort scale (see Table 1.) and section 5 was designed to provide information on work interruption and office cleanliness.

Data Analysis and Presentation

Data was analyzed using IBM SPSS® v. 21. This software addresses the analytical process in conducting a research, from planning, to data collection to analysis and reporting. Numerical data obtained from questionnaires was analyzed using frequencies and means which was achieved by running the Analysis of Variance (ANOVA).

Research question 1, Methodology/steps:

i. First, different means of the five variables were computed i.e. acoustic, thermal & visual comfort, indoor air quality and office cleanliness. We observe from the descriptive summaries that means are different.
ii. To test whether distributions were significantly normal or not, we tested for normality (Table 3) considering the sample was generally small (less than 50).
iii. Table 3 Kolmogorov-Smirnov and Shapiro-Wilk tests suggestted non normal distributions for all variables except acoustic comfort (values less than 0.05, highlighted). Because we were testing the hypothesis that there were no significant differences between the distributions of all means, it was safe to assume non normal distributions. We therefore employed non parametric tests/ANOVA. The QQ plots confirmed the dots did not all fall on the line for all the variables (if they did, the distributions would be considered normal).

Table 3: Tests of Normality

	Kolmogorov-Smirnov[a]			Shapiro-Wilk		
	Statistic	df	Sig.	Statistic	df	Sig.
Thermal Comfort	.177	33	.010	.881	33	.002
Acoustic comfort	.139	33	.105	.965	33	.361
Visual comfort	.163	33	.026	.941	33	.075
Cleanliness	.232	33	.000	.922	33	.021
Indoor Air Quality	.196	33	.002	.940	33	.067

iv. Because the distributions were non-normal, we employed Related samples Friedman's ANOVA to statistically test the hypothesis that all the distribution of means for the 5 variables were equal. The test confirmed that means were significantly different (N=33, dof=4, p=0.023 which is less than 0.05)

Hypothesis Test Summary

	Null Hypothesis	Test	Sig.	Decision
1	The distributions of THERMAL COMFORT INTERFERENCE, Acoustic comfort, Visual comfort, Cleanliness and Indoor Air Quality are the same.	Related-Samples Friedman's Two-Way Analysis of Variance by Ranks	.023	Reject the null hypothesis.

Asymptotic significances are displayed. The significance level is .05.

Figure 1: Hypothesis Test Summary

Research question 2, Methodology/steps:

i. We computed means for the variable "Satisfaction with general Comfort (SC)" using responses from the two departments, Architecture and QS (Table 4). Analysis confirmed $Arch_M$=2.74, QS_M=3.57
ii. To test whether these were significantly different, we employed the independent samples T-Test in two ways
iii. Levene's test for equality of variances (Table 5a/5b): this was non-significant (F=0.402, p=0.531 as p was greater than 0.05). So we made use of the T test results equal variances assumed from Table 5a-c
iv. Results from the T test confirmed that means were significantly different (N=33, t=-2.226, p=0.033, less than 0.05) see last column Table 5b, Table 5c all figures in green text.
v. We then concluded that satisfaction with general comfort was significantly higher based on perceptions from QS users than from users in Architecture.

Table 4: Group Statistics

	Department	N	Mean	Std. Deviation	Std. Error Mean
Satisfaction with general comfort	Architecture	19	2.74	.991	.227
	QS	14	3.57	1.158	.309

Table 5a: Independent Samples Test

		Levene's Test for Equality of Variances		t-test for Equality of Means
		F	Sig.	t
Satisfaction with general comfort	Equal variances assumed	.402	.531	-2.226
	Equal variances not assumed			-2.173

Table 5b: Independent Samples Test

		t-test for Equality of Means		
		df	Sig. (2-tailed)	Mean Difference
Satisfaction with general comfort	Equal variances assumed	31	.033	-.835
	Equal variances not assumed	25.467	.039	-.835

Table 5c: Independent Samples Test

		t-test for Equality of Means		
		Std. Error Difference	95% Confidence Interval of the Difference	
			Lower	Upper
SATISFACTION WITH GENERAL COMFORT	Equal variances assumed	.375	-1.599	-.070
	Equal variances not assumed	.384	-1.625	-.044

RESLUTS AND DISCCUSSION

Results from the Survey Questionnaires: Research Question 1

Results from questionnaires show that based on user perception, staff in both departments had more satisfaction with acoustic comfort and less satisfaction with thermal comfort. The reasons are because more offices belonging to academic staff were located on the last floor of

both buildings, this means academic staff do quiet focused work in their offices, because there are less noise interruptions from people walking, interacting or carrying out other activities on other floors. Also, presence of window blinds in offices of Q/S contribute to acoustic comfort, and in Architecture Dept., large trees, planted around the building act as noise buffers. Next, office cleanliness is ranked second because more staff acknowledge that their offices are cleaned by workers on a weekly basis (on the average) all through the year. However, a few staff complained that their offices were never cleaned (Architecture Dept.). Indoor air quality and visual comfort have the same ranking (third), reasons why indoor air quality is ranked third include; offices within the buildings of both departments are zoned away from public facilities (student toilets), as a result, more staff report clean air in their offices. Also, ceiling fans provided in the Architecture department and stack ventilation, aid movement of air so that there is no stale/stuffy air in offices. Although trees planted around the Dept. of Architecture contribute a great deal to acoustic comfort, they however, disturb visual comfort, connection with the exterior space is important, these tress prevent office users from getting good views of the exterior space and also buffer against daylight coming into the office space. The courtyard system employed in the Q/S Dept. building hinders good views, as well interior offices on the ground floor are not well lit because of obstruction of daylight by other spaces built above. Questionnaire responses noted users are not affected by glare in both departments. Thermal comfort is ranked the least although offices are well oriented, with shading devices and mechanical cooling systems, more staff have little control over thermal comfort, and this is because there are shared offices so while a user would want a mechanical cooling unit on, the other user might not and the office becomes uncomfortable for that user.

Table 6: Ranking of variables (with means all below 3, the neutral mark for satisfaction)

Variable	Mean	Rank
Acoustic Comfort	2.91	1
Office Cleanliness	2.83	2
Indoor Air Quality	2.64	3
Visual Comfort	2.64	3
Thermal Comfort	2.55	4

Results from the Survey Questionnaires: Research Question 2

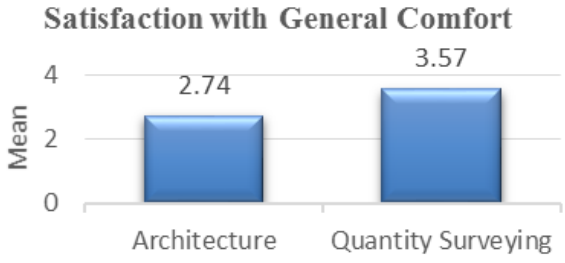

Figure 2: Satisfaction with general comfort

According to figure 2 above, staff of the Dept. of Q/S have more comfortable offices than staff of Architecture Department. This is true, staff have more control over comfort conditions in Q/S than in Architecture because they have more single user offices. The building is properly oriented in the north/south direction, staff report daily and weekly cleaning of offices, good daylighting, less noise interruptions. More staff report clean air in offices. This is unlike the Dept. of Architecture where staff complain of stale/stuffy air,

obstructed views, no consistent cleaning and more shared offices in this department means less control over indoor comfort conditions.

Discussion on Findings

One major finding is that the ability of users to control the indoor environmental quality of their office is a strong variable in determining comfort in offices. This is one reason why more staff prefer the private (single user) offices because they are able to control the conditions that make their offices comfortable, unlike the shared office where there is less control over comfort conditions e.g. one/more staff in a shared office might prefer to work with artificial lights switched on while the other staff might not. Also, it's seen that user comfort is affected by the five variables but to different degrees. While more acoustic comfort has been achieved, users are not thermally comfortable.

CONCLUSIONS

Comfort in the office is important for better work and productivity and there are factors that interfere with work when offices are not comfortable for users. Architects play an important role in making sure offices are comfortable for users. The extent to how comfortable an office is can be determined by the Architect by considering those factors that cause discomfort in offices. If offices are designed to provide good indoor air quality, satisfy thermal, visual, and acoustic comfort, and cleanliness, then to a large extent, they become comfortable for work. The factors that contribute to high comfort conditions in offices (in the Depts. of Architecture and Q/S) include; Ability of office users to control the indoor environmental quality of their office, building orientation, presence of window blinds, shading devices, trees used as sound buffers, window openings, location of offices (zoning). Also, it was confirmed that the TETFund building selected for this research was more conducive to work in. It satisfied the IEQ requirements of its users with less employee complaints. However, better offices can be provided if future TETFund projects improve on IEQ requirements of users through post occupancy evaluation.

RECOMMENDATIONS

Offices should be cleaned more frequently and effort should be made to improve thermal comfort. Comfort and environmental friendliness should be the focus when constructing future office buildings making sure to meet the IEQ requirements of users. Architects and other design professionals should take into consideration the following at the planning phase; building orientation, trees and plants improves the IEQ, room should be given for more private (single user) offices, offices should be zoned away from public toilets, offices should be located on upper floors in storey buildings where work interruption is not needed. Also, Managements should endeavor to carry out POE of their buildings and further research on a larger scale on user comfort in Nigerian offices should be carried out to provide feedback that will improve Nigerian offices and add to knowledge.

ABSTRACT

The coherence of a firm in terms of the relatedness of its activities is often considered an important performance factor to exploit competence and explore new technologies and markets to gain competitive advantage. However, the competitive advantage of firms is crucially dependent on the capabilities of the workforce and specific to the job of an individual while the revolution of ICT and innovative construction disciplines has caused a serious mismatch of skill requirements for professional service delivery. Therefore, this paper focuses on measuring the relatedness of quantity surveyors' skill requirements for diversification of professional services. The paper adopted questionnaire survey on the population of registered quantity surveying firms (principal partners) that have diversified their practices using snowball sampling technique. The questionnaire was structured on the rubrics of quantity surveyor's skill requirements for diversification and relatedness of skill areas to future growth. The data collected were analysed using Dendrogram of data cluster analysis and Pearson correlation to establish the relatedness of skill areas. This paper showed that quantity surveying firms in Nigeria diversified in the areas of arbitration and other dispute resolution; project management and other business development related to core competence and concluded that business opportunities abound in the areas of taxation, insolvency, valuation, insurance and property investment. This paper recommendsthat principal partners should encourage professionals to diversify in these marketable areas of optional competence for quantity surveyors to ensure business sustainability.

Keywords: Competence, diversification, quantity surveying firm, relatedness, skill requirements, Nigeria

INTRODUCTION

Growing the business of professional service firms required serving more clients/customers with a wider array of services, thereby broadening the scope of the business. This implies learning about new technologies, markets and customers that borders on the challenge of measuring diversification in services; not only in terms of scope of these firms but also the relatedness or unrelatedness of service diversification. Corroborating this submission, Shahin *et al* (2014) noted that advanced technology, fast transportation, convenient communications, effective knowledge transfer, integrated markets and trade liberalization has made professional service firms to have grown in scope and scale. They have diversified vertically and horizontally into a wide range of professional services. Thus, firms can exploit the latent capacity of their employees to work in related industries by diversifying to activities that are related to the firm's current activities. Neffke and Henning (2012) submitted that relatedness is a key notion in corporate strategy. The coherence of a firm in terms of the relatedness of its activities is often considered an important factor in its long-term performance. To be successful, firms, on the one hand, need to exploit their core competence, while on the other hand, they must explore new technologies and markets as well as adapt their production to new economic conditions. The tension that exists between exploiting core competence and exploring new technologies can be overcome by developing new activities that are related to a firm's core activities, thus combining both exploration and exploitation.

Studies abound in the literature that highlighted and described core competency of quantity surveyors (Dada and Jabgoro, 2012; Perera *et al*, 2011 and Oyediran, 2011;). However, Boyatzis (2009) described competence as the sum of experience, knowledge, skills, values

Akinola, J. A.; Ogunsemi, D. R. & Awodele, O. A. (2016). Assessment of the Relatedness of Quantity Surveyor's Skill Requirements for Diversification of Practice Firms in Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1194-1202

and personal qualities of a professional during lifetime while RICS (2005) categorized competence standard of quantity surveyors into three as basic; core and optional competence with optional competencies as areas of future diversification of professional quantity surveyor. Therefore, this paper focuses on measuring the relatedness of quantity surveyors' skill requirements for diversification into areas of optional competencies.

LITERATURE REVIEW

Firm's Diversification

Industries are often depicted as a groups of firms that compete among each other for a greater share of the same market. However, large firms seldom operate only on a single market; as innovations developed in one industry often find its ways into the products and processes of other industries. Hence, interconnected industries form geographically collocated clusters, and many firms switch industries at some point in their career development (Olivier and Root, 2014). This suggests that the boundaries of an industry are permeable especially in terms of technological innovations. This view was corroborated by Talli and Dovev (2013) that the consequence of the porous nature of inter-industry boundaries, diversification is an important phenomenon in a range of economic entities. Firms diversify into new industries to expand their product ranges or to engage in higher margin activities. Thus, a diversification strategy should focus on identifying new activities that require resources that a firm already possesses but that are currently underleveraged. Stefan and Dodo (2013) noted that diversification strategies are used to expand firms' operations by adding markets, products, services, or stages of production to the existing business.

The purpose of diversification is to allow the company to enter lines of business that are different from current operations. When the new venture is strategically related to the existing lines of business, it is called concentric diversification while conglomerate diversification occurs when there is no common thread of strategic fit or relationship between the new and old lines of business; the new and old businesses are unrelated (Talli and Dovev, 2013). These were separately described by Olivier and Root (2014) as internal and external diversification. Diversification strategies can also be classified by the direction of the diversification. Vertical diversification occurs when firms undertake operations at different stages of production. Involvement in the different stages of production can be developed inside the firm (internal diversification) or by acquiring another firm (external diversification). Horizontal diversification involves the firm moving into operations at the same stage of production. Vertical diversification is usually related to existing operations and would be considered concentric diversification while horizontal diversification can be either a concentric or a conglomerate form of diversification (Olivier and Root, 2014).

Skill Relatedness

Qian *et al* (2010) noted that human capital and skills are the prime resources in modern economies while the competitive advantage of firms crucially depends on the capabilities of the workforce. This human capital is often specific to the job of an individual. When changing jobs, an employee often has to accept that a significant part of his or her acquired skills will become obsolete. However, such destruction of human capital can be limited by moving to related industries. Neffke and Henning (2012) proposed the concept of skill-relatedness to measure the degree to which sets of industries have similar human capital requirements. The skill-relatedness among industries is inferred from cross-industry labour flows, relying on the fact that employee are likely to switch to jobs in industries that value their previously acquired work-related skills to avoid rendering large parts of their human capital redundant.

The study of Neffke and Henning (2012) differentiated among three types of relatedness measures. The first type measures relatedness as the distance between the industry codes within the hierarchical structure of the industry classification system. The second type of measures, co-occurrence or outcome-based relatedness measures, assumes that the composition of industrial portfolios of productive units (e.g., firms, plants, or even countries or regions) reflect economies of scope. The third type, resource- or input-based indicators, directly investigates the similarities of industries in terms of their resource use. This paper focus on resource-based view of the firm with emphasis on human capital. An important antecedent to the resource-based view (RBV) literature is Penrose (1959). The study argued that firms possess resources from which they derive services that the firms use in their productive processes and has incentive to grow as long as some of its resources are left idle in its current activities. However, firm's resources can often provide different services, and the amount and quality of these services grow as the firm gains more knowledge about them through learning-by-doing. This view were corroborated by Gathman and Schoenberg (2010) and Nedelkoska and Neffke (2010) that human resources is strongly specific to the tasks that are carried out. As a consequence, individuals who change jobs risk rendering part of their human capital redundant. In order to limit this kind of human capital destruction, individuals will switch to jobs in industries that value the same kind of skills as their previous employer. Summarily, individuals will predominantly switch jobs between industries that are skill-related.

Quantity Surveying Professional Services

Oyediran (2011) emphasized the importance of quantity surveyors as members of the design and construction teams in both private and public sectors of a nation. Their pivotal roles in construction project development and delivery are well acknowledged by literature while Ajanlekoko (2012) described quantity surveying as the amalgamation of several other disciplines such as law, accountancy, business management, information management and construction technology within the unique context of the built environment. However, Phoya and Kikwasi (2008) noted that in the course of reviewing the development of quantity surveying that there has been a shift in the emphasis from cost to value with many quantity surveying firms expanding the horizons of services offered. Quantity surveyors are becoming increasingly involved in project management, value engineering, risk and facilities management, life cycle costing among other new innovations. Also, in the United Kingdom, some quantity surveying firms carry out insolvency and corporate restructuring, survey on hazardous materials and environmental audit; but in Nigeria; the growth rate from the traditional core competence areas to new directions is steady and slow. This view was corroborated by Ajanlekoko (2012) that quantity surveying practice is still in the mainstream areas in Nigeria.

Professional service firms are noted to play a key role in the knowledge economy by acting as sources of new knowledge for client and by mastering the intricate process of both producing and using knowledge (Qian *et al*, 2010). Yet, the reasons why certain professional service firms turn out to be more successful than others remain poorly understood. Traditionally, professional service firms have been defined as human capital-intensive activities; indeed, the success of developing and delivering customized services to clients is directly linked with the skills of firm employees. Hence, Babalola (2009) considered the uniqueness of services offered by quantity surveying firms in the areas of financial probity in the execution of construction projects and noted that the major concern of the client is for the project to be completed to cost, quality and schedule. However, it has been observed that it is not all executed projects that the clients are satisfied. This dissatisfaction brings to focus the quality of services rendered by construction professionals. Phoya and Kikwasi (2008) corroborated

that the demand for quality, accountability and efficacy of professional services has highlighted the need for quantity surveyors to demonstrate that they are keeping abreast of new knowledge, techniques and developments related to their professions while the proliferation of knowledge in the construction sector, combined with the impact of technology in the workplace, means that construction professionals must maintain the currency of their qualifications by learning about such advances and developments. This will enable the service firm to identify sources of quality, discover quality problem and offer possible courses of action.

Quantity Surveyor's Competence Standard

Nuran *et al* (2010) noted that with the growing levels of competition across industries, competence is increasingly viewed as crucial for businesses to maintain long-term competitive advantage. The study opined that the notion of competence is rooted in the resource-based view, dynamic capability and knowledge-based theories. The development of a resource-based view provides a clearer understanding of when resources and capabilities are likely to have positive effects on new product outcomes and developing and maintaining competitive advantage. The dynamic capabilities view underlines that competence need to change over time to respond to changing environment while the knowledge-based view suggest that organizations can play a critical role in articulating and applying different types of knowledge through transfer or replication as well as integration and coordination efforts to attain competitive advantage. Therefore, Madter *et al* (2012) suggested a meta-list competency model that described the functional dimensions of professional competence as cognitive function (acquiring and using knowledge to solve real-life problems); integrative function (using professional reasoning); relational function (communicating effectively with clients and colleagues); affective/moral function (the willingness, patience and emotional awareness to use skills judiciously and humanely); and habits of mind.

Table 1: Competency Required of Professional Quantity Surveyors

Basic competence	Core competence	Optional competence
Personal and interpersonal skills	Construction contract practice	Arbitration and other dispute resolution procedure
Business skills	Construction technology and environmental services	Development appraisal
Data management and information technology	Economics of construction	Facility management
Professional practice	Procurement and financial management	Insolvency
Law		Insurance
Measurement		Project management
Mapping		Property investment funding
		Research methodologies and techniques
		Valuation
		Taxation allowance and grant

Source: RICS (2005)

The definition of competence has been widely discussed in literature (Boyatis, 2009; Dada and Jagboro, 2012). These studies described competence as the demonstration of an integration of knowledge, skill, personal attributes and value orientation. However, a justification for the competencies required of quantity surveyors is the ability of that quantity surveyor to meet differing and changing client's needs and; to expand the horizon of market for quantity surveying services depends on the knowledge base of the profession. Studies have identified Quantity Surveyors are key professionals in the construction industry that are involved in cost planning, cost management, project procurement, contract administration, feasibility studies and financial management of any developmental project. This wide array of responsibilities means that they have to be educated, trained, and highly skilled in diverse

subjects. Hence, RICS (2005) categorised competence of a professional quantity surveyor on three bases as follows:

Inference from the three categories of competency implied that basic competence are applicable to all professionals in the built environment; core competence are peculiar to professional quantity surveyors while optional competence are areas of future diversification and further development for professional quantity surveyors. Therefore, this paper focuses on measuring the relatedness of quantity surveyors' skill requirements for diversification of professional services.

RESEARCH METHODOLOGY

The paper adopted questionnaire survey on the population of diversified registered quantity surveying firms (principal partners) in Nigeria using purposeful snowball sampling. The

questionnaire was structured on the rubrics of quantity surveyor's skill requirements for diversification and relatedness of skill areas to future growth. This entailed coding the identified eighteen skills requirement of optional competencies. A total of eighty quantity surveying firms were surveyed using structured questionnaire out of which sixty-six were returned representing 82.5 % response rate that is above the usual rate of 20 - 30% for questionnaire survey in construction management studies (Kline, 1994). The data collected were analysed using percentile and Dendrogram of data cluster analysis to establish the relatedness of skills necessary for diversification of quantity surveyor's services.

Table 3: Areas of Business Diversification

S / N	Business areas	Frequency	Percentage
1.	Project management	20	25.64
2.	Other Business development	16	20.51
3.	Facility management	14	17.95
4.	Arbitration and other dispute resolution	10	12.82
5.	Valuation	8	10.26
6.	Property development appraisal	4	5.13
7.	Property investment	4	5.13
8.	Insurance	2	2.56
9.	Taxation	-	-
10.	Insolvency	-	-
	Total	**78**	**100.00**

Data Presentation and Analysis

Table 2 indicates areas where principal partners have acquired additional skills and competence. This shows that 30.30% and 16.67% are members of Nigerian Institute of Construction Arbitrators and Nigerian Institute of Building respectively. Also, 6.06% are members of Nigerian Institute of Estate Valuers; Nigerian Institute of Project Managers and Nigerian Bar Association respectively while 4.55% are members of Nigerian Institute of Town Planners; Nigerian Institute of Facility Managers; Nigerian Institute of Auditors and foreign professional bodies respectively. This also indicated that 1.52% are members of Nigerian Society of Engineers. However, it is noted that among the respondents, none are members of the Nigerian Institute of Architects and Institute of Chartered Accountants of Nigeria.

Table 3 shows the areas of business diversification by quantity surveying firms. This revealed that 25.64%; 20.51% and 17.95% have diversified into project management; other business development and facility management respectively while opportunities in business area of insurance; insolvency and taxation has not been explored.

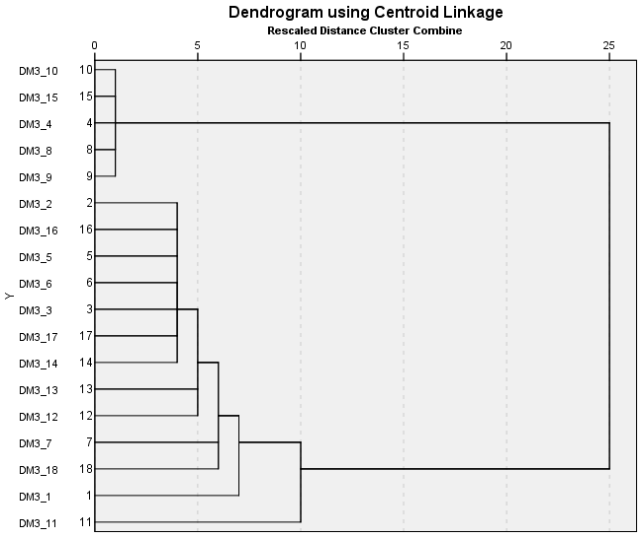

Figure 1: Dendrogram of Multiple Hierarchical Skill Clustering

Table 4: Agglomeration Schedule of Multiple Skill Clustering

Stage	Cluster Combined		Squared Euclidean Distance Coefficients	Stage Cluster First Appears		Next Stage
	Cluster 1	Cluster 2		Cluster 1	Cluster 2	
1	10 (Organisational learning)	15 (Taxation)	0.000	0	0	2
2	4 (Compliance issues)	10 (Organisational learning)	0.000	0	1	4
3	8 (Insolvency)	9 (Insurance)	0.000	0	0	4
4	4 (Compliance issues)	8 (Insolvency)	0.000	2	3	17
5	2 (Auditing	16(Quality assurance)	1.360	0	0	7
6	5 (Cost information database)	6 (Development Appraisal)	1.694	0	0	7

8	2 (Auditing)	3 (Business management)	1.525	7	0	9
9	2 (Auditing)	17 (Technical due diligence)	1.589	8	0	10
10	2 (Auditing)	14 (Research and development)	1.437	9	0	11
11	2 (Auditing)	13(Property investment funding)	1.855	10	0	12
12	2 (Auditing)	12(Risk management)	1.854	11	0	13
13	2 (Auditing)	7 (Facility management)	2.249	12	0	14
14	2 (Auditing)	18 (Valuation)	2.378	13	0	15
15	1 (Arbitration)	2 (Auditing)	3.002	0	14	16
16	1 (Arbitration)	11 (Project management)	4.108	15	0	17
17	1 (Arbitration)	4 (Compliance issues)	10.986	16	4	0

Table 4 shows the skills requirement for diversification in areas of optional competencies for quantity surveyors through the use of agglomeration schedule of cluster analysis while Figure 1 indicated seven levels of hierarchy of skill groupings or relatedness. This was further interpreted by Dendrogram grouping in terms of skills requirement necessary for diversification under each hierarchical groupings as shown in Table 5.

Discussion of Results

Table 2 shows that a high majority of the respondents (95.46%) have diversified skills to supplement their competence as a professional quantity surveyor. This finding corroborated the recommendation of Perera *et al* (2011) that commercial quantity surveying is necessary for corporate sustainability. Table 3 shows quantity surveying firms have diversified into project management; other business development and facility management respectively while opportunities in business area of insurance; insolvency and taxation has not been explored. This new business/service area are in conformity with the findings of Jewell *et al* (2014) as required to minimize the risk of over reliance in a single domestic market with a cyclical and fluctuating demand. The Centroid linkage of Dendrogram in Figure 1 reveals seven different levels of relatedness among the eighteen skills requirement of optional competencies of quantity surveyors. This implied that Valuation (18) is related to Compliance issues (4); Project management (11) is related to Facility management (7). Also, Arbitration (1) is related to Risk management (12); Compliance issues (18) is related to Research & development (14) and Risk management is related to Business management (3). This implied

that quantity surveying firms need to explore these new marketable areas where relatedness of service provision could lead to competitive advantage and business growth. This finding is in tandem with Stefan and Dodo (2013) that diversification strategies are used to expand firms' operations by adding markets, products, services, or stages of production to the existing business.

Table 5: Interpretation of Dendrogram Skills Cluster

S/N	Skills Requirement	Hierarchical Level	Dendrogram Grouping	Interpretation of Relationship
1.	Organisational learning (10); Taxation (15); Compliance issues (4); Insolvency (8) and Insurance (9)	1	Compliance issues	Compliance issues is related to Valuation
2.	Auditing (2); Quality assurance (16); Cost information database (5); Development appraisal (6); Business management (3); Technical due diligence (17) and Research & Development (14).	4	Business management	Business management is related to Compliance issues
3.	Business management (3); Technical due diligence (17); Research & development (14); Property investment funding (13) and Risk management (12).	5	Research & development	Research & development is related to Business management
4.	Research & development (14); Property investment funding (13); Risk management (12); Facility management (7) and Valuation (18).	6	Risk management	Risk management is related to Research & development
5.	Risk management (12); Facility management (7); Valuation (18) and Arbitration (1).	7	Facility management	Facility management is related to Risk management
6.	Facility management (7); Valuation (18); Arbitration (1) and Project management (11).	10	Project management	Project management is related to Facility management
7.	Valuation (18) and Compliance issues (4)	25	Valuation	Valuation is related to Compliance issues

CONCLUSION

The future challenges and opportunities facing the professional service firms have been hinged on cutting-edge services which is flexible, innovative and internationally focused. Quantity surveying service firms in Nigeria had to cope with irregular businesses thereby necessitating diversification in the area of arbitration and other dispute resolution; project management and other business development such as such as supplies and business ventures to sustain the firm. Hence, this paper concluded that business opportunities abound in the areas of taxation; insolvency; valuation; insurance and property investment. It is therefore recommended that principal partners should encourage professionals to diversify in these marketable areas of optional competence for quantity surveyors to ensure business growth and sustainability.

Assessing the CAD Proficiency Level of Architecture Graduates in Selected Architectural Firms in Akure, Nigeria

Fagbemi, O. S.[1]*; Ojo, A. M.[2] & Ayeni, Dorcas. A.[3]

[1, 2 & 3] Department of Architecture, Federal University of Technology Akure, Ondo State, Nigeria
[*] summex2003@gmail.com

ABSTRACT

The level of Computer Aided Design (CAD) proficiency of graduate architects in architectural firms needs critical assessment. The reason is because many schools of Architecture in Nigeria produce graduates with little or no skills in CAD. This paper assessed the CAD proficiency level of graduates in selected Architectural firms in Akure. The study explored the quantitative method of data collection and analysed the proficiency levels of architecture graduates in selected architectural firms in Akure. Findings from the study revealed the comparative CAD proficiency level of graduates from various schools in Nigeria as well as the impacts of CAD design tools in architectural firms and the basic requirements of the firms. It further revealed that architectural firms in Akure only employ graduates with the knowledge of CAD, at least basic 2D and 3D modeling software as against the manual drafting skills acquired from their various schools. The firms that conduct formal training programs for fresh graduates before or after given employments are infinitesimal. The study concludes that professional bodies should champion concerted effort to improve existing CAD training programs both in institutions and firms.

Keywords: Architectural Education, CAD, Graduates, Nigeria, Proficiency

INTRODUCTION

The advancements in Information and Communication Technology (ICT) are reshaping the Architectural design studio, Architecture pedagogy and design practices all around the world. Reffat (2007) stated that the digital imperativeness to switch from analogue to digital mode has already begun to manifest itself in various schools of Architecture and Design. It is common knowledge that the profession of Architecture is currently undergoing enormous strains as it battles to keep abreast of trends and developments in a period of series of rapid advancement in Science, Technology and Management (RIBA, 1992). The Architecture programs in Nigerian schools of Architecture, though fashioned after the British and/or American model, are tailored to meet the nation's socio-economic needs and cultural values within the general context of the Nigerian National Policy on Education (Olotuah, et al, 2007).

The relationship between the knowledge derived in educational institutions and work experience is of utmost importance in the practice of Architecture. Over the years, the practice of Architecture has evolved from the use of pen and paper to the use of computers. Despite the changes in practice, Architecture schools in Nigeria have not adopted the adequate changes necessary to enable graduates to adequately cope with the changes the practice of the profession is subjected to. Olotuah and Adesiji (2005) likewise opined that Architectural education in Nigeria has not seen many changes in its programs from the inception of the first school of Architecture in 1952. According to Olotuah (2000), schools of Architecture are struggling to keep up with issues that have transformed Architecture practice in other parts of the world. Consequently, it can be inferred that the laxity in our Educational system have resultant effects on our graduates. According to Sa'ad (2001), this trend has not only negatively positioned our graduates to gain from the wider knowledge and market offered by globalization in the industry in this 21st Century, but has equally diminished their knowledge. The use of CAD (Computer Aided Design) for Architectural drawings and

Fagbemi, O. S.; Ojo, A. M. & Ayeni, D. A. (2016). Assessing the CAD Proficiency Level of Architecture Graduates in Selected Architectural Firms in Akure, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1203-1210

analysis is the trend in Architectural practice nowadays and Architecture graduates are usually faced with this reality, among others, once they are actively involved in practice. CAD software is computer based design software used in the field of architecture for two-dimensional and three-dimensional drawings as well as modeling and analysing the proposed buildings. This paper assessed ways in which Architectural education in Nigeria has had impact on the CAD proficiency of graduates and Architects in selected Architectural firms in Akure.

The issue of manual drafting preference to the use of CAD by Architecture students in some universities in Nigeria has not been sufficiently cleared and understood. Students are not allowed to use CAD for their Architectural designs in schools and yet Architectural firms expect CAD proficient graduates. It becomes pertinent to assess the CAD proficiency level of Architecture graduates in firms and comparatively review the course curriculum of some universities.

The main aim of this study is to examine the CAD proficiency level of employed Architects in selected Architectural firms in Akure. This will be achieved by investigating the roles schools of Architecture have to play in the CAD proficiency of graduates, as well as fashion out strategies by which CAD knowledge can be improved amongst Architecture graduates.

CAD SYSTEMS IN ARCHITECTURAL EDUCATION

Bilalis (2000) defined Computer Aided Design (CAD) as the use of Information Technology (IT) in the Design Process. He further described CAD system stating that it consists of IT hardware, specialised software (depending on the particular area of application) and peripherals, which in certain applications are quite specialised. The requirements for Architectural education are yet to fully forge a coherent strategy for the implementation of CAD/IT in the curriculum of schools of Architecture. In almost every other field, including Engineering, Medicine and the Humanities, Computing Application to problem-solving and decision-making CAD/IT has been seen as a way forward as we moved into 21st century. Architectural education must integrate CAD/IT into the teaching of core modules that give the Architect distinctive competence: studio design. That is one of the best ways of doing justice to the education of the Architect of today and the future. Some approaches to the teaching of CAD in schools of Architecture have been touched upon in the recent past.

Yakubu, (2015) examined ways of maximising the benefits of CAD systems in Architectural education and of bringing Computer Aided Designing into the studio, not only to enhance design thinking and creativity, but also to support interactive processes. In order to maximise or optimise any function, one approach is to use the hard systems methodology which utilises analytic, analogic and iconic models to show the effect of those factors which are significant for the purposes being considered. The other approach is to use the soft systems methodology in which the analysis encompasses the concept of a human activity system as a means of improving a situation. The use of soft systems methodology is considered more appropriate for dealing with the problem of design which is characterised by a flux of interacting events and ideas that unroll through time.

The Practice of Architecture and the Use of CAD in the Contemporary World

Architectural design is a complex process that takes into consideration various parts that make the whole. In contemporary Architectural practice, flat sections and plans drawings are no longer a primary means of representation and communication with clients. Nowadays the widely used media in Architecture include visualisations, animations and three-dimensional models. (Guzik, 2009). Ogunsote and Prucnal-Ogunsote (2002) identified CAD Software to

include 2D and 3D modeling software, rendering software and animation software. Examples are shown in Table 1. Proficiency in this software should be acquired directly in departments.

Table 1: Examples of CAD software.

Category	Examples of Software
2D and 3D architectural modelling software	3D Home Architect, AutoCAD, Autodesk Architectural Desktop, Autodesk Revit Building, ArchiCAD, Form-Z, TurboCAD.
Rendering software	3D Studio Viz, AutoDesk 3D Studio Max, Accurender, AutoDesk Architectural Desktop, ArchiCAD, AutoCAD, Form-Z, TurboCAD.
Animation software	Amorphiurn , AutoDesk 3D Studio Max, Autodesk Architectural Desktop, Blender, Bryce, Corel Photo Paint, Flash, Poser, Ray Dream Studio, SoftImage XS1, True Space.

Source: Ogunsote, et al (2006)

Elegant software such as Lumion, Edificius, SketchUp Pro, Microstation, Softplan, ConceptDraw Pro, Arcon Evo, Envisioneer, DataCAD, Easy Blue Print, Domus Cad, Vector Works and Chief architect are also recommended for architectural designs.

COURSES REQUIRED FOR CAD PROFICIENCY

Ogunsote (2006) suggested some basic skills that should be acquired by all students of Architecture, planning and engineering. These skills can be acquired through common courses. The more advanced skills should however be taught within the department. CAD is best taught directly by each department, but there are circumstances where it is more efficient to offer some courses as service courses to several departments. CAD proficiency requires expertise in the following areas:

i. Basic computer literacy
ii. CAD concepts and theory
iii. Graphics software
iv. 2D CAD
v. 3D CAD and visualization

CAD Concepts and Theory

There are several concepts and theoretical constructs that form the basis of CAD software. While these concepts are best understood when demonstrated on a computer, it is important to teach these concepts in a classroom environment. Good understanding of these concepts is essential in understanding and using CAD software.

A workshop environment where theory can be discussed and concepts demonstrated is best. However, these concepts can still be taught successfully where there are very few computers.

Courses covering these concepts can be offered centrally to several departments with mainly lectures, practicals, assignments and written examination as components. The courses may for example be named Introduction to Computer Aided Draughting, CAD Concepts and Methods, Advanced CAD Concepts and Methods, et cetera. While examples should be given using a popular package like AutoCAD, the course content should be generally applicable to most CAD software.

Graphics Software

Even the best CAD design will lose its impact if poorly presented. Many aspects of students' training also require advanced skills in report writing, sketching, formatting and presentation. A good knowledge of graphics software such as Adobe PageMaker, Adobe Photoshop, Corel Draw, Corel Photo Paint, Harvard Graphics, Micrografx Designer, MicroGrafx Picture

Publisher, Microsoft Paint, Microsoft Power Point and Microsoft Publisher is essential. These courses are best offered as common courses.

2D Cad

Proficiency in two-dimensional (2D) Computer Aided Draughting includes the ability to independently produce basic drawings such as plans, elevations, sections, details and schedules at a professional level. Mastering CAD software such as AutoCAD is essential. This course can be offered at departmental level or as a common course depending on student population and facilities available.

STUDY LOCATION AND RESEARCH METHODOLOGY

The study was carried out in Akure, Ondo State. Akure town is the capital of Ondo State in South-western Nigeria. It lies in the southern part of the forested Yoruba Hills and at the intersection of roads from Ondo, Ilesha, Ado-Ekiti and Owo. Akure is an agricultural trade centre for food crops like yam, palm oil and kernels and cocoa as the major commercial crop, with a population of 484,798 people according to 2006 population census. (National Population Census 2006). Akure is the site of The Federal University of Technology, Akure" (founded in 1981). In order to gather information on the status of architectural firms in Akure and how CAD proficient their employed staff are, questionnaires were administered to the firms and various interviews were also conducted. Questions were asked on the level of CAD usage in the firms, the types of software used in the selected firms, availability of CAD personnel in the firm and how often they conduct training for staff. Questions were also asked on the criteria considered before employment is given to any graduate as touching CAD literacy and the level of knowledge/skills gained during training in their various schools.

A semi-structured questionnaire was developed and standard open-ended interview was carried out in selected architectural firms in Akure. A total of Ten (10) architectural firms were randomly listed to be examined out of which only six (6) representing 60% were successful being the very few registered architectural firms entitled to architectural practice, with employed architecture graduates and registered principal architects. The research questions were aimed at having details on the CAD proficiency of the architecture graduates and to also determine if the CAD software they know were taught in their respective schools or learnt individually.

REVIEW, FINDINGS AND DISCUSSIONS

The response on the level of software literacy in architectural firms showed that high priority given to manual drafting in schools should be equally given to CAD knowledge as the firms employ just proficient graduates and not just an amateur. A total of 24 (Twenty-four) questionnaires were administered to staff which including various level of qualification ranging from HND holders to Master's degree holders in the selected firms and only 19 (Nineteen) were duly returned representing 79% of the total questionnaires.

Number of Staff in the Architectural Firms

The study examined the number of staff that work in each firm. The results show that 2 firms have up to 5 employed graduates comprising HND, B.Tech and M.Tech holders representing (33%) of the sample. Three (3) firms have 2 fully employed graduates which measures (50%) of the sample. Just one (1) firm has a total number of 3 architectural graduates representing 17% of the total selected architectural firms.

The above number of staff provided information on employed architectural graduates alone as some of the firms have other professionals working in the firms, such as Quantity

Surveyors, Civil engineers, Electrical and Mechanical engineers and others. The firms as well have other staff such as secretary, receptionist, Industrial Training Students and Draftsmen.

Qualifications of Staff

Table 2: Analysis of the qualifications of staff in firms.

	Frequency	Percent	Valid Percent
HND	7	36.8	36.8
PGD	1	5.3	5.3
B.TECH	8	42.1	42.1
M.TECH	3	15.8	15.8
Total	19	100.0	100.0

(Source: Author's field survey 2015)

From Table 3, the study examined the qualifications of the staff in the sampled firms. The result of the analysis shows that 36.8% of the staff are HND holders, 5.2% are PGD holders, and 42.1% of the staff are B.Tech holders while 15.8% are M.Tech holders. This results shows that the highest percentage of qualifications are the B.Tech holders followed by HND holders while the lowest percentage is the PGD holders which confirmed the response of some staff during the interview that most HND and B.Tech holders have acquired CAD skills before graduating from school either through personal tutorial or they were taught in schools.

CAD Proficiency Level of Newly Employed Staff

Information gathered from certain personnel in some of the selected architectural firms revealed that no firm is ready to waste resources on employee that cannot deliver and this propelled the motive of these firms not employing architectural graduates without at least a 2D drafting software skill. The table below shows the proficiency level of Staff against the various CAD software they can use.

From Figure 3, 52.6% of the staff use AutoCAD architecture majorly for 2D drafting. The software dominates the chart as it is very flexible compared to other drafting software. 26.3% of the staff used Revit Architecture, 15.8% of the staff are ArchiCAD proficient, 5.3% are averagely skilled at using Google SketchUP and none of the staff is proficient at using 3D Studio Max. It was observed that most of the firms are currently into solely 2D drafting and any further request by the client for 3D presentations attracts extra fees as it will be contracted out to experts that are not member of staff. This suggests that more attention is paid into 2D presentations. Depending on the clients, some are interested in 3Ds but firms do not see reasons to fully employ just 3D modelling experts. The staff were asked to state means by which they gained proficiency in the CAD software of their choice.

Means of Learning Cad by Staff/Graduates

Table 3. Staff means of learning CAD software of their choice.

	Frequency	Percent	Rank
Self-learning	9	47.4	1
Self-learning & Private Tutor	6	31.6	2
Private Tutor	4	21.1	3
Part of School Curriculum	0	0	4
Total	19	100.0	

(Source: Author's field survey 2015)

From Table 4, 47.4% of the staff learnt CAD on their own, some when they were still in school and some after leaving their various institutions, while 31.6% of the staff acquired their CAD skills through both self-learning and private tutor. Due to the complexity of some of these software. According to some of the respondents, even after learning individually through either downloaded online tutorials or trial and error methods, the attention of more

proficient architects in that particular CAD were still needed, while 21.1% of the staff learnt CAD through solely private tutor. The knowledge was acquired under the tutelage of their colleagues both in the institution and in their respective firms. None of the staff had CAD as part of their school curriculum. This revealed that to be CAD efficient as an architectural graduate or staff in a firm, it all lies on the individual as none of the institution has fully adopted CAD into their training programme.

Some of the respondents affirmed that they were allowed to present some certain percentage of their school projects and course works in CAD, yet it is not part of their departmental curriculum but a major condition for employment by architectural firms in Nigeria.

Staff Training Programmes by Firms

The study unveiled the non-existence of formal staff training programmes in architectural firms in Akure. Instead staff engaged in one-on-one method, a more proficient staff in the firm trains less proficient staff irrespective of their position in the firm. This method is also adopted for students undergoing their Industrial Training Programmes at the firms. There is no strict measures towards IT students, even if they do not have prior knowledge of any CAD they will be trained at the firms starting with AutoCAD Architecture. Interviews sessions with some of the staff also revealed that most of them developed personal skills in software proficiency through online materials, book and constant practice.

General Challenges Faced by Staff in the Firms

To improve the CAD proficiency of graduate architects and staff in architectural firms, there is need to examine the possible barriers to the increase of CAD proficiency level in both schools and firms. The table below shows the challenges encountered by staff at their various firms in Akure.

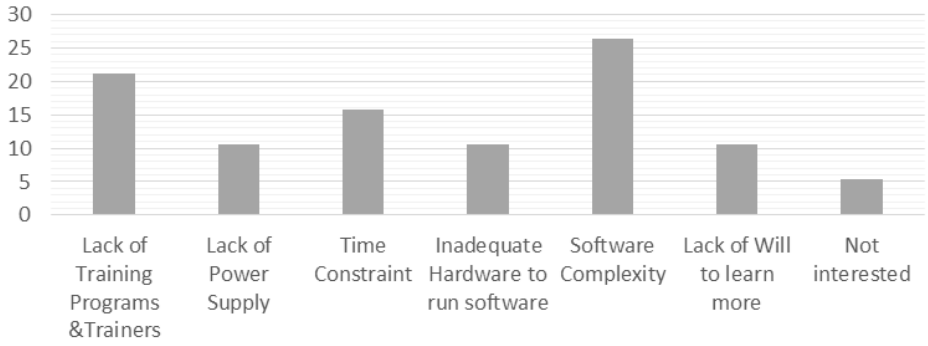

Figure 3: Barriers to CAD proficiency in firms
(Source: Author's field survey 2015)

From figure 5, 26.3% of the respondents attributed complexity of the software as their major barrier to being proficient in CAD usage. This has highest frequency of respondents followed by Lack of intensive training programme and CAD proficient personnel having 21.1% of the total percentage, while 15.8% of the staff said they do not have the time to improve their proficiency level in CAD. However, 10.5% of the total staff said lack of power supply was the major challenge, 10.5% also said inadequate hardware to run the software was their drawbacks, also 10.5% also said they are not interested in learning some other software aside the ones they already know since their firms do not even make use of other software apart from 2D software such as AutoCAD. However, 5.3% of the staff said they do not have any challenge. This suggests that staff in these firms are interested in learning and improving their proficiency level but along the way they encounter difficulties with the software which will require the help of an expertise in the field. This training/trainer is what is missing in these firms.

SUMMARY OF FINDINGS

The main aim of this study is to examine the CAD proficiency level of employed staff architects and suggest ways of improving the CAD knowledge of architectural graduates. The findings of the study are summarised below:

i. In the selected architectural firms in Akure, the major architectural CAD software they use is AutoCAD architecture to produce just 2D designs for clients and if there is need for 3D modelling, it is contracted out to a 3D expert not necessarily employed in the firm. Almost all the staff in the selected firms are more proficient with AutoCAD as this is the major software used in the firms.
ii. Before employment is given to any architectural graduates in selected firms, the person must have the basic knowledge of AutoCAD for 2D presentation drawings. However, it was realised that even if the person does not have site experience but knows how to use AutCAD, he or she will still be employed.
iii. There are no formal training programmes organised by the firms for staff at any level. Instead a more proficient CAD personnel trains staff with less knowledge of CAD. This has nothing to do with age, position or hierarchy as even principal architects in firms learn from lower ranked staff.
iv. None of the schools that produced these graduates have CAD as part of their curriculum instead students engaged themselves in personal training through online tutorials, books and constant lunching and learning techniques.
v. Staff that see the complexity of these software as the major barriers to their CAD proficiency level have the highest percentage. The complexity of the software interface and slower rate of assimilating the ideas behind the software require the expertise of a more proficient personnel.

CONCLUSION AND RECOMMENDATIONS

The issue of balancing the traditional drafting method and the use of Computer Aided Design in architectural schools is yet to be properly established resulting in architectural graduates not enjoy the full benefits of CAD even at their early years in schools. However, a basic knowledge of CAD has to be acquired from school before employment is given to graduates in architectural firms. With the circumstances and challenges faced by employed staff, graduates and students in institutions, to be CAD proficient may be quite challenging but it can be achieved and technology is really advancing in this age so a lot is expected of architectural graduates. The following are some recommendations with the intent that they serve as models to improving the CAD proficiency levels of staff in firms and student architects.

i. In order to improve the proficient level of staff in architectural firms, intensive formal training should be conducted perhaps yearly where experts in different digital design technologies and software application train the staff as this increase the efficiency of the firm.
ii. CAD proficiency should be integrated into architectural curriculum thus exposing architects to the rudiments of CAD at an early stage. Curriculum should be dynamic not static and is expected to be reviewed every five years for continuous updating.
iii. Architectural staff with less CAD knowledge should be encouraged to learn from more proficient ones and not rely on the training programmes by the firms.
iv. Architectural firms should also encourage staff to go for conferences and seminars with subsidised funding by the firms.

v. Various forms of interactive education systems such as video tutorials, electronic handbooks and so on should be adopted in the teaching of CAD. The creation of a CAD studio well stocked with high-end computers that should at least conform to the minimum specification for teaching and learning of CAD software both in institutions and firms should be encouraged.

vi. The criteria for employing architectural graduates in firms should not be limited to just 2D software but also 3D modelling and other software.

Sustainable Architectural Education: Perceptions from University of Jos Post Graduate Students

Allu, E. L.

Department of Architecture, University of Jos, Nigeria
evelynallu28@yahoo.com

ABSTRACT

Sustainable education has been acknowledged to promote the future of sustainable development (SD), and one of the key factors for achieving SD in developing countries is driven by contributions from professionals and future practitioners within the built environment. This study presents the perceptions of postgraduate students of architecture from the University of Jos on the role of sustainable architectural education and the future of sustainable architectural practices for Nigeria. An inductive survey was employed to sixteen (16) students from the two arms of the postgraduate classes, representing 30% of the students. Results from the survey show that, about 50% of the students are well aware of the concepts of sustainability. Yet, sustainability as a course in not taught in the department, beyond the expiration of the UN Declaration- which declared 2005-2014 as the decade of sustainable education. This study aims at promoting the SD practices and skills application through sustainable architectural training for the future practitioners. The study's relevance is hinged on the global concern for sustainable practices, especially within the built environment. This study's recommendations include; new and common pedagogical curricula for all schools of architecture, continuous professional sustainable training and its application in practices. This study is also intended to spur future studies on sustainable architectural education in Nigeria.

Keywords: architecture, built environment, education, Nigeria, sustainable development

INTRODUCTION

Buildings, architecture and sustainability are linked. Globally buildings contribute about 50% to the causal processes of climate change due to their high consumption of energy and carbon emissions (IPCC, 2007). In the Sub-Saharan Africa buildings consume about 90% of energy (Earth Trends, 2005). The continuous negative impact of climate change to the built environment (IIPC, 2007) and the global concern for sustainable development (Ebohon et al., 2013) have necessitated the changes in industries and societal expectations (O'Rafferty et al., 2014). As a follow-up there was also an immediate reciprocal shift in the curricula of many western universities and particularly the architectural education agenda (Zuo et al., 2010; Iulo et al., 2013). The shift is primarily to accommodate the principles and practices of SD design solutions (Altomonte, 2009; Allu and Ebohon, 2015).

Other studies have also acknowledged and linked sustainable architectural design to link technology, businesses, people and social solutions for societal problems (European Commission (EC), 2009; O'Rafferty et al., 2010; Rasmussen, 2011). Furthermore, Botha et al. (2013) in their study concluded that one of the key drivers of promoting SD in developing countries is driven by the contributions of professionals and future practitioners from the built environment. The above discourse underpins this study's pursuits as presented in the following sections. Therefore, the aim of this study is to promote sustainable skills acquisition and applications for SD practices through sustainable architectural training of future practitioners. The UN 57th session declaration of 2005 – 2014 as the Decade of Education for Sustainable Development (DESD) is examined and recognised the importance of integrating sustainable development into architectural education. The UN DESD Report also stated that, "Education is motor for change" and further stated that "...education is the

Allu, E. L. (2016). Sustainable Architectural Education: Perceptions from University of Jos Post Graduate Students. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1211-1218

key to sustainable development" (UN DESD 2014, Report, p. 4 and 6). Consequently, this study presents the place of UniJos in actualizing the DESD resolution and the ways forward for architectural training in Nigeria are highlighted.

SUSTAINABLE DEVELOPMENT AND EDUCATION

Education and learning have influence on its recipients beyond the period of training. University values are guided by government and policy makers, while professional institutes and accreditation boards have control over its curriculum (Dunbly et al., 2007; Cockrell, 2010). On the other hand, university education also influences an impact on its products, their practices and the society (Thomas and Day 2014). Furthermore Haines (2011) asserts that education and training are the cheapest and most effective way to realign the thinking of future practices. This assertion is most likely having a bearing on the DESD declaration which seeks to achieve a sustainable world, using education as the means as was captured in summation of UNESCO which spelt out what DESD is intended to achieve as follows:

> *...seeks to integrate the principles, values, and practices of sustainable development into all aspects of education and learning, in order to address the social, economic, cultural and environmental problems we face in the 21st century.*
>
> (UNESCO, 2010, p. 1)

The best practices are in this regard are therefore, linked with the ability to practice sustainably in the face of environmental challenges. The UNESCO interpretation also implies that sustainable education is a capacity building strategy. Education is therefore, identified as the necessary channel to ensure future of best practices in the face of the global climate change challenges on the environment. Earlier research has also observed that in some countries SD education starts at the primary schools (Tilbury et al., 2005) and later researchers argued that SD education is most effective at the university level (Lozano, 2006; Lukman and Glavic, 2007; Leal Filho and Manolas, 2012). The study supports the later argument because the study is professionally inclined.

Recent studies by Barth and Timm (2011) and Lozano et al. (2011) observed that in many western countries, Higher Education (HE) have embedded environmental education and Education for Sustainable Development (ESD) into their curriculum as a commitment towards actualising the future practices of sustainability. Notably, also is that architectural education has been pointed to lead in the global concern for a professional shift towards sustainability (Cortese, 2003). Current architectural education has also been emphasising environmental conscious design training (Zuo et al., 2010; Leslie, 2012). This shift According to Capuzocca and Sarni (2012) adds value to innovation and efficiency, particularly to design exploration and enhances the ability and skill application for future practices (Second Nature, 2011; Kamal and Asmuss, 2013). Another study observed the tendency for non-studio and studio courses in architecture to have conflicting priority and taught independently thus, creating a gap in knowledge transfer (Smith, 2011), however, a later study by Demirkan and Afacan (2012) notes that sustainable design education is a means to achieving value added design solutions and consequently bridging the gap between non-studio and studio courses.

The preceding discourse has established the advantages of mainstreaming sustainable education into the curricula of all HE and to architectural education in particular. It is also apparent that mainstreaming ESD into the curriculum of HE in architectural education within the period of DSED has been adopted in many countries and supported (UN DSED Final Report, 2014). Yet beyond 2014 there are universities that have not aligned with this global

agenda for change and the shift from the traditional ways of developmental developments towards achieving worldwide sustainability (Lozano et al., 2011; Allu, 2014). Thus, this study forms part II of the study carried out by Allu (2014) on the need for sustainable architectural education in the department of architecture at the University of Jos.

The University of Jos is one of Nigeria's second generation universities. The department of architecture is one of the leading schools of architecture in Nigeria established in 1979. The department like most schools of architecture runs both the undergraduate and postgraduate programmes. Unfortunately there is no known sustainable development course being run in this department, two years beyond the UN declared decade of sustainable education. Perhaps, the department's position is related to Bardaglio (2007) opinion which states that ...*the academic program is an area that traditionally has been most resistant to change."* The motivation for this study is derived from UNESCO (2014) Final Report which was developed after DESD period lapsed, this evaluation report states the UN resolve to continue the pursuit towards promoting sustainable development beyond 2014.

Given that relevance of mainstreaming sustainable development education and the role of HE in ensuring that future sustainable practices are enhanced through skill acquisition and the ability for its application. Reflecting on the aforementioned discourse architecture like other disciplines has also keyed into ESD. It is important to also identify approaches employed by architectural programmes in universities that have successfully embedded ESD in their curricula.

APPROACHES TO SUSTAINABLE EDUCATION IN ARCHITECTURE

Embedding ESD into the architectural education has multidimensional positive effects to the future architect. The importance of embedding ESD into architectural programmes has multifaceted advantages including; harmonised training and qualification, employability, professional competence, mobility, value added curriculum, capacity building and promotes global sustainability (Lipscombe et al., 2008; Cadima, 2009; Tilbury, 2011; Thomas and Day, 2014). It is worth noting that these advantages are also to the profession and the society at large because sustainable education provides the opportunity for holistic approach to design solutions. Barth and Timm (2011) also noted that embedding ESD into HE does not only bring an educational change but introduces new approaches to teaching. While the study undertaken by Iulo et al. (2013) on "Environmentally conscious design: educating future architects" examined the curricular-based programmes on architectural programmes in the US. Their finding reveals that there are four approaches to curriculum based approach to ESD architectural programmes. These four approaches are: core value, technological domain or systems-focused, choice, and specialization.

Table 1 highlights the four approaches at a glance, what they entail, actions required and remarks. In the overall, the 'core value' approach covers all aspects of learning unlike the 'specialization' which is mainly for the postgraduate students however, 'technological' and 'choice' approaches restricted to specific technologically focused and the choice approaches is seen as an elective course. Based on the investigation with ESD educators in some American Universities Iulo et al. (2013) summation was that a composite approach should be adopted and their study also suggested the need for future studies to examine the perceptions of the student on the four approaches. Their suggestion agrees with an earlier conclusion that students' perceptions are important to the success of ESD (Barth and Timm, 2011). Hence this study attempts to gauge the perceptions of the postgraduate students on the most suitable approach of ESD to introduce to the architectural programme at the University of Jos.

Table 1 Approaches Sustainable Education (SE) in Higher Education

S/N	Approaches	Actions	Remarks
1	Core value: sustainable education is seen as a "core value" course	Included in the content of all courses	Addresses sustainable conscious design
2	Technology domain: contained in environmental systems courses	fulfil the sustainable education needs of architecture students	Specific to technology courses only
3	Choice: sustainable education optional	students select sustainability-related courses by choice	Seen as an elective course only
4	Specialist knowledge: sustainable education is a specialty course	Occurs mainly at the graduate level and in concert with centres or institutes also focused on sustainable research.	Limits future career of student who may not pursue graduate research opportunities

Source: Adopted from Iulo et al., 2013

METHODS

The four approaches to ESD identified in Table1underpins the inductive inquiry of this study. In line with the Myers (2009) assertion that face-to-face group interviews are; comprehensive, provide in-depth information and suitable for any qualitative research. Thus, this study adopts a face-to-face group interview for collecting its primary data. 16 (n= 16) post grads, 8 from each arm of the MSc programme (MSc 1 and MSc 2) were engaged in the interview session. Five (5) main Semi-structured interview questions guided the interview sessions. The interview questions were as follows:

i. Are you well aware of the concept of Sustainability?
ii. What is your understanding of Education for Sustainable Development? What about the UN Decade of Education for Sustainable Development?
iii. Which of the four approaches earlier discussed would you recommend to your department? Please explain.
iv. Why do you think your department is yet to embed ESD into its curricula?
v. Do you think ESD has the potential to promote sustainable practices beyond the university training period? Please explain?

Some follow-up questions are highlighted in italics.

The interview sessions were conducted in September, 2015 and the session lasted about 90 minutes. Secondary data were robustly sought from relevant literature. Ethical research considerations were sought and obtained for this study and participation was voluntary.

Descriptive analysis was employed to analyse the primary data. The data are set to provide a baseline for the choice of the most suitable approach to adopt in the architectural programme for the University of Jos and other programmes within the context of this study.

FINDINGS

This section presents the summary of key findings from the qualitative survey. At the start of the interview session the study's subject was introduced and a sheet of paper with Table 1 was given to each participant. The interview invitation letter had also relayed the study's focus to the interview. Thereafter, the interview session was arranged in one of the post grads studio.

Responses for Question I

Only a total of 8 (50%) of the 16 interviewees were confident and are able to explain the concept of sustainability, while the others claim that sustainability is a familiar term. This

finding translates to an average result and being familiar to sustainability does not in itself translate to skill acquisition. By implication it means these set of post grads and not well informed about sustainability and therefore, they are not well prepared for sustainable practice after their education.

The Responses to Question II

About ESD were unsurprising as many of the respondents thought it was an academic discipline. One of the response was "... just like special education, education for sustainable development is a specialised field." The closest response was "It is about the education aspect of sustainable development." At this point about 7 minutes was used by the author to explain what ESD means. Furthermore, only two students claimed to have read a journal article that referred to DESD. Surprisingly, a respondent said he perceived DESD would commence in 2016. Otherwise other interviewees had no opinion on what DESD is supposed to achieve.

There were divergent **views on question III**

As each participant was only allowed to choose the approach that seems the most suitable. 7 (44%) of the interviewees chose the first approach "core value" and their reasons included:

i. It is a continuous process of learning
ii. Unified curricula to all students
iii. Non selective
iv. Offers equal opportunities

Views expressed for the choice of the other 3 approaches revealed that, for the 'Technology domain' the views expressed by the 2 (13%) interviewees who preferred the approach was that sustainable development seem technically inclined and secondly, that it is likely to be taken more seriously by students. The 3 (20%) interviewees who opted for "Choice" as the most suitable approach were of the opinion that; since there is no compulsion with the approach, students who are interested would learn faster with this approach. Another 2 (13%) chose the "specialist knowledge" for the reason that it would offer them an opportunity to diversified and likely to enhance their chances for employment. Although the views are at variant, it does portray negativity but that each of the four approaches to ESD has their merits. The views expressed also reveal that the students are interested in learning more about sustainability.

Question IV

Again this question also attracted different opinions and some selected verbatim responses were as follows:

i. It is likely that the university administration is not informed of about ESD as I am until now.
ii. Maybe the lecturers are not qualified
iii. ... it may not be part of the accreditation criteria for National University Commission (NUC) and for Architects Registration Council of Nigeria (ARCON).
iv. It is possible that much funds are required to introduce the curricula for all the levels
v. It may be in the pipeline for the curriculum review
vi. NUC may be test-running the ESD curriculum in another university before it is adopted by the commission.

The above responses have validated and re-echoed some of the underpinning theoretical discourse in the preceding sections. Particularly, it is wake up call for the university of Jos governing board, NUC, ARCON and the department to align their architectural programme with the global agenda for sustainable practices.

Question V: the interviewees who seem not too excited at the commencement of the interview session suddenly came alive and provided many positive responses on the potentials of ESD. Their responses are highlighted below to include:

i. It would set the department at par with other architecture programmes international
ii. Introducing ESD into our curriculum is most likely to improve our university rating
iii. It means we can compete professionally with architects from other countries
iv. ESD would knowledge and understanding of sustainability
v. More students may prefer UniJos to other universities running architectural programmes
vi. It would be relevant and timely, considering information this interview session provided me.

These positive comments by the students further validates the arguments for the mainstreaming ESD into HE architecture programme. Some of the many advantages of ESD have also been stated by these post grads who have not formally been introduced to ESD. It is deducible to note that amongst the interviewees, that a new interest has been reawaken and it is most likely for each of them to want to pursuit this new interest and seek further knowledge in the context of sustainable architecture.

CONCLUSION

This study has presented theoretical arguments to demonstrate that embedding ESD in every country's architectural education systems promotes harmony of architectural qualification, standards and practices. The relevance of ESD has also been established and the importance for architectural programmes to key into the global agenda for sustainable practices is not questionable. As much as some universities may not be susceptible to change, however, in order for these universities to have a positive impact to the profession of architecture and the global society would require their active participation in the sustainable drive through ESD.

As noted by the study conducted by Barth and Timm (2011) students' perceptions are important for ESD to succeed. Although the students whose perceptions formed the data for this study have no formal ESD learning experience, the data collated from them is informative to the study and the future considerations by the architecture programme at the University of Jos. Beyond the architecture programme in the university of Jos, the findings from this study can be considered relevant to other schools of architecture. In addition, students who participated in this study recognised its potentials and the knowledge the 90 minutes interview session provided. This attempt is likely the first in this regard from the sub-Saharan region of Africa and has the potential to spur future studies from allied professions within the built environment in Nigeria.

Consequently, this study recommendations that new and common pedagogical curricula for all schools of architecture, continuous professional sustainable training and skill acquisition, and the application of sustainable practices.

ABSTRACT

Several studies have identified the importance of managing stakeholders as major criteria for determining project success, thus stakeholder management is an important aspect of project management. In Nigeria, studies conducted in the research area have not assessed the adoption of stakeholder management. Therefore, this study explored the levels of awareness of Stakeholder Management practice and how stakeholder analysis is conducted in TETFUND construction projects. Interviews were conducted with ten (10) project managers that have managed at least two (2) TETFUND construction projects in tertiary institutions. Comparative content analysis method was used to analyse the interview responses. The result shows that there is awareness of the concept but no proper adoption of stakeholder analysis guidelines as stated in literature within the firms. The study recommends that proper adoption of stakeholder analysis guidelines should be embraced by consulting project management firms in managing project stakeholders. This study will further help subsequent project managers toward recognising the importance of carrying stakeholder analysis and employing more resources to conduct it in managing projects.

Keywords: Project Stakeholders, Stakeholder analysis, Stakeholder Management, TETFUND

INTRODUCTION

The importance and role of the construction industry to other sectors of the economy makes it to have different stakeholders with wide range of interests that need to be managed. Farinde and Sillars (2012) described the construction industry as a complex and huge industry with several key players with different interests. Therefore, a project can be successful in its entirety when the construction organisation is able to effectively manage all human and non-human resources; this is done in order to deliver a facility that satisfies and exceeds the needs of the client at the time it is required and within considerable budget range.

Traditionally, construction projects are deemed to be successful if they were delivered within the set of objectives of budget, schedule and quality (Chua et al., 1999). However, the planning and construction of a facility can affect many interests due to the different people involved from different backgrounds and disciplines. Also, construction projects involve many phases, and at each phase/stage, there are key people that are needed to act. Dosumu and Onukwube (2013) further recommended that for construction projects to be successful, attention must be paid to user's related factors, professionals' factors and organisation's factors. Looking at the users, professionals involved as well as the organisations all constitute the project stakeholders.

Newcombe (2003) defined Project stakeholders as groups or individuals who have a stake in, or expectation of the project's performance and include clients, project managers, designers, subcontractors, suppliers, funding bodies, users and the community at large. Stakeholders either affect or are affected by the accomplishment of the project (Freeman, 1984). Satisfying stakeholders need is one of the criteria for project success (Turner, 1999; Smith et al., 2001) and their buy-in and support is important aspect of Project Management (Takim, 2009).

Ibrahim, M. L.; Ibrahim, Y. M. & Adogbo, K. J. (2016). Appraisal of Stakeholder Management Practice in Tertiary Education Trust Fund (TETFund) Construction Projects. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1219-1225

Adequate involvement of stakeholders in construction projects will help in accommodating different interest towards realizing the project success.

Onarinde (2011) identified the importance of stakeholders and their management to successful projects before, during and after construction process in Nigeria. However, the question that still lies is how the concept is applied in Nigeria. Therefore, this research seeks to further appraise the practice of stakeholder management in the Nigerian Construction Industry using TETFUND construction projects.

STAKEHOLDER MANAGEMENT AND STAKEHOLDER ANALYSIS

The subject of project success criteria and its determination has enjoyed considerable discussion in project management practice. Success criteria are unique and cannot be generalized for all projects due to the nature and variability of all projects (Adinyira et al., 2012). However, there is a paradigm shift from the traditional perception of project success to the modern approach which uses tools that includes stakeholder management. Berk and Kartal (2012) pointed out that the key elements for success in construction projects are life cycle management and stakeholders.

Stakeholder management is an aspect under project management that deals with managing the relationships and interests of the different stakeholders involved in a project. Stakeholder management is now considered a key concept for the completion of construction project work (Atkin and Skitmore, 2008). Therefore, Stakeholder management is a significant component in managing a firm as well as a project.

In any project, and especially in construction projects, many different and sometimes discrepant interests must be considered (Olander and Landin, 2005). Successful stakeholder management can be achieved through conducting a careful stakeholder analysis. This is supported by Aaltonen (2011); Bourne (2009); Jepsen and Eskerod (2008); Rowlinson and Cheung (2008); and Yang et al. (2011) as they all assert the importance of stakeholder analysis. As such, it is important for the project manager/team to effectively carry out a stakeholder analysis which will subsequently help(s) in designing the strategy that will be used in managing the stakeholders involved in the project.

Yang et al. (2011) indicated that because of the uncertain and complex nature of construction, it is important that a proper stakeholder analysis and engagement process is carried out in order to successfully manage the process. They further went to explain stakeholder analysis as consisting of stakeholder identification; stakeholder categorisation; and stakeholder assessment based on influences and relationships.

Stakeholder analysis identifies all primary and secondary stakeholders who have a vested interest in the issues with which the project or policy is concerned. The goal of stakeholder analysis is to develop a strategic view of the human and institutional landscape, and the relationships between the different stakeholders and the issues they care about most.

According to Aaltonen (2011) conducting a stakeholder analysis helps project managers to attempt to paint a picture of the stakeholder environment which will be used to make decisions as regards management of stakeholders in the project. Stakeholder analysis should be a continuous process that spans throughout the process of a project life cycle to retain effectiveness and this should be done alongside stakeholder engagement which requires managerial skills and effective communication (Rowlinson and Cheung, 2008).

Therefore, it can be summarize that stakeholder analysis is the process of identifying all the persons, groups and institutions who may have an interest in a project and taking steps to manage their interests and expectations so that the project runs as smoothly as possible.

For the purpose of this research, Tertiary Education Trust Fund (TETFUND) construction projects were selected, being projects with the same scheme. The TETFUND was established as an intervention agency under the TETFUND ACT – TERTIARY EDUCATION TRUST FUND (ESTABLISHMENT, ETC) ACT, 2011; charged with the responsibility for managing, disbursing and monitoring the education tax to public tertiary institutions in Nigeria. One of the mandates of TETFUND is to administer and disburses the amount in the Fund to Federal and State tertiary educational institutions, specifically for the provision and maintenance of essential physical infrastructure for teaching and learning which includes construction projects.

METHODOLOGY

Qualitative approach was adopted for this study and semi-structured interview guide was used to conduct an interview among the respondents of the study. The interview questions were structured to provide information on the firm's background, its understanding/perception on project stakeholders and the approach use in conducting stakeholder analysis in TETFUND projects.

The sample of the study was drawn using purposive sampling technique by selecting only firms that managed more than a single TETFUND construction project to form the sample size. A total number of ten (10) firms that managed TETFUND construction projects were used to retrieve the data needed for the study. The samples for the research were selected from construction projects within tertiary institutions located within North-western region of Nigeria. The data obtained from the interview responses were analysed with using constant comparative content analysis method of analyzing.

FINDINGS AND DISCUSSION

Results and Discussions

The research conducted ten (10) interviews to representatives of the firms that form the sample size used for this research. Table 1 shows the general questions' section of the interview guide used which represents the details of the project management firms with regards to: the range of services offered, number of employees and those with project management qualification.

The details of the firms obtained showed that most of the firms concentrated on the provision of architectural, planning and project management services. However, three (3) of the firms venture into other services with two being multi-disciplinary firms (P1 and P3), while P5 extends it services beyond architectural and project management, by providing structural services. The two (2) other firms, i.e. P7 and P9 offer Quantity Surveying and Project Management services.

P1 has a unique organisational structure, because it only engages staff when the need arise as it does not keep permanent technical staff, although its present director is a well-qualified Project Manager. P5, P6 and P8 have more than ten (10) technical employees while the other six respondents all have less than ten (10) technical employees. Four (4) of the firms operate without any properly trained project manager. P4, P6 and P9 have qualified project managers with master's degree while P5 and P7 have employees that are certified chartered project managers. From literature, the responsibility of managing project stakeholders lies with the project managers. Therefore, there is the need to have well trained and qualified project managers in any firm that offers Project management services.

The different definitions obtained from the interview indicate that all the respondents have a good awareness and knowledge of the concept of stakeholder management. From Table 2, the

PMI (1996) definition is the most closely related definition referred to by the majority of respondents. This has further supported the findings of Onarinde (2011) that practitioners have a good knowledge of stakeholder management in the Nigerian construction industry.
The respondents were also able to mention the project stakeholders ranging from the sponsors, the beneficiary institutions' management and their technical units, other consultants, contractors, end users etc. The result agrees with the checklist of stakeholders included by Newcombe (2003) in his list. This further established the awareness and understanding of the concept of stakeholder management by the respondents.

Table 1: Respondents' Details

PM Firms	Ranges of services offer	Number of Employees	Number of Employees with PM qualification
P1	Multi-disciplinary consultancy	Dependent on nature of job	All
P2	Architectural and PM	3	None
P3	Multi-disciplinary consultancy	7	None
P4	Architectural and PM	7	3 (MSc. PM)
P5	Architectural, Structural and PM	20	4 (PMP)
P6	Architectural and PM	15	2 (MSc. PM)
P7	QS and PM	5	None
P8	Architectural and PM	15	2 (PMP)
P9	QS and PM	7	1 (MSc. PM)
P10	Architectural and PM	5	None

Table 2: Comparison between the definitions obtained in the Field Survey and Literature

Firm	Definition	Related in literature
P1	Anybody who can affect or can be affected by a project	Freeman (1984)
P2, P6	All interested parties that are committed to the execution of the project and its success.	Savage et al. (1991); McElroy and Mills (2000)
P5, P4,P3	Involves all the people that are involved in a particular project.	(PMI, 1996)
P9, P7	All those involve in a project	(PMI, 1996)
P8, P10	People involved directly in project either as an individual or a group.	(PMI, 1996);

All the respondents asserted the importance of stakeholders in successful project delivery and how very crucial it is in determining project success or failure. This is in line with the suggestions of Turner (1999) and Smith et al. (2001) that satisfying stakeholders' need is one of the criteria for project success. Another importance of stakeholders highlighted by the respondents is that they help in determining the project scope. Black (1995) attributed the tendency of poor scope and work definition due to improper engagement with stakeholders. Thus, stakeholders help project managers in determining the scope of a project. Also, the respondents agreed that the collective contributions of stakeholders make the entire project success. According to Bourne (2010), stakeholders have the ability to affect the outcomes either through action or inaction; therefore, they are the major determinants of project success or failure. This shows that all the respondents have acknowledged the relevance of stakeholders in a project which also indicates a good knowledge of the concept. Hence, the importance of stakeholders in project delivery is recognised by all the respondents.

The respondents see the stakeholder analysis as a pre-determined exercise stating that the management and technical unit of the various institutions have already carried out all the necessary exercise. The literature asserts that successful stakeholder management can be achieved through conducting a careful stakeholder analysis. Rowlinson and Cheung (2008) recommended that stakeholder analysis should be a continuous process that spans throughout the process of a project life cycle; hence, it is not just at the inception stage that the analysis is carried out. Aaltonen (2011) emphasised on conducting stakeholder analysis because it helps

project managers to make decisions as regards management of stakeholders in the project. This shows that it is the responsibility of the project manager to conduct the analysis which should be a continuous process. One of the respondents admitted that the analysis had really helped him in developing a project brief as well as breaking the project into phases in order to accommodate the stakeholders‟ needs and expectations in the project. Another respondent who had carried out an analysis posited that it was quite challenging. This is in line with findings of Jespen and Eskerod (2008) that stakeholder analysis is quite challenging and time consuming.

The three (3) respondents i.e. P1, P5 and P6 that carried out the stakeholder analysis could not follow the steps identified in the literature. The respondents do acknowledge the identification step as the first step which conforms to the existing literature. However, none of them was able to categorize them as suggested in literature, even though one of them insisted that they were able to assess the stakeholders' influences and relationships. According to Yang et al. (2011) the steps in conducting the analysis include: stakeholder identification; stakeholder categorisation; and stakeholder assessment based on influences and relationships. Thus, in conducting the analysis, it is important to employ all the identified steps in order to yield an effective result.

Summary of Major Findings

The following were found or derived from this study:

i. Some of the project management consulting firms offer the services of project management without any trained and qualified personnel in project management in their organisations.
ii. The firms have good awareness of the concept of stakeholder management, mostly acquired from their years of working experience.
iii. Stakeholder analysis is seen as a pre-determined exercise that does not extend beyond the inception phase of the project.
iv. The guidelines for stakeholder management provided in the existing literature seem too formal to be adopted by people who are not academically trained and oriented.

CONCLUSION

This study concentrated on projects with almost the same set up and project stakeholders' community so that the results could be comparable. Thus, the conclusion is that despite the awareness and acknowledgements of the importance of managing stakeholders, the survey discovered that there is no proper adoption of the guidelines for stakeholder management as stated in literature.

ABSTRACT

The role of higher education in the development of nations is well acknowledged. Successful completion of educational pursuits is usually determined by acceptable standard of academic performance. Poor academic performance will often lead to students' dropping out of school, waste of resources and frustration of both students and their parents. There have been serious concerns over the decline in academic performance of students in higher institutions in many parts of the world, including Nigeria. Consequently, the factors determining academic performance of architecture students in selected Nigerian private universities are investigated in this study. This has been necessitated by increasing number of private universities offering architectural training in Nigeria, the challenges they often face and their high financial burden on parents. The survey method was adopted to obtain quantitative data from students in selected schools using structured questionnaire. Data was subjected to both descriptive and principal components analysis (PCA) of factor analysis using the Statistical Package for Social Sciences (version 20). Results indicate that determinants of academic performance are multi-faceted and include learning environment, parents' characteristics and level of study, ethnic group, mother's occupation and source of counselling, students' personal characteristics, learning resources, parents' profession, gender of students and their receipt of counselling services. The paper thus recommends that institutions should strive to provide conducive learning environments including cordial student/lecturer relationships in order to enhance students' academic performance. Findings of the study will provide both government and the universities empirical evidence that will guide policies and reforms aimed at improving the academic performance of architecture students in Nigerian private universities.

Keywords: Academic performance, Architecture, Private universities, Students

INTRODUCTION

Education especially at higher levels plays a crucial role in the economic and social development of nations and individuals. Olotuah (2006) identified architectural education as an important tool in sustaining the health and general productivity of the populace and invariably the achievement of a great and dynamic economy. Unfortunately, the benefits of higher education have eluded many developing countries like Nigeria. Two main reasons adduced by Saint, Hartnett, & Strassner, (2003) include non-articulation of development strategies that link knowledge to economic growth and lack of capacity to do so. Building the requisite capacity has been constrained by several challenges which include poor funding, inefficiency, inequity, dwindling quality and poor governance (Saint, Hartnett, & Strassner, 2003). This is further complicated by poor academic performance of students thereby leading to growing student attrition rates and inability of graduating students to contribute meaningfully to nation building. Poor academic performance places doubts on the ability of graduating students to fit into the work environment, thus resulting in delayed employment or underemployment.

Over the years, there have been growing concerns over decline in the academic performance of students in higher institutions in many parts of the world, including Nigeria. Universities in Nigeria are classified into three namely the federal, state and private universities. Private universities are relatively new, being the latest entrant into the Nigerian university system. Nevertheless, they are projected to dominate the Nigerian university system landscape in the near future. Although a considerable amount of research exists on various factors

Opoko, A. P.; Oluwatayo, A. A. & Ezema, I. C. (2016). Factors Affecting Academic Performance of Architecture Students in Nigerian Private Universities. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1225-1236

contributing to students' academic performance in higher education the case is different for Nigeria especially for private universities. This paper investigates, from the perspectives of students in selected Nigerian private universities, factors determining academic performance of architecture students in Nigerian private universities. This study has been necessitated by several reasons. First, some authors have opined that the quality of education offered in Nigerian private universities is lower when compared to what obtains in federal and state universities. Second, there is increasing number of private universities offering architectural training in Nigeria. Third, architecture plays a pivotal role in the provision of infrastructure needed for the socio-economic development of any society and the wellbeing of its people. Finally, architectural training places huge time and financial burden on universities, parents and students alike. Consequently, any failed or truncated attempt will not only be wasteful but also frustrating to all stakeholders. Findings from this study could serve as a blueprint for improving academic performance of architecture students in Nigerian private universities in particular and other higher institutions in general.

In the following sections, the paper reviews past research on academic achievement of students; outlines the methodology (including analyses) adopted for the study; presents the findings and concludes with a discussion of the implications of the findings with regard to both future research and present policy.

LITERATURE REVIEW

Higher Education in Nigeria

University education in Nigeria can be traced back to 1932 when the colonial government established the then Yaba Higher College to meet the national need for medium level manpower. In 1948, the University College, Ibadan was established as an affiliate of the University of London (Enahoro & Badmus, 2013). Apparently in anticipation of the manpower need of a post-independent Nigeria, four regional universities emerged in Nsukka, Ife, Zaria and Benin between 1960 and 1970 in addition to a second federal university in Lagos. Following the oil boom of the 1970s, the federal government upgraded the existing regional universities to federal status and established seven new universities across the country. The third generation of universities comprised of both federal and state universities and universities focusing on specific areas of perceived national needs emerged between 1979 and early 1990s. Private universities did not emerge until the fourth dispensation of universities (1991 to date).

As at 1980, the Nigerian higher education system had attained international acclamation wining global recognition in areas like tropical health and agriculture (Saint, Hartnett, & Strassner, 2003). However, the tide turned in the 1980s with a decline which sadly has persisted to date. Reasons adduced for this include rapid expansion of the university system both in number and enrolment; erosion of autonomy of universities by government interference in leadership appointments; poor funding; decline in incentives and rewards for research productivity, teaching excellence and innovation; decay in infrastructure and loss of academic staff to brain drain. Between 1990 and 1997 funding for higher education declined by 27% while student enrolment rose by 79% and the recurrent expenditure /student dropped by 62% (Harnett, 2000).

Evolution of Private University Education in Nigeria

The first three Nigerian private universities were licensed in 1999 and by 2015 the number had risen to fifty nine (59) compared to forty (40) federal and thirty nine (39) state universities. As at 2013, private universities accounted for 10.4% of university admission in Nigeria. The share of private university admission is expected to steadily rise as new ones are licensed and existing ones consolidate and increase their carrying capacities. Other

contributions of private universities include introduction of market-driven programmes, maintenance of stable academic calendar, optimum balance between academic and non-academic staff ratio effective check on the menace of secret cults and increased female participation in university education (Omuta, 2010).

According to Akpotu & Akpochafo (2009), privatisation of education is a global phenomenon. The World Bank (1994) noted the efficiency and effectiveness of the private sector in responding to changing demands by offering broadened educational opportunities. In Nigeria, advocation for private sector participation in tertiary education has been premised on the insufficient carrying capacity of tertiary institutions due to inadequate, overstretched, dilapidated and sometimes improvised facilities (Rufa'i, 2013). Baskerville (1998) attributed emergence of private universities, driven by globalization to cultural change in pedagogy; realisation of importance of human capital in development; growth in international education; willingness and ability of private entrepreneurs to invest in higher education; and expected contributions of university graduates to economic development. Many of the above reasons hold true in the Nigerian context. In addition, scholars including Ige (2013) and Onwe (2013) have identified prolonged academic programmes due to strikes; excessive students population; unmet demand for admission; limited and decaying infrastructural facilities; student unrest and cultism; high teacher-student ratio; fall in the quality of graduates; general indiscipline among staff and students; ineffective resources management and low ranking of public universities;.

Apart from being late entrants into the Nigerian university system, private universities have certain distinguishing characteristics. According to Ajadi (2010), they are self-financing and generally profit-oriented. Many of them also have religious inclinations (Enahoro & Badmus, 2013). In addition, they tend to offer courses that have a premium both in the education and labour markets. Preference is also given to courses that require less investment in terms of infrastructure and equipment. This is in contrast to countries like India where some private universities opt for resource-intensive courses like Engineering and Medicine. Enahoro & Badmus (2013) pointed out the clandestine operation (without license and accreditation from regulatory authorities) of some private universities in Nigeria. Several of those operating legally are constrained with limited number of approved courses, staffing challenges, including high labour turnover and enrolment problems (Oloyede & Adekola, 2010). Staffing appears to be a major challenge as many of the private universities are only able to attract less qualified permanent academic staff. Consequently, staff strength is augmented by reliance on retired academic or sabbatical staff from public universities and adjunct lecturers. In addition, Obasi, Akuchie & Obasi (2014) highlighted the challenges posed by high costs of education and inadequate facilities in many Nigerian private universities.

The Private Universities Inspection and Monitoring Division of the National Universities Commission oversees the running of private universities in Nigeria. Specifically, the Division is responsible for the following: analyses of past accreditation results of private universities; inspection and monitoring visits to private universities; periodic review of the instruments for inspection and monitoring of private universities; database development for the activities of private universities; monitoring of compliance of private universities with the provisions of BMAS (Benchmark Minimum Academic Standards) and other quality assurance guidelines, as well as those of their individual Academic Brief, Master Plan and University Law; regular inspection of private universities to assess compliance with admission guidelines, carrying capacity, curriculum and staff mix and highlighting areas of remediation; participation in ad-hoc activities in the commission; and any other assignment from the Director or Executive Secretary from time to time.

Architectural Education in Nigeria

Architecture is one of the choice courses offered in Nigerian universities. Indigenous training of architects commenced in 1952 at the Nigerian College of Arts, Science and Technology (NCAST), Ibadan which was later relocated to Zaria in 1955 and metamorphosed to the Department of Architecture at the Ahmadu Bello University (ABU) Zaria in 1962 (Arayela, 2001). That same year a second school of Architecture was establishment as a pioneer course at the University of Nigeria, Nsukka in order to meet growing demand for architectural education in Nigeria. A third school of Architecture was established in 1970 at the University of Lagos, Akoka-Lagos. As at 2015, there are twenty seven (27) universities in Nigeria accredited by the Architects' Registration Council of Nigeria (ARCON) to offer Architecture (NIA, 2015). These include eleven (11) federal, eleven (11) state and five (5) private universities.

Many schools operate a two-tier (4-year and 2-year) under-graduate Bachelor of Science (B.Sc.) and postgraduate Master of Science (M.Sc.) degree structure. The universities of technology however adopt the B.Tech/ M.Tech structure with a 5-year/ 2-year structure. The curricula comprise of both practical and theoretical courses. The prerequisite courses however include architectural design, building components and building structures. The design studio and jury system are unique features of all architecture schools. Yorgancioglu (2013) opined that architectural education should cultivate in students values and attitudes along with knowledge, skills and understanding, covered in but not limited to a specific disciplinary area. Thus, architectural education requires scientific and creative approaches that help students acquire skills for logical thinking, analysis, synthesis, induction and deduction needed to effectively tackle design problems.

Academic Performance

Academic performance of students measures the extent to which a student has been able to achieve the set educational goal. It is used to ascertain the academic status of a student which may determine whether such student proceeds to the next level or not. Few literatures have investigated the academic performance of students in private higher institutions and even fewer have focused on students studying architecture in such institutions.

Kyoshaba (2009) investigated factors affecting academic performance of undergraduate students of Uganda Christian University. Variables investigated included admission points, parents' socio-economic status and previous school background. The study found significant relationship between students' pre-admission qualifications, parents' socio-economic status and academic performance, but there was no relationship between mature age points and academic performance. Ali et al (2013) found age, parents' social economic status and daily study hours as significant predictors of the academic performance of university students in a Pakistani university. Meltem (2004) found significant gender differences in academic performance among a sample of Turkish undergraduate students that included students studying architecture. The paper showed that female students outperformed their male counterparts even after controlling for the field of study. This was explained by the general tendency of females attaining maturity earlier than males.

Opoko et al (2014) used panel data to investigate the correlation between pre-admission qualification and academic performance of architecture students in a Nigerian private university. The study focused on a particular subject building structures - a core course for the study of architecture in Nigerian universities. Two conclusions emanating from this study were that: (i) pre-admission scores in mathematics and physics had insignificant impact on students' performance in Building Structures after the second year; and (ii) female architecture students generally performed better than their male counterparts in Building

Structures. Earlier, Adewale & Adhuze (2013) had carried out a similar study on architecture students from selected Nigerian polytechnics. Their study found low correlation between student's academic performance and their pre-admission aptitude in physics and mathematics. Koranteng & Essel (2013) also empirically demonstrated that for architecture students, those with pre-admission qualifications in creative areas like visual arts and technical drawing performed better than their peers. The study examined effects of educational background on students' academic performance in an architecture school in Ghana.

Several studies like Korir & Kipkemboi (2014) have suggested that the school type can influence students' academic outcomes. The study by Alimi, Ehinola, & Alabi (2012) examined influence of school type and facilities on students' academic performance in Ondo State. Although it found significant differences in facilities available in public and private schools, it did not find any significant difference in academic performance of students in both school types. This suggests that facilities may not affect academic performance. Their findings however are at variance with other studies (Oginni et al, 2013; Duruji, Azuh & Oviasogie, 2014) which concluded that facilities had profound influence on academic performance of students. Alos, Caranto, & David (2015) focused on nursing students found teacher-related factors followed by study habits, school-related, personal and home-related factors very significant.

Findings of Tomul & Polat (2013) indicate that school type more than family characteristics is an essential predictor of students' academic achievement. This is in line with literature review by Ali et al (2013) which explained that the educational environment of the school sets the parameters of students' learning outcomes. According to Buder (2000), conducive school learning environments include the physical environment of the school, physical setting of the classrooms, teaching aids/materials and the quality of the teachers. With reference to private schools Ali et al (2013) and Korir & Kipkemboi (2014) rationalize that better funding, small sizes, motivated faculty and access to resources such as computers provide more conducive learning environments which invariably enhance academic performance and educational attainment of their students. Okon & Archibong (2015) opined that stimulating school environments arouse students' desire to learn. Similarly, Ossai-Ugbah (2010) who investigated universities in Nigeria, including private universities concluded that access to modern facilities like automated electronic information services enhanced students' academic performance.

The foregoing review suggests that several factors influence academic performance of students. Variations in results from previous studies can be attributed to differences in the data sets and variables used (Lubienski & Lubienski 2006) as well as methodological and contextual differences. The current paper contributes to the existing body of knowledge by empirically examining the factors that affect academic performance of students enrolled to study architecture in selected Nigerian private universities.

METHODOLOGY

Respondents for this study were drawn from students in the Departments of Architecture in Covenant University, Ota and the Bells University of Technology, Ota. Both schools were chosen because they are the first private universities to commence training in architecture; their sizeable student populations and proximity. Data were collected through a self-reported questionnaire which elicited information on students' personal demographics, parents' socio-economic characteristics and students' evaluation of the learning environments in their respective schools. Hard copies of the questionnaire were distributed to students from the 2nd year through to the 6th year of study in the selected schools and retrieved by the research

team. The questionnaire was developed following a review of literature and feedback from pilot studies which investigated aspects of academic performance in one of the schools investigated. The academic performance of students was captured through the cumulative grade point aggregate, CGPA reported by the respondents. Most studies of this nature rely on the CGPA. A total of two hundred and sixty three architecture students from both schools participated in the survey on a volunteer basis. The collected data were processed using version 20 of the Statistical Package for Social Sciences (SPSS). The variables investigated are categorized into three as follows: students' personal characteristics (level of study; age on admission; gender; ethnic group; receipt of counseling before choosing to study architecture; source of counseling; city of residence), parents' characteristics (highest educational level attained by father; highest educational level attained by mother; profession of father; profession of mother; occupation of father; occupation of mother; family income group) and learning environment characteristics (library; hostels; classroom/studio/workshops; cafeteria; shopping facilities/buttery; relationship with other students; relationship with staff; campus environment).

The quantitative data obtained were subjected to principal components analysis (PCA) of factor analysis. The Kaiser Meyer-Olkin Measure Sampling Adequacy (KMO) value, the Bartlett's Test of Sphericity value and the correlation matrix were examined to ensure appropriateness of factor analysis. Nine factors were extracted based on examination of the Eigen values, the data screeplot and the component matrix. Identified predictor factors were further correlated with personal characteristics of respondents in order to identify any relationships.

FINDINGS AND DISCUSSIONS

Respondents' Personal Characteristics

Results of the data analysis on the personal characteristics of respondents are presented in Appendix 1. The results show that majority of students who participated in the survey were from the Covenant University. About a quarter each of the respondents (24.7% and 24.3%) are in their fourth and third years of study. While 55.1% of the respondents were males, 41.1% were females. Only 3% of respondents were aged over 25 years on admission. 16.3% of the students were below 16 years of age. The age of majority of the respondents ranged from 16 – 25 years. Majority of the respondents are Yorubas (48. 3%) and reside in Lagos (42.6%). Although 51.3% of respondents claimed to have received counseling prior to embarking on their architectural training, counselors differed. Many respondents (46.8%) declined to respond on who they sought counsel from. Main sources of counsel were parents (19.8%), architects (13.7%) and professional guidance counselors (13.3%).

Parents' Characteristics

Results show that respondents' parents are well endowed socio-economically. Most parents (75.7% of mothers and 86.3% of fathers) have university degrees and have some form of employment (91.6% of mothers and 91.3% of fathers). However, only 5.4% of mothers and 36.1% of fathers are professionals in the building industry. While fathers are reportedly mainly self-employed (45.2%) and civil servants (22.8%) mothers are mainly civil servants (38.8%) and self-employed (36.9%). Only 1.1% and 0.8% of respondents' households are classified as low or lower medium respectively. Other households were classified as medium (27.8%), upper medium (47.5) and high (16%) income. Majority of the respondents (47.5%) classified their households as Upper medium income. Others were classified as medium (27.8%) and high (16%) respectively.

Learning Environment Characteristics

To assess impact of learning environment on academic performance, respondents were asked to rate on a Likert scale how they felt various attributes influenced their performance. Results are presented in Appendix 2. While results for shopping facilities were mixed, majority of respondents claimed that the hostels, studios/classrooms and Campus environment played significant roles. Only 3.5% and 12.2% of respondents felt the studios/classrooms and hostels respectively had little or very little impact on their performance. Respondents also claimed that interpersonal relationship with their colleagues and staff significantly impacted on their academic performance.

Factors Predicting Academic Performance of Respondents

To determine the predictors of academic performance of the respondents, principal components analysis (PCA) of factor analysis using SPSS version 20 was carried out on the twenty-two variables earlier identified based on literature and presented in Table 2. Factor analysis also served to resolve multi-colinearity that may arise due to the intercorrelation of the variables. Kaiser Meyer-Olkin Measure Sampling Adequacy (KMO) value of .636 was above the recommended .6 while the Bartlett's Test of Sphericity (Bartlett 1954) reached statistical significance at p = .000. Extraction of factors was done automatically based on components with Eigen values of 1 or above. Nine components with Eigen values above 1 were identified and accounted for 61.21% of the variance. The choice of the nine factors was also supported by the data screeplot that revealed a clear break after the ninth component thus suggesting a nine-factor solution based on Catell's (1966) scree test.

The first factor that essentially captures the learning environment, accounted for 13.60% of the variance. It loaded on seven variables namely: campus environment, relationship with staff, cafeteria, shopping facilities/buttery, relationship with other students, classroom/studio/workshops and hostels. Four variables loaded on the second factor termed Parents' characteristics and level of study that accounted for 8.204% of the total variance. The variables are fathers' occupation, fathers' highest educational level attained, students' Level of study and mothers' highest educational level attained. Ethnic group of respondents was the third factor and accounted for 6.853% of the total variance. Accounting for 6.550% of the variance and loading on the fourth factor named mother's occupation and source of counseling were the occupation of respondents' mothers as well as persons who provided counseling to respondents. The fifth factor, students' personal characteristics accounted for 5.722% of the variance and loaded on age of respondents when they commenced their study and their places of residence. Loading on the sixth factor, learning resources and accounting for 5.390% of the variance was library. The seventh factor, parents' profession loaded on the professions of the mothers and fathers and accounted for 5.289% of the variance. The eighth and ninth factors, respondents' gender and receipt of counseling services accounted for 4.831% and 4.770% of the variance respectively. Description of the predictor factors is provided in Appendix 3.

DISCUSSIONS

The focus of this paper has been identification of factors that affect the academic performance of students of architecture in Nigerian private universities. The results of this study highlighted nine major factors that are believed to affect the students' academic performance. These include learning environment, parents' characteristics and level of study, ethnic group, mother's occupation and source of counseling, students' personal characteristics, learning resources, parents' profession, gender of students and their receipt of counseling services. These are areas that need major attention in any effort geared towards improving students' academic performance. Further examination of the results presented in

Table 6 reveals that many of the variables had values above .5 suggesting that respondents considered them very significant in evaluating their academic performance. The top six variables with values above .6 however were identified to be campus environment (.722), mothers' profession (.684), relationship with staff (.651), cafeteria (.632), fathers' occupation (.619) and Shopping facilities (.610). It is significant to note that income, which was captured in this study by respondents' income group classification of their families, was not considered significant at all. This appears attributable to the homogenous nature of the income composition of the respondents' families, most of who belong to upper medium and high-income groups. Because of the high fees charged in private universities, it is rare for students from poor families to study there. Relationship with other students, Classroom/studios and libraries though significant received less weighting. This suggests the dwindling importance of studio culture and peer review in the study of architecture in private schools. Traditionally, the studio is seen as a second home for architecture students, where they spend greater part of their time. Observations in both schools studied showed that the studio appears to have lost this unique place. Similarly, less importance given to libraries could be due to availability of information technology gadgets like computers, i-pad and internet which have erroneously taken the place of libraries. It may be pointed out here that these gadgets offer limited information compared to the wealth of knowledge available in libraries. The long term effect will be lack of depth of knowledge among students.

The role of learning environment is shown in the fact that four of the six top variables considered very influential in academic performance, namely, campus environment (.722), relationship with staff (.651), cafeteria (.632) and Shopping facilities (.610) are captured by this factor. Although many of the students reported transportation and movement on campus, availability of trees and shades, and aesthetics on their campuses, they considered availability of relaxation spots and gardens inadequate. A conducive campus environment is necessary for students of architecture to think and develop their creativity, a vital skill needed by architects. Ease of movement within the campus will also reduce travel time and create more time that can be dedicated to academic work. Students' relationship with staff in a course like architecture that requires high levels of mentoring and contact hours will no doubt enhance academic performance. Through such interactions and the high level *in loco parentis* observed in one of the schools, students are more relaxed and feel free to ask questions. Cafeteria and shopping facilities provide avenues for students to access their daily needs including food and refreshments needed to nourish their bodies. Several studies have indeed shown that consumption of good quality food is vital to maintaining a healthy body and mind. What is not very clear however is the nutritional quality of the items the students in this study consume.

The other important factors are mothers' profession and fathers' occupation. .8% of the mothers are architects, while 4.6% others are professionals in other building industry disciplines. Majority of the mothers are professionals in other disciplines. Results of cross-tabulation analysis between students' academic performance and their mothers' profession however revealed that there were no significant differences in performance of the students especially when the number of students in each group is accounted for. This suggests that architecture is not hereditary. Further analysis revealed that 45.2% and 22.8% of best performing students are self-employed and civil servants respectively. Children of civil servants and retirees performed averagely.

CONCLUSION

The desire for higher education by many students and their households who are willing to make sacrifices in order to achieve this goal have been sharpened by observed benefits and

imperatives of education over the years. Paramount to the realization of this dream is good academic performance of students. There is thus a need for university administrators to strike a balance between their institutional objectives and the expectations and preferences of their students. In this regard, realistic mechanisms for obtaining honest feedback from students are very crucial. This is more so for private universities offering premium and expensive courses like architecture. This study has identified nine critical factors that influence academic performance of architecture students in the private universities studied. These factors deserve attention from both the institutions and the government regulatory agency. Programme accreditation evaluations should be reviewed to include more robust criteria for evaluating components of the learning environment in line with the findings of this paper. In doing this, more creative and anonymous methods of obtaining students' views are critical.

The size and representative nature of the samples/respondents used in the study reported in this paper support the reliability of the analysis carried out. However, a major limitation of the study is the cross-sectional rather than longitudinal nature of the data set that did not allow for examination of the academic performance of the students over time. It is also likely that school characteristic differences including differences in course curriculum and pedagogical approach may have affected the students' academic performance assessment methods and outcomes. For instance grading criteria and weighting may vary from one school to the other. Another limitation of this study is reliance in respondents' self-reported CGPAs. Although this was done to ensure anonymity of the data collection process which was expected to allow respondents to be truthful in the provision of information, it cannot be ruled out that some respondents may hide under this cover to give fictitious information

ABSTRACT

Mapping of schools as a technical exercise has become a relatively normalized and institutionalized practice in education micro-planning. Its function in offering technical input into any educational micro planning effort is virtually self-evident. Mapping of school is a tabular, graphical or cartographical representation of a particular space or place, school mapping involves the consideration and inclusion of various forms of technical data that impact and "populate" the physical and social context of analysis. In Nigeria, School databases are scattered all over the agencies, and there are those that are not integrated into digital format, thus comprehensive school location analysis using GIS has never been carried out. GIS data, and spatial information data are not available, or not open to the public. The application of GIS to the school mapping is very useful to find the appropriate sites of locating new school buildings efficiently. The major objectives of this paper are; identify and locate secondary educational institutions, determine the wards of educational institutions. Establish relation with educational statistics and its spatial analysis, ratio for population and schools, update of current data with future data needs. The spatial distribution of the schools was achieved and the location of the schools were determined and located in various wards. The wards that need the development of schools were also determined. School Mapping using GIS supports the careful conceptualization and implementation of educational micro-planning required to leverage the emerging global expectation of interactive user-controlled visualization.

Keywords: GIS, Mapping, GPS, School, Database

INTRODUCTION

Mapping of schools as a technical exercise has become a relatively normalized and institutionalized practice in education micro-planning. Its function in offering technical input into any educational micro planning effort is virtually self-evident. It should be noted that school mapping (a process) is not the same as a school map (one typical product of the school mapping process). More than simply being a tabular, graphical or cartographical representation of a particular space or place, school mapping involves the consideration and inclusion of various forms of technical data that impact and "populate" the physical and social context of analysis. As a process that produces specific functional products, SM is fundamentally an educational micro-planning effort focused on increasing school resource efficiency and equity (Caillods, 1983; Varghese, 1997).

GIS school mapping as a term has much been used in educational planning in recent years. Conceptually it covers wider scope of educational planning and management and relates to allocation of resources, efficiency delivery of school system and improving efficiency of learning. Mapping is tool commonly used to reveal the apparent relationships between the distribution of school and the distribution of school age population to be served by them in a given area.

The use of GIS Maps could greatly help improve the frequency with which better decisions are made. It can minimize the irrational and unjustified demand regarding establishment of new school and providing financial support to non-deserving institutions. It makes

Oseni, A. E. & Ode, G. O. (2016). Mapping of Secondary Educational Institutions using GPS and GIS Technology in Shomolu Local Government Area of Lagos, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1237-1246

geographical perspectives to education more readily available. Educational planning and scenarios are made simple through the map itself, assuming that an ocular visit to the area could not be made; information about the features are clearly marked with symbols or signs. Present and future requirements can be determined as one goes through the map including the appropriate and comprehensive characterization of the area and its relationship to the other features of the map. GIS database provides comprehensive framework and organization of spatial as well as non-spatial data and has become a focused tool to help planning and decision making. Mapping of an educational institution along with the information of administrative boundary and the biophysical layers such as, major road network, rivers, and major settlements provides the ground reality in terms of geographic coverage and social reality. Reuse of the data for different purpose is another possibility provided by GIS database.

LITERATURE REVIEW

Development and Implementation of School Mapping

School mapping as technical exercise has become a relatively normalized and institutionalized practice in education micro-planning. Its function in offering technical input into any educational micro planning effort is virtually self-evident. It should be noted that SM (a process) is not the same as aschool map (one typical product of the school mapping process; see Figure 1 below). More than simply being a tabular, graphical or cartographical representation of a particular space or place, mapping of schools involves the consideration and inclusion of various forms of technical data that impact and "populate" the physical and social context of analysis. As a process that produces specific functional products, school mapping is fundamentally an educational micro-planning effort focused on increasing school resource efficiency and equity (Caillods, 1983; Varghese, 1997). While the practical and conceptual road in school mapping is well travelled, a very brief review of the origin, typical functions, and standard procedures in school mapping will be presented.

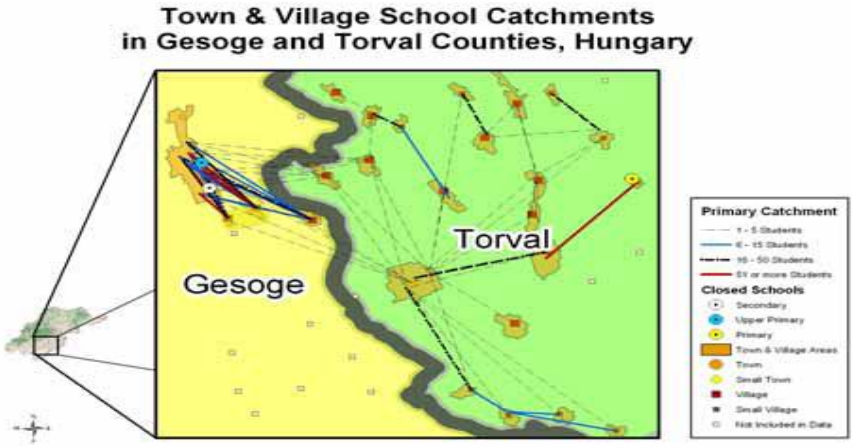

Fig 1: School map of Gesoge and Torval Counties, Hungary (S. J. Hite, 2006)

GIS in Micro-planning

When considering GIS in micro-planning, an obvious question is whether GIS is simply a better, more precise and flexible spatial analysis tool for representing schools and their physical, social and geopolitical contexts or whether GIS provides a different way to understand and plan those contexts geo-spatially. Another relevant consideration is whether GIS, which is clearly a financially and technically costly approach, might in fact create a larger and more challenging set of problems in the tensions between decentralised and centralised participants than has been experienced in school mapping. Before further

exploring whether GIS is simply a tool or is a potentially different approach to micro planning, a brief history of GIS will be valuable preparation.

Brief History of GIS

The mapping of physical and social space to consider and represent complex human-environmental systems perhaps finds its first recorded modern manifestation in Dr. John Snow's 1855 map of the Soho, London cholera outbreak, E. W. Gilbert's Version, 1958 (see Figure 2). Most contemporary efforts at mapping social and physical space, including GIS applications, acknowledge Snow's work as seminal, W. Gilbert's (1958)

Fig 2: E. W. Gilbert's Version (1958) of John Snow's 1855 Soho Cholera Map

While the actual origins of GIS are somewhat in dispute, most experts assert the Canadian Geographic Information System (CGIS) of circa 1965 as the first to develop GIS applications. Most early efforts at GIS were seen as costeffective technical solutions to relatively mundane administrative problems (i.e. planning urban transportation routes). In the 1970's, the real potential of digital computers to facilitate the analysis of geographic information emerged (Goodchild, 2006). The technology "revolution" of the mid- 1970's facilitated the explosive emergence of truly sophisticated GIS solutions by virtue of the rapid development of relational database management systems (RDMS) and the precipitous fall in the cost of computing power with the introduction of mini- and micro-computers by companies like IBM and DEC (Forseman, 1998; Maguire, Goodchild, & Rhind, 1991). Early implementations of GIS were clearly oriented at "GIS as a tool" mechanical operations – specifically, faster and more complex administrative computations. Since national, military and intelligence community applications of GIS bloomed quickly in the 1980's, asocio-political critique of GIS emerged by the late 1980's that generated notions of GIS well beyond mechanical and computational performance. This critique and its repercussions created a wave of analysis, some positive and some negative, around the potential of GIS as much more than a tool (Pickles, 1995).

Finally, compared to disciplines such as quantitative geography and business marketing, education policy and planning has been somewhat of a "reluctant latecomer" to the use of GIS. A number of important works in this area have been produced by the IIEP/UNESCO (Attfield, Tamiru, Parolin and DeGrauwe, 2002; Mendelsohn, 1996). As of yet, however, a consistent consideration and normative inclusion of GIS has not emerged as a consistent strand in education policy and micro-planning. That emergence is not likely to occur unless GIS can be shown to either be an extremely cost-effective and useful tool, or if new ways of GIS-facilitated thinking in education micro-planning emerge as clearly superior to current alternatives.

GIS and School Mapping as Educational Decision Support System (EDSS)

GIS is typically used in most application fields as an advanced and technologically-elegant tool. Even if GIS is considered as simply a better tool, the progress in presentation, preparation and flexibility appear to justify consideration of the benefits that GIS provides to micro-planning as potentially highly significance (Hite 2006).

The contribution of the rapid advancement and innovations in the applications of geographic information system and geo-imaging technology contributes an essential role in planning and decision making process. It acts as the infrastructural base for building on top other information from various perspectives. It is in fact, the current trend in modern organization towards flatter structures and the involvement of many stakeholder groups in solving decision problems based on what can be called spatial decision support system (Jankowaski et. al 1997, quoted in Al-Hanbeli 2005) In developing countries, the need for GIS technology is even more exacerbated as there are more resource management problem as well as urban and rural planning problems and in many situations there is no planning strategies. In this milieu, we need more information to help break down the complication of the problem for decision making.

The trend toward using GIS and school mapping to support decision making in the work is becoming very important for planning purpose (Al-Hanbeli 2005) In order to have proper planning, the educational sector should not start any project unless a comprehensive database of schools, pupils, teachers and resources. Building that part of GIS layers showing school locations and other significant geographic features such as road networks, administrative boundaries, distribution of settlement and public utilities, river system and other geographic features would provide an excellent tool for concerned planners

METHODOLOGY

Data Acquisition

Shomolu Local Govermnent office provided Ward information of our study area and also a complete gazette containing approved public and private primary and secondary schools. Field data acquisition where coordinates of all the schools located in the study area was obtained and this was done using a mobile mapper 12 channel GPS. Digital camera was also used to obtain the pictures of various schools for better visualization and analysis.

Data Manipulation

The aspect of data manipulation is one that requires a great level of precision in terms of data quality and integrity. It involved Data vectorisation

Database development & Management

A database is a collection of data that can be shared by different users. It is a group of records and files that are organized so that there is little or no redundancy. This is possible because in a database, there would be only one file so that an inquirer could ask, for example, either for the name of the owner of a particular property or for details of the property that a particular person owns. The file of names would contain pointers to the address file, and vice versa (Dale and McLaughlin, 1988).

The database was developed using ArcGIS 9.2 by using the already created “shapefiles”., an extension of the ArcGIS software, called ArcCatalogue, was used to create the shape files. These shapefiles represented the different spatial features that were going to be analyzed. These shapefiles were then projected to the same coordinate system as the Satellite imagery and topographic map to ensure conformity and accuracy of results obtained. The next stage of the database development stage was the creation of fields and tables for each of the

Shapefiles. These fields and tables are created so that the attribute or descriptive data for each of features (represented by shapefiles) can be put into them. These tables and fields represent the database via which results can be obtained when queries are performed by the ArcGIS Software. Microsoft Excel was used to create a tabular database for additional attribute data that was needed. The points obtained from the field using the GPS were the different primary and secondary (Public & Private) in the study area. These points were put into the Excel tables. These Excel files were then saved in a .DBF format, so that it could be recognized by the ArcGIS software and subsequently exported into the ArcGIS environment.

FINDINGS AND DISCUSSIONS

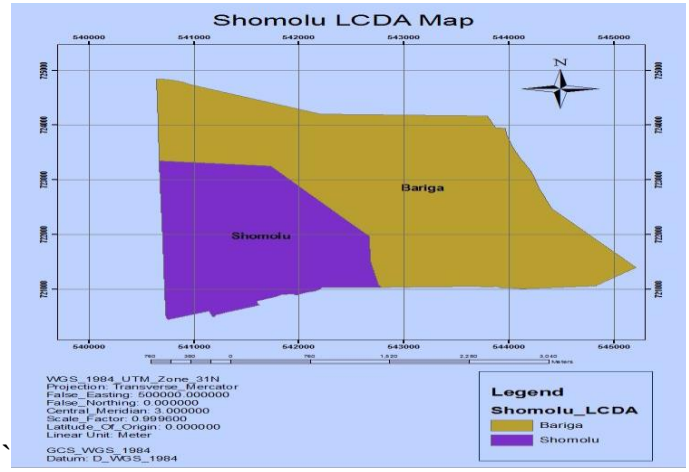

Fig 4.1: Map of Shomolu L.G.A showing the Local Council Development Areas

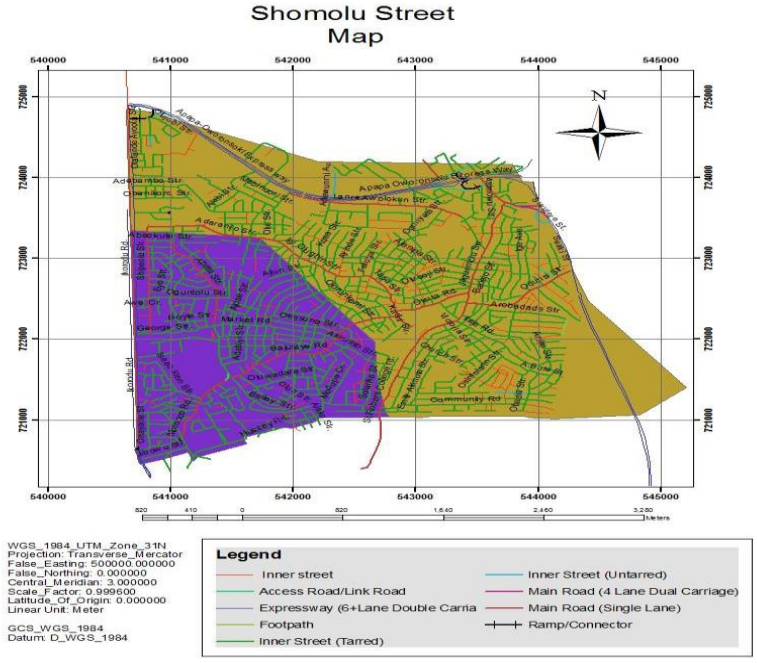

Fig 4.2: Street map of Shomolu LGA showing the different classes of roads

The street map of Shomolu LGA is shown above. Different classes of roads are contained within the Local Government as depicted in the legend above

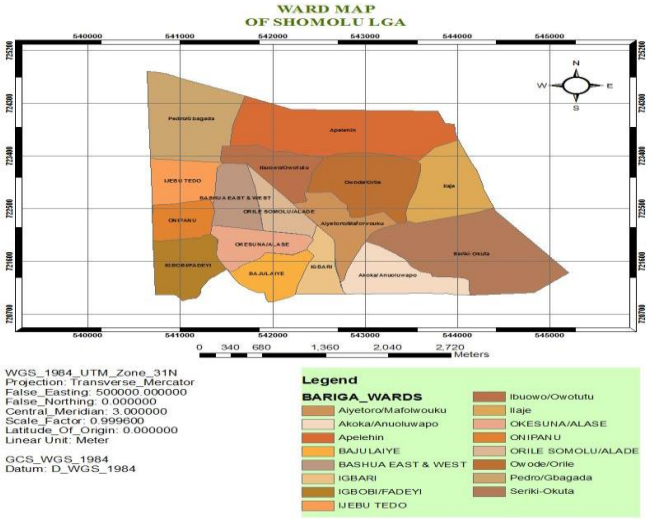

Fig 4.3: Map showing Wards in Shomolu LGA

Figure 4.3 above shows Shomolu LGA divided into wards. The wards are spread across the two LCDA's which are; Shomolu and Bariga.

The wards include: Seriki-Okuta, Ibuowo/Owotutu, Aiyetoro/Mafolwouku, Owode/Orile, Akoka/Anuoluwapo, Pedro/Gbagada, Apelehin, Ilaje, Onipanu, Ijebu-tedo, Orile-Somolu/Alade, Igbari, Igbobi/Fadeyi, Bajulaiye, Bashua East & West and Okesuna/Alase.

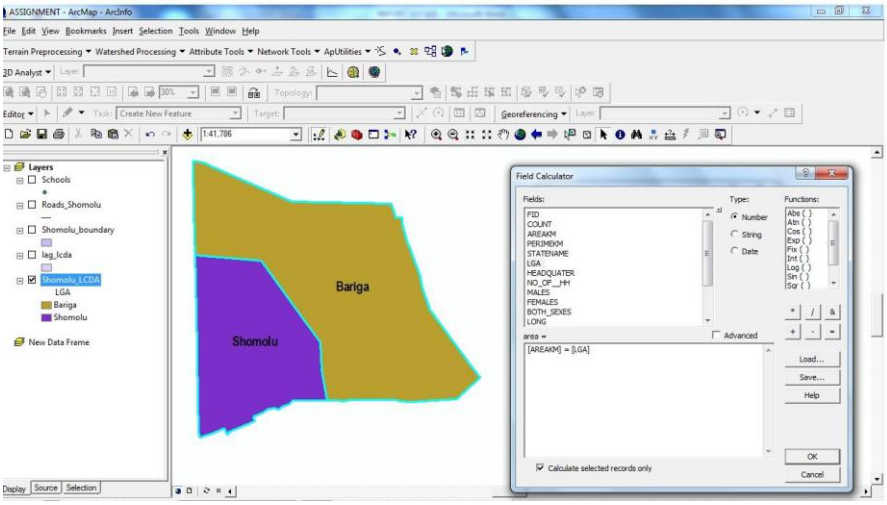

Fig 4.4: Advanced Field calculation

Figure 4.4 above shows a field calculation query. An area calculation was performed on the two LCDA's that make up Shomolu LGA

Table 4.1: Area extent of Shomolu LCDA

LCDA	Area (Square Km)	Percentage
Shomolu	4.35	30.27
Bariga	8.57	69.73
TOTAL	12.92	100

Table 4.1 above shows area extent for the two LCDA in Shomolu LGA. Shomolu LCDA covers an area of about 4.35 Square Km which is 30.27% of the total spatial extent of Shomolu LGA and Bariga LCDA covers an area of about 8.57 Square Km which is approximately 69.73% of the total land extent of Shomolu LGA.

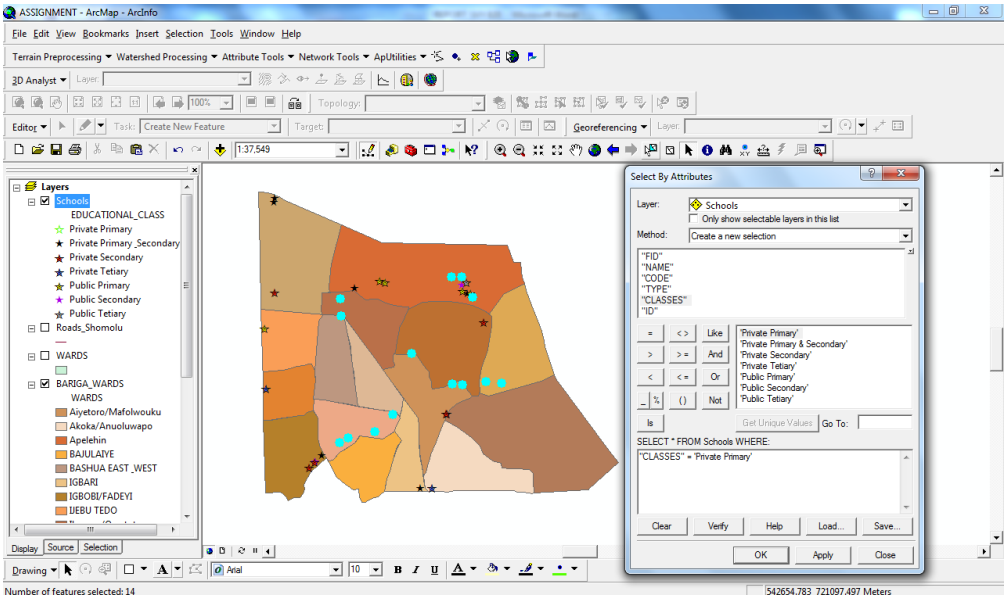

Fig 4.5: Query showing private primary school

Figure 4.5 above shows all the private primary school within Shomolu Local Government Area. The green dots in the figure above shows the private primary schools that are the result of the query performed

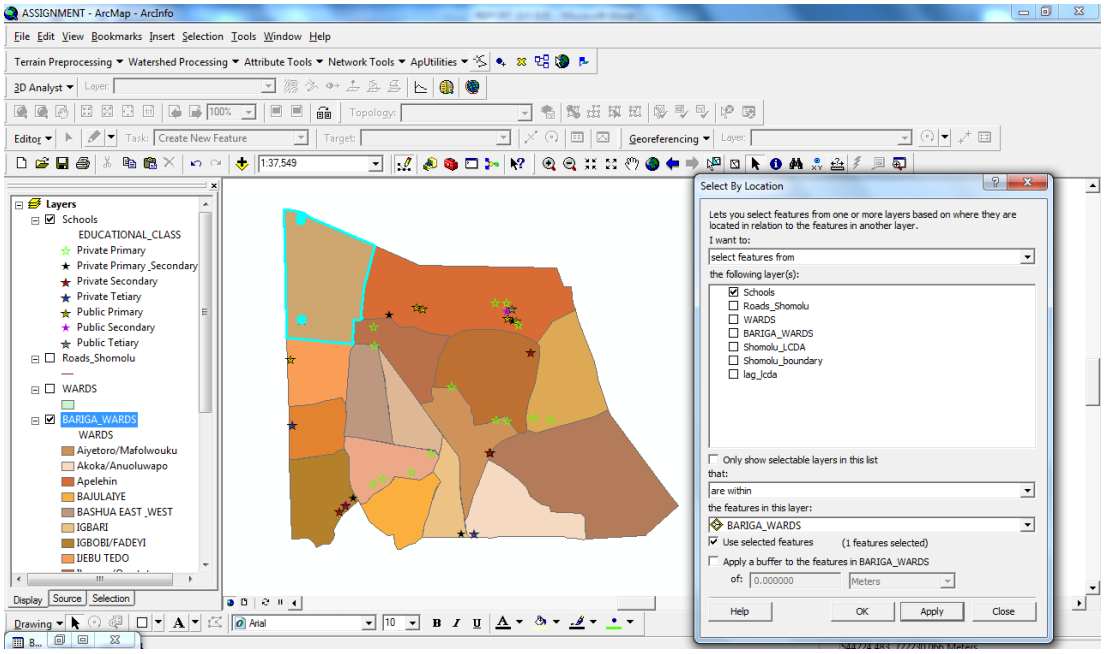

Fig 4.6: Query showing Educational Institutions in a ward

The query performed above shows all the educational institutions that are within Pedro-Gbagada ward in Shomolu LGA. The green dots and line depict the result of the query performed.

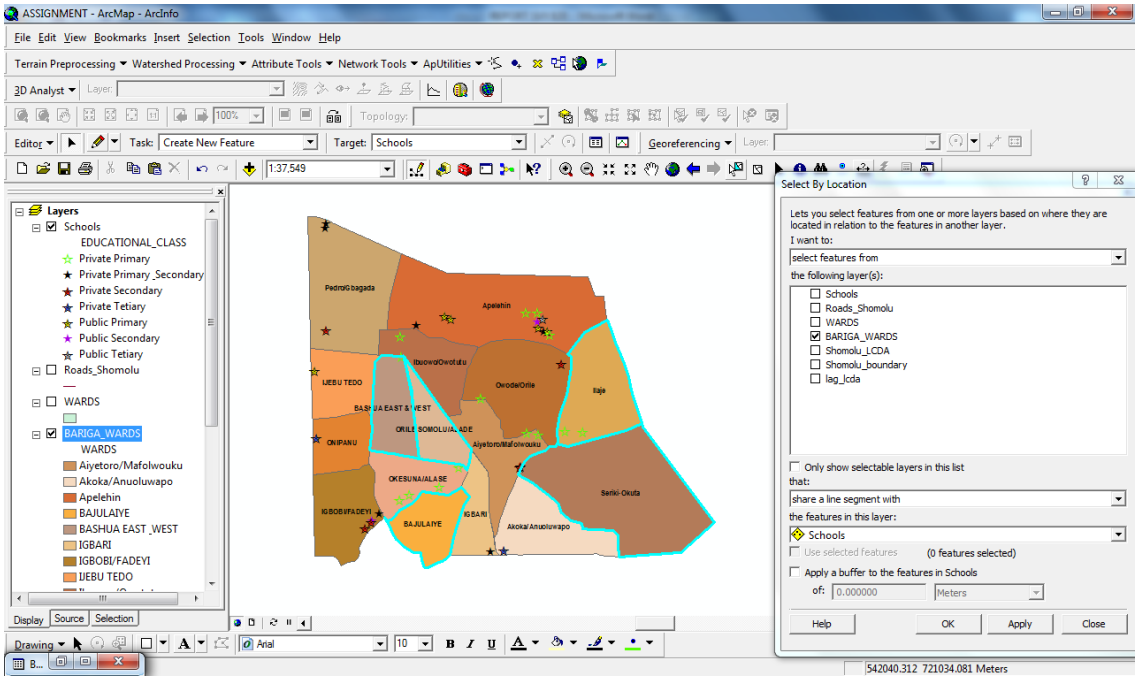

Fig 4.7: Query showing Wards without any educational institutions

The spatial query above shows the wards within Shomolu LGA that do not have any educational institutions within them

CONCLUSION

Social geographers claim that nearly 80% of our thinking and public discourse involves some form of geo-spatial thinking. However, this geo-spatial way of thinking about our world seldom exerts a significant impact on education policy and planning for a number of reasons. Among those reasons is the lack of formal representation, or even a jointly acknowledged way of talking about and presenting the geo-spatial characteristics of our physical and social world – even though so much of our awareness references and indexes space and place.

In future trends in School Mapping and GIS it is important to contemplate that interactive user controlled visual displays of reality, such as those facilitated by Google Earth 2 on the internet, are becoming ubiquitous in most parts of the world. These visual representations are creating an increasing expectation that should indicate a move in educational micro-planning efforts toward more visually-conceptualised and oriented planning at all levels of decentralisation. In this regard, it is reasonable to expect that GIS and other user-controlled visualisation techniques and solutions should become more prominent in education micro-planning efforts in the near future.

These efforts, however, must represent more than simply high-tech versions of static cartographical representations and visualization of complex physical, social and geo-political contexts. New ways of thinking about those contexts will certainly emerge – a more recursive geo- and politico-spatially aware way of thinking in multiple physical and social "layers." Movements toward global awareness, as well as more physical- and cyber-space-mobile populations and contexts, will inevitably lead to different ways of viewing, thinking and interfacing in micro-planning approaches. These approaches will help facilitate more relevant and effective educational micro-planning in a fast-changing "flattening" world (Friedman, 2007).

School Mapping and GIS certainly can, and perhaps should, have a significant role in the education micro planning future. In this visually-oriented and geo-spatially aware future, "a well designed and implemented GIS can draw upon the technical expertise of centralized staff, while preserving, using, and enhancing the context-rich knowledge and ability of locally situated administrators, teachers, and community members" (S. J. Hite & Hite, 2004, p. 61). Nonetheless, tension between the capacities and imperatives of centralized and decentralised participants and agencies will remain.

School Mapping using, GIS can, and most likely will, increasingly support the careful conceptualization and implementation of educational micro-planning required to leverage the emerging global expectation of interactive user-controlled visualization.

ABSTRACT

This research work aims at investigating the most effective training type that can optimize the productivity of the Nigerian construction craftsmen. In achieving this the following objectives were set-up: identification and determination of training types, most severe factors militating against, most suitable and efficient type of training applicable to construction craftsmen in Nigeria. This research adopted literature review, oral interview and use of questionnaires in its methodology. Only construction professionals were used for the ranking of severe hindrances and efficient type of training to be adopted for construction craftsmen. Analysis of findings involved the use of statistical methods (ranking). Hindrances to training were identified as poverty, lack of effective regulatory body, government negligence and lack of support from the construction industry. Lack of effective regulatory body was ranked as most severe with a combined rank agreement of 67.69% while "poverty" was least with 0.00%. Similarly, 22 types of trainings that can be applicable were established. The most efficient type "Vestibule Schools" ranked 83.24% and the least was "Sink – or – Swim" type with 0.03%. This study recommends increase in support both from Government and the construction industry in financing technical and vocational institutions. They should also be instrumental in promoting stringent measures on craftsmen's registration. Regulatory body should also be put in place to monitor the activities of these construction craftsmen.

Keywords: Apprentice certificate, Construction process, Nigerian construction craftsmen, Reservoir of trained replacements, Vocational training

INTRODUCTION

The building industry plays a key role not only in terms of the national economy of any country but stands as a central function in providing the urban fabric necessary for man's progress towards greater civilization. The saying that the level of building achievement and activity in any country is a measure of the country's success correctly reflects the two relevant factors: a high level of building activity indicates a healthy vigorous national economy; and highly developed building forms indicate a high level of construction industry development in a country. (Obiegbu, 2003; Usman, Inuwa, & Dantong, 2012). For the construction industry in Nigeria be able to service the economy, it has to parade competent hands in its operations; this includes credible consultants and contractors with qualified and competent operatives inclusive of craftsmen. The need for maintaining standards in construction operations is overwhelming; it requires investment in research, human and technical capital developments. Critical to this strategy is the empowering of craftsmen, there is a need for continuing upgrading of skills so as to meet the ever-increasing demands in today's constantly changing world. Hence, the need to train its operatives has become imperative so as to meet its responsibility in the economy.

According to Lawal, (2012) training is impacting skills into a person or persons in order to bring him or her to a desired standard of behaviour, efficiency or physical condition. He further defined training as: "submitting a person to discipline and instruction, to educate, to bring up, rear in habits of good behaviour and conduct". This is precisely what must be done in the Nigerian construction industry where, as a result of death of skills it has become

Dantong, J. D.; Prucnal-Ogunsote, B. & Awulu, S. (2016). Effective Training for Construction Craftsmen and Optimisation of Productivity in the Nigerian Construction Industry. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1247-1258

necessary to educate, instruct and above all, discipline and bring up habits of "good behaviour". Failure to do so will result ultimately in poor on the job performance and eventual unsatisfactory output, resulting in huge correction expenditure. However, training types/methods are numerous, and to achieve the desirable objective of having skilled workforce, it is necessary to adopt the most suitable training types and methods that are affordable and relevant to the needs of Nigeria's construction industry.

Training of Construction Craftsmen in Nigeria

The developmental process of any nation is largely a function of the emphasis placed on human resources development and utilization To achieve this, opines that, first the overall and projected manpower requirements should be identified at all cadres (lower level, middle level and higher level), this will help in knowing whether the expansion of existing educational and training facilities will suffice or the establishment of new ones would be preferable in achieving the national manpower requirements. (Kolawole & Frank, 1999; Olayeni, 2011).

The construction industry according to (Pam, 2002; as cited in Iro, Inuwa & Dantong, 2013) has three broad cadres of manpower needs, which are closely inter-related, one cannot do without the other; these are: the lower technical cadre, the middle - level technical cadre and the professional cadre. The lower level technical cadre, he reported are: labourers and tradesmen; whose qualifications range from apprentice certificate (formally trained) to other formal trade certificate, which fall below the National Diploma. This cadre is one much directly involved in practical construction, with a few of them rising to headmen capacities which includes nominal supervision of specific trades in the construction process. The position of the lower level technical cadres, which includes craftsmen is very sensitive and important to the survival and growth of the industry, because they are the ones directly involved in the practical aspects of construction and a bridge between management and the operative when serving as frontline managers (headsmen of various trades). For a company and for a nation to survive productivity improvement is imperative.

Training of Nigerian Construction Craftsmen has seriously declined as Bamisile (2004 as cited in Lawal, 2012) reported that:-In the time past, many of the tradesmen (craftsmen) were generally trained through trade cadres, vocational training institutes and technical colleges. Some even took examinations at the end of the apprenticeship period such as the examinations of the City and Guild Institute of Great Britain, trade test certificate of the ministry of labour and productivity, etc. it is regrettable to note that, there are no more serious formal vocational training centres for training craftsmen. The average age in trained craftsmen and artisans in Nigeria for instance is between 45 - 50 years. If care is not taken, in another ten years craftsmen and artisans that are really worth their salt would have gone into extinction. Reasons for this situation is not far fetch; Government neglect to funding, let alone enforcement of the training and corruption where craftsmen who care to get these certificates barely pay for them without any requisite training or examination as it used to be. Bamisili concluded that; there is an urgent need to embark on serious, well-funded and coordinated formal training and retraining programs for artisans and craftsmen. This has become necessary in order to address the issues of labour cost and workmanship. According to Abiola, (2004) for enterprises productivity is essential if they are to remain competitive and viable. Enterprises with high productivity are better able to create and sustain quality jobs and are in a better position to pay good wages of their employees. Training of construction craftsmen is imperative to the construction industry, since it is confirmed that training improves productivity and productivity improvement if achieved will ensure survival and growth of an enterprise; of which construction is one.

Statement of the Problem

The construction industry is routinely accused of being wasteful, inefficient, and falling short of quality and working to costs and time schedules. (Osei, 2000 as cited in Iro et al., 2013) . This accusation might be partially due to poor workmanship of the workforce, which can also be traced to the negligence of the employers. Morale in the industry, according to Osei is at its lowest ebb. He stressed that; *companies are concentrating on financial gains and forgetting the people that make the job and money. This perhaps contributes to the poor performance of the industry.* But the fact is that this is more a problem of externality where no contractor is willing to train workers as there is no guarantee that the worker will stay with the company, hence training of all sorts are often undertaking by the industry and government. (Bamisile, 2004; as cited in Dantong, 2006) reported that the industry has a poor performance rating, it is too fragmented, individualistic and out-dated in its operation and thinking.

The impact of the craftsmen in the industry is very conspicuous in its end products, especially where competent craftsmen are involved. However, where an end product of the industry wears a look characterized by poor work, poor quality, low productivity, late completion, cost overruns, increased accident rate, poor work practices and conflicts will also clearly be in evidence. This problem is mostly attributed to poor level of workmanship. (Abiola, 2004) Looking at the craftsmen in the construction industry, they play a crucial role in the practical realization of any construction project, they are mostly engaged in the technical aspect of construction and at the management level serve as frontline manager (supervisor); giving the role of interpreting the company policies into practical realization of the organizational goal of employer. Olayeni, (2011), enumerated qualitative and quantitative deficiencies in workmanship, is one of the factors militating against the attainment of success in the construction industry.

Need for the Study

The nature of the human resource problem and its pervasive effects in the Nigerian construction industry indicate the need for extraordinary action to upgrade managerial and technical skills, broaden their range of skills and enhance their professionalism. Education and training are, consequently, needed at all levels and across a wide spectrum of technical disciplines, indeed, what is required more than ever before is a highly trained cadre of people who are alive to the needs and realities of their own societies, sensitive to cultural values of intrinsic worth, conscious of the social nature of design and imbued with philosophy, which leads to the efficient use of indigenous materials and techniques. (Usman et al., 2012)

Housing, education, religion, entertainment, sport, government, industry, transport, commerce, and all the amenities of civilization all present claims on the resources of the construction industry, and so the activities of the industry never cease. Unless an adequate supply of appropriately trained workers can be ensured, the industry will consistently fail to satisfy the demands of the market for an adaptive, innovative and capable service. The industry has a responsibility to its customers to be an enlightened, progressive employer: the needs of the workforce are inextricably linked with the requirements of its consumers and need must be paid to each. History has shown that the effort of an ill-prepared and disenchanted workforce has failed to produce good service, and as a result, the industry is burdened with a poor image.

Aim and Objectives

The aim of the research is to investigate on the best training type that will optimize the productivity of construction craftsmen in the Nigerian construction Industry. To achieve this aim, the following objectives were set up:

i. To identify factors militating against training of the construction craftsmen in Nigeria.

ii. To determine the most severe factor militating against the training of the construction craftsmen in Nigeria.

iii. To identify the various types of training that can be applicable to the Nigerian Construction Craftsmen.

iv. To determine the most efficient type of training applicable to construction craftsmen that will enhance their productivity in the Nigerian Construction Industry.

Research Hypothesis

H0 - There is a significant relationship between training of construction craftsmen and productivity improvement

H1 - There is no significant relationship between training of construction craftsmen and productivity improvement.

RESEARCH METHODOLOGY

According to Usman et al., (2012) the guiding principle for developing a research strategy is that it must address the research questions. This research is intended to follow this guiding principle to achieve the desired objectives.

This Research collected and adopted both qualitative and quantitative data which is a *triangulation* that offer more clarity and explanation of the research question, leading to possible solutions. Quantitative data refers to data extracted out of existing literature on the subject and used in designing a well-structured questionnaire which was used in collecting the qualitative data through questionnaire survey.

Scopes and Delimitation

The research is concerned with the investigation into the factors hindering training and the different types of training that can be applicable to construction craftsmen in the construction industry with a view to finding the best method of training adopted to improve productivity of the craftsmen. The research confined itself to the following craftsmen: Bricklayers (Mason), Reinforcement Benders/Welders, Carpenters and Electricians. The research work covers the activities of craftsmen in five selected states of Northern Nigeria; Nasarawa, Kaduna, Niger, Plateau and the Federal Capital Territory (FCT). The selection of these cities is for no bias reason but for the fact that they are the major towns in north-central Nigeria where major construction work takes place and due to advantage of proximity.

CONSTRUCTION CRAFTSMEN TRAINING

Types of Training

Apprentices or other workers can have benefit of either day release, which means attendance one day a week at a local technical college or commercial institute, or block release, which means attendance over several weeks at a time. In both cases there is a marriage between "know - how" picked up on the job and the theory/practice learnt elsewhere. Types of training are: Trade group training programmes, Craft apprenticeship courses, on - the - job training, Sink - or - swim method, Sponsor system, Time release training and Self - teaching approaches. (ITF, 2000 as cited in Dantong, 2006). Training types can be further classified as follows:

Evaluation of Training

Training and development programmes should always be evaluated. Typical evaluation approaches include measuring one or more relevant criterion (such as attitudes or performance) before and after the training and determining whether the critical changed.

Evaluation measures collected at the end of training are easy to get, but actual performance measures collected when the trainee is on the job are more important. Trainees may say that they enjoyed the training and learned a lot, but the true test is whether their job performance improved after their training. Usman et al. (2012). According to Iro et al., (2013), Training is said to have "worked" if it accomplishes its objective. Since the training objectives are (or should be derived from the strategic objectives. However, training is only one of dozens of factors that determine if an organization accomplishes its strategic objectives, and one that is often far removed in time from the final result. To harness training effectiveness we need measures of success is required and the need to measure near the time the training has been completed.

Except in academic settings (Pyzdek, 1991; Lawal, 2011) further stressed that imparting knowledge or wisdom is seldom the ultimate goal of training. Instead, he added, it is assumed that the knowledge or wisdom will result in improved judgements, lower costs, better quality, and higher levels of customer satisfaction In other words, the training will produce "observable" results. The results should be the focus of the training plan development and training needs analysis. Training evaluation requires that they be converted to training measurable or objectives. Irrespective of the format of the presentation, the basic unit of training is the lesson. A lesson is a discrete "chunk" of information to be conveyed to learners. The training objectives should form the basis of each lesson, and the lessons must provide guidance for the development of measurements of success. At the lowest level, lesson plans provide the basis of measurement. The objectives in the lesson plan must be specific and designed to attain these specific objectives. The assumption is that by meeting the objectives of all of the training activities, the objectives of the training plan will be met. Finally, it is assumed that by meeting the objectives of the training plan, the objectives of the strategic plan will be met, or at least will not be compromised due to training inadequacies. For evaluation to be complete as a process, these assumptions must be subjected to evaluation. For training to be effective and efficient and subsequently improve productivity of the construction workforce or any business organization, post training evaluation is necessary.

Post Training Evaluation

According to Nmadu, (1998 as cited in Usman et al., 2012) training observations involve a four step process called job instruction training, and it requires that trainees during training be: told how to do it, shown how to do it, asked to perform the behaviour and; given a review of their performance until correct behaviour is learned. For training to be effective and efficient evaluation of the whole process is inevitable. According to Philips, (1996 as cited in Iro et al., 2013) the evaluation process in training involves four elements:

i. **Reaction** - How well did the conferees like the program? This is essentially customer satisfaction measurement. Reaction is usually measured using comment sheets, surveys, focus groups and other customer communication techniques
ii. **Learning** - What principles, facts, and techniques were learned? What attitudes were changed? It is entirely possible that conferees react favourably to training, even if learning does not occur. The learning of each conferee should be quantified using pre - and post - test to identify learning imparted by the training. Results should be analysed using proper statistical methods. In 9 exceptional cases, for example, evaluating a consulting company for a large training contract; a formal designed experiment may be justified.
iii. **Behaviour** - What changes on-the-job behaviour occurred? If a candidate leaves the seminar and immediately begins to effectively apply control charts where none were used before, then the training had the desired effect on behaviour. However, if the

conferee's tests indicate that there is gained competence in the subject matter from the training, but no change in the behaviour took place, the training investment was wasted. Note that behaviour change is dependent on a greater number of factors besides the training, example; management must create systems where the newly learned behaviours are encouraged.

iv. **Results** - What were the tangible results of the program in terms of reduced cost, improved quality and improved quantity. This is the real payback on the training investment. The metrics used for measuring results are typically built into the action plan, project plan and budgets etc. Again, as with behaviour change, there are many factors other than training that produce the desired results.

The Importance of Training

According to Nmadu, (1998; Lawal, 2011) training aims at changing the behaviour at the work place into efficiency and higher performance standards. They pointed out the major values of training are: Increased Productivity- Increase in skill usually result in an increment in both quantity and quality.

Heightened Morale - Possession of needed skills helps to meet such basic human needs as security and ego satisfaction.

Reduced Supervision - Trained employees can perform with limited supervision. Reduced **Accidents** – More accidents are caused by deficiencies in people than by deficiencies in equipment and working conditions, proper training reduces the accident rate.

Increased Organization Stability and Flexibility - The ability of an organization to sustain its effectiveness despite the loss of key personnel can be developed only through creation of a reservoir of trained replacements. Flexibility - the ability to adjust multiple skills to permit their transfer to jobs where demand is greatest. The biggest organizational asset is trained and motivated personnel.

The Effect of Training on Productivity

Like most developing economies, Nigeria has been identified as a region with construction-productivity problems (Izam and Adeagbo, 1999). In an attempt to proffer solution to the problems, much has been done on issues or factors affecting productivity with little or no success. According to (Lim & Alum, 1995; Winch & Carr, 2001) productivity aspect of the Nigerian construction industry is characterised by low productivity as noted by various researchers. The productivity problems cut across both the public and the private sectors (FOS, 1997) noted that capacity utilization of the manufacturing industry in Nigeria was said to be 30% on the average from the time of Structural Adjustment Programme (SAP) in Nigeria in 1986.

Training an aspect of human resources in improving productivity according to Iro et al., (2013) focuses more on doing, "it is job - focused". The emphasis is on maintaining or improving skills needed to perform the current job, or on acquiring new job skills. Often, training is employer - specific and the skill acquired may not always transfer readily to another employer. Bamisile, (2004), observed that in spite of advancement in technology, plant and equipment and in particular robotics, the construction industry is one of the few that still relies on individual skill of a tradesman. Abiola, (2004) reported that managers are being asked to get more mileage out of all their resources: human, financial, informational and materials. To achieve this, training is proffered as one of the "cannon" that can improve productivity. In support of this Dantong, (2006) agreed that staff training enhances and facilitates productivity improvement in any business undertaking. Through improvement and self-development of staff to meet the ever-changing challenge and requirements of new

equipment of new techniques of production and management is a continuous process. When observing the definition of training, which is understood as the process of acquiring knowledge, skills and attitudes for the sole purpose of executing a specific or present job more effectively and efficiently, it can be deduced that training has a positive effect on productivity, hence, a tool for improving productivity.

Factors Militating Against Training of the Nigerian Construction Craftsmen

Osei (2000), stated hindrances militating against training that affects all departments (Junior Technical Workers from maintenance department who are craftsmen, are inclusive) as follows:

Lack of Departmental Approval

Osei, (2000) revealed that most departments in the construction industry view training as a capital intensive venture that increase overheads to their company, as such put them at a disadvantage when tendering for a job, due to high cost reflected in their tender. However, few companies who really acknowledged the importance to training view it as an incentive towards achieving customer satisfaction consequently serve as a marketing mechanism that can improve the company's income in the long run. Training no doubt has been proven by many as a means of increasing productivity; in view of this it is necessary to support the training of construction craftsmen in the industry. Lack of departmental approval can however be viewed as lack of support and encouragement from the company on training.

Lack of Implementation of Training Policies by Organizations

Most companies prefer to recruit operatives they think will no longer require training, this is a measure been adopted by some managers to cut down Cost (ITF, 2002). However, the world is always changing with customer taste changing every day and also innovations coming up every day, to meet the rising demands of people, therefore it is imperative for managers to embark upon training and retraining of their operatives. Most construction companies don't have a training programme, and those that have, hardly implement these policies and programmes in training (Osei 2000).

The Problem of Craftsmen applying for irrelevant Fields of Study

Osei, (2000) revealed that application for irrelevant training programmes is common to the junior staff of the National Institute Kuru, of which the junior technical workers (Craftsmen) are majority. According to ITF, (2002). One main reason why training is believe to be a wasted venture by managers in the industry, emirate from the operatives inability to go for suitable training type/method relevant to their trades.

Lack of Funds

According to Osei, (2000) poverty or lack of funds could hinder someone from undergoing training especially where it involves payments of fees and so on. But the most important thing is the willingness and interest to undergo training is most paramount. He also revealed that training can be capital intensive and because of the "stop go" attitude of the construction industry most operatives hardly sponsor themselves for a training course. In view of the above, hindrances to training of the Nigerian Construction Craftsmen can be summarized as:

i. Lack of support and encouragement from the construction industry.
ii. Lack of effective regulatory body
iii. Poverty/Lack of funds.
iv. Lack of adequate encouragement and support from government for the training of construction craftsmen.

DATA PRESENTATION AND ANALYSIS

The obtained data are presented and analysed using the standard statistical methods explained in 5.1 below. Also simple bar and pie charts are also used for easy understanding of the presentation and analysis of the data at a glance.

Construction professionals with respondents from fifty six (56) Architects, thirty four (34) Quantity surveyors, twenty Six (26) engineers and thirty eighty (38) Builders. All questionnaires were distributed within five (5) states of central Nigeria including the Federal Capital Territory (FCT), Kaduna, Niger, Nassarawa, and Plateau States.

Presentation and Analyses of Construction Professionals' Responses to Questionnaire

Table 1 below shows the random distribution and responses of construction professional to questionnaires in five selected state of Nigeria 80 questionnaires were distributed within the Federal Capital Territory (F.T.C) where 58 of the construction professionals responded, that means 72,5% responded. In Kaduna state, only 6 construction professionals responded out of the 40 questionnaires distributed, that means only 15% responded. In Niger State 38 responded out of 60 questionnaires distributed that means 63.3% responded. Also in Nassarwa State 16 responded from the 40 questionnaires distributed that responded from the 60 questionnaires distributed, that means 60% response was received from Plateau State. A total of 280 questionnaires were distributed, from which 154 responded. Therefore, percentage responses were 51.4. The high response from Abuja, Niger and Plateau states cannot be unconnected to the familiarity of the researcher to the states. (see Figure 1)

Table 1: Distribution and responses of construction professionals to questionnaire

S/No	Location states	No. Distributed	No. responded	% responded
1.	FCT	80	58	72.5
2.	Kaduna	40	6	15
3.	Niger	60	38	63.3
4.	Nassarawa	40	16	40
5.	Plateau	60	36	60
Total	5 states	280	154	51.4

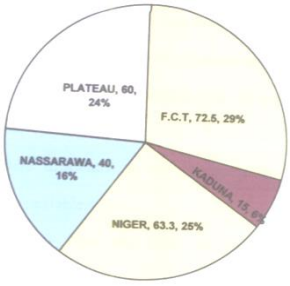

Figure 1: Percentage of Construction professionals to questionnaires in 5 states

Construction professional's responses to questionnaire

Table 2 shows construction professionals' percentage response to questionnaire in five states, which was randomly distributed. In the FCT 19 Architects responded from 25 questionnaires distributed to them with 79% response. Also 11 Quantity Surveyors responded from the 20 questionnaires distributed to them, that is 55% response. And 10 Engineers responded out of 15 questionnaires distributed with 66.67% response. In Kaduna, Niger, Nassarawa and Plateau States, different numbers of questionnaires were distributed to the professionals and different numbers responded as shown on table 2. In the summary from the table 56 Architect responded from 73 questionnaires distributed. That is 76.71% of Architects responded. Similarly 34, 26 and 38 Responses came from Quantity Surveyors, Engineers and Builders respectively from 67, 53 and 67 questionnaires respectively distributed. The resultant percentage responses were 50.74, 49.05 and 56.72 respectively.

Table 2: Construction professionals' response to Questionnaires

Professional		Architects			Quantity surveyors			Engineers			Builders		
S/N	Date	Number distributed	Number of	Percentage response	Number Distributed	Number responses	Percentage response	Number distributed	Number of responses	Percentage response	Number distributed	Number responses	Percentage response
1	FCT	25	19	79	20	11	55	15	10	66.67	20	18	90
2	Kaduna	10	2	20	10	2	20	10	-	0	10	2	20
3	Niger	20	15	75	15	8	53.33	10	8	80	15	7	46.67
4	Nasarawa	10	6	60	10	4	40	10	2	20	10	4	40
5	Plateau	28	14	50	12	9	75	8	6	75	12	7	58.33
	Total	73	56	76.71	67	34	50.74	53	26	49.06	67	38	56.71

Combined Rank Agreement Factor (R.A.F) of Construction professionals on most severe factor militating Against Construction Craftsmen

The combined Rank Agreement factor (R.A.F) on table 4.15 si >ws the most severe factor to be: "lack of effective regulatory body for the Nigerian construction craftsmen" that came 1st with Rank order sum (R. O. S) o 6, Rank Agreement factor (R.A.F) of 1.5 and percentage Rank Agreement factor (PRAF) 53.85 (see table 3).

The least severe factor is poverty/lack of funds that came 4th with Rank order sum (R.O.S) of 13, Rank Agreement factor (R.A.F.) 3.25 and percentage Rank Agreement factor (PRAF) 0.00.

Table 3: Combined Rank Agreement Factor (R.A.F.) of Construction Professionals on most severe factor militating against Training of Construction Craftsmen.

S/N	Types/ Methods of training								
	Factors	Architects	Quantity Surveyors	Engineers	Builders	Rank order sum	Rank Agreement Factor (R.A.F.)	Percentage Rank Agreement Factor (PRAF)	Rank Order
I.	Lack of effective regulatory body for the Nigerian construction craftsmen	1	1	3	1	16	1.50	53.85	1
2.	Poverty / lack of fund	4	2	3	4	13	3.25	0.00	4
3.	Government negligence of training construction craftsmen	3	4	1	3	11	2.75	15.38	3
4.	Lack of encouragement & support for training of construction craftsmen by the construction industry	2	3	3	2	10	2.50	28.07	2

Combine Ranking Agreement of Construction Professionals on Most Efficient Type of Training that can improve productivity

Table 4 below shows the combine ranking agreement of construction professionals on most efficient training type. Vestibule Schools came first with rank order of 1st, 1st, 10l" and 1st from Architects, Quantity Surveyors, engineers and Builders respectively. Vestibule Schools emerge first with a Rank Sum (RS) of 13, Rank Agreement Factor (RAF) of 0.59 and Percentage Rank Agreement Factor (PRAF) 83.25. Trade group training came second with Rank Sum (RS) 15, Rank Agreement Factor (RAF) 0.68 and Percentage Rank Agreement Factor (PRAF) 80.68. Time-release training came third with 20.5, 0.93 and 73.58% as RS, RAF and PRAF respectively. The 20th position was "Action Research" with results 70, 3.18, 9.66 as RS, RAF and PRAF respectively. The last but not the least was Transactional Analysis, which came 21s1 position with RS - 73, RAF - 3.32 and PRAF - 5.68%. The least efficient type/method of training was sink - or - swim training with rank orders 19.5th, 17th, 21st, 20th from Architects, Quantity Surveyors, Engineers respective!) Sink - or - swim

method had Rank Sum (RS) of 77.5, Rank Agreement Factor (RAF) 3.52 and Percentage Rank Agreement Factor (PRAF) 0.00 (see Figure 2). From the analysis of results above vestibule school is the most efficient training type to be adopted for the Nigerian Construction Craftsmen.

Table 4: Combined Ranking Agreement of Construction Professionals of Most Efficient Type of Training for Construction Craftsmen that can Improve Productivity

S/N	Types/ Methods of training	Architects' Rank order	Quantity Surveyors' Rank order	Civil Engineers Rank order	Builders' Rank order	Sum of Rank orders	RAF= $\frac{\text{Sum of Rank orders}}{\text{Number of factors}}$	PRAF = $\frac{RAF_{max} - RAF_{considered}}{RAF_{max}} \times 100$	Rank order (R O)	Rank order (R O)
1.	Trade group training	3	6	3	3	15	0 68	80.68	2	2
2	Craft Apprenticeship programme	7.5	3.5	2	9	22	1.00	71.59	4	4

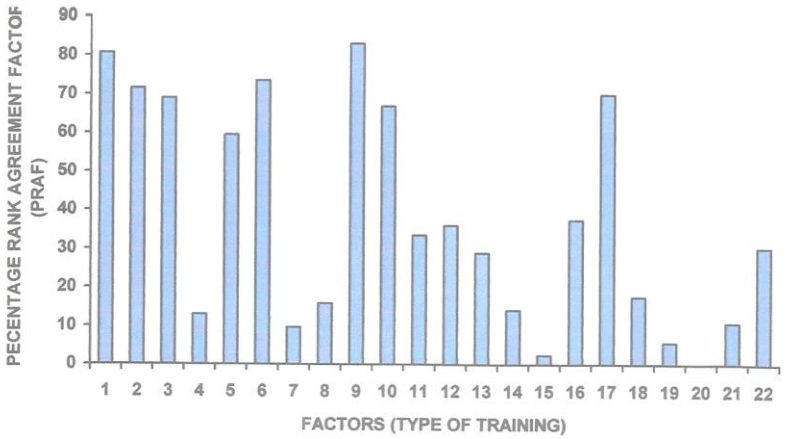

Fig. 2: Combined Ranking Agreement of Construction Professionals of most Efficient Type of Training for Construction Craftsmen that can Improve Productivity

SUMMARY AND CONCLUSION

From the investigations carried out in the form of literature search, twenty- two (22) different types of training were identified. From the analysis also, four factors militating against training of construction craftsmen were also identified. Lack of effective regulatory body was found to be most severe. The types of training were presented in a questionnaire and ranked by professionals in the four sampled groups. Based on the rankings, it was discover that, vestibule school was the most efficient method of training with a combine rank of 83.24%. Sink - o r - swim method was the least efficient type of training with combine rank of 0.00%. The hypothesis test arrived at a Kendall's coefficient of concordance of 0.0469, from which a calculated. X^2 value of 3.9396 was obtained. The critical X value at 5% level of significance and 95% degree of freedom is 32.671, which higher than the calculated X value. This means the null is accepted. From analysis of the responses by construction craftsmen, it was found that the older age-group underwent training more than the younger age-groups. From the summary of the findings above, it can be concluded that;

The Training of Construction Craftsmen is diminishing with time and may die out completely if nothing is done to revive it.

The most severe hindrance to training of the Construction Craftsmen was found to be lack of standard type of training adopted for the Construction Craftsmen in Nigeria. The least severe was found to be lack of funds/poverty.

It was also discovered that the most efficient and effective type/method of training to improve productivity is vestibule school.

RECOMMENDATIONS

In view of the analysis, findings and scope of this study, the following recommendations are made in order to increase the efficiency of training, of the Nigerian construction craftsmen for increase in productivity: -

Government should increase support to technical and vocational institutions to increase standards and to make these institutions attractive for Nigerian construction craftsmen.

The relevant trade bodies in collaboration with Government should ensure high standards by re-designing an appropriate standard curriculum and programmes and adopt standard equipped vestibule schools

Stringent measures be exerted on craftsmen's trade registration. This registration is a situation where a craftsman must have duly passed through a vestibule trade school and duly confirmed qualified to practice and can perform in the trade.

Training and re-training of construction craftsmen in companies should be made compulsory and enforced by government.

Nigerian construction companies should be made to ensure not only the existence of a training policy but its full implementation.

Government should encourage private entrepreneurs who wish to set-up similar training institutions, but insist its conditions.

Recommendations for Further Studies

i. This research work was carried out to improve productivity of the Nigerian construction craftsmen through training based on situations in the Nigerian construction industry. Comparative studies should be carried out in other parts of the world to ascertain productivity of the construction craftsmen through effective training.

ii. The four major hindrances identified as factors militating against the training of Nigerian construction craftsmen, could be studied and analysed further, in order to proffer solutions to the problems of diminishing training amongst construction craftsmen.
iii. Further studies should be carried out on Design of effective curriculum and Establishment of standard programmes for the Nigerian construction craftsmen.

Contribution to Knowledge

Adopting an effective and efficient training type/method can increase productivity. It was discovered with dismay that training of the Nigerian Construction craftsmen is dying out as a result of falling standards of training type. It was also observed that training of craftsmen is fast diminishing with age. Therefore, if the situation is left unchecked; training of the Nigerian construction craftsmen will die out completely in the near future.

Architectural Transformations in an Educational Facility and its Impact on Teaching and Learning: a Study of the Department of Architecture Ahmadu Bello University Zaria

Sani-Katsina, H. [1*] ***& Shuaib, A. U.***[2]

[1&2]*Department of Architecture, Ahmadu Bello University Zaria, Nigeria*
[*]*jcdantong@yahoo.com*

ABSTRACT

Transformations are common and generally perceived to bring improvements to the built environment (Sani-Katsina, 2013; 2015) However there are underlying issues with transformations. This study is concerned with looking beyond the physical quality of the educational facility upgrade in the Department of Architecture Ahmadu Bello University Zaria. The aim is to assess the impact of the transformation on teaching and learning. The study is particularly interested in the effect of the transformations on the quality of life of the students in the department of Architecture Ahmadu Bello University Zaria between 2010 and 2015. The study adopts a mixed method strategy and draws on data collected in 2015. The findings show that during the prolonged transitional period the facility users experienced difficulty mostly resulting from lack of instruction and demonstration spaces which impacted negatively on the teaching and learning. This study recommends that architectural transformations in educational facility should be executed when school is not in session. The conclusion drawn gives direction for future policy and research on the general standards and requirements of university regulatory bodies.

Keywords: Architectural transformations, educational facility, quality of life, renovation, upgrade

INTRODUCTION

The Department of Architecture Ahmadu Bello university Zaria has undergone major renovation works which have transformed and upgraded the educational facility in the department. This upgrade was carried out when the school was in session. therefore, the purpose of this research is to study the impact of the Architectural Transformations on Teaching and Learning.

This paper is in two parts; the first part presents the present day physical condition of the department of Architecture. The second part presents the impact of the ongoing transformation on teaching and learning and seeks to contribute to the understanding of the impact on the quality of life of students.

THE DATA COLLECTION TECHNIQUES EMPLOYED

The study has used mixed methods as indicated in Table 1 below.

Table 4: shows the data collection tools and techniques

	Data collection tools and techniques
1	10 number face to face in depth interviews conducted with the academic staff
2	15 number face to face in depth interviews conducted with the students
3	Observation of the physical structure
4	Archives and library for existing records and documents
5	Image recording equipment to capture actions and events through photographs
6	Measuring tapes to determine measurements to produce architectural plans

Present Day Physical Condition of the Department of Architecture

Upgrade is generally considered by researchers to mean architectural transformation (see, Peng, 2012; Sani-Katsina, 2013, 2015; Tipple, 2000). Similarly according to Popoola (1996) upgrade in educational facilities can mean replacement, repair, conversion, improvement enhancement and modernization. This study therefore considers upgrade and renovation to mean architectural transformation.

Sani-Katsina,H. & Shuaib, A. U. (2016). Architectural Transformations in an Educational Facility and its Impact on Teaching and Learning: a Study of the Department of Architecture Ahmadu Bello University Zaria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1259-1263

The reasons for the transformation of the educational facility of the department of Architecture arose from the need to cope with demand in the increase in annual intake of students (NIA/ARCON, 2014), to impart quality education, train and develop creative professionals, produce top grade manpower that measure up to global standard and to maintain the departments position in the development of architectural education in Nigeria and beyond (Department of Architecture, 2014). It is important to note the many changes resulting from the upgrade include a change in the curriculum and this change in the curricular activity was to support the transition of the upgrade from a department to a faculty in order to support academic and teaching staff in their move to a new learning and teaching landscape (Department of Architecture, 2012). However this study focuses mainly on the architectural transformations and its impact on teaching and learning.

Figure 1 and Table 2 below show the present day facilities in the department

Figure 1 shows the workspaces in the transformed studio

Source: Umar 2015

However the implementation and transition phase in educational facility upgrade presents a range of critical issues to consider which Blackmore et al.(2011) discuss, including: security and access, changing perceptions, adaptation, managing transition, school and class size, formation of learning communities, curriculum, school social and academic culture, scheduling and facilitation of group work. According to Darling and Hammond (2002) facilities and spaces may have an impact on teacher and student perceptions. While Bullock (2007) suggests that there is a correlation between renovated educational facility and student learning. In line with this there is the need to assess the impact of the transformation on teaching and learning in the Department of Architecture, Ahmadu Bello University Zaria during the prolonged period of the exercise.

Impact of the Transformation on Teaching and Learning during the Upgrade Exercise

The impact of the transformation on teaching and learning during the upgrade exercise was accessed based on effect on students' performance, lecture delivery mode and students understanding, major inconveniences experienced by teachers and students and finally how the students coped with the situation during the upgrade exercise between 2010-2015.

Through this time staff and students experienced some difficulty in finding venues to conduct lectures and studio sessions as the classrooms and studios were being upgraded. Figure 3 below shows a summary of the students' perception of how the upgrade period impacted on their quality of life

Table 2: Facilities in the department of Architecture based on the NIA/ARCON /NUC Requirements

Spaces/Floor finish/wall finish	NUC/NIA/ARCON Requirements	No. Available	Average Carrying Capacity	Advantages
Lecture room/ Vitrified tiled floor(grey)/ Grey paint	i. Adequate and well equipped classes ii. space allocation and accessories iii. ICT iv. IEQ tools [natural/artificial [supplements]	5	50	i. Advanced technology ii. Adequate space for fast teaching and fast learning iii. Spaces appear wider , more calm and flexible
Offices/ Vitrified tiled floor(grey)/ Grey paint	i. Adequate and well equipped offices for academic and non-academic staff ii. Pc's and accessories iii. IEQ tools	5-small 30-large	1 2	i. To aid teaching and learning ii. Advanced technology iii. Facilitate research works iv. Avenue for brain capacity building v. Spaces appear wider , more calm and flexible
Cafeteria	Provision for eatery/cafeteria	nil	Nil	-
Studio	i. Adequate and well equipped studio ii. Emphasis on studio facilities iii. Manual Drawing tables and stools iv. Digital studio v. ICT connectivity vi. Sockets ports vii. Display areas viii. Smart/white boards ix. Loud Speakers	1-small 2- twin 2- large 1 - medium.	30 200 250 80	i. Maintain studio culture ii. Sharing of new ideas iii. studio design classes iv. Critique sessions
Research laboratory	i. Adequate and well equipped research facilities for staff and students ii. Acoustical tools, survey tools, model tools, testing, iii. Pc's and accessories iv. IEQ tools	2	40	i. Facilitates teaching/learning ii. Technology modernization iii. Facilitate research works iv. Specialization v. Avenue for brain capacity building
Computer laboratory	i. Adequate and well equipped computer laboratory ii. computers & accessories, iii. personal work stations, iv. ICT connections	1	40	i. Aids software skills ii. Facilitate teaching and learning
Data room	i. Adequate and well equipped library for staff and students ii. IEQ iii. Thesis collection iv. Books, journals, articles	1	80	i. Fast learning ii. Facilitate research iii. Avenue for brain capacity building iv. library
Lounge	Provision for staff and students lounge .minimum of one (1) each	1	20-30	i. Relaxation ii. Common room iii. Visitors waiting

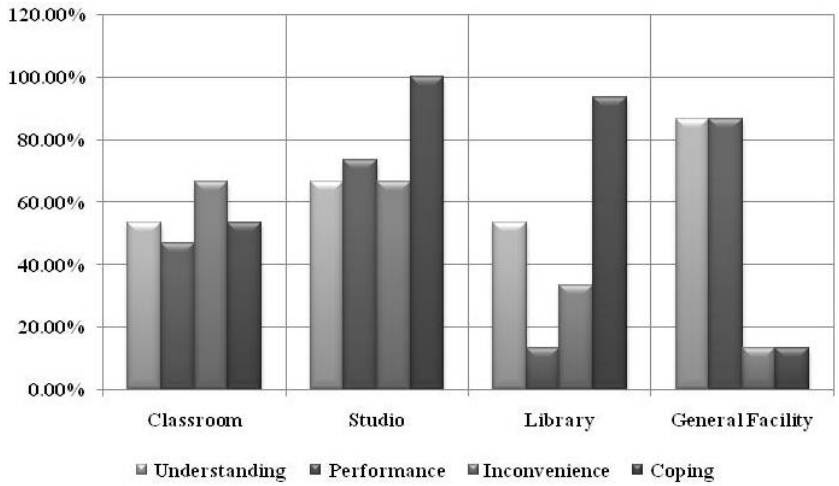

Figure 2: shows students perception on the impact of transformation on teaching and learning in Department of Architecture, Ahmadu Bello University Zaria

Student Performance

Darling and Hammond (2002) and Bullock (2007) agree that there is a relationship between educational facility renovation and student learning. In Figure 2, this relationship is observed when in an interview conducted with 15 students of the department of Architecture, 46.66% and 73.33% of the respondents agreed that lack of classrooms and studios consecutively affected their performance with 66.66% of the respondents adding that lack of classrooms and studios caused much inconvenience and 100.00% of the respondents couldn't cope with lack of studios. In the interview one of the students added that because of the competition for studio spaces the duration for consultation was reduced which lead to the students poor final presentation. However another student (Source, R3S)said it was also difficult for the lecturers to conduct studio sessions as the spaces were over crowded. while another student believes that the insufficient tables, choked circulation spaces " didn't really affect my performance the drop in performance was due to personal issues" (Source, R4S).

This argument is supported by a member of staff who said that;

I don't have all the answers but am doing my best. My worry is how do you give the students back what they have lost?"(Source, L8R1). Other members of staff acknowledge the difficulties associated with teaching and learning design especially within the upgrade period but add; "That the department is in transitional upgrade for positive change. changing from manual/traditional methods to new e-teaching/learning for fast and effective learning and the upgrade changes in the department is in harmony to their history, goals, aim, and objectives"(Source, L5R2).

Another staff said that; "The result is obvious! As a result of the upgrade changes, adequate but technologically sound educational facilities are being provided"(Source, L5R2).

According to the current Head of Department; I am optimistic that we will overcome our difficulties and emerged triumphant"(Department of Architecture, Student's Prospectus, 2012, p. 3)

This is already obvious in the completed general facility which include smart boards, library and computing facility as 86.66% of respondents as indicated in figure 2 believe that this transformation has increased their performance and their understanding as summarised by a student that, " lectures are now very interesting"(Source, R1S)

CONCLUSION

The study has looked at the impact of the architectural transformation on teaching and learning during the upgrade period and found that the many difficulties experienced by staff and students of the Department of Architecture Ahmadu Bello University Zaria resulted mainly from lack of spaces for teaching and learning especially design and studio work. Students believe that during this period the lack of studio culture during the upgrade activity lead to low performance in design. This study did not verify this fact by looking at final grades for the design courses during this period. This is however recommended for further study. Furthermore Staff and students believe that the facility provided at the end of the exercise will move teaching and learning of Architecture in the Ahmadu Bello University to a higher level in terms of technological advancement. This study finally concludes that all transformation works in terms of educational facility upgrade should be carried out when the university is not in session to avoid any inconvenience which will ultimately affect the teaching and learning process.

Community Participation in Education: The Role of Parent Organizations (POS) in Decision Making Process

Alfa, Muhammad Gimba

Staff School, Ahmadu Bello University, Zaria-Nigeria
gimbaalfa@gmail.com

ABSTRACT

Parent Organizations play a vital role in the decision making process in schools. This study was descriptive survey in design. It was aimed at determining the role of Parent Organizations in decision making process in schools. The researcher used teachers and parents as sample for the study. The simple random sampling technique was used. In addition, structured questionnaire was used as an instrument for data gathering. The instrument was adapted and modified from the work of Hammayero (2015). Mean, standard deviation and independent sample t-test were used as data analysis instruments. The study revealed no significant difference between the opinions of teacher and parents on the contributions of parent organizations in school decision making process. The work further revealed the consensus opinions of teachers and parents on the role played by Parent Organizations (POs) in decision making process in schools. In the light of the above findings the researcher recommends the revitalization of Parent Organizations in initial education (Primary and Secondary schools). This will assist in promoting and enhancing community participation in education for better service delivery in Nigerian education sector.

Keywords: Community, Decision-Making, Organizations, Parent, Participation

INTRODUCTION

Parents Organizations (POs) is a formal organization that consists of parents, teachers and non-teaching staff in the school. It is a voluntary association of parents and teachers in a particular school established for its development Hammayero (2015). The main objective of the Parent Organisation (PO) is to help enrich the educational environment and learning experience of all students. The organization is not only concerned with fund raising, but is also involved in the Open Day, Special events, and as a board for development. The main aim of Parent Teacher Association is to provide the school with those items not normally provided by the government and foster more extended relationship between home and school.

The objectives of the organisation assert Murtaza and Khan (2011) are: to work for the well being of every student of the institution in the home, the institution and society, to enhance awareness and understanding of parents that they have a vital role to play in the provision of quality education, to encourage active involvement of parents in improving the standard of the institution, to create awareness among the people involved that optimum use should be made of the educational facilities being offered by the government, and avail expertise of the communities members, to motivate the parents especially in the rural areas to send their children to school, to consider ways and means to decrease dropout ratio and teacher absenteeism in the institutions, to develop a congenial and harmonious relationship between parents and teachers avoiding bureaucratic rigidity on the both sides, to mobilize community resources for improvement of the institution and benefit of the students.

The Federal Ministry of Education in Nigeria insists as a matter of policy, that every approved school (primary or secondary) in the Country must have a functional Parent Organisation (PO) (Abdullahi, 2006). The Federal Republic of Nigeria in its National Policy on Education (FRN, 2013) recognised the importance of parents in the school management when it stated that "the local people particularly parents will be encouraged to participate in

Alfa, M. G, (2016). Community Participation in Education: The Role of Parent Organizations (POS) in Decision Making Process. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1264-1268

school management". In compliance to this, there is a PO established in every secondary school in Nigeria. The association is usually headed by a Chairman/Chairperson. According to Onderi and Makori (2013), POs provide a link through which parents and the rest of community assumes a partnership responsibility and in that way participate in the education of their children. In this circumstance, Igwe (1999) highlighted some functions of POs as applicable to public schools (a) promoting better acquaintances and healthy working relations between teachers and parents (b) serves as effective channel of communication between the school a community (c) advise the school staff, the board of governs or the school committee on pressing education needs of the community as perceived by parents amongst others.

Many communities in Nigeria have been playing very useful roles in their local schools. The involvement of parents in school matters in most of the communities is usually through the Parent Teacher Association or Parent Organisations (Ejieh 2005). Some schools asserts Ejieh (2005) still depend on the parents for money with which to purchase examination materials each term. The involvement of the community in the life of their schools has recently gone beyond mere financial contributions. In her study Hammayero (2015) discovered that the Parent Organizations (POs) contribute in the management of secondary schools in the following area: provision of infrastructure, instructional facilities, promotes school-community relationship, maintenance of discipline, decision-making process and extra-curricular activities.

Traditionally, schools have isolated themselves from the communities which they served and teachers would prefer to do their work quietly in their schools with minimum interference from parents and other community members. Parents and other members of the community appear to be no longer satisfied with this state of affairs. Increased parental and community involvement in school affairs is desirable in our quest for the qualitative development of our school system especially in these days of continued cutbacks in the votes for education. Equally desirable in this respect is increased interaction between teachers and parents and other members of their pupils' community (Ejieh 2005).

Schools are located in communities, but are often "islands" with no bridges to the "mainland." Families live in neighborhoods, often with little connection to each other or to the schools their children attend. Nevertheless, all these entities affect each other, for good or ill. Because of this and because they share goals related to education and socialization of the young, schools, homes, and communities must collaborate with each other if they are to minimize problems and maximize results(Adelman & Taylor 2007).

Despite the crucial role played by Parent Organisations (POs) in decision-making process of schools, personal experience and observations revealed that few schools in the study area did have vibrant and functional POs. The problem of this study hinges on a determination of the role of Parent Organisations in decision-making process in schools.

Purpose of the Study

This study is aimed at determining the contributions of parent organizations (POs) in schools decision making process. Specifically, the study examines the views of teachers and parents on the contributions of parent organization in decision making process in schools.

Research Question

i. To what extent do Parent Organizations contribute to decision making process in schools?

Null hypothesis

H_{01}: There is no significant difference between the opinions of teacher and parents on the contributions of Parent Organizations in decision-making process in schools

METHODOLOGY

Design

The design used in this study is descriptive survey design. The study utilized simple random sampling technique to select teachers of primary schools from Zaria Education zone, Kaduna state-Nigeria. The study used structured questionnaire titled "Contributions of Parent Organizations Decision Making Process in Schools (COPODMPS) as an instrument for data gathering. The instrument was adopted and modified from the work of Hammayero (2015). The respondents reacted to each item on a four point scale ranging from strongly agreed (S.A) 4, Agreed (A) 3, Disagreed (D) 2, and Strongly Disagreed (S.D) 1. The instrument was duly validated. The study's research question was answered using mean and standard deviation. In addition, the t-test independent sample was used in testing the research hypothesis at 0.05 level of significance.

RESULTS AND DISCUSSIONS

Research Question: To what extent do Parent Organizations contribute to decision making process in schools?

Table 1.1 Opinions of parent and Teachers on the Contributions of parent organizations in decision making process in schools

S/N	ITEMS	Respondents	Response Categories				Mean	STD
			SA	A	D	SD		
1	POs participates on students disciplinary decisions in the school	Teachers	130	12	62	13	3.1935	1.0449
		Parents	71	14	59	9	2.9605	1.0443
2	POs participates in decision making process that involves staff discipline	Teachers	113	57	18	29	3.1705	1.0556
		Parents	74	51	19	9	3.2415	.8887
3	POs participates in decision making process that involves procurement in the school	Teachers	149	25	6	37	3.3180	1.1407
		Parents	126	13	2	12	3.6536	.8531
4	POs participates in decision making process that relates to recruitment of teachers	Teachers	114	55	36	12	3.2488	.9243
		Parents	87	30	27	9	3.2745	.9544
5	POs participates in decision making process that relates to school time tabling	Teachers	43	129	31	14	2.9263	.7722
		Parents	42	93	11	7	3.1111	.7214
6	POs performs an advisory role on school expenditure	Teachers	95	66	40	16	3.1060	.9539
		Parents	62	53	26	12	3.0784	.9426
7	POs liaises with the school heads to advice the government on appropriate projects needed in the school	Teachers	99	57	42	19	3.0876	.9984
		Parents	70	39	21	23	3.0196	1.0970
8	POs ensures that projects and contracts awarded by the government are executed	Teachers	83	75	28	31	2.9677	1.0425
		Parents	43	50	28	32	2.6797	1.0951
9	POs advices on review of school fees	Teachers	86	85	17	29	3.0507	1.0056
		Parents	82	53	5	13	3.3333	.8959
10	POs assists in organizing extra lessons for students	Teachers	89	36	68	24	2.8756	1.0750
		Parents	45	18	63	27	2.5294	1.0946

Decision Mean= 2.50

The Outcome of the statistics in table 1.1 revealed the opinions of teachers and parents on the contributions of Parent Organizations (POs) to decision making process in schools. Therefore, taking into account the decision mean of 2.50 against the individual mean of the items in the table1.1 above, it can be concluded that the responses were positive as all the individual mean of the items as seen in the table were higher than 2.50 decision mean. In another development, their cumulative mean responses were 76.7097 and 76.4967 for teachers and parents respectively. It can therefore be deduced that Parent Organizations (POs) contribute to schools decision making process.

Hypothesis Testing

H_{01}: There is no significant difference between the opinions of teacher and parents on the contributions of Parent Organizations in decision-making process in schools.

Table 1.2: Independent t-test sample statistics on the mean opinions of teachers and parents on the contributions of parent organizations to decision making process in schools

Gender	N	Mean	std.dev	Df	t-Cal	t-Crit	Sig (p)
Teachers	**217**	**76.7097**	**6.59360**				
Parents	**153**	**76.4967**	**6.43093**	368	0.309	1.96	0.757

Calculated p > 0.05, calculated t < 1.96 at DF 368

The result emanating from the above Independent sample t-test statistics showed that there was no significant difference between the views of teachers and parents on the contributions of Parent Organizations (POs) to school decision making process. This was due to the fact that the calculated significance (P) value of 0.757 is higher than the 0.05 alpha level of significance while the calculated t value of 0.309 is lower than the 1.96 critical t value at Df 368. Similarly, their calculated mean responses were 76.7097 and 76.4967 for teachers and parents respectively. Therefore, the null hypothesis which states that there was no significant difference between the views of teachers and parents on the contributions of Parent Organizations (POs) to decision making process in schools is hereby retained.

Major Findings

The study revealed no significant difference between the opinions of teacher and parents on the contributions of Parent Organizations in school decision making process in the areas of disciplinary matters affecting staff and pupils', decision on procurements, decisions on recruitment and school time tabling, advisory role, oversight roles and financial assistance in organising extra-lessons among others. The study further revealed the consensus opinions of teachers and parents on the role played by Parent Organizations (POs) in decision making process in schools.

Discussion on Findings

The study revealed that Parent Organizations (POs) play an important role in school decision making process. The finding of this study corresponded with that of Hammayero (2015). In her study Hammayero (2015) discovered that the Parent Organizations (POs) contribute in the management of secondary schools in the following area: provision of infrastructure, instructional facilities, promotes school-community relationship, maintenance of discipline, decision-making process and extra-curricular activities. This study centred on the role of parent organisations in decision making process in primary schools while that of Hammayero looked into the organisation's role in management of secondary schools. Although this study centred on only one aspect of management (decision-making process) it further validates Hammayero's findings on the crucial role played by POs in decision-making process and by extension the management of secondary schools. This study filled the gap left by Hammayero as her worked covered only primary schools. This study in an attempt to bridge the gap used primary schools as case study.

CONCLUSION

Based on the findings of this study, it is concluded that Parent Organisations' (POs) participation in schools is an important way a community can participate on matters effecting education of their children in Nigeria especially in primary schools that concerns this study. The benefits of POs in decision-making process as identified by this work include: disciplinary matters affecting staff and pupils', decision on procurements, decisions on

recruitment and school time tabling, advisory role, oversight roles and financial assistance in organising extra-lessons among others.

RECOMMENDATIONS

Based on the above findings this study recommends the revitalization of Parent Organizations in primary schools in the study area. This will assist in promoting and enhancing amicable and just resolutions on disciplinary matters affecting staff and pupils', effective and all-inclusive decisions on procurements, recruitment and school time tabling, advisory role, oversight roles and financial assistance in organising extra-lessons in order to minimize problems and maximize results.

ABSTRACT

The symbiotic relationship between man and his physical environment is an important area of interest to social studies education. This study assesses the opinion of students on the role of Social Studies Education in promoting environmental sustainability for the attainment of Agenda 2063 in Nigeria. The study was descriptive survey in its design. One question was answered using Frequency counts, Mean and Standard Deviation and a null hypothesis was tested using independent sample t-test at 0.05 level of significance. The respondents were NCEII & NCEIII Social Studies students of the two Colleges of Education in Niger state-Nigeria. The instrument for data collection was Social Studies Environmental Sustainability Questionnaire (SSESQ). The study discovered that the students regardless of their study level have positive opinion on the potency of social studies education to promote the development of sustainable environment. In the light of the findings made, the study recommends the teaching of social studies at all levels of education in Nigeria and a need for the government to use social studies as a means to create awareness and enlightenment campaigns on the need to promote environmental sustainability among its citizenry.

Keywords: Agenda 2063, Environment, Nigeria, Social Studies, Sustainability

INTRODUCTION

Background Statement

Social studies has been defined as the study of man and his physical and social environment. According to Dubey and Barth (1980) in Muhammed (2014) among the focus of social studies education is the creation of an "awareness and understanding of the evolving social and physical environment, its natural, man-made, cultural and spiritual resources, together with the rational use and conservation of these resources for development". In a related development, Dubey and Barth (1980) cited in Salihu (2015) state that one of the objectives of social studies is to develop in the students an appreciation of his cultural heritage and a desire to preserve it". Thus, social studies education strives towards sustaining and preserving the physical environment through its teachings and advocacies at all levels of education where it is offered. Students of social studies often embark on excursions under the guidance of the school at regular intervals to acquire first-hand information on the nature, typology and geographical distribution of environmental challenges with a view to determine their causes, effects and the way forward. This is because social studies education asserts Ololobou (2010) is a problem-oriented area of study and a response to the problems of society with a view to seeking rational solutions to the identified problems.

The symbiotic relationship between man and his physical environment is an important area of interest to social studies education. This is because man and the environment are inseparable twins. They co-exist side by side. Man influences his physical environment and he is in turn influenced by the environment. The relationship between man and the environment has been mutual from time immemorial. The advancement in the area of science and technology in recent times have made this mutual man-environment relationship to be less mutual and more of parasitism in favour of man and at the detriment of the physical environment. Human beings in an attempt to make ends meet depletes and injures the environment. In the light of the above Jimoh (2000) in Ibimilua & Ibimilua (2014) observes that man-environment

Salihu, J. J. & Muhammed, A. (2016). Promoting Environmental Sustainability for the Attainment of Agenda 2063 in Nigeria: The Role of Social Studies Education. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1269-1274

interaction emanates from the effort by man to meet his needs, and that allowances have never been made to accommodate possible environmental stress. According to Ibimilua & Ibimilua (2014:248):

> *"Human activities in Nigeria have also resulted into environmental challenges like biodiversity loss, oil spillage, bush burning, urban housing problem, water scarcity, as well as pollution (water, soil, air, marine, noise, thermal, radioactive and vehicular). Broader worries have also arisen about the environmental challenges of deforestation, urban flooding, destruction of aquatic habitats, over-exploitation of forest resources, illegal mining activities and dereliction, road transportation mishaps as well as solid waste problems (municipal, agricultural, industrial, hazardous radioactive and biomedical). Other forms of environmental degradation are desert encroachment, ozone layer depletion, global warming, poor environmental sanitation, unlawful exploitation of fossil fuel resources, oil spillage, gas flaring and many other challenges relating to oil exploration and production. The environmental challenges are aggravated by poverty and rapid increase in human population."*

This brings about the issue of sustaining the environment for healthy living by the present occupants (living things) and for the future generation.

Environmental sustainability is aimed at utilizing the environment without depleting it or causing serious injuries to it. Environmental sustainability is defined as responsible interaction with the environment to avoid depletion or degradation of natural resources and allow for long-term environmental quality (study.com). The practice of environmental sustainability helps to ensure that the needs of today's population are met without jeopardizing the ability of future generations to meet their needs.

One of the critical issues of concern to most national governments world over is the need to stem the rate of environmental challenges caused by various human and industrial activities. However, recognizing the importance of a sustainable environment to overall national and continental development, the African Union (AU) in 2013 incorporated environmental sustainability in its vision for the future tagged Agenda 2063. Agenda 2063 according to African Union Commission (2014) is "a shared strategic framework for inclusive growth and sustainable development and a global strategy to optimize the use of Africa's resources for the benefit of all Africans. Among the ambitious aspirations of the African Union in the agenda 2063 is the promotion of "Environmentally Sustainable and Climate Resilient Economies and Communities". The above implied that by 2063 Africa will be recognized globally as a continent respectful of its environment, ecologically conscious with well-established green economy and green energy. The aspired prosperity of Africa will be based on inclusive growth and sustainable development (AU Commission 2014).

The Nigerian environment not only plays a vital role in life support system, it particularly provides the basic resources for virtually all socio-economic activities in the country (Nwachukwu, 2002:1) in Ibimilua & Ibimilua (2014). Human actions can deplete natural environment, and without awareness of environmental sustainability methods through education and enlightenment as did social studies education, the long-term viability can be compromised.

Nigeria is a bonafide member of the African Union and an active partner in the formulation of Agenda 2063. Apart from being a signatory to the Agenda 2063, Nigeria has a long history of environmental issues and challenges of various nature, typology and magnitude that need

to be checked. There is a unanimous decision by all stakeholders throughout the world that environmental degradation should be effectively and completely checked using any means possible. Education is an all-time tool for creating awareness and understanding of the various challenges facing human habitat with a view to finding out lasting solution to these problems. Social studies education is an aspect of education that is aimed at instilling the right types of attitudes, values, skills and competencies to enable man solve his socio-economic, political and environmental challenges. Studies have shown that social studies education is a viable tool for attitudinal change and adjustment among its adherents. The problem of this study hinges on a determination of the role of Social Studies Education in promoting Environmental Sustainability for the attainment of Agenda 2063 in Nigeria.

Objective of the Study

The main objective of this study was to determine the Role of Social Studies Education in promoting Environmental Sustainability for the attainment of Agenda 2063 in Nigeria. In the light of the above, the following specific objective was stated:

i. To determine the opinion of students on the Role of Social Studies Education in promoting Environmental Sustainability for the attainment of Agenda 2063 in Nigeria relative to their study level.

Research Question

On the basis of the objectives identified above, the following question was raised:

i. To what extent does the opinion of students differ on the Role of Social Studies Education in promoting Environmental Sustainability for the attainment of Agenda 2063 in Nigeria relative to their study level?

Research Hypothesis

In the light of the above, it is hypothesized thus:

H_{01}: There is no significant difference between the opinions of students on the Role of Social Studies Education in promoting Environmental Sustainability for the attainment of Agenda 2063 in Nigeria relative to their study level.

Scope of the Study

The study is delimited to NCEII and NCEIII students of social studies in Federal College of Education, Kontagora and Niger state College of Education, Minna, Niger state, Nigeria.

RESEARCH METHODOLOGY

Design and Sampling Procedure

The design of the study was descriptive survey. The simple random sampling technique was used in selecting the required sample size. A total number of 280 student respondents from NCEII and NCEIII were sampled. The decision to use the sample size was based on the Krejcie and Morgan table (1970) and Research Advisors (2006).

Instrumentation

The study used structured questionnaire titled “Social Studies Environmental Sustainability Questionnaire (SSESQ). The instrument was validated by experts for content and construct validity. The Cronbach alpha formular for determining reliability co-efficient of instrument was used and has been found reliable for the main work.

Data Collection and Analysis

The distribution and retrieval of the questionnaires was done simultaneously. This is aimed at reducing unnecessary loss of the questionnaires.

The data analysis was done using mean and standard deviation in the case of answering the question raised by the study. The null hypothesis was tested at 0.05 level of significance using independent sample t-test. The choice of t-test was based on Ekeh (2003), who states that t-test should be used in comparing two mean. The hypothesis tested in this study has two mean.

Table1.1 Descriptive statistics on the mean opinion of NCEII & NCEIII students on the role of social studies education in promoting environmental sustainability

S/No	Items	Study Level	Response Patterns SA	A	D	SD	Mean	Stan Dev.	Remark
1	Social studies education develops knowledge of the interconnections and interdependency of ecological, social, and economic systems	NCEII	70	54	31	23	2.9607	1.0134	Agreed
		NCEIII	52	28	14	8	3.2157	.9608	Agreed
2	Students of social studies acquire and apply the knowledge, perspective, vision, skills, and habits of mind necessary to make personal and collective decisions and take actions that promote environmental sustainability	NCEII	66	55	32	25	2.9101	1.0538	Agreed
		NCEIII	41	39	14	8	3.1078	.9217	Agreed
3	Students of social studies engage in inquiry and systems thinking and use information gained through learning experiences in, about, and for the environment to understand the structure, components, and processes of natural and human-built environments	NCEII	71	67	24	16	3.0843	.9440	Agreed
		NCEIII	40	30	19	13	2.9510	1.0471	Agreed
4	social studies education develops in the students critical appreciation of the concepts of sustainable development and conservation	NCEII	66	55	32	25	2.9101	1.0535	Agreed
		NCEIII	41	39	14	8	3.1078	.9217	Agreed
5	social studies education increases in the students' knowledge and awareness about the environment and associated challenges	NCEII	82	54	25	17	3.1212	.9855	Agreed
		NCEIII	40	30	19	13	2.9510	1.0471	Agreed
6	Social studies education develops in the students the necessary skills and expertise to address environmental challenges and fosters attitudes, motivations, and commitments to make informed decisions and take responsible action	NCEII	52	51	45	30	2.9022	1.0662	Agreed
		NCEIII	41	39	14	8	3.1076	.9217	Agreed
7	Students of social studies learn skills, perspectives, and values that guide and motivate them to seek sustainable livelihoods	NCEII	82	54	25	17	3.1292	.9858	Agreed
		NCEIII	40	30	19	13	2.9510	1.0471	Agreed
8	Students of social studies demonstrate understanding of how the health of the ecological, social and economic systems determines the sustainability of natural and human communities at local, regional, national, and global levels.	NCEII	50	16	104	8	2.6067	.9462	Agreed
		NCEIII	25	10	62	5	2.5392	.9192	Agreed
9	Students of social studies investigate variety of ways in which different societies respond to and value the environment	NCEII	64	58	32	24	2.9101	1.0396	Agreed
		NCEIII	40	30	19	13	2.9510	1.0471	Agreed
10	Students of social studies use technology to collaborate, communicate, generate innovative ideas, investigate and solve environmental problems	NCEII	73	64	24	17	3.0843	.9619	Agreed
		NCEIII	41	39	14	8	3.1078	.9217	Agreed

Decision Mean 2.50

RESULTS AND DISCUSSIONS

Answering Research Question

Details from table 1.1 above reveal the mean opinions of NCEII and NCEIII students on the role of social studies education in promoting environmental sustainability for the attainment of Agenda 2063 in Nigeria. The frequency counts, mean and standard deviation were used to analyse and interpret the response pattern of the respondents in relation to their study level. The decision mean adopted for determining the response pattern of the respondents on all the questionnaire items was 2.50.

Looking at the individual mean responses of the entire questionnaire items in relation to the decision mean adopted for the study (2.50), it can be deduced that the response pattern of the respondents was positive. This is because of the fact that the individual mean response was equal to or greater than the decision mean (2.50). In the light of the above, it can be said that the respondents regardless of their study level, agreed with all the statements presented in the questionnaire. Based on this therefore, it can be said that both NCEII and NCEIII student respondents had high positive opinion on the ability of social studies education to promote environmental sustainability for the attainment of agenda 2063 in Nigeria.

Test of Hypothesis

H_{01}: There is no significant difference between the opinions of students on the Role of Social Studies Education in promoting Environmental Sustainability for the attainment of Agenda 2063 in Nigeria relative to their study level;

Table 1.2: Independent t-test sample statistics on the mean opinion of respondents on the role of social studies education in promoting environmental sustainability relative to their study level

Variable	Study Level	N	Mean	STD	DF	t-cal	t–crit	Sig (p)
Opinions of NCEII & NCE III on the role of social studies education in promoting environmental sustainability	NCEII	178	83.20	8.25				
						0. 96	2.00	0.
	NCEIII	102	84.19	8.33	278			34

Calculated p > 0.05, calculated t< 2.00 at DF 278

Results of the above independent t-test statistics in table 1.2 above showed that there was no significant difference between the opinions of students on the Role of Social Studies Education in promoting Environmental Sustainability for the attainment of Agenda 2063 in Nigeria relative to their study level. Reason being that the calculated significance (P) value of 0.34 is higher than the 0.05 level of significance while the calculated t value of 0.96 is lower than the 2.00 critical t value at DF 278. However, their calculated mean opinions were 83.20 and 84.19 for NCEII & NCEIII student respondents respectively. Therefore, the null hypothesis which states that there is no significant difference between the opinions of students on the Role of Social Studies Education in promoting Environmental Sustainability for the attainment of Agenda 2063 in Nigeria relative to their study level is hereby retained.

Summary of Findings

In the light of the above, the study discovered that there was no significant difference between the opinion of NCEII and NCEIII students on the role of social studies education in promoting environmental sustainability for the attainment of agenda 2063 in Nigeria. In addition, the students regardless of their study level have positive opinion on the ability of social studies education to promote the development of sustainable environment.

Discussion on Findings

The study discovered that social studies education is a viable tool for promoting environmental sustainability for the attainment of agenda 2063 in Nigeria. It has been mentioned earlier that social studies education centres on man and his environment. It

studies mutual relationship and parasitism between man and the environment. Social studies is a viable tool in creating awareness and understanding of issues of national and international importance. Several studies like that of Mohammed (2014); Idris (2015) and Abdullahi (2015) have identified the viability and potency of social studies education in promoting desirable attitudes, values, skills and competencies among its adherents. This was buttressed by in their different studies on the role of social studies in solving national problems and creating awareness on important issues. As an aspect of education, social studies education provide learners' with tools for problem-solving in the area of social, political, economic, environmental, technological, education among other aspects. Buttressing on the above, Ololobou (2010), asserts that social studies is "the integrated study of man as he battles for survival in the environment both physical and social. It promotes awareness, appreciation, and understanding of the reciprocal relationship between man and the environment. The essence of studying social studies is to make out of learners, persons who are responsive and responsible citizens". Therefore in the light of the above findings, it can be said that social studies education is a potent tool in promoting environmental sustainability for the attainment of agenda 2063 in Nigeria and beyond.

CONCLUSION

In the light of the above findings, this study concludes that social studies education in Nigeria is a viable instrument and a mega-force in promoting environmental sustainability through its well-articulated objectives, dynamic and time-tested curricular.

RECOMMENDATIONS

This study recommends the teaching of social studies at all levels of education in Nigeria. The government should use social studies as a means to create awareness and enlightenment campaigns on the need to promote environmental sustainability among its citizenry.

ABSTRACT

Man and his immediate environment lies at the heart of social studies. Human beings in an attempt to make ends meet create serious environmental health hazards that have negative consequences to their survival and well-being. This study is aimed at determining the cognition level of students taught environmental health hazards by way of field trips and those taught using Lecture, Group Discussion and Simulation Techniques respectively. The study was quasi experimental in design. The population of the study was JSSIII students of social studies. The purposive sampling technique was used to select four (4) Junior Secondary Schools to participate in the study. A total number of One Hundred and Fourteen (114) students participated in the study. The data collection instrument was a Teacher-Made Achievement Test titled "Environmental Health Hazards Achievement Test" (EHHAT). The Pearson Product Moment Correlation test re-test formula was used to determine the reliability coefficient of the instrument using ten (10) students of JSSIII of Demonstration secondary school, Ahmadu Bello University, Zaria. The mean and standard deviation were used to answer the research question raise by the study and has been confirmed fit for the main work. The One Way Analysis of Variance (ANOVA) was used to validate the null hypothesis postulated by the study. The null hypothesis was validated at 0.05 level of significance. The study discovered that the cognition level of students taught by way of field trip was higher than those taught using other teaching techniques as used in the study. In the light of the above findings, the study recommends the use of Field Trips technique in the teaching of environmental health hazards to Junior Secondary school social studies students.

Keywords: Cognition Level, Environmental Hazards, Field Trip, Impact, Social Studies

INTRODUCTION

Background Statement

Man and his immediate environment lies at the heart of social studies. In this regard, social studies is defined as the study of man and his physical and social environment. Social studies study man in relations with his physical and social environment. The way man influenced his environment and how the environment in turn influences man is of critical importance to social studies. Human beings in an attempt to make ends meet create serious environmental health hazards that have serious consequences to their survival and well-being. Environmental hazard' is the state in which the surrounding natural environment is potentially threatened with severe consequences to human health and wellbeing. In a related development, Ibimilua & Ibimilua (2014) see environmental hazard as any form of harm, danger, peril or any risk of loss in the environment.

Environmental health hazards include traditional hazards of poor sanitation and shelter, as well as agricultural and industrial contamination of air, water, food and land. In relation to the above, Chen (2005) cited in (Ibimilua & Ibimilua, 2014) observes that humankind currently faces significant global environmental problems including climate change, shortage of clean and accessible freshwater, ecosystem degradation, soil erosion, and biodiversity loss.

Consequently, social studies teacher needs to acquaint himself with effective teaching techniques especially in the teaching of physical environment of man, issues, challenges, typology, spatial distribution and its repercussions on human settlement and wellbeing in order to enhance effective transaction and communication in the teaching and learning process. Field trip technique is one of such techniques that give learners first-hand experience on environmental issues and challenges.

Muhammed, A. & Salihu, J. J. (2016). Impact of Field Trip Technique on Students' Cognition Level of Environmental Health Hazards in Junior Secondary Schools, Kaduna State-Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1275-1279

A field trip occurs when students leave school grounds for an educational purpose. It is a student trip for the purpose of curriculum related study. According to Shakil, Faizi and Hafeez (2011), field trip technique is a progressive method of learning by which the student goes through the necessary learning experiences under the leadership and guidance of the teacher. In a related development, Krepel and Divall (1981) in Salihu (2015) assert that educational field trip is a trip arranged by the school and undertaken for educational purpose in which the students go to places where materials for instruction may be observed and studied directly in their functional setting. The use of the term 'field trip' emphasizes some of the formal exercises, which are done outside the classroom usually in Biology and Geography, Social studies among others at secondary and tertiary levels. It is helpful in developing the complete personality of the students like their physical, mental, social and emotional development. Educational field trip gives students the opportunity to have first-hand experiences and to explore world. It helps students to interact with what they are learning (Salihu 2015).

However, buttressing the above point of views, Aggarwal (2003) in Salihu (2015) states that educational field trip is also helpful for the teachers to clarify, establish, co-relate and coordinate accurate concepts, interpretations and appreciations and enable him to make learning more concrete, effective, interesting, inspirational, meaningful and vivid. In the light of the above, it can be said that educational field trip is helpful in completing the triangular process of learning that is; motivation, clarification and stimulation.

The National Council for the Social Studies (1994) advocates that students explore real world issues and utilize the tools and resources of social scientists. These tools and resources abound in our natural physical environment. Thus, educational field trip is an opportunity for students to interact with and use these resources as well as practice various social studies skills, such as asking questions, gathering data, and drawing conclusions. This partly informed the study's decision to take students on a trip to their immediate natural physical environment to have first-hand experience on various typologies of hazards and their adverse effects on man and the environment.

Students need to be actively involved in their own learning. This will help them to become increasingly independent as learners especially in the 21st century teaching and learning where learner-centred approach is the most favoured. Experiential learning is a process by which students are actively engaged in authentic and relevant experiences that allow them to make their own discoveries and experiment with knowledge. Experiential learning is focused squarely on the students, and promotes research, experimentation, and problem solving. It is inquiry based and encourages students to reflect on their experiences, so as to develop new skills, attitudes, and ways of thinking that, in turn, can be reinvested in other learning experiences. Field-based experiences are but one of many activities that allow educators to apply the concept of experiential learning at all grade levels.

The problem of this study hinges on a determination of the extent to which field trip technique is used to achieve instructional effectiveness in teaching environmental health hazards among Junior Secondary School social studies students.

Objective of the Study

The main objective of this work was to examine the Impact of Field Trip Technique on Students' Cognition of Environmental Health Hazards in Junior Secondary Schools, Kaduna state-Nigeria. The study was guided by the following specific objectives:

i. To determine if there is difference on the cognition level of students taught environmental health hazards by way of field trip technique and those taught through other teaching techniques.

Research Question

The study answered the following questions:

i. To what extent does cognition level of students taught environmental health hazards by way of field trip technique and those taught through other teaching techniques differ?

Null Hypothesis

In the light of the above, it is hypothesized as follows:

H_{01}: There is no significant difference between the cognition levels of students taught environmental health hazards by way of field trips and those taught using other teaching techniques.

RESEARCH METHODOLOGY

Population and Sample

The study used Junior Secondary School (JSSIII) students' as the population of the study from which the sample was derived. The JSSIII students were chosen because the topic environmental hazards and related issues are within their syllabus covered at that level. A total number of 114 students of social studies were purposively sampled for the quasi experiment based upon their capacity and willingness to participate in the research. The choice of the sample size was supported by Olayiwola (2010) who asserts that 15 to 30 participants can be utilized as sample for this kind of study. The table below shows the sample distribution of the study participants according to teaching techniques.

Distribution of study participants by Teaching Techniques

S/N	Techniques	Sample Size
1	Lecture	40
2	Group Discussion	37
3	Simulation	22
4	Field Trip	15
	Total	114

In the light of the above, four (4) schools were selected to participate in the study as follows: Government Junior Secondary School, Zaria was used as Simulation Learning Environment (SLE), Government Junior Secondary School, Tudun-Jukun was used as Group Discussion Learning Environment (GDLE), the Government Junior Secondary School, Muchiya was used as Lecture Learning Environment (LLE) while Government Junior Secondary school, Dakace was used as Field Trip Learning Environment (FTLE).

Instrumentation and Statistical Analysis Procedure

The study used a Teacher-made Achievement Test titled "Environmental Health Hazards Achievement Test" (EHHAT) as data collection instrument. The instrument is organised in an objective format. The students were pre-tested to ascertain their previous knowledge before the applications of various treatments. The pre-test served as the basis for comparison after the post-test is administered. The instrument was validated and ascertained as adequate for the study. The mean and standard deviation were used to answer the questions raised by the study while the One Way Analysis of Variance (ANOVA) was used to test the null hypotheses postulated by the study at 0.05 level of significance.

RESULTS AND DISCUSSIONS

Answering Research Question

Research Question One: To what extent does cognition level of students taught environmental health hazards by way of field trip technique and those taught through other teaching techniques differ?

Tables 1.1: descriptive mean statistics on cognition level of students taught by diverse teaching techniques

Teaching Techniques	N	Mean	Std Deviation
Lecture	40	91.9250	9.30781
Group Discussion	37	100.0811	8.71263
Simulation	22	97.4091	7.93221
Field Trip	15	103.5333	6.92683

The details from table 1.1 above showed the mean cognition level of students taught environmental health hazards by way of field trip and those taught using lecture, group discussion and simulation techniques respectively. It shows the following mean score 91.9250, 100.0811, 97.4091 and 103.5333 for Lecture, Group Discussion, Simulation and Field trips groups respectively. This showed that differences existed between the mean cognition level of students taught environmental health hazards by way of field trips and those taught using Lecture, Group Discussion and Simulation techniques. This means that the mean cognition level of students taught environmental health hazards with field trip was higher than those taught with other teaching techniques.

Test of Null Hypothesis

H_{01}: There is no significant difference between the cognition levels of students taught environmental health hazards by way of field trips and those taught using other teaching techniques.

Tables 1.2: One Way Analysis of Variance (ANOVA) statistics on the differences on Cognition Levels of students taught by diverse teaching techniques

Interest group	N	Mean	Std Deviation	95% Confidence Interval for Mean		Minimum	Maximum
				Lower Bound	Upper Bound		
Lecture	40	91.9250	9.30781	88.9482	94.9018	78.00	115.00
G/Discussion	37	100.0811	8.71263	97.1761	102.9860	88.00	120.00
Simulation	22	97.4091	7.93221	93.8921	100.9260	82.00	109.00
Field Trip	15	103.5333	6.92683	99.6974	107.3693	89.00	112.00
Total	114	97.1579	9.46683	95.4013	98.8145	78.00	120.00

Analysis of Variance (ANOVA) statistics on the differences on Cognition Levels of students taught by diverse teaching techniques

	Sum of Squares	Df	Mean Square	F	Sig.
Between Groups	2022.575	3	674.192	9.151	.000
Within Groups	8104.583	110	73.678		
Total	10127.158	113			

The null hypothesis states that there was no significant difference between the cognition levels of students taught environmental health hazards by way of field trips and those taught using other teaching techniques (Simulation, Lecture and Group Discussion). This was carried out using Analysis of Variance (ANOVA) statistics because it involves more than one variable as shown in the tables above.

The results of the analysis of variance (ANOVA) statistics revealed significant difference between the cognition levels of students taught environmental health hazards by way of field trips and those taught using other teaching techniques (Simulation, Lecture and Group Discussion). This was due to the fact that the calculated P values of 0.0000 is less that the 0.05 alpha level of significance, while the calculated F value of 9.151 is greater than the F critical of 2.60. However, their mean scores were 91.9250, 100.0811, 97.4791 and 103.5333 for Simulation, Lecture, Group Discussion and Field Trip techniques respectively.

Consequently, the null hypothesis which states that there was no significant difference between the cognition levels of students taught environmental health hazards by way of field trips and those taught using Simulation, Lecture and Group Discussion teaching techniques is hereby rejected.

Major Findings

The study discovered that significant differences existed between the cognition levels of students taught environmental health hazards by way of field trips and those taught using Simulation, Lecture and Group Discussion teaching techniques. It was also discovered that the cognition level of students taught by way of field trip was higher than those taught using other teaching techniques as used in the study.

Discussion on Findings

The higher cognition level recorded for students taught environmental health hazards using field trips technique was not a coincidence. This is because of its potency in appealing to the senses of the learners and its ability to give learner first-hand experience of the subject matter. The findings of this study also concurred with that of Salihu (2015); Salihu and Tanko (2015) and Ajaja (2010) which show higher academic performance of students taught using field trips and those taught using lecture teaching technique in social studies and biology respectively.

This study filled the gap left by other studies as it compared field trips technique against other learner-centred teaching techniques like Simulation and Group Discussion techniques and found field trip technique to be more potent. Other studies like that of Salihu (2015) and Salihu and Tanko (2015) compared field trips technique with lecture technique and the outcome of the study was criticized as being pre-determined as lecture technique cannot be compared favourably with field trips technique. Therefore, this study filled the gap left unfilled by other studies.

CONCLUSION

Based on the findings of this study, it is concluded that field trips technique is more effective in teaching environmental health hazards to Junior Secondary school students.

RECOMMENDATIONS

In the light of the above findings, this study recommends the use of Field Trips technique in the teaching of environmental health hazards to Junior Secondary school students during social studies lessons.

ABSTRACT

Inquiry teaching strategy is widely acknowledged for its potency in developing independent investigative and study skills among learners. This study delve into the impact of inquiry teaching strategy on cognition levels of Lower and Middle Basic pupils in Kaduna state. The study used 120 pupils purposively selected from two schools in the study area. The Lower Basic III and Middle Basic VI pupils participated in the study. The study used teacher-made test called "Lower and Middle Basic Achievement Test" (LOMBAT) as data collection instrument. A mean standard deviation was used to answer the research questions raised by the study and the independent sample t-test was used to validate the null hypotheses and decision rule established at 0.05 level of significance. The study discovered that Inquiry Teaching Strategy enhances pupils' cognition level at Lower and Middle Basic levels in social studied lessons more than traditional didactic lecture method. This study recommends the use of Inquiry Teaching Strategy among Lower and Middle Basic pupils to build in them the capacity to investigate and take informed position on social issues.

Keywords: Cognition, Inquiry, Lower Basic, Middle Basic, Strategy

INTRODUCTION

Background Statement

The choice of effective, adequate and relevant teaching technique by a qualified social studies teacher putting into consideration the topic to be taught and the learners' level and ability is the starting point and a foundation for attaining effective transaction and communication between teacher and students in social studies classroom. This is because the success or failure of social studies lessons depends on the choice and utilization of effective teaching technique by the social studies teacher.

The teachers of social studies asserts Salihu (2015) are still accustomed to traditional methods of teaching especially the lecture and didactic techniques despite the availability of learner-centered and activity-based teaching techniques which encourage effective communications and transactions between teacher and the students. This has contributed to poor performances among students and their attitude towards social studies as a subject and inversely affected their performances in the subject.

One of the leading causes of students' poor performance in Social Studies in Nigeria as reported by (Ayodeji, 2009) and (Edozie, 2009) and(Okobia, 2012) in Tanko (2015) has to do with the instructional methods used by teachers, which are inadequate to bring about desired level of achievement and classroom participation in both male and female learners. Some of the methods used by teacher are expository and makes students to become very passive. (Edinyang, 2012, Osakwe and Oganwu, 2005, Eze, 2009) in Tanko (2015) also found that many Nigerian Social Studies teachers mostly used the Traditional Lecture Method that centers on the teacher, text book, the chalk and the chalkboard.

Salihu, J. J. ; Yahaya, I. A. & Abdullahi, M. B. (2016). Developing Independent Learning Among Lower and Middle Basic Pupils: The Impact of Inquiry Teaching Strategy on Learners' Cognition Level. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1280-1284

Several investigators recommended the use of learner-centred instructional strategies to improve performance in Social Studies lessons. One of such strategies is the Inquiry. Inquiry is an aspect of transformational teaching which has been spurred by the development of several learning principles and methods of instruction, including active learning, student-centered learning, collaborative learning, experiential learning, and problem-based learning (Tanko 2015). It is a student-centered method of teaching whereby students interact actively, question assumptions and provide their viewpoints on any area of subject matter. As described by (Akinlaye, 1998) in Tanko (2015), in this approach to instruction, the teacher facilitates and prompts students to conduct investigations and construct their own meaning. The problem of this study hinges on a determination of the extent to which inquiry teaching strategy impact on pupils at Lower and Middle Basic levels in social studies lessons in Kaduna state-Nigeria.

Objectives of the Study

The main objective of this study was to determine the Impact of Inquiry Teaching Strategy on learners' Cognition level in Lower and Middle Basic levels. The study was guided by the following specific objectives:

i. To determine the Impact of Inquiry Teaching Strategy on Pupils cognition level at Lower Basic stage;
ii. To find out the Impact of Inquiry Teaching Strategy on Pupils cognition level at Middle Basic stage.

Research Questions

The study answered the following questions:

i. To what extent does Inquiry Teaching Strategy Impacted on Pupils cognition level at Lower Basic stage?
ii. To what degree does Inquiry Teaching Strategy Impacted on Pupils cognition level at Middle Basic stage?

Research Hypotheses

In the light of the above, it is hypothesized thus:

H_{01}: Inquiry teaching strategy does not significantly impact on pupils' cognition level at lower basic stage;

H_{02}: Inquiry teaching strategy does not significantly impact on pupils' cognition level at Middle basic stage.

Scope of the Study

The study covered Pupils of Lower and Middle Basic levels in Zaria Metropolis, Kaduna state, Nigeria. Social studies lesson periods were used. Environmental Pollution was the topic used in the study.

METHODOLOGY

Design

The study was the non-equivalent comparison group design. The sample consisted of 120 pupils from Lower and Middle Basic levels. Therefore, 60 pupils were chosen from Lower Basic III out of which 30 were controlled and the other 30 were used for the experiment. This process was repeated at the Middle Basic Level using Middle Basic VI Pupils. Purposive sampling technique was used to select school for the study. However, Olayiwola (2010) states that 30 participants are adequate for each group in this kind of study. This guided the choice of 120 participants for the study.

Instrumentation

The instrument used for data collection was a teacher made test called "Lower and Middle Basic Achievement Test" (LOMBAT). The validity and reliability of the instrument was ascertained using table of specification and vetting by experts in Education Research, Test and measurement. The students were first pre-tested to check their knowledge base line. The students were then exposed to different treatment. The data collection covered the period of fifteen (15) working days.

Data Analysis

The data were analysed using mean, standard deviation and t-test independent sample. A mean standard deviation was used to answer the research questions raised by the study. The independent sample t-test was used to validate the null hypotheses postulated by the study. The null hypotheses were analyzed at 0.05 level of significance and 95 percent confidence level.

RESULTS AND DISCUSSIONS

Answering Research Questions

Research question one: To what extent does Inquiry Teaching Strategy Impacted on Pupils cognition level at Lower Basic stage?

Table1.1: Descriptive statistics on the mean cognition level of Lower Basic pupils taught with Inquiry teaching strategy and those taught with Lecture Method

Variable	Treatment Groups	N	Mean	Std. Dev
Cognition Level	Inquiry	30	68.2667	10.0685
	Lecture	30	52.2167	11.7566

Details of the descriptive statistics in table 1.1 above revealed the mean cognition scores of Lower Basic Level III pupils who were taught using inquiry teaching strategy and their counterparts taught with lecture method. Their calculated mean cognitive scores were 68.2667 and 52.2167 for Inquiry strategy and Lecture method respectively. The mean cognitive level difference was 16.05. This implies that Lower Basic Level Pupils taught with inquiry teaching strategy had higher mean cognition level than their counterparts taught with lecture teaching method.

Research question two: To what degree does Inquiry Teaching Strategy Impacted on Pupils cognition level at Middle Basic stage?

Table1.2: Descriptive statistics on the mean cognition level of Middle Basic Level pupils taught with Inquiry teaching strategy and those taught with Lecture Method

Variable	Treatment Group	N	Mean	Std.Dev
Cognition Level	Inquiry	30	32.4667	5.32873
	Lecture	30	26.0333	9.98096

The descriptive statistics in table 1.2 revealed the mean cognitive level of Middle Basic Level VI Pupils who were taught using Lecture teaching strategy and their counterparts taught through Lecture teaching method. According to the outcome, their computed mean cognition levels were 32.4667 and 26.03333 for inquiry teaching strategy (experimental group) and Lecture method (control group). The mean academic difference was 6.4334. This indicate that Middle Basic VI pupils taught with inquiry teaching strategy had higher cognition level than their counterparts taught by way of lecture method.

Test of Null Hypotheses

Hypothesis one: Inquiry teaching strategy does not significantly impact on pupils' cognition level at Lower Basic stage

Table 1.3: Independent t-test sample statistics on the mean cognition level of Lower Basic pupils taught with inquiry teaching strategy and those taught using traditional lecture method

Variable	Treatment Group	N	Mean	Std.dev	DF	t-cal	t-crit	Sig (p)	Decision
Cognition	Inquiry	30	68.2667	10.0685	58	5.679	1.96	0.000	H_{01}
Level	Lecture	30	52.2167	11.7566					Rejected

Calculated p < 0.05, calculated t > 1.96 at DF 58

The result emanating from the Independent sample t-test statistics in table 1.3 above showed that significant differences exist between Lower Basic pupils taught with Inquiry teaching strategy and their counterparts taught with lecture method in their mean cognition level. This was due to the fact that the calculated significance (P) value of 0.000 is less than the 0.05 level of significance while the calculated t value of 5.679 was higher than the 1.96 critical t value at DF 58. Their calculated mean cognition levels were 68.2667 and 52.2167 for inquiry teaching strategy and lecture method respectively. Therefore, the null hypothesis which states that Inquiry teaching strategy does not significantly impact on pupils' cognition level at Lower Basic stage is hereby rejected.

Hypothesis two: Inquiry teaching strategy does not significantly impact on pupils' cognition level at Middle Basic stage.

Table 1.4: Independent t-test sample statistics on the mean cognition level of Middle Basic pupils taught with inquiry teaching strategy and those taught using traditional lecture method

Variable	**Treatment Group**	**N**	**Mean**	**std.dev**	**Df**	**t-cal**	**t-crit**	**Sig (p)**	**Decision**
Cognition	Inquiry	30	32.4667	5.32873					H_{02}
Level	Lecture	30	26.0333	9.98096	**58**	3.114	1.96	0. 003	Rejected

Calculated p < 0.05, calculated t > 1.96 at DF 58

Results of the Independent sample t-statistics in table 1.4 above revealed that significant difference exist between the mean cognition levels of Middle Basic level pupils taught using Inquiry teaching strategy and their counterparts taught using lecture method. This is because the calculated significance (p) value of 0.003 is lower than the 0.05 level of significance while the calculated t value of 3.114 is higher than the 1.96 critical t-value at DF 58. Their computed mean cognition levels were 32.4667 and 26.0333 for Inquiry. Hence the null hypothesis which states that Inquiry teaching strategy does not significantly impact on pupils' cognition level at Middle Basic stage is hereby rejected.

Major Findings

The study discovered that Inquiry Teaching Strategy enhances pupils' cognition level at Lower and Middle Basic levels in social studied lessons. By implication, the study revealed that didactic traditional lecture method isn't good enough for Lower and Middle Basic level Pupils in Social studies classrooms.

Discussion of Findings

The study revealed Inquiry Teaching Strategy enhances the cognition level of pupils in the Lower and Middle Basic levels (primary school) compared to the traditional didactic method that is widely used by teachers in the study area. The findings of this study is not a surprise in view of the fact that Inquiry teaching strategy apart from promoting independent study attitude and skills in the pupils, is widely acknowledged for enabling the learners to gain first hand information about what they are learning. The findings of this study concur with those of Dauda (2015); Tanko (2015) and Yahaya & Salihu (2015). Although the above studies were conducted among Junior Secondary School students using Social studies lessons these study affirmed the potency of Inquiry teaching strategy on students' academic performances over traditional lecture method.

CONCLUSION

In the light of the above findings, this study concludes that the Inquiry teaching strategy is effective in raising the cognition level of Lower and Middle Basic level pupils in the study area.

RECOMMENDATIONS

This study recommends that use of Inquiry Teaching Strategy among Lower and Middle Basic pupils to build in them the capacity to investigate and take informed position on social issues.

ABSTRACT

An idle mind is the devil`s workshop, thus goes a common saying. This paper examines how women in selected locations in Akure, Nigeria created jobs for themselves thereby liberating themselves from poverty. Data for this study were sourced through administration of questionnaires from selected cassava processing centres. Direct participation and observation methods were employed. Field data were analysed using simple frequency, cross-tabulation and correlation analysis. Findings show that the driving force of the operations was as a result of their self-determination to break the york of poverty and to create wealth for their families. Socio-economic factors such as income, age, level of education among others have influence on the level of production and level of achievement of the operators. The paper recommends a more organized environment for the processing of cassava, an organized community based soft loan facility, an efficient export package system and a functional Agro-based mechanism to aid the local processing methods.

Keywords: Cassava processing, Poverty, Soft loan and Wealth Creation

INTRODUCTION

Background Information

Globally, the traditional use of cassava is changing from primarily human consumption to processing into industrialised products such as starch, flour and ethanol. Studies have shown that cassava has the potential to industrialise Nigeria more than any other product, if its potential is properly harnessed. Awoyinka (2009) affirmed that Nigeria can earn about US$5 billion per annum from cassava and its by-products, making it a key foreign exchange earner and instrument for job creation and catalyst for development. In Nigeria, cassava is currently being promoted as industrial raw material in the form of starch, flour and ethanol. Hence, many development initiatives are underway by government and private sector for the processing of cassava into intermediate products for use by local industries and for export. Nigeria is the largest producer of cassava in the world, Food and Agricultural Organisation (FAO 2002). Cassava has become a staple food for most Nigerians (Not only among rural people but also among the urban dwellers) possibly because of the ease with which its major food product (Garri) can be prepared and used as a source of food, International Institute of Tropical Agriculture (IITA, 2004).

A lot has been done by the Nigerian women in alleviating poverty in Nigeria. Nigerian women take job where and whenever they find it, that is, by the roadside, in the fields, in bazaars, in brothels and so on. Women combine works with wage labour in households with poor economic status (Duniya 2010). Nigerian women engage in works such as embroidery and formation of cooperatives. They are involved in various income generating activities such as small scale farming in processing of agricultural produce such as poultry, sheep and goats rearing among others, they also engage in borrowing money from relatives, joining groups such as “Esusu” in Yoruba land or “Adashi” in Hausa land in which individuals come together to contribute money on regular basis and collect on rotational basis.

J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1286-1296

Worst still, Nigeria women sell assets acquired in the past in other to send their children to school, they deny themselves of food at times, they engage in cutting firewood, carrying load for money, going to ceremonies (parties) to pick left over foods etc. These and many more are practiced by Nigerian women in other to make ends meet and alleviate poverty. In this study, women's effort in Garri processing is the focus due to the fact that it is becoming common and a major source of job creation for women in the study area.

The primary target of every enterprise is to make profit that is sufficient to sustain the output as well as maintain a good standard of living. Cassava is grown in almost all the states and thrives in all agro-ecological zones in Nigeria. Its production is characterized by small scale producers who use old varieties and traditional production technologies which largely accounts for low yield. Oyebanji, *et al*, (2003) noted that these small-holders account for over 80% of cassava production in Nigeria. Over 90% of cassava produced in the country is consumed locally with less than 10% utilized for industrial purposes.

It is therefore clear that the success of a given innovation requires an analysis of the local situation and the creation of conditions that not only make the change feasible but people concerned to desire the proposed changes and identify them with their own personal and social goals. Improvement of simpler household user-friendly technological methods that will embrace agricultural productivity and economic growth is therefore necessary. Processing of a special flower called Garri a major delicacy serves as a major food source for both the high and low economic class of people, and currently, a major exportable food and industrial product. It is expected, thus, that demand for Garri will be very high and considered to be an essential commodity.

Therefore, this study focuses on cassava processing as a means by which women migrate from poverty to wealth in Akure, Nigeria. However, the study looked at the location of organized cassava processing industries, demographic characteristics of the respondents, assess the processing technology and the problems encountered in cassava processing in the study area.

STUDY AREA

Akure is a traditional Nigerian city and like other traditional Yoruba towns in the country, it has been in existence long before the advent of British colonial rule in the country. The city is located within Ondo State in the south western part of Nigeria. Ondo State is one of the 36 states of Nigeria. It lies approximately on latitudes 7^0 5`` and 8° 00`` North of the Equator and longitude 5^0 45`` East and longitude 6°00`` East of the Greenwich Meridian at an altitude of 370m above sea level. Akure is a medium-sized urban centre and became the provincial headquarter of Ondo State province in 1939. It also became the capital city of Ondo State and a Local Government Headquarters in 1979. Consequently, there was heterogeneous massing of people and activities in the city (M.W & H, 1980). The city's morphology has changed over time to assume its present status with its attendants land and housing problems, as experienced in similar medium sized urban centers in Nigeria.

Akure is located approximately 700 kilometers South West of Abuja, the Federal Capital of Nigeria and about 350 kilometers to Lagos the former capital of Nigeria. It is located within the tropical rain forest region of Nigeria where rainfall is high throughout the year. The increased relative political influence of Akure as a state capital since 1976 has greatly promoted its rapid growth and increased socio-economic activities resulting in its spatial expansion from an area of about 16 square kilometers in 1980 to about 30 square kilometers in 2000 (Ministry of Works, Lands and Housing, 2000). The population of the city grew from 38,852 in 1952 to 71,106 in 1963. Its population was estimated to be 112,850 in 1980

(DHV, 1985); and 157,947 in 1990 (Ondo State of Nigeria, 1990). The 1991 National Population census however, puts the population of Akure at 239,124 and its population in 2006 was 353,211 (NPC, 2006). At 2014, using a growth rate of 3.18 percent, the city was estimated to have 453,731 (Gabriel, 2014).

Scope of Study

The study focuses on Akure city where field survey was conducted on the effects of cassava processing on women migrating from poverty to fortune within the study area. This is with the view of collating much needed first-hand information on the subject matter over the study area. The survey constituted the major data source on which the research thrived. The study identified the location of organized cassava processing industries, examined the socio-economic traits of the respondents and assessed the processing technology. It also investigated the problems encountered in cassava processing in the study area. Apart from this, the study dwelt on extensive literature search on the research focus.

Concepts and Literature Perspective

A review of the massive literature on poverty shows that a standard concept of poverty remains elusive because of its multidimensional nature as well as its dynamic properties. It is always difficult to define the concept of poverty because drawing the line between the rich and the poor is not usually easy. Amaka (2007) sees poverty like an elephant which is easily recognized than defined. According to Garba, (2006), Poverty, like the term development and underdevelopment is a contested and politically sensitive term and how it is defined usually change from place to place and across time.

Garba (2006) refers to poverty as a lack of command over basic consumption needs, which means, there is an inadequate level of consumption giving rise to insufficient food, clothing and/or shelter, and moreover the lack of certain capacities, such as being able to participate with dignity in society. The World Bank has also defined the concept in the same context as the inability to attain a minimum standard of living (World Bank Report, 2008). Egware, (1997) viewed poverty as a state where individual is not able to cater adequately for his or her basic needs of food, clothing and shelter, unable to meet social and economic obligations; lack of gainful employment, skills, assets and self-esteem and has limited access to socio-economic infrastructures.

Poverty is a state of the mind. This state, psychologically places the person in question in want, either materially or spiritually. Materially, it involves the want of food clothing and shelter, spiritually, it involves want of peace of mind, the spirit and the inner man (Ogwumike, 2012). World Bank (1999) also sees poverty as lack of opportunity and freedom. It is hunger and malnutrition, disease and lack of basic social services. It is an equity gap between countries and within countries. Poverty is still the gravest insult to human dignity. It is the scar on humanity's face. According to Soludo, (2008), Poverty has predominantly female face, poverty particularly burden women because of their role in the economy, they work both inside and outside the home, as home makers and sometimes as head of households, they seek to provide the sole means of survival for their families or try to make up for their shortfalls in their males subsistence wages. Odebode (2006) pointed out clearly that poverty is the state of deprivation of fundamental human needs and desire and this involves the desire for sufficient food and water, adequate shelter, good health, long life, education and the capacity to provide materials for oneself and family through productive ventures.

Suich, (2012) view poverty as lack of originality to achieve, a socially acceptable standard of living and/or, the possession of insufficient resources to meet basic needs required for sustenance and wellbeing. It is a plaque that has eaten deep into different people across

nations of the world. Although it is a universal phenomenon that affects socio-economic and political wellbeing of its victims across board, available statistics shows that poverty in poor country is absolute and more pronounced in the rural areas (Yakubu & Aderonmu, 2010). Some people believed poverty of others is part of a divine order after all the Bible says "the poor shall not cease from the land" (Deutronomy 15:11).However, this study refers to poverty simply as the inability of an individual to live an easy and comfortable livelihood due to difficulty in accessing basic means of daily survival, such basics include things like food, shelter, clothing, education, health, employment, information etcetera.

Putting all these literatures together one can summarise that poverty is a state of the mind, lack of opportunity and freedom, it is a state of deprivation of fundamental human needs and finally it is the inability to achieve, a socially acceptable standard of living.

Effects of Poverty

Poverty contributes in no small measure to crimes in the society.The increasing rate of crimes such as armed robbery "419" corruption, prostitution, nepotism, drug trafficking, cultism and other social vices strongly correlates with the rate of poverty in the society(CBN 1998). In a society where most of its members are poverty-stricken, production may remain largely subsistence as the poor cannot afford capital to expand production. Mandama (2010) stated that persistent poverty has been responsible for most revolution. Poverty results in the general loss of confidence in the constituted authority which in turn renders government policies ineffective, this is because, as long as people feel un-catered for, their loyalty for the system will not be reciprocated. The poor suffer in many ways in Nigeria, among which are;

i. Consumer Problem: The poor pay higher prices in purchase of consumer items, this is because they buy in small pieces and do not enjoy any form of discount.
ii. Health Nutrition: The poor has less nourishing diets and more birth defects, accidents, diseases, and reported mental illness than others. These affect their productivity and quality of life.
iii. Politics: The poor are ill organized to influence or make any impact on contesting for an electoral office.
iv. Justice: The poor are likely to be arrested (rightly or falsely) and often receive stiffer sentences than non-poor for similar offences.

These and many more are the effects of poverty in Nigeria and Africa at large.

Causes of Poverty

The causes of poverty are divergent. The World Bank, (1996) categorized the major causes of poverty in Sub-Sahara Africa as follows:

i. Inadequate access to employment opportunities for the poor
ii. Inadequate physical assets such as land and capital and minimal access by the poor to credit even on a small scale.
iii. Inadequate access to the means of supporting rural development in poor regions
iv. Inadequate access to market where the poor can sell goods and services
v. Low endowment of human capital.
vi. Destruction of natural resources leading to environmental degradation and reduced productivity.
vii. Inadequate access to assistance to those living at the margin and those victimized by transiting poverty.
viii. Lack of participation, failure to draw the poor into the design of development programs
ix. Inadequate access to education, health, sanitation and water services.

Major causes of poverty in Nigeria according to Aigbokhan (2000) are; allocative inefficiency, particularly in the public sector, low rate of investment in the private sector, rapid population growth and use of inappropriate technology. Mandama (2010) also attributed causes of poverty in Nigeria to low level of savings and investment, subsistence orientation of production, unequal distribution of wealth of other productive assets, market imperfection and policy failure on the part of the government. These among others are responsible for poverty in Nigeria and Africa at large.

Women and Poverty in Nigeria

Women constitute a vital social group in all known human societies. Apart from playing a very significant role in the continuity of society through reproduction and socialization, their economic, social and political roles cannot be over emphasized. Yet, this vital group has been muffled with very harrowing challenges in their various respective societies. In Nigeria, the level and rate of poverty have skyrocketed over the years and women have continue to face intimidating and devastating challenges. Abject poverty has been associated with the history of women from time immemorial. In Nigeria and other parts of the world, the culture has been the responsibility of women, like other members of the underprivileged and downtrodden class, to fed, serve, work, and fight, even die for the privilege class.

Ogwumike (2012) reported that two-third of work in the world were done by women. Yet, women owned only ten percent of the world's income and one tenth of the world's property. In Nigeria, 70% of the population lives below the poverty line without any access to basic goods, services and commodities (NBS, 2012). Since women constitute almost half of the population going by the latest population census in the country, it is convenient to say that most women are the victims of poverty in Nigeria today. Most households in Nigeria are more concerned with the survival needs of their families' members due to the escalating poverty profile of the country, (Ogwumike, 2012). Poverty is not only a reality in Nigeria, but it is also saddened to know that most Nigerian women who ought to put a helping hand to their family's income are likewise poor. With low educational status, lack of basic skills and general unemployment condition, the poverty status of rural women in Nigeria is even worse.

In Nigeria today, poverty have spread across the nation, it can only be more degrading for women to access some common basic things such as good drinking water, food, toiletries, housing, employment, cooking utensils, drugs and medical attention, and other socio-psychological requirements that are needed for average quality living. Yet, some level of socioeconomic and psychological stability would be required by women for them to be able to effectively do their expected role to the society (Amaka 2007).Given their present situation of both absolute and relative poverty in the country; women can only do little or nothing both to themselves and to the society.

However, Nigeria as a nation is not poor, as this unfortunate poverty situation exist in the midst of abundant resources, which is enough to cater for the general needs of the entire citizens. According to Opeyemi, (2012), Nigeria is the sixth richest oil producing country in the world. In terms of agriculture, the country has great potentials owing to its highly fertile soil and it has abundant land mass adequate enough for any socioeconomic and technological activity. With over 150 million people, there is enough potential for adequate manpower which may be required for any kind of developmental activity. Again, the country boast of over 50 universities and that is beside other higher institutions that should be involved in manpower development (Okoh, 2004). Yet, poverty, especially among women, thrives in the country. Nevertheless, the reason for this paradox is not farfetched.

Onoge (2003) argued that structural forces within the societal class shape the way in which socio-economic resources are distributed. The ruling class in Nigeria control instruments of distributions of resources and instead of ensuring equitable distribution; they only serve their own class and personal interest to the disadvantage of the masses that constitute the majority. Incidentally, most women in the country fall within this structurally disadvantage group and this explains why there is wide spread poverty among women in Nigeria. In this process women end up with little or no income. The system unjustly treat the women, especially in the rural areas and the low ranked in their working places, without recourse to their basic survival needs and as such leaving them in helpless and hopeless conditions of poverty (Duniya (2010). As most women wallow in perpetual impoverishment, the ruling class members continue to enjoy their loot in their comfort zones.

Women like other Nigerian masses hoped for a better deal with the coming of democracy in the country in 1999, but this hope was dashed as the Obasanjo administration pursued and implemented anti-people economic and fiscal policies (Adelakun, 2008). Although women were included in the top echelon of government policies and programmes, however, resources supposedly meant for the provision of meaningful education, employment opportunities, and infrastructure that will better the living standards of the people, especially the women were diverted, siphoned, corruptly embezzled or mismanaged by the ruling class occupying powerful positions of influence in the society (Ribadu, 2006). Several billions of naira from the public treasury meant for overcoming poverty has been looted by political leaders. New York Times (2005) reported that Nigeria is the epitome of wasted potentials and squandered opportunity in Africa. This has negatively impacted on many generations of Nigeria women who with no good school to attend, no employment opportunities, and no sufficient basic infrastructures have to contend with poverty. The past administration of President Goodluck Jonathan has not done any better as incessant cases of corruption at all levels of governance is the order of the day.

The issue of poverty in Nigeria is heartbreaking, official sources shows it is a northern phenomenon (Soludo, 2008). The Nigerian economy, under the Obasanjo's Administration, was hurriedly pushed into the global neo-liberal capitalist economic system through programmes like privatization and commercialization of the public sector. Ake (2003), observed that the various liberalization programmes have succeeded in selling the Nigerian economy into the hands of a very few bourgeoisies to the disadvantage of the masses. It was followed by retrenchment of workers and sales of public properties. These actions of the government forced poverty on the people, especially women who will have to grapple with both personal and domestic challenges.

When women lag behind in their expected positive role as it is the case of Nigeria today, the society suffers greatly in terms of achieving profound peace, order, stability, growth and sustainable development. No wonder, Nigeria is currently militated by perpetual crisis as characterized by chains of social milieu ranging from corruption, to ethno-religious conflicts and terrorism, all threatening the very foundation of the corporate existence of the country as a political entity. A lot has been done by both the Nigerian authorities and other non-governmental bodies towards poverty alleviation specifically among women and Nigerians in general.

The creation of established poverty alleviation programmes such as the National Poverty Eradication Programme (NAPEP), National Directorate of Employment (NDE), Better Life Programme (BLP), National Land Development Authority (NALDA) are among many other good examples (Ogwumike and Amolaran, 2000). Nevertheless, all these schemes never made great impact in effectively addressing the problem. In fact, despite every efforts

made by the Nigerian authorities and other none-formal organizations towards poverty reduction in the country, this problem has continued to mitigate women from living happily and contributing their own quota to national growth and development. In actual fact, women's condition is becoming worse by the day and if drastic steps were not urgently taken towards effectively addressing poverty in Nigeria, especially among women, there is likely to be a wanton catastrophic impact on the country and perhaps Africa. Thus, this negative trend calls for urgent attention.

RESEARCH METHODOLOGY

Data for this research was sourced from both primary and secondary sources, the secondary sources include materials from the internet and published materials such as journals, articles, and text books while the primary data were obtained by personal observation, oral interview and the administration of multiple-choice questionnaires randomly on women engaged in Garri processing in selected organised (Garri Industries). The target population for this research includes women in organised Garri processing industries in Akure town, Ondo State.

The study identified Eleven (11) organised Garri processing centres in Akure and seven (7) out of the total identified organized Garri processing industries, that is, 64 % was randomly selected for administration of questionnaire. Therefore, five (5) questionnaires were administered at each of the selected centres and this gives a total of thirty five (35) questionnaires administered in the study area. The selection of the Garri processing factory was done by snow ball sampling method in which a subject nominates another subject with the same trait for sampling. Both descriptive and inferential statistics were used in data analysis. Tables and charts were employed to present the magnitude of occurrences of the variables that were obtained.

DATA ANALYSIS

Table 1 describes the socio-economic characteristics of the workers of cassava processing small scale industry sampled for the study. It was observed that majority of the workers were from the south-western part of the country, categorized as the Yorubas. They constituted about 85.7% of the workers while a small percentage of 14.3% represented the Igbos. The workers were majorly Yoruba because this study was carried out in Akure, south-western part of the country. Among these workers, 28.6% of them had stayed in the locality between 1-5 years, 14.3% had stayed between 6-10 years, and 14.3% had stayed between 11-15 years while 42.9% had stayed in the locality above 15 years.

Cassava processing has helped in alleviating un-employed people from poverty through wealth creation. From the analysis, 14.3% of the workers earned less than ₦20,000, 42.8% earned between ₦21,000 to ₦40,000, 28.6% earned between ₦41,000 to ₦60,000, 14.3% earned between ₦61,000 to ₦80,000 and 14.3% earned above ₦100,000. Cassava processing is dominated by females. 28.6% were male while 71.4% of them were female. Based on the age, 28.6% were between the 18 to 35 years, 42.8% were between the age 36 to 50 years and 28.6% were between the ages 51-56 years. In terms of marital status, 14.3% were single while 51.4% were married. Based on religion, 85.7 practiced Christianity while 14.3 practiced Islam. However, this type of job description does not require high level of education. 57.1% had primary education, 14.3% had secondary education while 28.6 % had tertiary education.

Based on the household size, 85.7% had a size between 4 to 6, 14.3% had a size from 10 and above. In terms of hours put to work, 14.3% spent between 4 to 6 hours, 85.7% spent from 7hours and above. Among these workers, 14.3% were marketers, 14.3% were firewood seller, 14.3% were clerk, and 42.9 were administrative officer. Some of these

operators engaged in other enterprise. For instance 28.6% were into trading, 28.6% were into farming, 28.6% were civil servant and 14.2% were artisan. This is to show that the enterprise allows for partial or part time operation. This makes it flexible for the operators to engage in other economic activities. 71.4% attended work daily and 28.6% attended work twice a week. This shows that majority (71.4%) are dedicate to cassava processing all through.

Table 2 below describes the processing technologies adopted by the cassava processing firms. Almost all of them engaged the use of one equipment or the other. Those that uses constituted a 85.7%, while 14.3% does not. Among the firms using these light equipments, it was discovered that all of them uses the mentioned light equipment. Example of the light equipment includes: Grater, Peeler, Fryer, Presser and Miller. It is also of note that 85.7% of them purchased their equipment while 14.3% hired. Also, in terms of monthly maintenance of these equipment, 34.3% spent ₦1000 to ₦3000 on maintenance, 42.9% spent ₦3000 to ₦5000 while 22.9% spent over ₦5000.

Table 3 describes the problems encountered by the cassava processing firm. Generally, most of them complained about three categories of problems. It was discovered that 31.4% of them complained of inadequate capital, 20% complained of lack of storage facilities while 11.4% complained of inadequate cassava supply while 5.7% chose others like erratic power supply. In a bid to find possible solutions to these problems, the study attempted to seek the respondents view for possible solutions. They proffered that government should ensure regular supply of electricity; availability of funds through provision of loans and provision of machine and equipment.

Table 3: Problems encountered

Problems Encountered	**Number of Respondents**	**Percentage**
Unavailability of inputs	03	8.6
Inadequate capital	11	31.4
High cost of transportation	03	8.6
High taxation	01	2.9
Poor road network	02	5.7
Price instability	02	5.7
Unavailability of labour	00	0
Exploitation by middlemen	00	0
Lack of storage facilities	07	20
Inadequate cassava supply	04	11.4
Others	02	5.7
Total	**35**	**100**

From the analysis of the result, it was observed that women where constraints by lack of market opportunities, access to credit facility, enabling environment, finance, poor road network, poor market information, poor managerial skills, inadequate information dissemination, poor equipments, high taxation and poor government policies on entrepreneurial development, all these deter not only the women but both youths and farming households from venturing into entrepreneurship world. Justifying inadequate credit facilities as a constraint to entrepreneurial development, it was also discovered that low productivity in quality Garri has led to limited market surplus which prevents the women from having enough cash to procure processing equipments and services. Again, the formal financial intermediaries are not helping issues as most do refuse this women from sourcing loan from their institutions due to lack of acceptable collateral, hence, branding the women as non-credit worthy.

CONCLUSION AND RECOMMENDATION

Based on the findings of this research, it was concluded that the women had been employing entrepreneurship skills in the organized Garri processing points. This has led to reduction of poverty among the women in this area. However, the extent of poverty reduction is still very insignificant, which is an indication that the women have not fully taken advantage of some of the entrepreneurial activities or have participated to a less extent. In these categories is branding and packaging of the processed Garri before taking it to the market. Hence, if the current transformation agenda of the present Federal Government on poverty eradication through farming activities must be actualized, there is urgent need to provide adequate entrepreneurship development programme for women and farmers while addressing factors that hinder the growth and development of farmers entrepreneur in the country.

The major conclusion of this paper is that the women Garri processors in the study area play major roles in alleviating poverty among the Nigerian women. Rather than going into prostitution and other social vices, these women have been able to assist in meeting the needs of their household. They have been able to assist their husbands in making sure there is food on the table. Some of them are even single parents who have been able to use the money earned to sponsor their children to school even up to tertiary institutions.

It is therefore, recommended that the efforts of women Garri processors be complimented with the formal financial Institutions and the government. It is believed that these will alleviate poverty and improve the standard of living of women Garri processors.

Analysis of Factors Responsible for the Location Pattern of Petrol Filling Stations in Akure, Nigeria

Olufayo, O.[1*] & Omole, F.K.[2]

[1&2]Department of Urban and Regional Planning, Federal University of Technology, Akure, Nigeria

ABSTRACT

The technological initiative of man towards the development of automobile and the discovery of petroleum triggered the building of Petrol Filling Stations (PFSs) at strategic locations to meet the demand of vehicle owners. The aim of this study is to investigate those factors influencing the location of PFSs considering the following objectives; to investigate the land value, examine the socio-economic characteristics of the respondents and the level of compliance of physical planning standards in the study area. Two sets of structured questionnaires were administered on the residents and the Owners/Managers in charge of the PFSs in Akure, while oral interview was conducted on the Directors of physical planning at the Ondo State Development and Property Corporation and Ondo State Ministry of Housing and Urban Development. Simple Random Sampling Technique was used in the administration of 415 questionnaires on the residents, while a total survey was conducted on the 87 functional PFSs. All data collected were analyzed using univariate and multivariate analysis. The study clearly shown that weakness enforcement of planning standards, accessibility of PFSs to customers, occupation status and income of respondents are some of the factors responsible for the concentration and haphazardly location of PFSs in Akure. It is suggested that there should be a synergy between the approving bodies on how to effectively enforce the planning standards also government should assist in procuring modern planning equipments which could be used for effective development control activities. Workable planning standards policy on location of PFSs should be enforcement. In addition, the Akure Master Plan is long due for review.

Keywords: Factors, Location Pattern, Petrol Filling Stations, Planning Standards, Sustainability

INTRODUCTION

In recent times, there has been a sustained increase in the number of Petrol Filling Stations (PFSs) located in different part of the country. The reasons for such unprecedented increase are not far-fetched: first, the growing number of people in the country and the attendant increase in the purchase of vehicles. Secondly, the attractive price of petrol both at control price and black market prices which made more people to go into the petrol retailing business (Smart, 2002). In view of this development, many oil marketers take advantage of this need and build PFSs haphazardly without giving consideration to the possible effect of its locations. It is evident from different studies that PFS has high potential hazards to the site and the surroundings. The hazards may be environmental, hydrological, geological or socio-economic. It is obvious that Nigerian cities and towns are getting congested with every nook and cranny filled with PFSs. Even in residential areas, PFSs are built on little available spaces, in-between residential buildings, raising real fears of environmental hazards and fire outbreaks (Oladoyinbo, 2013).

However, there is the need to properly emphasize those factors that influence the location pattern of PFSs and how its understanding could facilitate a balanced and sustainable national development. Hence, this paper focuses on the analysis of factors responsible for the location pattern of PFSs in Akure.

LITERATURE REVIEW AND CONCEPTUAL FRAMEWORK

Omole (2001) posits that a petrol filling station by definition is a commercial facility where fuel and lubricants for automobiles among other goods are sold. Fuels sold at petrol filling stations include Petrol (Premium Motor Spirit [PMS], Liquefied Natural Gas [LNG], diesel

Olufayo, O. & Omole, F.K. (2016). Analysis of Factors Responsible for the Location Pattern of Petrol Filling Stations in Akure, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1297-1306

(Automated Gas Oil [AGO]) and Kerosene (Dual Purpose Kerosene [DPK]). Location in spatial planning connotes "situation" rather than "site" (Omole, 1994). The site is concern with the actual place or position of a particular activity, project or structure, while location is a term embracing the site with additional information on the location of the site relating to other existing surrounding site which influences the activity on site. This is because the systematic linkages among activities on land are to ensure sustainability. The linkages are such that a wrongful placement could mar the physical setting and siting of these facilities and services.

Losch's (1954) theory on location of an activity is one of the most realistic theories of urban facilities location. The theory was therefore concerned with finding place of maximum profit. His approach was known as profit maximization and market area approach. Maximization of profit is only possible when demand patterns are taken into consideration. The concept of maximization of profit is mostly directly relevant to the planner in the locations of services. The assumption from the location theory is that the PFSs marketers in quest to maximize profits concentrate their PFSs in certain areas including the study area.

Standards and regulations for PFSs are the requirements to be satisfied before locating or developing filling stations. Such standards and regulation may vary slightly among states, but they all tend towards achieving a high degree of compatibility and excellence in the location and design of filling stations (Alabi, 2004).

Concept of Physical Planning

One of the most acceptable and popular definition of physical planning was given by Keeble (1969) as the art and science of ordering the use of land and the character and sitting of buildings and communication routes so as to secure maximum practicable degree of economy, convenience and beauty. Similarly, Olujimi (2009) sees Land use as the spatial reflection of human activity on land; and whose efficient arrangement and harmonious coordination are basic to physical planning. The Nigeria Institute of Town Planners conceives physical or land use planning as requiring 'participatory and integrated processes of allocating land for promoting sustainable development' (Falade, 2012). Olajuyigbe and Rotowa (2012) opine that physical planning ensures compatible land uses, guarantees orderly development and provides functional and visually pleasing environment and satisfactory services in a sustainable manner. From the above definitions, Physical Planning is a conscious but comprehensive approach to orderly and healthy use and management of the natural environment of human settlements (Bakare, 2012). Location pattern of PFSs in the study area may be difficult to attain without the role of physical planning and how its understanding could facilitate a balanced and sustainable national development (NPC, 2009). As noticed in the study area that many of the PFSs were located within residential areas and also too close to residential buildings as against physical planning specification of the State Ministry of Housing and Urban Development. It is obvious that physical planning roles are to regulate and control the establishment and location pattern of PFSs.

Man and Environment Interaction

The environment is defined as those components (water, air, land, etc) which support the survival of man. The environment is very complex as there are many factors that shape it (Olajuyigbe, 2014). The word "environment" has been defined as the total outer physical and biological system in which man and other organisms live (Aina, 1991). The well being of man and the sustenance of his livelihood are closely associated with the environments. In planning parlance, George (2006) describes the environment as the spatial surrounding of the home, work place or public place which is the physical entity where both flora and fauna thrive, also is the natural environment which is very important to the sustenance of life, and it

must be ensured that development efforts are not harmful to environmental factors that support life.

Concept of Sustainable Development

Sustainable development can be defined as development that caters for the needs of people without compromising the needs for the future generations (Barrow, 2006). The quest for the quantification of the probable positive or negative influence of man on the environment is the genesis of the concept of Environmental Impact Assessment (EIA) (Ojo-Fajuru, 2001). EIA needs to include the social participatory and economic issues alongside the environmental issues. If these elements are included, the key links between EIA and sustainable development would be addressed. EIA is a planning and management tool that can be used to promote sustainable development and is aimed at providing decision makers with enough information on the consequences of projects, especially those with a potentially high impact as in the case of filling stations. EIA is therefore a crucial step toward a cleaner and healthier environment without compromising the need for development (Pretorius and Sandham, 2006).

The need for the development of filling stations must always be balanced with the need to protect the environment (Govender, 2009). As with other infrastructure developments, the development of filling stations forms part of a growing economy. An increase in development also results in an increase in employment opportunities, which results in a greater proportion of the population owning cars and utilising public transportation systems. The three basic components of sustainable development are economic, social and the environment, these components need to work together for the concept of sustainable development to function. If the economic aspect is not there to support the environment, there will be a malfunctioning, so also, if the social framework is lacking there will be a great abnormality. In turn, filling stations need to be developed to cater for the needs of the larger amount of cars on the road networks and not to the detriment of the environment (Govender, 2009).

THE STUDY AREA AND RESEARCH METHODOLOGY

The Study Area

Akure South LGA is located in Ondo State in the South-Western geopolitical zone of Nigeria. It occupies a land area of 37,134 hectares (35 sq.km). It lies between latitude 6^0 95' and 7^0 15' North on the Equator and longitude 5^0 15'and 5^0 40' East of the Greenwich Meridian (Macmillan, 2006). The study area is bounded by Owo Local Government Area in the East, Akure North and Ifedore Local Government Areas to the North, Ile-Oluji/Okeigbo Local Government Area in the West and Idanre Local Government in the South. Also the study area has some notable roads, which include; Akure/Owo express way, Ilesa road, Oyemekun road, Oja-Oba road, Arakale road, Ondo road, Alagbaka road and Ijoka road among others (figures. 2 and 3). The population growth in Akure agrees with the increase in vehicular ownership which gives rise to the number of PFSs in Akure. However, this increase of PFSs and their location pattern is of great concern to urban planners.

Research Methodology

Two (2) different sets of structured questionnaires were administered on the residents and the Owners/Managers in charge of the PFSs in Akure, oral interview was also considered where necessary. Simple Random Sampling Technique was used in the administration of questionnaire on the residents (household-heads) of the sampled buildings, while total survey (100%) was conducted on the Owners/Managers of the PFSs in the study area for detailed survey. Marta, *et al* (2011) measured the quotients for the levels of an aromatic compound

(benzene) and a hydrocarbon (n-hexane) at three Murcia PFSs and discovered that the distance at which the PFSs stop having an impact on the environment is about 100 metres. But the distance depend on the number of petrol pumps, the amount of fuel drawn from them, traffic intensity, the structure of the surroundings, and weather conditions. The same view was expressed by Blamah, *et al* (2012) in their study on Location Impact Assessment of PFSs, that residential, commercial and public/semi-public buildings within a distance of 150 metres stand the risk of hazards that emanate from PFSs.

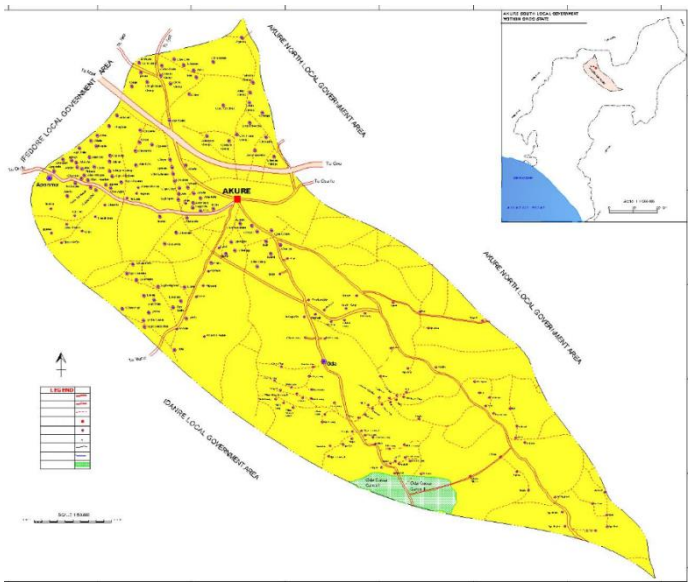

Figure 2: Akure South Local Govt. Area Map

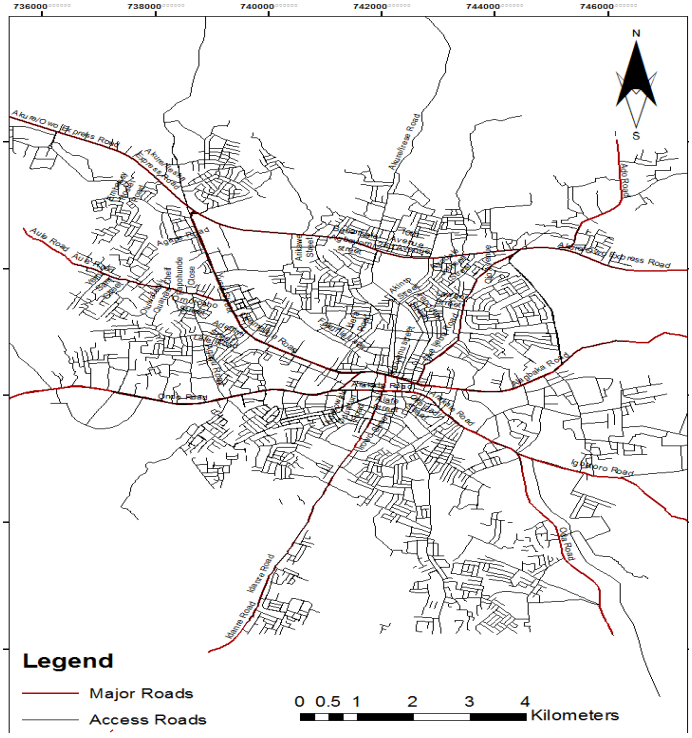

Figure 3: Road Network Map of Akure
Source: Ondo State Ministry of Housing and Urban Development, 2013. Digitized by the Author, 2015

DPR (2010) reveals in the planning criteria for the location of PFSs, that the minimum distance of PFSs to public and residential buildings should be 100 metres. On these premise, the researcher maintained 150 metres radius around all functional PFSs after the researchers

maintained 150 metres radius around all functional PFSs after dividing Akure the study area into its eleven (11) wards. These are existing political wards. The researchers only made use of the existing 11 wards out of which the 7 relevant ones were identified. The seven (7) wards identified during reconnaissance survey with concentration of PFSs were focused on. However, buildings within 150 metres radius form the basic sampling frame for the residents, while all the PFSs form another sampling frame (table 1, 2 and fig. 4, 5). This was captured using the Global Positioning System (GPS) in picking the coordinates of the PFSs on site, while the Satellite Imagery of the study area was gotten and updated by the researchers in order to know the total number of buildings within the 150 metres radius. From Table 2.7% (415) of the total buildings within 150 metres radius to PFSs were randomly selected for the administration of questionnaires. The sample size of 2.7% (415) is reasonable considering the fact that in similar studies on Akure, a sample size of 2.3% (150) was used by Omole (2001), while Emmanuel (1998) used a sample size of 5% (330) and got reliable results. Total survey was carried-out on the 87 PFSs. The analyses were done using Univariate, Bivariate and Multivariate analysis.

Table 1: Number of PFSs in the Eleven Wards of Akure the Study Area

Table 2: *Number of Buildings within 150 metres radius in the Seven (7) Wards selected for Sampling*

S/N	**Ward**	**Total number of PFSs**	**Total number of buildings within 150metres radius around PFSs (Sampling frame)**	**7% of Buildings (Sample size)**
1	Gbogi/Isinkan I	10	764	53
2	Gbogi/Isinkan II	14	1098	77
3	Ijomu/Obanla	20	1526	107
4	Oke-Aro/Uro I	11	813	57
5	Oda	07	470	33
6	Oshodi/Isolo	05	181	13
7	Owode/Imuagun	20	1072	75
	TOTAL	**87**	**5,924**	**415**

It was revealed in the analysis on Table 3 that 8% of the respondents were retiree, 25% were traders also on the analysis are the artisans which accounted for 14%, while civil servant in the study area recorded 53% of the total respondents. This analysis implies that majority of the respondents are civil servants who are beneficiary of the minimum wage as well as loan from the government. These opportunities made it possible for some of the civil servants to have vehicles of their own which triggered the building of PFSs at strategic locations to meet the demand of vehicle owners.

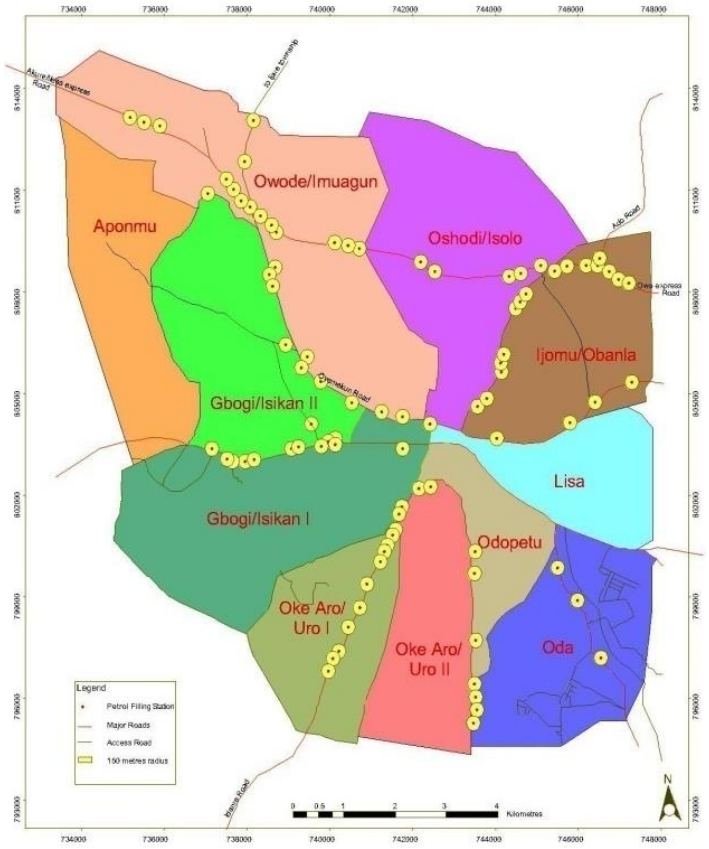

Figure. 4: *Location of PFSs in the Eleven Political Wards of Akure*

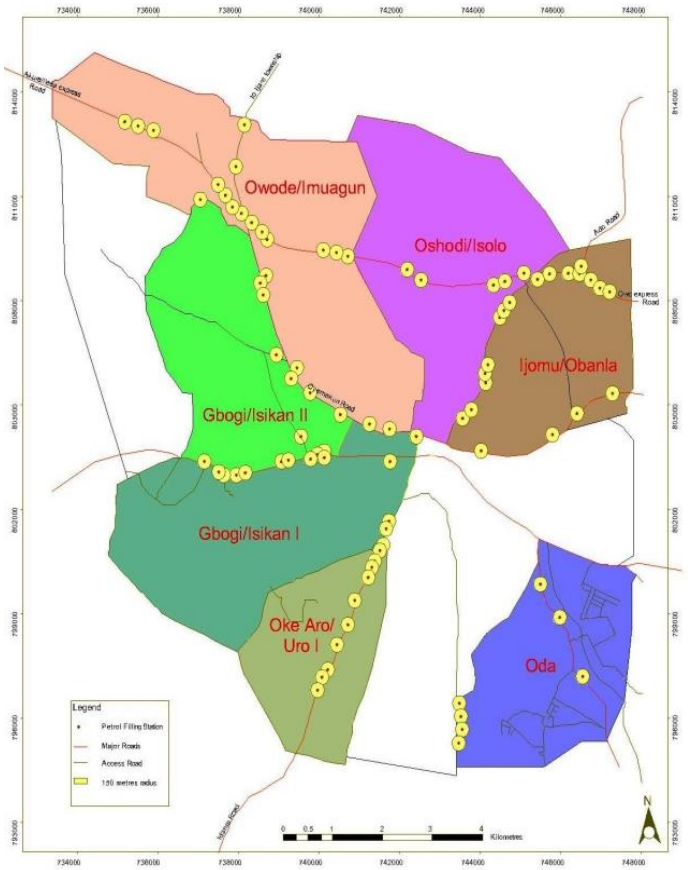

Figure. 5: Location of PFSs in the Seven Political Wards Selected as Sampling Frame

RESULTS AND DISCUSSION

Occupational status of respondents

Table 3: Occupational Status

Occupation	Frequency	Percent
Retiree	33	8
Trader	104	25
Artisan	58	14
Civil Servant	220	53
Total	415	100.0

Monthly income of respondents

The monthly income of the respondents in the study area as shown on Table 4 reveals that 22.6% was dominated by less than N20,000, the monthly income of N20,000-N40,000 accounted for 24.8%, also N40,001-N60,000 recorded 47.7% of respondents, 2.6% claimed to be receiving N60,001-N80,000 per month, while 0.8% of the respondents earn between N80,001-N100,000 per month and 1.5% earn above N100,001 in a month. This reveals that over 50% of the respondents live above one dollar per day and therefore enhances their standard of living which can also lead to increase in vehicle ownership; also there is tendency for each household or family to have a generating plant which operates on petrol so as to ease the problem epileptic power supply.

Table 4: Monthly Income of Respondents

Monthly income	Frequency	Percent
Less than N20,000	93.8	22.6
N20,000-N40,000	103	24.8
N40,001-N60,000	198	47.7
N60,001-N80,000 N80,001-	10.7	2.6
N100,000	3.1	0.8
Above N100,000	6.4	1.5
Total	415	100.0

Land Value in the Study Area

The oral interview conducted on the PFSs owners is revealed on Table 5 shows that the land value per plot in the study area varies, such that land value between N10.1m-N15m accounted for 55% of the total respondents, 40% of the respondents are of the opinion that land value in their area is between N5.1m-N10m while 5% reveals that land value in their area is between N1.1m-N5m. It is obvious from the analysis that the minimum cost of land in which PFSs are located is between N5m – N10m. This is based on the premise that there were no vacant plots in the core of the study area; therefore, some of the buildings in the core area that were in bad or dilapidating conditions were bought by some oil marketers at a very high cost of money. Most of these plots sizes are between 648m^2 – 1,295m^2 (1 plot and 2 plots) which are not within the recommended land area for siting of PFSs. As a result of this some of the PFSs owners did not seek for approval because of the political backing they enjoy.

Table 5: Land Value in the Study Area

Land Value	**Frequency**	**Percent**
N10.1m-N15m	48	55
N5.1m-N10m	35	40
N1.1m-N5m	4	5
N0.5m-N1m	-	-
N0.1m-N.5m	-	-
Total	**87**	**100.0**

Accessibility of PFSs to customers in Akure

Table 7 reveals that 82.8% of the respondents were of the opinion that their PFSs are highly accessible to customers while the remaining 17.2% of the PFSs were fairly accessible to customers. The above analysis infers that accessibility to customers is one of the important factors that is considered by oil marketers before locating PFSs. Apparently, accessibility of PFSs to customers determines the level of patronage.

Table 7: Accessibility of PFSs to customers in Akure

Accessibility	Frequency	Percent
Highly accessible	72	82.8
Fairly accessible	15	17.2
Poorly accessible	0	0
Total	**87**	**100.0**

Enforcement of Planning Standards on PFSs in Akure

The enforcement of planning standards on establishment of PFSs were not strongly enforced as indicated in the analysis. Planning standards were slightly enforced in the study area on the physical planning parameter highlighted on Table 8. Having obtained the standards for the location of PFSs from relevant authorities, the researchers then carry out field investigation to ascertain how many PFSs complied with the standards. It was discovered that many of the PFSs did not comply with the standards. The authorities in charge of the approval and enforcement of planning standards on location of PFSs were of the opinion that inadequate modern planning equipments such as Handheld Multigas Analyzer, Handheld Hydro Analyzer, Handheld Traffic Counter, etc and shortage of manpower that could effectively carry-out development control activities in the study area are the bane for the enforcement. These weaknesses on the part of the Institutions encourage PFSs owners to haphazardly locate their PFSs.

Table 8: Enforcement of Planning Standards on PFSs in Akure

Enforcement	Setback to road		Air space of 100m to residence		Maximum percentage Developed		Distance of 2 PFSs on the same lane		Distance of 2 PFSs on adjourning lane	
	Freq	%	Freq	%	Freq	%	Freq	%	Freq	%
Strongly enforced	10	11.5	0	0	7	8.0	0	0	0	0
Enforced	19	21.8	13	14.9	20	23.0	8	9.2	5	5.7
Slightly enforced	58	66.7	65	74.7	48	55.2	32	36.8	29	33.3
Not enforced	0	0	9	10.3	12	13.8	47	54.0	53	60.0
Total	87	100	87	100	87	100	87	100	87	100

Regression Result on the Factors Responsible for the location of PFSs in Akure

Table 11 shows the regression analysis on the factors responsible for the location pattern of PFSs in Akure. five predictor variables were accommodated in the model which was developed for the study. These are: occupation (OCCU), enforcement (ENFORCE), land value (LAND), accessibility to customers (ACCESS) and income of respondents (INCOME). The overall regression using the five predictor variables was significant at 0.01 alpha level with F-value of 615.347, meaning that 5 major factors jointly contributed to the location pattern of PFSs in Akure. The coefficient of determination (R^2) is 0.775 signifying the combined influence of independent model parameters accounting for approximately 78% of the factors responsible for the location pattern of PFSs. Individually, variation occurs in the level of contribution of each factor. Highest here is accessibility to customers, followed by enforcement of planning standards and lastly occupation. The implication of this is that if

appropriate physical planning measures are not considered, the study area will be experiencing haphazardly increase concentration of PFSs.

Table 11: Regression Result on the Factors Responsible for the Location Pattern of PFSs

Model	Unstandardized Coefficients		Standardized Coefficients		
	B	Std. Error	Beta	t	Sig.
OCCU	-.181	.105	-.143	-1.722	.089
ENFORCE	.363	.233	.127	1.556	.124
INCOME	-.983	.178	-.465	-5.539	.000
LAND	1.267	.258	.497	4.908	.000
ACCESS	.023	.468	.004	.050	.961
Constant	-2.539				
R	0.735				
R^2	0.775				
df	6				
F-value	615.347				
Sig	0.000				

The regression equation is as follows;

(NUPET)=2.539+0.181(OCCU)+0.363(ENFORCE)-0.983(INCOME)+1.267(LAND) +0.023(ACCESS) …….....(i)

This model is helpful in making prediction with increase or decrease in the levels of predictors.

CONCLUSION AND RECOMMENDATIONS

It is pertinent to note that the subsequent increase in vehicular ownership and the use of petroleum products have resulted in the proliferation of PFSs in towns and cities today. The rapid growth in urbanization has produced greater demand of vehicles, which results in more fuel consumption. It is obvious that Nigerian cities and towns are getting congested with every nook and cranny filled with PFSs. Consequently, some insidious effects of the indiscriminate location of PFSs in Akure have been over-looked. Based on the findings of this research, the study has clearly shown that weakness enforcement of planning standards, accessibility of PFSs to customers, occupation status and income of respondents are the major factors responsible for the concentration and haphazardly location of PFSs in Akure. On this premise it is recommended that workable planning standards policy on location of PFSs be enforcement. There is also an urgent need of a policy framework that will strengthen the professionals in the ministry, local and state governments to fulfill their constitutional obligations. In addition, the Akure Master Plan should be reviewed in order to incorporate the existing physical development with the future, so as to prevent further physical deterioration of the town through indiscriminate location of PFSs. On the whole, it is recommended that modern planning equipments such as Handheld Multigas Analyzer, Handheld Hydro Analyzer, Handheld Traffic Counter, etc should be provided by the government which could be used for effective development control activities so as to create an enabling environment for living and qualified personnel should be recruited.

Assessment of Housing Condition and City Liveability in Ogbomosho, South Western Nigeria

Enisan, G.[1*] & Omole F. K.[2]

[1&2]Department of Urban and Regional Planning, Federal University of Technology, Akure, Nigeria
[*]ofenisan@futa.edu.ng

ABSTRACT

This paper examines issues on housing condition and city livability in Ogbomosho, South Western Nigeria, with a view of determining and the contributions of housing provision to urban sustainability. No doubt, the modern age is an age of urbanization, where villages are fast growing into towns and towns into cities but the consequences are unimaginable. The research on one part, examined the socio economic characteristics of residents and the physical infrastructures in the study area. It also examines the condition of buildings in the area and carries out the assessment on the types of houses in the study area. Using systematic random sampling technique, data were collected with the aid of structured questionnaires. Interviews were held to complement data from questionnaire survey while descriptive statistic methods were employed to analyze the objectives set for the study. Findings reveal the socio-economic characteristics of residents and its effects on physical environment of the area. The study showed inadequate provision of facilities such as pipe – borne water, erratic power supply, poor solid waste management and presence of substandard houses in the study area. This study however, makes recommendation for the enforcement of planning regulations to improve the housing quality and facilities in the study area. It is therefore necessary for various organizations and government institutions to provide create and implement comprehensive and coordinated housing programmes for the area.

Keywords: housing, city livability, sustainable development, infrastructural facilities

INTRODUCTION

Cities are focal points in an economy where people come together primarily to exchange goods and interact. The alarming growth of urban population and poor response of government are factors that partly contribute to high rate of physical development mishap in cities (IFPRI, 2002). A city is considered a place with relatively large population that has a legal status, granted by the national or provincial government, and that is associated with specific administrative or local government structures (Brockerholf, 2000). It can be likened to the human body. The flesh of the city is the residential area. The blood circulation is the movement of people or commuters. The blood arteries and veins are the various circulatory systems and the heart is the central business district (CBD). Despite opportunities in cities, African cities over the years are experiencing increasing rate of urban infrastructural inefficiency. Interestingly, scholars perceive cities in its various manifestations as catalyst to development in the country. It had also been sounded over time that, nowhere in West Africa is the rate of urbanization in the last few years as unprecedented as the city of Lagos (Agboola and Agunbiade, 2007). This implies that the city has a persistent rate of growth with a resultant effect on the carrying capacity and ecological footprint of the city.

The rapid expansion of urban population has brought with it many problems associated with the difficulties of providing basic infrastructure such as electricity, inter-urban and intra-urban transportation and communication services and the problems of providing medical, educational, and recreational facilities (Abiodun, 1976). The rapid increase in the population of urban centers has resulted in an increase in the cost of living because of higher demand on urban commodities. There is a dearth and high cost of urban land, and high cost of housing, which is often in short supply and out of the economic reach of the majority of the urban

Enisan, G. & Omole, F. K. (2016). Assessment of Housing Condition and City Liveability in Ogbomosho, South Western Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1307-1314

households (Oladapo and Olotuah**,** 2007). The urban centers are populated by a large mass of people on low wage and who face irregular employment. This segment of the urban population is indeed poor, and is constrained to limited, insufficient, crowded, cold and dirty shelter and a generally degraded environment (Mabogunje, 1985). These are the urban poor who are subjected to a life characterized by precarious conditions of nutrition and health, little or poor material possessions.

The issue of livability has become very insistent of late, especially with the increasing environmental deterioration in the large metropolitan centers. It involves not only living conditions but also ease of circulation in the city. This is as a result of tremendous pressure of population on limited facilities and is manifested in growth of squatter settlements, overcrowded habitation, breakdown of waste disposal arrangements, inadequate power and water supply and generally poor condition of environmental sanitation (Mabogunje, 1974).

Many aspects of urban design and new approaches to city form are based on the concept of liveability. These approaches recognize that design and structure can be very influential in the life of a town or city and indeed to the building of community in and of itself. They also create novel contexts for a community to develop in a more sustainable way (Enisan and Rotowa, 2013). The formation and development of Ogbomoso was not planned and have gone through ages. The structures are old, the environment is unplanned and the infrastructure is dilapidating which tends to put more pressure on issue of liveability in the town.

Housing is one of the basic human needs and ranks third after food and shelter which therefore makes it a prerequisite for the survival of human beings (Onibokun, 1972). Housing is defined as "the process of providing a large number of residential buildings on a permanent basis with adequate physical infrastructure and social amenities, (services) in planned, decent, safe, and sanitary neighborhoods to meet the basic and special needs of the population. Adequate housing therefore should provide protection from the elements, minimize the risk of disease and injury, and contribute to the physical, mental and social wellbeing of the occupants. Housing provides the physical frame work and the environment in which the economic value of man, socio-cultural and aesthetic value of man and society are realized; enriched and integrated housing is an essential part of productive infrastructure item as a productive investment. Housing is expected to satisfy certain biological, psychological, social, cultural and economic needs of the people. Housing development in both rural and urban is therefore an important aspect of a nation's development program. Although housing problems exist in all nations of the world. These problems however differ in terms of their fundamental causes, magnitude and dimension from one nation to another (Ahianba, Dimuna, and Okogun 2008).

In Ogbomosho where the study area is situated, previous studies show that situation of housing has been deteriorating fast and there is no solution in sight by the land lords to improve the standards of their houses. Most of the good houses there are either built by rich individuals or provided by the government, the lack of quality housing in Ogbomosho has led to several environmental problems in the area. One of the major noticeable problems are improper disposal of human waste, open defection, this is caused by the lack of toilets by most houses in Ogbomosho. Another problem is the absence of an aesthetically pleasing environment; this is as a result of uncoordinated planning and building arrangement. Another point of note is high number of abandoned houses in, this is mainly due to the collapse of the buildings and it is caused by the poor construction materials and method used in building the houses (Toyobo, Muili, and Ige, 2011). These problems mentioned above led to the interest

of the study to focus on the provision of housing quality and also a livable city which makes Ogbomosho a place of interest.

THE STUDY AREA

Ogbomosho is a pre-colonial urban center and the second largest city, both in terms of population and spatial extent, in Oyo State, Nigeria. The city is located at a distance of about 100km north of Ibadan, the Oyo state capital and about 80km from both Ilorin and Oshogbo, respectively the Kwara and Osun State capital. It is one of the main gateways to the northern part of Nigeria from the Yoruba land. It is bounded by river Ora to the east, while no major physical barrier is encountered to the north, west and south. It develops laterally towards the north and south along Ibadan-Ilorin road. The city is surrounded by a number of villages and medium sized towns such as Ikoyi, Odo-Oba and Iressa Apa which all have organic linkage with it, but at distances considered far enough to be out of range of influence of expansion of Ogbomosho (Adeboyejo and Abolade, 2007). The town is divided into two local governments and they are; Ogbomosho North and the Ogbomosho South Local Governments with 10 political wards each and their headquarters are at Kinnira and Arowomole respectfully.

The city of Ogbomosho is one of such numerous Yoruba settlements, South-West of Nigeria, where urbanism as a way of life predates European Colonization of the country. Like the originand development of most Yoruba settlements in the early 18th century, the city emerged from the activities of five different waves of migrants, who settled in different areas of the present city. It was the last wave of migrants, led by Soun Ogunlola, who as a result of warring prowess, subjugated and pacified the separately developing villages and hamlets in the surrounding areas into a large settlement that is known today as Ogbomosho (Adeboyejo and Abolade 2007).

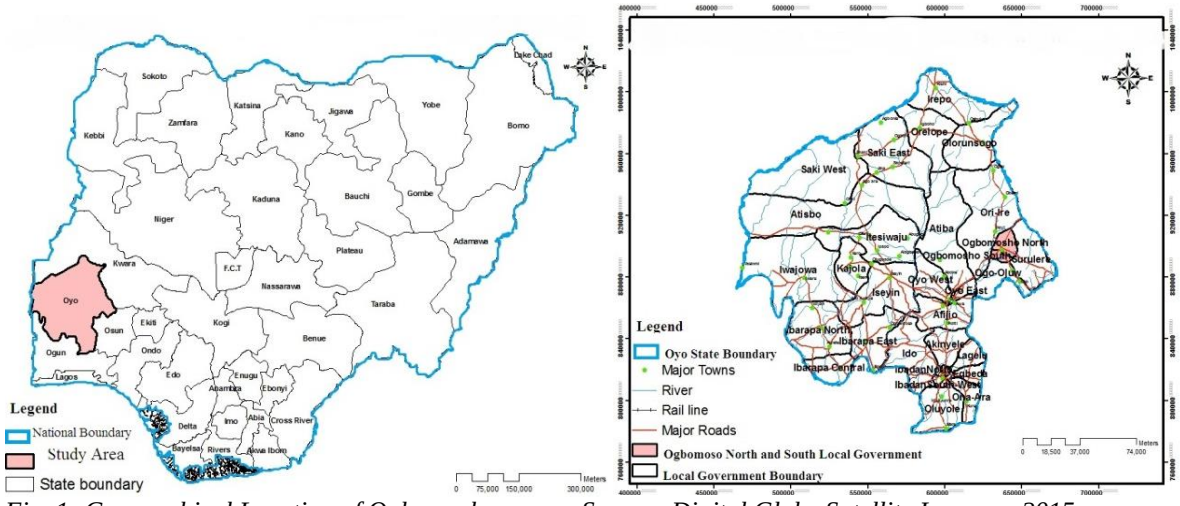

Fig. 1: Geographical Location of Ogbomosho *Source: Digital Globe Satellite Imagery, 2015*

Ogbomosho lies approximately, 8˚08′ North of the equator and 04˚15′ East of Greenwich Meridian.

MATERIALS AND METHOD

The data for this research project was collected from primary sources. A large proportion of the needed data for this research project were generated directly by the researcher. Information and data were obtained directly from the targeted populations at the research site using formal, structured questionnaires. A close ended type of questionnaire was adopted.

This is to enable the questionnaires to be easily subjected to quantitative analysis. The data obtained include such socio economic characteristics of respondents as number of male and female persons in the household; number of households in the house; age; sex; tenure status; occupation; educational status; income among other variables of home environment. The residential densities of the study area were identified and systematic random sampling was adopted within the stratum to capture the primary data and other relevant information to the study. Consulting extensively relevant textbooks, publications, records, maps, and dictionary were also done. These materials dwelled largely on housing generally and how it affects city livability. The survey covered notable areas in Ogbomoso.

Source: National Population Commission, Oyo State, 2014; Field Survey, 2015

A total number of 213 respondents were randomly sampled and interviewed during the field survey. The residential density is the population of building per 10,000square meters (buildings per hectare). Data obtained from the study was analyzed with the aid of relevant quantitative techniques using appropriate software that produced accurate result on the

relationship between housing and city livability. All the data collected from the field were collated, processed and presented in form of tables and charts. The used of Statistical Package for Social Sciences (SPSS) was employed for data analysis and presentation. The use of Microsoft Excel was used in the collation of data. Information was given on frequency distribution of the variables for proper comparison.

FINDINGS

The role of housing in human survival cannot be over emphasized. Every person is affected in his day to day activities by the type of house where he or she lives. This study was concerned with a survey of houses and the facilities available in Ogbomoso, Nigeria. For this research, houses in Ogbomoso were classified as follows: family house, single house on one lot occupied by one family, apartment in a building with more than one apartment, duplex and brazillian houses. Analysis also revealed that majority of the residents in the family and brazillian houses were of low income category and residents in the apartments and single house on one plot occupied by one family belonged to middle income category while bulk of residents in duplexes belonged to the high income category. This study also revealed that socio economic characteristics such as education, occupation, monthly income of respondents and household size determined the choice of housing types (See Table 2).

Table 2: Livability Structure in the Study Area

Type Of House	**(%)**	**Monthly Income (N)**	**%**	**Household Size**	**%**
Brazilian Bungalow House	40.8	Less Than 10,000	32.4	Above 7	38.7
Brazilian Storey House	27.2	10,000-20,000	47.4	5-7	30.3
Flat	20.7	20,000-30,000	15.5	3-5	22.1
Duplex	11.3	Above 30,000	4.7	Below 3	8.9
Total	**100.0**		**100.0**		**100.0**

Fig. 3: Example of the Type of Building Common in the Study Area

The study established that there are more of untarred and dusty roads which are always slippery during rainy season in Ogbomoso. Even out of the ones that were tarred, some due to lack of maintenance quality, are already worn out and filled with pot holes. Self-employment is most rampant form of occupation with little income per month, which rates poverty at high level. The survey showed that respondents are mostly craftsmen and self-employed and under this category, we have trading, farmers, tailoring, mechanic, bricklaying, carpentry, furniture making, hairdressing, bead making, Ifa divination , civil servants represents a little percentage owing to the fact that most of the inhabitants are illiterates with low education which limits their income.

The presence of low income earners coupled with the level of education of respondents are factors that contributed to the quality of housing standard in the study area. Findings show

that hand-dug well is the main source of water supply in the environment. This situation does not guarantee adequate supply of good quality water in the area. Most of the wells are located in unkempt surroundings, some of which are without cover while the water is used raw without treatment. The rain water used as substitute during raining season has the possibility of being contaminated as majority of the roofing sheets are rust and dirty.

According to the survey, pit latrine is the most rampant type of toilet found and used in the study area due to the building design and also the level of literacy which leads to neglect on part of the inhabitants. Water Closet is not common in the study area and the usage of open defecation also practiced in the area. Some of the respondents burn their solid waste, and some which are constituted mostly by educated people give their solid waste to waste disposal management, the most rampant practice amongst the inhabitants is the dumping of their refuse on refuse dumps. When refuse are dumped on the refuse dumps and are not taken care of properly, mosquitoes, rodents and small animals scatter, ruminate and spreads the refuse, which makes the city an eyesore and can propagate easy outbreak of diseases like cholera.

Table 4.19: Method of Solid Waste Disposal

Method of solid waste disposal	Frequency	Percent (%)
Open space	97	45.5
Waste management	73	34.3
Burning/incinerating	29	13.6
Stream/drainage channel	14	6.6
Total	213	100.0

Condition of Street Road	Frequency	Percent (%)
Tarred	58	27.2
Not tarred	91	42.7
Tarred with potholes	64	30.0
Total	213	100.0

Fig 5: Condition of Access Roads in the Study Area

The findings revealed that Ogbomosho is an urban area in transit, that is, it is still a developing urban area. The reason is because Ogbomosho still possesses some rural area characteristics, the qualitative housing problem in Ogbomosho is a housing problem that is peculiar to houses in rural areas. The main problems of the houses include the lack of quality drainages by most houses in the area, lack of environmental facilities and poor environmental conditions of the housing environments. The government is also inactive when it comes to evaluating housing problems in Ogbomosho, most of the houses that are rented by the occupants are owned by the informal sector and aside the Government Reserve Areas (G.R.As), there are no housing estates in Ogbomosho. The study therefore, underscores the need for the overall improvement of housing environments in Ogbomosho and the provision of environment facilities like the waste disposal facilities in housing environments. It also highlights the importance of government participation in the improvement of housing quality in Ogbomosho.

RECOMMENDATIONS AND CONCLUSION

Based on the major findings in the study, the following recommendations are put toward as policy guidelines toward a sustainable management of the area of study. These include the development and upgrading program through rehabilitation/renovation approach as well as provision of urban basic services. This simply involves rejuvenation of the area by retaining some structures that are retainable; rehabilitate old buildings and structures, upgrading the roads that are not tarred and introduction of more roads. It also involves improving the existing infrastructures as well as providing new ones. These are improving the structural quality and aesthetic of the area. The issue of economic revitalization of the area will leads to the generation of employment opportunities. This will help to improve the level of capital base and potential for capital formation among the residents that will enhance their level of provision for basic household facilities and proper maintenance of buildings. This approach offers future proceed that can sustain any improvement effort that may be put in place to revive the area. Similar to this is the use of effective public enlightenment strategies to affect public awareness and community participation in area of personal hygiene and need for improving sanitary condition in the area. According to Owoeye (2013), an enforcement of environmental sanitation laws on citizens has a little prospect of success without an enlightened public. The starting point therefore is to educate the people on the dangers of poor sanitation on their health and the need for an improved healthy environment.

Beside all these, sanitary services in the areas need urgent attention, particularly water supply and waste disposal facilities. However, mini-water-works or boreholes and public toilets in strategic places in the area are recommended under urban basic service program. Also, the efforts of the Waste Management Authority should be well supported through adequate funding so that facilities for effective services to more areas can be enhanced. In the light of this, Local Government Authority should be called to their primary responsibility to ensure regular collection of refuse in these areas. Meanwhile, the reintroduction of old sanitary inspectors, called *'Wolewole'* would be needed to reawaken the unconcerned attitude of the residents towards sanitary laws and regulations. Inspections should be made without prior notice so that the people can always prepare to keep their surroundings clean at all times. Efforts should be made as well to ensure punitive measure on any culprit who violates such orders.

The study revealed the presence of low income earners, substandard buildings, different forms of housing development and inadequate facility and poor environmental management in the study area. It is therefore necessary for a vital agency(s) be assigned the responsibility of creating and implementing a comprehensive, coordinated housing program for

Ogbomosho town. It is difficult to specifically define the activities and elements of the program because of availability and funding uncertainties. However, the program should include rehabilitation grant and low interest loan program should be established in Ogbomosho. This program should be similar with the federal program that provides grants to individual for the development of dwelling units. An intensive code enforcement program requiring strict compliance with housing, building and other codes should be established for areas in Ogbomosho which are in need of this type of action. A capital improvement program should be initiated including a complete inventory of condition of existing facilities and the creation of plans and cost estimates for implementation. Those needed improvement should be programmed to provide the study areas with facilities and services at the earliest possible date. Government should make purchase of essential building materials in bulk for the distribution to members. This could be subsidized by government funding. Finally, there should be re-orientation of people for new construction towards a home improvement scheme for the rehabilitation of the existing housing stock.

ABSTRACT

Student housing has been a major area of concern with increasing student population as a result of increasing demand for higher education over the years. The rise in student population has led to various problems in student housing which range from inadequate infrastructural facilities to overcrowding, has indeed met with renewed interest in sourcing and reaching the best practicable approach towards the enablement and efficient, conducive academic driven environment. This research assesses the student housing condition in Federal University of Technology, Akure, Ondo State, Nigeria. A total number of 152 questionnaires were administered and data collected was presented through the use of tables, graphs, and photographs. The study reveals that there is a high level of dissatisfaction with the state of available student housing facilities. The inadequacy of the existing housing facilities which has created high occupancy ratio which has invariably led to over utilization of the available resources putting the facilities in deplorable conditions. It is therefore recommended that the existing housing facilities need to be rehabilitated. In addition, more hostels should be built in order to meet the student bed-space population of two persons per room.

Keywords: Academic, Environment, Housing, Student, University

INTRODUCTION

Housing is often regarded as one of the basic human needs. It ranks third, after food and clothing. It is a pre-requisite for the survival of man (Onibokun, 1999). The importance of housing covers the entire aspect of human life. It involves physical protection from hazards which ordinarily may be regarded as shelter but also provides the setting for many of the biological and social processes necessary to sustain life, which permits the healthy growth and development of the mind. According to Aluko (2009), housing as a unit of the environment of man, has a profound influence on the health, social behavior, satisfaction and general welfare of the community. It reflects the cultural, social and economic values of a society as it is the best physical and historical evidence of civilization in a country.

Students' housing is a major form of accommodation for university students who are in a transitory stage of life. Akpan (2000) states that, student hostel has for long been thought of as a vital component of university campuses, further explains its necessity by reporting that a well-planned out housing facilities promote desirable educational outcomes and helps to achieve the broader objectives such as social cohesion and responsible citizenship. Objectives of Universities worldwide have been realized through development of facilities and infrastructure made towards housing (Hassanain, 2007).

Student housing has been a major area of concern due to increase in students' population as a result of increasing demand for higher institution of learning and this had made the issue of students housing a major area of concern. This rise in population had led to various problematic conditions of student housing. This ranges from inadequate infrastructural facilities to overcrowding. The basic infrastructural facilities needed by students include toilets, water, electricity, reading rooms, canteen, buttery, kitchenettes and recreation area among others. These facilities are expected in good working order but in contrary, they are either unavailable or in a state of disrepair.

Rotowa, O. O.; Akinbode, T. & Gabriel, E. (2016). Environmental Assessment of Students Hostels in Federal University of Technology, Akure, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1315-1324

Nigeria has the biggest university system in sub-Saharan Africa with 114 accredited tertiary institutions and more than 50% of these facilities have over 20,000 students each (Okoh 2004). Nigerian universities have experienced a significant rise in student enrolments over the past decades. However, the surge in the number of students has not been matched by a corresponding growth in student accommodation and the available ones have not been properly managed. Figures from the National Universities Commission show that the provision of student housing is less than 30% of demand. The vast majority of students live in privately rented accommodation.

The bulk of "first generation" Universities in Nigeria have stopped funding student accommodation. Many of the newer universities have taken the private sector participation route, although the quality of accommodation varies widely. The student enrolment in tertiary institutions is growing at an average of 12% per annum and the provision of new purpose-built student housing is limited. This in itself creates opportunities for the development of student housing in many cities in Nigeria (Ubong, 2001).

It is obvious from the scarcity of literature on hostel accommodation for students in tertiary educational institutions in Nigeria that not much attention has been given to the problem in the past in spite of its enormity and sensitivity. Ubong (2001), had observed that hostel accommodation has not been receiving adequate attention in Nigeria Institutions, although it is an important component of pupil personnel management. This might be due to the national indifference arising from the people being used to general poor performance of social services.

In 2003, Hostel accommodation in Tertiary institutions in Nigeria became a topical issue following the decision of the Federal Government to increase hostel fees from the rate of N90.00 (less than$1.00) per session to N10,000.00 (about$73.43 at an exchange rate of N140.00 to $1.00). This announcement led to wide spread demonstration by students in Tertiary Institutions in Nigeria. Though the Federal Government eventually backed down, but many of the institutions have revised their rates upwards including the Federal University of Technology, Akure.

Regrettably, the institutions have over the years, not been able to keep the hostels even in minimum residential conditions because of lack of funds. According to Akpan (1998), the student population is increasing at a rapid rate, while the infrastructural amenities are declining in supply and their standard also depreciating. The facilities in Nigerian institutions (Hostels) are in deplorable conditions and are congested.

According to Okoh (2004), the complex problem of maintaining good hostels at 'near zero' charge to the users or charging realistic fees to enable the institutions maintain the hostels and risking violent demonstrations by students and possibly the Nigeria Labour Congress must have informed the directive by the Federal government to the tertiary institutions in 2004. The government directed that Tertiary Education Institutions must immediately withdraw from the management of students' hostels and hand them over to private operators who will determine the rent to charge to those who are willing to pay. The rational is that if the charges are high, and the services are low, the students will challenge the operators rather than the Management of the institutions and the governments that own the institutions. The view of the Federal Government is that a private management arrangement will free the administrators from the problems associated with hostel accommodations while focusing on the management of other aspects of institutional life. The question therefore is, should the institutions continue to run the hostels at the current level of fees or should economic rates be charged, or alternatively, should hostels come under Federal Government's privatization arrangements?

The need for effective and conducive housing facilities in the Federal University of Technology, Akure, Nigeria cannot be overemphasized due to the fact that students are expected to be in a sound state of mind to excel in their academic endeavors which can be achieved by a good student housing system. Since student housing provides not only physical protection but also a healthy social and behavioral stability, the productivity of a set of students may not be totally unconnected with their housing condition.

Olawunmi, Akinjare & Oluwatoyin, (2012) affirm that adequate provision of students hall of residence within a university has notable advantages which include: reduction in the rate of vagabond, punctuality to classes as against having to come from outside the university campus, which most times, is prone to traffic congestion fostering perpetual lateness to school. The peace and tranquility derivable from a campus environment is also very important in an institution where adequate housing is being provided and students from various parts of the country can be attracted to because of infrastructural provision such as security, internet connectivity, functional public utility, constant power supply and portable water. This will ultimately increase human productivity in terms of output.

The objectives of the study are to assess the physical environment. The aim of this study is to assess the environmental sanitation, housing condition and user's satisfaction of student housing in the Federal University of Technology Akure, with a view to proffering solutions to the housing problems identified. In order to achieve this aim, the following objectives are formed. They are to: assess the physical environment of the hostels; examine the infrastructural facilities in the students hostels; identify the problems facing the students housing in Federal University of Technology, Akure; investigate the level of student's satisfaction of housing provided; and suggest possible strategies to solve the housing problems in the hostels.

Most large universities facilitate dormitories for its students. While a few mandate the students to live in dormitories, most keep it optional for the students to choose. As established by various studies, it is obvious that the benefits enjoyed by college and university students who reside on-campus housing are many and significant. Those who have lived in hostels provided by schools will appreciate the usefulness of the facility for students. In addition to convenience, these benefits include greater academic success and enhanced social/personal development. Some of these benefits are explained in details below.

In term of enhancement of reading and learning, living in the school hall of residence or hostel gives students an academic edge as it enhance the desire to read. There are fewer distractions. It is also easier to relate with colleagues who are close by or teachers where a student has a difficulty on a subject matter. In addition, students who reside in hostels have a greater chance of participating in sports, games, club, and social activities that are expected to make them more rounded individuals and citizens than those living off-campus who may find themselves forced into domestic activities once they are at home.

Students are more secure on campus than off-campus despite the presence of cult activities in higher educational institutions in Nigeria. Reasons being that institutions maintain security personnel on campus and do monitor the activities of students. Some private Universities lock their gates early and do insist on students obtaining exit permits before they travel home. Graduates from tertiary educational institutions are graduated based on satisfactory performance 'in character and in learning'. Moral training includes individual behavior in group situations as in hostels. All institutions have Codes of Conduct that guide and regulate student behavior in hostels.

It is one of the desires of the Federal Government of Nigeria to use education as a means of attaining national integration as stated in the 1998 National Policy on Education. Hostel accommodation is one of the ways though which this can be achieved as students from various parts of the country Reside together in the same hostel. Private relations in hostel rooms could blossom into live- time positive relationships that would be beneficial to both parties.

MATERIALS AND METHODS

Research Locale

The study was carried out at the Federal University of Technology, Akure, in Akure South Local Government Area of Ondo State, Nigeria. The University is one of the Federal Universities of Technology established by the Federal Government of Nigeria in 1981 in a quest for technological development. The Institution is located between latitude 07^{o} 16^{i} and 07^{o} 18^{i} N and longitudes 05^{o} 09^{i} and 05^{o} 11^{i} E. It lies along Akure-Ilesa expressway, with Awule and Ibule as the neighbouring villages.

The University as at present has a population of about 15,000 students, with the undergraduate students making up about 13,000 while the post-graduate is about two thousand (2,000) students. The School's undergraduate halls of residence have 1,923 bed spaces meaning they were built to accommodate 24% of the total undergraduate population (Student Affairs Division, 2014). The population of students in the undergraduate hostel is currently 1,923). The post graduate hostel on the other hand has 50 rooms and 90 bed spaces which means about 4.5% of the total population of post-graduate students can reside there.

The land use of Federal University of Technology, Akure can be classified into two broad types which are built up areas (developed) and the forest area (undeveloped). The forested area include all the vegetative areas of the University which include forestry and wood technology plantation/nursery site, teaching and research farms including livestock section, cocoa plantation, natural forest, farm lands and wildlife park/fish pond among others. The developed areas include academic area, administrative area, residential area, commercial area, communal facilities area including religious area, parking and sporting areas among others.

Database Description

The research made use of primary and secondary data. Oral interview was conducted with the student affairs officer, hostels hall warden, and questionnaires were administered to the students in various hostels after the recognizance survey of the students` hostel environment. The secondary data include documented information from textbooks, dissertations, theses, magazines, journals, maps and information from the net.

Table 1: Questionnaire Distribution for Respondents

Hostel/Stratum	Category	Bed Space	No. of Rooms	8% Sample Frame Per Hostel	Sampling Interval
Akindeko	Male	630	157	50	3
Abiola	Male	315	78	25	3
Adeniyi	Male	188	47	15	3
Jibowu	Female	330	82	26	3
Annexes 1,2,3	Female	240	60	19	3
Jadesola	Female	220	54	17	3
Total		1,923	478	152	

The research population comprises all students in the Undergraduate hall of residence in

Federal University of Technology Akure. The hall of residence in the study area has a population of 1,923 undergraduate students and this form the research population. Aluko (2011) in his research on student hall of residence in the University of Lagos made use of a sample size of 3% per hostel. On the basis of this, this research made use of 8% sample size. It is believed that this sample size is more manageable and evenly represented. 8% percent of students in the selected hostels were interviewed at a fixed interval of three (3).

Stratified sampling technique was employed for this research. Each selected hostel represents a stratum. A random sample is taken from each stratum in a number proportional to the stratum's size when compared to the population.

RESULTS AND DISCUSSION

This research investigated the environmental sanitation, hostel condition and the user satisfaction level of undergraduate halls of residence in Federal University of Technology, Akure (FUTA). FUTA has seven (7) undergraduate halls of residence

Sex of Respondents

Earlier, it was reported that there were 1943 bed spaces provided by the university. Out of this, 58% were for males, while 42% were for females. This research in line with the above shows that 59% of the respondents were male, while 41% are female. This shows that we have more males in hostels than female. This is a reflection of the fact that there are more male hostels than that of the females in FUTA.

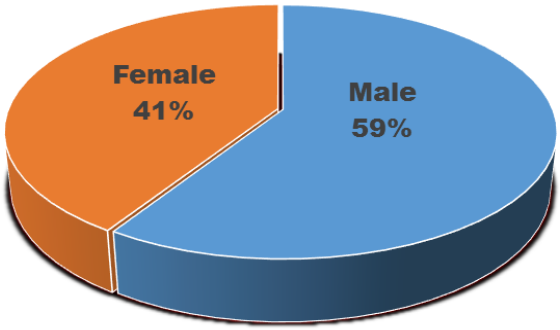

Figure 1: Percentage Rate of Male and Female

Toilet Facilities

The study carefully assessed the level of students' satisfaction with toilet facilities and the following findings were discovered; 65 percent of the students sampled were of the opinion that the toilet facilities were not satisfactory, 9 percent were indecisive, while the remaining 26 percent were of the opinion that the toilet facilities were satisfactory.

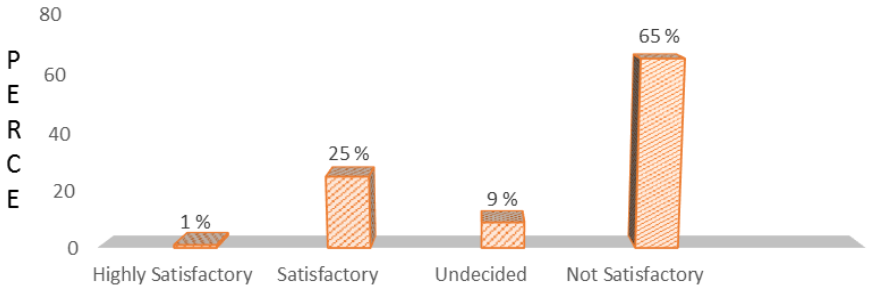

Figure 2: Level of Satisfaction with Toilet Facilities

Plate 1: Recently Used Toilet in Jadesola Hostel

Plate 1 shows the condition of toilet facilities in one of the hostels (Jadesola Hostel). It can be observed that the floor and the surrounding of the toilet is messy. This is not appropriate, which might be due to inadequate supply of water. There is the need for proper monitoring of toilet facilities and provision of toiletries in the student hostels.

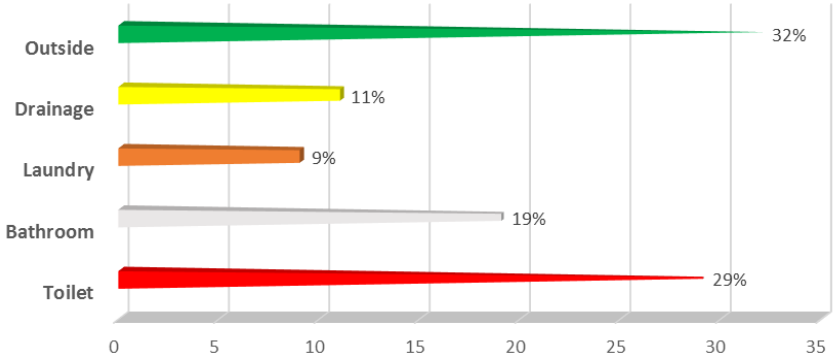

Fig 3 Locations Where Respondents Ease Themselves at Night

The research evaluated the various points where respondents ease themselves at night in the hall of residence and the following were identified. Figure 7 shows the frequency and percentage of each option. 29% of the respondents ease themselves in the toilet, 19% use the bathroom, 9% use the laundry, 32% ease themselves outside and 11% use the drainage. This depicts that more students go outside to ease themselves at night than using the toilet. The reason being that most of the toilet facilities are not well kept hence are in a very deplorable condition. Some of the students also complain about scarcity of water, this account for reasons why the toilets are easily soiled. Additionally, some of the toilets have been vandalized, such that they can no more control water and are blocked.

Bathrooms

The level of satisfaction of students with the bathroom facilities shows that 47 percent of the students interviewed agreed that the toilet facilities are satisfactory, while 48 percent states that the toilet facilities are not satisfactory, only 5percent were indecisive.

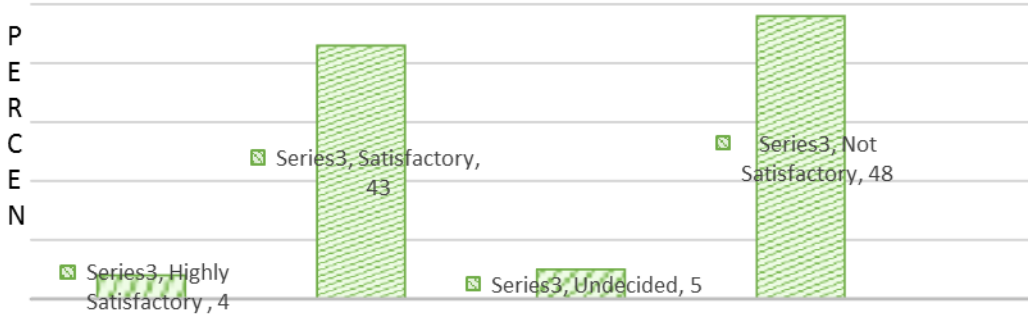

Fig 3: Level of Satisfaction with Bathroom Facilities:

Plate 2: Bathroom facility in Adeniyi Hostel

Solid wastes management

The level of satisfaction with the facilities provided for solid waste disposal was assessed and the result shows that 39 percent of the sampled students agreed to the fact that the facilities provided for solid waste disposal was satisfactory, the same percentage (39 %) states otherwise while we have 10 percent respondents who were indecisive.

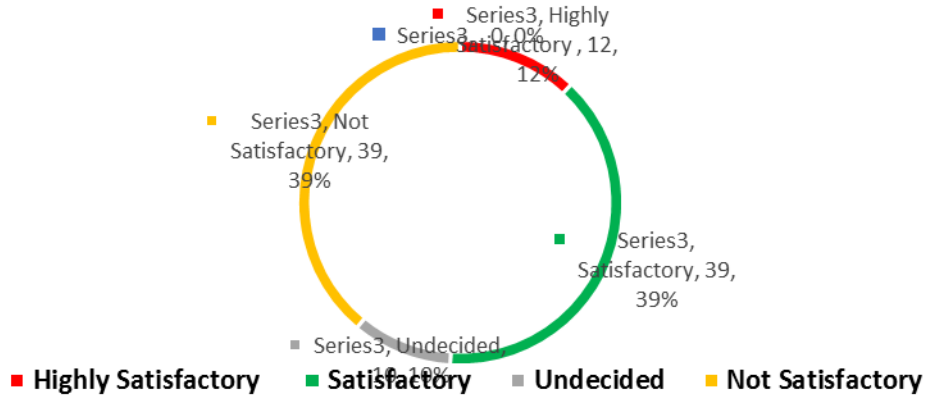

Fig 4: Level of Satisfaction with Facilities Provided for Solid Waste Disposal

The research also finds out the percentage of rooms with waste paper basket (dustbin). Findings show that 67% percent of the respondents have dust bins to their room while only 33% of the respondents are without dustbin in their room.

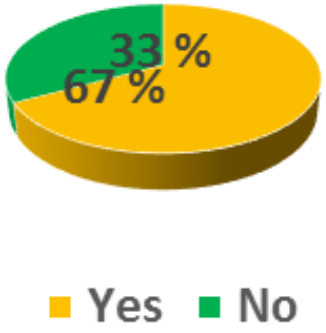

Fig 6: Availability of Dustbins in Hostel Rooms

Plate 3: Overflowing Dustbin in Jadesola Hostel

Laundry facilities

Respondents satisfaction on laundry facilities shows that 53% of the respondents are satisfied the laundry facilities while 10 % were indecisive and 37% were not satisfied with the laundry facilities.

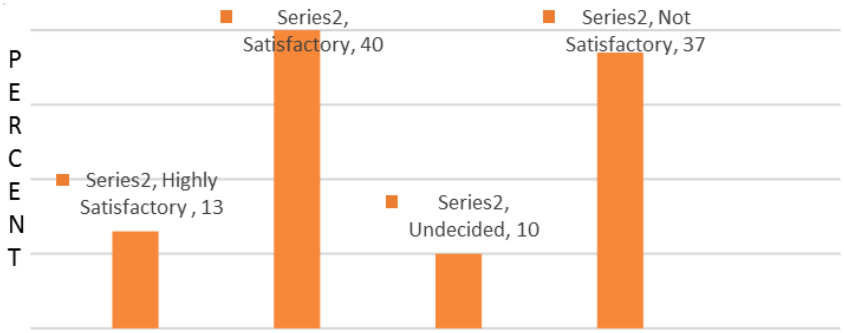

Fig 5: Level of satisfaction with Laundry Facilities

Table 2: Frequency and percentage of responses on utilities

S/No.	Facilities	Assessment	Frequency	Percentage (%)
1	Electricity	Highly Satisfactory	42	28
		Satisfactory	62	45
		Undecided	00	00
		Not Satisfactory	41	27
2	Water Supply	Highly Satisfactory	18	12
		Satisfactory	53	35
		Undecided	6	4
		Not Satisfactory	75	49
3	Water quality	Highly Satisfactory	7	5
		Satisfactory	34	22
		Undecided	25	16
		Not Satisfactory	86	61
4	Security	Highly Satisfactory	20	13
		Satisfactory	42	28
		Undecided	20	13
		Not Satisfactory	69	46

Electricity

Some utilities within the University hostels were assessed to determine their level of satisfaction. Table 2: explains the respondent's satisfaction about each of the facilities assessed. Electricity within the university is provided by Benin Electricity Distribution Company and Generating set maintained by the university. It was discovered that when there were no electricity, the university do provide it at crucial hours of study. These are between 8am and 4pm and between 8pm and 10pm, In terms of electricity supply, 73 % of the respondents were satisfied with the number of hours they have access to electricity per

day while only 27 percent of the respondent were not satisfied with the situation of electricity supply in the hostels.

Water supply

Water is very Germane to human existence, the water supply within the Federal University of Technology, Akure is through the Bore-hole maintained by the institution. It was discovered that in periods when there were no electricity, water scarcity do occur. 49% of the respondents were of the opinion that the frequency of water supply in the University hostels were not satisfactory whereas, 47% agreed that the frequency of water supply is satisfactory. The study further revealed that 27% of the students agreed that the water supplied in the hotel is drinkable and satisfactory. Contrariwise, 61% of the respondents were of the opinion that the water supplied in the hostels are not drinkable. The reason adduced to this was that the water is tasty and sometimes turbid.

Security

Security in the university hostels are provided by the staff of the university from the security section. This outfit is run specifically as a civil service outfit, hence most of them were not ex-service personnels. The opinion of the 46% of the students was that they were not satisfied with the performance of the security personnel. The reason been that they are nonchalant about their work. On the other hand, the study reveals that 28% were satisfied with the performance of the security personnels, while 13% were highly satisfied.

CONCLUSION AND RECOMMENDATIONS

The findings of this research show that there is need for the following recommendations;

i. There is need for the rehabilitation of the existing toilets and baths. There is need for increase in the frequency of water and electricity supply, cleaning of the hostels both in and outside the surrounding environment.
ii. It is recommended that the management should build more hostels in the institution in other to meet up with the increasing number of students being admitted yearly by the institution.
iii. It is suggested that the management of the hostels should be left in the hands of a private manager as it is believed that closer attention towards the management of the hostels would be ensured.
iv. It is necessary to introduce an effective internal evaluation system in order to build a feedback mechanism by which the state of facilities and their performance can be monitored periodically. It is believed that this will ensure a high level of users' satisfaction.
v. The management should make sure toilets and bathrooms including bedrooms are disinfected regularly, to prevent/reduce the outbreak of bedbug, mosquitos, cockroach etc.
vi. The university should encourage equity participation with private investors to site private hostels at affordable prices within the school premises. Under such arrangement, a proportion of their annual profit would be collected for the development of the instituttion.
vii. In conclusion the school management need to pay a closer attention to the welfare of students in the institutions hostels as it would affect their performance in school as well as other aspects of their lives.

ABSTRACT

The study identifies and assesses the environmental impact of shoreline changes and coastal flooding on Victoria Island in Eti-Osa Local Government Area of Lagos State, Nigeria. This was with a view to suggesting an integrated strategy and management plan for sustainable environment in the study area. Structured questionnaires were administered specifically in Victoria Island where flood hazard was prominent. There were 3248 buildings in the study area which constitute the research population. The sample size of 10% was adopted; hence 325 copies of questionnaires were administered for the study. The study adopts Geographical Information System (GIS) to examine flood hazard and shoreline changes in the study area. Digital Elevation Model (DEM) and slope map was generated from the topographical map of the study area. Topographical map of 1962 was used as the base map; Landsat TM of 1984, ETM+ 2000 and 2011 of Eti-Osa was used while all geo-processing operations and analyses were carried out in ILWIS 3.1 and ArcGIS 9.3. Findings show that, narrow drainages coupled with high rainfall in the study area are the major causes of flooding. DEM map shows that the study area is between 0-33.33m, while the slope map shows the Elevation range, revealed that about 90% of the study area were between the heights of about 0-16.667m. The results also reveal that between 1962 and 1984 there was loss in landmass while between 1984 and 2011 there was increase in land gain overtime. The study recommended construction of standard paved surface and drainages, law enforcement on waste disposal, integrated approach to flood management and control.

Keywords: Coastal flooding, DEM, GIS, Shoreline, Victoria Island

INTRODUCTION

Current research in Environmental Science has linked flooding with Global Warming effect. Global warming can be described as the greatest threat facing humanity, evidence of climate change impacts is strong and most comprehensive for natural systems. Some impacts on human systems have also been attributed to climate change, with a major or minor contribution of climate change distinguishable from other influence, the weather has been unpredictable; seasons have been shifting, fairly unpredictably (Ayo, 2009). The effect of global warming include: the melting of the polar ice and glaciers, warming of the oceans which expands the ocean volume and raises sea level, consequently floods the coastal regions, and even entire islands. Coastal erosion and shoreline changes are two consequences of sea level rise and coastal hazards working separately or together. Loss of land, including important tidal marshes, is due partly to active erosion of the shoreline and partly to passive submergence caused by the natural component of relative sea level rise. Sea level rise makes coastal areas even more susceptible to hazards such as flooding, wave inundation, or erosion from storms, hurricanes, and tsunamis. Consideration of sea level rise impacts is one of the many adaptation planning measures to protect life and property. Sea level rise affects the erosion zone by moving the shoreline inland. Proper shoreline change analysis requires a thorough understanding of the coastal processes that cause the change as well as coastal mapping methods (Intergovernmental Panel on Climate Change, IPCC, 2007).

Coastal flooding is generally caused by a combination of high water levels, which may be caused by tides and storm surges, together with waves, which can lead to overtopping of coastal defenses and inundation of low-lying areas, potentially causing damage to life and

Oyinloye, M. A. & Olanibi, J. A. (2016). Environmental Impact of Shoreline Changes and Coastal Flooding on Victoria Island in Eti-Osa Local Government Area, Lagos, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1325-1341

property. Waves and storm surges are caused by storm events with high winds blowing over the adjacent sea. In some areas such as deltas and estuaries, precipitation and river flow may also contribute to coastal flooding. Tsunamis, caused by undersea earthquakes, landslides, volcanic eruptions and meteorites can also be important in causing coastal flooding in some areas of the world, notably the islands (Adegbasa and Ige Olumide 2012). Coastal flooding causes salt water to inundate the soils and impregnate them with soluble salts, thereby rendering the soils and subsoil water saline. Salinity causes unfavorable environment and hydrological situation that restricts normal crop production. In general, soil salinity is believed to be mainly responsible for low land use as well as crop intensity (Rahaman and Ahsan, 2001).

Coastal Flooding has been examined as one of the phenomena that are threatening human race and physical environment. The recent occurrences of flooding in Nigeria such as Sokoto flood in 2010, Ibadan flood in 2011, Lagos flood in 2011, and most parts of the country in 2012 had shown that flooding is one of the major environmental problems faced in Nigeria. Floods in Nigeria occur in three main forms, viz; coastal flooding, river flooding and urban flooding (Ologunorisa, 2004). Offiong, Atu, Njar Amuyou (2008) pointed out that, flood hazards occur basically in two distinct areas: coastal areas and areas bisected by rivers (water-fronts). In the coastal area, flooding may be caused by volume of water within the body of water, for example in case of river or a lake which overflows or breaks levees and water escapes its usual boundary. This is a correlate of body/volume of water with seasonal changes (Henson, 2010). In the study area, the bar beach suffers ocean surges, often resulting in; disruption of communication, structural damages to buildings and loss of lives. The high rate of urbanization in the area also means a high rate of housing construction and encroaching on open spaces and wetlands. The generally low lying terrain, coastal influences on its micro-climate, heavy precipitation, blockage of drainage, all coalesce to exacerbate coastal flooding in Victoria Island in Eti-Osa Local Government Area. The study is therefore designed to assess the environmental impact of shoreline changes and coastal flooding on Victoria Island in Eti-Osa Local Government Area, Lagos State using remotely sensed data, with a view to ensuring sustainable living environment. The objectives are therefore to:

i. identify factors responsible for coastal flooding in the study area
ii. examine the effect of coastal flooding on the physical, social and economic status of Victoria Island in Eti-Osa Local Government Area; and
iii. assess the extent of coastal flooding and shoreline changes in the study area using remotely sensed data.

REVIEW OF EMPIRICAL LITERATURE

The term coastal and water front community refer to the settlements which are built along the seacoast, estuaries, mangrove, swamps, lakeshore, and riverbeds and in most cases extended right above the surface waters (Intergovernmental Panel on Climate Change, IPCC, 2007). Coastal flooding occurs when normally dry low-lying land is flooded by sea water. Flooding always occurs in coastal areas, high tides or storms cause the water level to rise, if the water level is higher than the level of the coastal lowland, flooding will occur. The extent of coastal flooding is a function of the elevation inland flood waters penetrate which is controlled by the topography of the coastal land exposed to flooding. Coastal flooding can result from a variety of different causes including storm surges created by storms like hurricanes and tropical cyclones, rising sea-level due to climate change and tsunamis (Doorkamp, 1998). Storm surges are main cause of coastal flooding. The biggest floods occur when larger than normal tides (‘king tides’) and storm surges occur at the same time caused by forces generated from a severe storm's wind, waves, and low atmospheric pressure. Storm surges are extremely

dangerous, because they are capable of flooding large coastal areas. Sea level rise is a relatively slow process, connected to Climate Change, which may increase the frequency and severity of storms, bringing unusually high tides, and changes in winds, waves and currents. Sea level rise may also increase the severity of tsunami. In some low lying areas, stop banks have been erected to protect against coastal flooding. However, many of these have not been designed to be effective against a significant change in sea level. Tsunami is giant waves that can flood coastal areas. They can occur after earthquakes, volcanic eruptions, and deep sea landslides. Coastal flooding can also threaten lifeline services such as water, power, telecommunication and transportation networks.

Shoreline changes generally are the intersection of the land with the water surface (NOAA, 2000), For marine and coastal applications, base elevations typically refer to local tidal datum that are defined in terms of specific tidal phases (NOAA, 2000). Calculated as the average or mean of a specified tidal height, tidal datum vary locally in response to local topographic and hydrographic characteristics such as the geometry of the landmass, the depth of near shore waters, and the distance of a location from the open ocean

Shoreline change, which refers to the gradual movement of shorelines and dune features in a landward direction, though not necessarily with any decrease in size or perceptible erosion. The causes of shoreline change are both natural and human-induced. Many factors caused shoreline changes on the beaches. The most important factors according to Trembanis and Pilkey (1998) that caused these changes are: Human activities; lack of sand deposits in the nears shore area; increase in tropical storm occurrence in the vicinity of the island; local wave regimes; flood events of all magnitudes and frequencies; and the presence of submarine canyons. Coastal erosion due to sea level rise along the shoreline is becoming especially in developing countries such as Nigeria.

Several studies have been conducted on the adverse effects of coastal flooding and shoreline changes in both developed and developing countries. Trembanis and Pilkey (1998) prepared a summary of identifiable beach nourishment projects in the Gulf Coast region that had been conducted before 1996. These records were used to identify shoreline segments that had been influenced by beach nourishment. Beaches along the west coast of Florida are some of the most frequently nourished beaches in the U.S. The frequent nourishment is reflected in the slow rates of shoreline retreat or stability, even though the natural rates of erosion may be higher (Trembanis and Pilkey 1998). Bilan (1993) reported that the erosion rate in the northern part of Jiangsu Province in China is serious and as high as 85 metres/year; in Hangzhou Bay the rate is 40 metres/year, while in Tianjin it is 16–56 metres/year. Erosion persists even where preventive measures such as sea dykes are constructed. Beach scour has been found along coasts with sea-dyke protection. This erosion is attributable to many factors such as river damming and diversion, that leads to less sediment supply to the coast, and the clearing of mangrove forests, which makes coastal areas more susceptible to the hazard.

Fan, Guo, Wang and Shi (2006) analysed cross-shore variations in the morphodynamic processes of an open coast mudflat in Changjiang Delta, where waves play a dominant role in shaping the tidal-flat profile during typhoons. Each year, roughly seven out of 16 typhoons directly strike China's coast with a 95 percent probability of hitting southwards and the coast of the Chanjiang Delta; they generate waves up to 6.2 metres in height. One-third of the mudflat is colonized by *Spartina alterniflora*, followed by scirpus (*Scirpus mariquete* and *Scirpus triquiter*), and then gradually transits into a less-vegetated pioneer zone behind the bar mudflat. In Thailand, intensification of coastal erosion came to notice during the past decade (Thampanya *et al.*, 2006). Overall, the net erosion is approximately 1.3 to 1.7 metres/year along the southern Thailand coastline. Total area losses amount to 0.91 square

kilometres/year for the Gulf coast and 0.25 square kilometres/year for the western coast. Most of the eroded areas increase with larger areas of shrimp farms, less mangrove forest area, and when dams reduce riverine inputs and coastal land subsidence transpires. In areas where erosion has prevailed, the presence of mangroves has reduced erosion rates.

In Indonesia, coastal erosion started in the northern coast of Java Island in the 1970s when most of the mangrove forest had been converted to shrimp ponds and other aquaculture activities, and the area was also subjected to unmanaged coastal development, diversion of upland freshwater and river damming. Coastal erosion is prevalent throughout many provinces (Bird and Ongkosongo, 1980; Syamsudin *et al.*, 2000; Tjardana, 1995) such as Lampung, Northeast Sumatra, Kalimantan, West Sumatra (Padang), Nusa Tenggara, Papua, South Sulawesi (Nurkin, 1994).The rapid erosion of the coast of Sagar Island in West Bengal, India, is caused by several processes that act in concert; these are natural processes that occur frequently (cyclones, waves and tides that can reach six metres in height) and anthropogenic activities such as human settlement and aquaculture that remove mangroves and other coastal vegetation. The erosion rate from 1996 to 1999 was calculated to be 5.47 square kilometres/year (Gopinath and Seralathan, 2005). The areas that are severely affected by erosion are the northeastern, southwestern and southeastern faces of the island. Malini (2004) reported coastal erosion and habitat loss along the Godavari Delta front owing to the combination of the dam construction across the Godavari and its tributaries that diminish sediment supply to the coast and continued coastal land subsidence. According to Othman (1994), nearly 30 percent of the Malaysian coastline is undergoing erosion.

Many of these areas are coastal mudflats, fringed by mangroves. Behind the mangroves there are usually agricultural fields protected from tidal inundation by bunds (dykes). Locally, mangroves are known to reduce wave energy as waves travel through them; thus, the Department of Irrigation and Drainage has ruled that at least 200 metres of mangrove belts must be kept between the bunds and the sea to protect the bunds from eroding. Sri Lanka's experience with coastal erosion dates back to 1920 (Swan, 1974). It has become more serious because mangroves are being eradicated by encroachment (human settlement), fuelwood cutting and the clearing of coastal areas for intensive shrimp culture. Mangrove forest cover was estimated to be approximately 12 000 hectares in 1986; this dwindled to 8 687 hectares in 1993 and was estimated to be only 6 000 hectares in 2000 (Samrayangke, 2003).

Approximately US$30 million has already been spent on breakwaters and other construction to combat coastal erosion on southern and western coasts (UNEP, 2006); however, coastal erosion still persists in some coastal areas. Mazda *et al.* (2002) also analysed coastal erosion caused by tidal forces at Loang Hoa, South Viet Nam, which is located in a wide, flat alluvial fan and lies between two major tidal rivers – the Mui Nai River and the Nga Bay River. Based on field and numerical studies, they found that degradation of mangroves along the tidal rivers led to intensification of tidal currents at the mouths of the rivers and erosion on the coast. This study reached the same conclusion as a study carried out by Wu, Falconer and Struve (2001) for Merbok Estuary, Malaysia. Coastal erosion and shoreline changes are natural processes; however, they may become a problem when exacerbated by human activities or natural disasters. They are widespread in the coastal zone of Asia and other countries in the Indian Ocean owing to a combination of various natural forces, population growth and unmanaged economic development along the coast, within river catchments and offshore. This has led to major efforts to manage the situation and to restore the ability of the coast to accommodate short- and long-term changes induced by human activities, extreme events and sea-level rise (Olanibi, 2014)

Many researchers have used Geographical Information System (GIS) in monitoring Shoreline changes and in the management of flood. Okude and Taiwo (2006) carried out an investigation on the Lagos shoreline change pattern using Geographical Information System; their study showed that, there is varying annual loss of land to coastal erosion and the attendant environmental and socio-economic implications of the changes. Oyedepo and Adeofun (2012) also carried out a research on environmental sensitivity index mapping of Lagos shorelines and concluded that animal biodiversities such as shorebirds, sea turtles, white crabs and other important biodiversities are more prominent on the western shores, therefore, there is a great need to protect the coastal environment from environmental hazards such as flooding and shoreline changes

Olamiju (2009) carried out a research on the application of Geographical Information System in Disaster Management on Ala river flood plain in Akure. He concluded that the major disaster in the flood plain is flooding and the causes were identified, that buildings are too closed to the river, poor refuse disposal practice, and construction of buildings by non-professionals among others and that most of the buildings in the floodplain did not secure approval before construction. Also Oyinloye and Olamiju (2011), carried out a research on Flood risk mapping and vulnerability analysis using GIS: empirical evidences from New Town area, Ondo, Ondo State, Nigeria; They concluded that, flood plains and river corridors have been misused resulting into severe environmental hazards; Eludoyin, Obafemi, and Oduore (2013), carried out a research on the Comparative Analysis of Shoreline Changes of Bonny and Andoni Islands, Nigeria using Remote Sensing and Geographic Information System. The results of their analysis revealed that the percentage loss of land due to sea level increase overtime as a result of erosion by wind which propelled ocean waves that hit the shores forcefully, which may also account for coastline erosion and influences sea-level rise. Ologunorisa and Abawua (2005), reviewed some techniques of flood risk assessment such as meteorological, hydrological, hydrometereological, socio-economic and those based on Geographic Information System (GIS) technique, using some case study from different countries of the world. They concluded that GIS technique appears to be most promising as it is capable of integrating all the other techniques of flood risk assessment.

MATERIALS AND METHODS

Research Locale

Lagos State lies specifically on Latitude 6˚27´11″ N and Longitude 3˚23´45″E. It lies in the South-Western Nigeria on the Atlantic coast in the gulf of Guinea, as shown in figure 1 and 2. Lagos State has a population of about 7,937,932 (NPC, 2006).

Eti-osa is one of the 16 local government areas in Lagos State as shown in figure 3 which has a population of about 283,791 (NPC, 2006). Figure 4 shows Victoria Island (the study area), which is one of the notable areas in Eti-osa Local Government. The location is governed by the general circulatory patterns in the tropical equatorial areas, which is associated with the apparent movement of the sun and the relative position of the Inter tropical Discontinuity (ITD), the front between the prevailing two air masses (the maritime South -West monsoon winds and the dry North-East winds from the continental origin). The climate is therefore, determined largely by the influence of these two air masses; the South-West monsoon winds and the North-East winds. The former are due to the hot and humid tropical maritime air mass blowing from the Atlantic Ocean, while the latter are due to the warm and dry air mass from the Sahara Desert, in the North.

The rainfall pattern in the study area can be explained in terms of the movement of the ITCZ. This movement explains the observed double rainfall maxima which characterizes the study

area. The apparent movement of the sun over the equator twice in a year is responsible for the occasional and localized rainfalls that are experienced over the area throughout the year. Table 1 shows the average monthly rainfall is about 151.83mm, with a high percentage of falling between the months of April and October. During the rainy season, the lowest monthly rainfall is December, while the highest monthly rainfall is June, July, September and October.

Table 1: Average monthly rainfall pattern in the study area over 1990-2010

Month	Jan	Feb	Mar	Apr	May	Jun	Jul	Aug	Sep	Oct	Nov	Dec
Rainfall (mm)	28	46	99	145	277	450	267	66	142	208	69	25

Source: Nigerian Meteorological Service (1990-2010)

The terrain of the study area is typical of that of most parts of North-Eastern part of Lagos State. The entire area has "light" surface in terms of degree of roughness of terrain and slopes. The terrain could be described as almost flat. However, there are patches of elevated areas and depressions. The geological history accounts for the almost flat terrain, where most land areas are between 18 and 25 meters above the sea level. Victoria Island and the entire axis are surrounded by Atlantic Ocean. Expectedly, the areas drained by the various water bodies are low lying. The water bodies are key ecological elements in the area, with great impacts on temperature and humidity. The mass of water around the town is believed to have also influenced the pattern of growth on Victoria Island and the adjoining development Water Bodies.

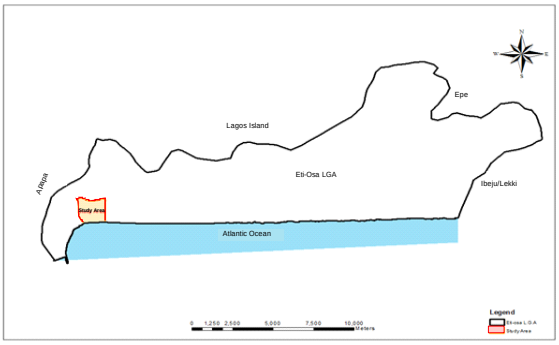

Figure 3: Map of Eti-Osa Local Government, Showing the Study Area

Figure 4: Map of Victoria Island, Eti osa Local Government)

Database Description

Data was collected through instrumentality of structured questionnaire to identify factors responsible for coastal floding as well as to examine the effect of coastal flooding on phsical, social and economic status of Victorial Island in Eti-Osa Local Government Area**.** The study area was divided into four (4) zones demarcated by major roads. Zone 1 has 799 buildings, zone 2 has 813, zone 3 has 749 and zone 4 has 887 buildings making totalof3248 buildings in the study area. However, in order to have reliable and manageable size, the sample size of 10% was considered. The justification for the use of 10% as sample size for this study was informed by many authors who believed of its reliability and efficacy in a research work. Casley and Lury (1991), opined that 10% sample size is considered reasonable for the purpose of a research work. Zone 1 has 799 buildings, zone 2 has 813, zone 3 has 749 and zone 4 has 887 buildings. 10% of the total buildings in each zone serve as the number of questionnaires administered in each zone. Three Hundred and twenty-five (325) samples were taken from all the four zones of the study area as shown in table 2.

Table 2: Questionnaires administered in each zone of the study area

ZONE	AREA (Hectares)	AREA (square/metres)	NO OF BUILDINGS	Questionnaires administered 10% of Building
A	55	550507.12	799	80
B	73	734400.04	813	81
C	65	653565.27	749	75
D	68	679382.51	887	89
Total	261	2617854.94	3248	325

The data acquisition also include topographical Map of Lagos State 1962 with the scale 1:50,000 produced by the Federal Survey Lagos served as the base map and collateral information with the satellite imageries used for the analysis of the shoreline changes. Landsat satellite imageries of Lagos shoreline (Eti-Osa) such as LANDSAT (Thematic

Mapper TM) and ETM (Enhance Thematic Mapper) at medium resolution was acquired for three Epochs; 1984, 2000 and 2011. The images were geometrically corrected and ground control points obtained through ground surveys permitted the co-registration of all images to a Universal Transverse Mercator (UTM). The satellite images were made to pass through process of image enhancement, geo reference, resampling, image classification and digitizing. A supervised classification was performed on false colour composites (band 4, 3 and 2) into built-up area, cultivation, dense vegetation, exposed soil, water body and wetland. All the questions were carefully analysed with GIS analysis to arrive at a desired results and conclusion.

RESULTS AND DISCUSSIONS

The results of the administered questionnaire and the GIS outputs are as presented below:

Socio-economic Traits of the Respondents

The age structure shows that, 16.6% of the respondents were 35 years, 37.2% falls within the ages of 36-45 years and 46.2% were 46 years and above. This shows that majority of the respondents are adults between the age of 36 -45 years and 46 years and above. This implies that majority of the respondents are likely to bear the burden of coastal flooding menace. The children and the aged rely on these set of people for their livelihood. Any adverse effect of coastal flooding on this set of people will surely have backwash effects on the social and economic life of the general populace.

The level of education of majority of the inhabitants in the study area is high. 1.5% of the respondents are not educated, 16.9% attained the level of primary education, 32.9% secondary education and 48.6% attained the level of tertiary education. Critically looking at the level of education of the respondents, it is revealed that 48.6% of them attained the tertiary education level. This may be as a result of the fact that the study area is a civilized and urban area, where it is expected that most of the residents should be educated, as it is supported by Ogbe (2011) that, rural dwellers are deficient in knowledge than the urban dwellers. This shows that most of the residents in the study area are educated.

However, investigation shows that 1.5% of the respondents received below N20,000 monthly, 15.4% received between N20,000-N30,000, 35.4% received between N40,000-N50,000 while 47.7% received above N50,000 monthly. The level of monthly income of the respondents shows that majority of the respondent still live below one dollar per day as indicated by the United Nation and this may affect the people's standard of living, their ability to demand for standard housing and requirement for other service (Agbola, and Agunbiade,2007). The variation in the monthly income of the respondents revealed why some of the respondents could not invest huge amount of money in the construction of standard drainage system meant for this type of environment (coastal area), which can convey freely large volume of water and in turn militate against flooding of the environment.

Environmental Impact of Coastal flooding and shoreline changes on Buildings

Table 3 shows the distance of buildings from the flood plain. The study revealed that 5.8% of the sampled buildings fall between the distances of 20-50m from the flood plain while 94.2% of the buildings were above 50m away from the flood plain. This revealed that most of the buildings in the study area have set- backs above 50m from the flood plain. This may be as a result of the compliance of the building to stream set back standards, that the minimum distance between a building and a stream or other water body or a gorge shall be determined by the peculiar circumstance of each case, but shall not be less than 30metres in any case (Oduwole, 2005).

Table 3: Distance of Building to flood plain

Distance of Building to flood plain	Frequency	Percentage
between 20-50m	19	5.8
Above 50m	306	94.2
Total	325	100.0

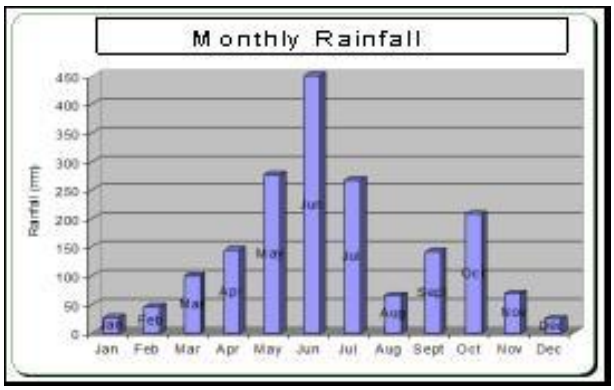

Figure 5: Average Monthly Rainfall Pattern in the study area over 1990-2010; Source: Nigerian Meteorological Service (1990-2010)

Figure 5 shows the pattern of rainfall in the study area. The average monthly rainfall in the study area is about 151.83mm, with a high percentage of its falling between the months of April and October. During these periods the effects of coastal flooding is very high in the study area. The reason for the high rainfall may be as a result of the proximity of this area to the sea, because, the impact of South-West Trade wind which brings rainfall to Nigeria is very high in this area. This wind blows across the Atlantic Ocean towards the coast of Nigeria, Lagos in particular. The implication of the above is that, areas closed to the Atlantic Ocean such as the study area will experience more rainfall than the area that is far from the coast.

Table 4 shows the condition of the drainage system in the study area. 0.6% of the respondents observed that there are well-drainage system in the study area, 24.9% observed it to be moderately drained, 67.4% observed the drainage system to be poor and narrow, while 7.1% observed that drainage system is absent. From the above, it was revealed that majority of the respondents claimed that most of the drainage systems in the study area are poor and narrow. This may be the reason for the incessant flooding in the study area, as poor and narrow drainages can lead to flooding resulting in property loss (Kolsky, 1998).

Table 4: Assessment of the drainage system in the study area

Assessment of the drainage system	Frequency	Percent
Standard-drainage	2	0.6
Moderately drained	81	24.9
Poor/ Narrow drainage	219	67.4
Absence of Drainage system	23	7.1
Total	325	100.0

Table 5 shows the critical investigation into the mode of waste disposal system of residents in the study area. It was revealed that 26.2% of the respondents claim that the mode of refuse disposal is dumping in the drainages, 8.9% claim that they rely on natural course of the river, 6.2% claim they rely on communal refuse dump site system while 58.8% observed that the disposal of waste through government agency. This implies that the major means of waste disposal in the study area is through government agency. Despite waste can be disposed through government agency, some of the residents especially the illegal occupants of the sand

filled part of the sea in the study area still dispose their wastes indiscriminate along water ways, impeding the free flow of water as seen in figure 6.

Table 5: Type of refuse disposal system

Type of refuse disposal system	Frequency	Percent
Disposal of waste in drainages	85	26.2
Disposal of waste along natural course of rivers	29	8.9
Disposal of waste in refuse dump site	20	6.2
Disposal of waste through government agency	191	58.8
Total	325	100.0

Figure 6: Flooded Plain due to refuse disposal beside the Ocean in Eti-osa

Table 6 shows the major causes of coaster flooding in the study area. The table revealed that, 7.1% of the respondents observed that lack of drainage facilities is the major cause of flooding, 34.2% attributed the major cause to block and narrow drainages, 9.5% observed the major cause as a result of building close to river flood plain while 48.6% attributed the major cause of flooding in the study area as result of heavy rainfall. From Table 6, it was discovered that the major causes of coaster flooding in the study area are blocked/narrow drainages and heavy rainfall. This may be as a result of narrow constructed drainages which cannot support the large volume of water flow during heavy rain fall resulting to the overflow of water from the drains thereby flooding the streets, roads and buildings in the study area. Example of this is seen in figure7 along Bishop Oluwole Street in the study area.

Table 6: Major causes of flooding in the study area

Major causes of Flooding	Frequency	Percentage
lack of drainage facilities	23	7.1
blocked/narrow drainages	111	34.2
buildings close to river flood plain	31	9.5
heavy rainfall	158	48.6
high paved surface	2	0.6
Total	325	100.0

Figure 7: Poor drainage in off Bishop Oluwole Street, Victoria Island in Etio-osa

Table 7 shows the impacts of Coastal flooding on the buildings in the study area. It was revealed that 17% of the respondents said the impact of flooding is causing damage and deterioration to buildings, 16% viewed it as causing deterioration of environmental infrastructure ,2% viewed it as carrying away of building, 11% claimed that it results to homelessness, 9% claimed that it results to dirty environment, 14% claimed that it results to Soaking and making water mark on the wall of the building while 15% viewed that it causes prevalence of malaria and diseases and 16 % of the respondents claimed that flooding obstruct movement and economic activities. The implication of this is that, damage and deterioration of buildings, deterioration of environmental infrastructure, continuous soaking and wetting of the wall of a building gradually weakens the wall and this may reduce the life span of the building and finally result to the unexpected collapse of the building. Obstruction of movement and economic activities may hinder mobility, break social ties, affect the business of the residents and may finally result to poverty. The prevalence malaria disease may result to incessant suffering from malaria diseases by the residents .This may be as a result of the fact that, the study area is closed to water body; as such area closed to water body cannot be devoid of stagnant water which serves as breeding ground for mosquitoes.

Table 7: Impacts of Coastal flooding on the Study area

Impacts of Coastal flooding	Frequency	Percentages
Damage and deterioration of buildings	56	17
Deterioration of environmental infrastructure	52	16
Carrying away of building by flood water	7	2
Result to homelessness	37	11
Result to dirty environment	30	9
Soaking / water mark on the wall of the building	44	14
Prevalence of malaria disease	48	15
Obstruction of movement and economic activities	51	16
Total	325	100

Geographical information System (GIS) Analysis of Coastal flooding and Shoreline Changes in the Study Area

Figure 8 shows the positions of shoreline in Eti-osa in the years 1962 and 1984. The base map of the shoreline position of 1962 was glued and crossed with the Eti-osa coastline supervise classified Landsat TM of the shoreline position in the year 1984, to analyze the variation in the shoreline position between these two years. The analysis shows that the water body-coastland is the volume of water that have been reclaimed to land between these years, water body- water body is the volume of water that remain unchanged, coastland- water body is the landmass in the coast that has been lost to water body while the coastland-coastland is the amount of the landmass that remain unchanged between these years. Also figure 9 showed the statistical results of the classification of the position of shoreline in the years 1962 and 1984. The analysis revealed that, between 1962 and 1984, 542.65 ha (4.91%) of land was lost to water-body, while 280.36 ha (2.54%) of water-body was gained as landmass. From this analysis, it was discovered that between the years 1962 and 1984, about 542.65 ha (4.91%) of landmass (shoreline) was lost to water-body than the landmass gained. The landmass lost to water between these years may be as a result of dominating fluvial deposits of mostly fine grained and loose sediments.

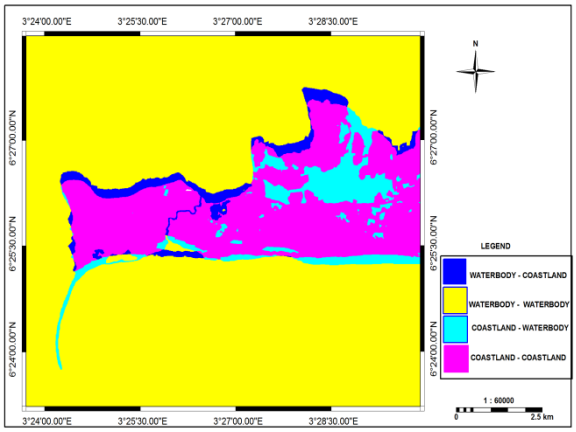

Figure 8: Shoreline position of Eti-osa (1962 and 1984)

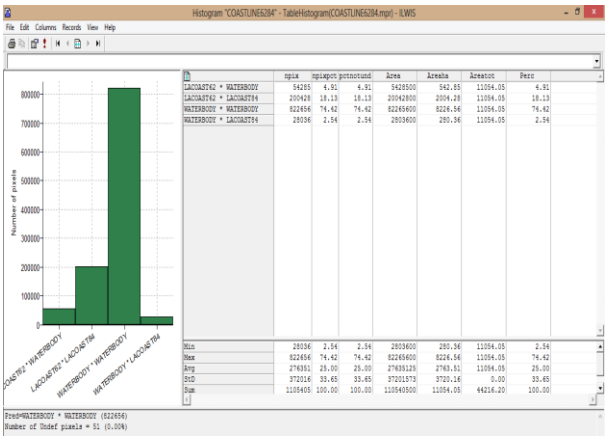

Figure 9: Statistical Results of the positions of shoreline in Eti-osa in the years 1962 and 1984

Figure 10 shows the positions of shoreline in Eti-Osa in the years 1984 and 2000.The Eti-Osa coastline supervised classification of Landsat TM shoreline position of 1984 was crossed with the supervised classification of Landsat ETM+ shoreline position in the year 2000 to analyze the variation in the shoreline position between these two years. The analysis shows that water body-coastland is the volume of water that has been reclaimed to land between these years, water body-water body is the volume of water that remain unchanged, coastland-water body is the landmass in the coast that has been lost to water body while the coastland-coastland is the amount of the landmass that remain unchanged between these years. Figure 11 shows the statistical results of the classification of the data set. The analysis revealed that, between the years 1984 and 2000, there was 476.18 ha (4.32%) landmass gained from water body while 47.00 ha (0.43%) of landmass was lost to water body. It was discovered that between the years 1984 and 2000, about 476.18 ha (4.32%) of water body was reclaimed to landmass than the landmass lost to water body. This more gain in landmass between these years may be as a result of spatial expansion and land reclamation exercise for different purposes especially for industrial and building purposes by the Lagos State government (Eludoyin, Obafemi, Oduore 2013).

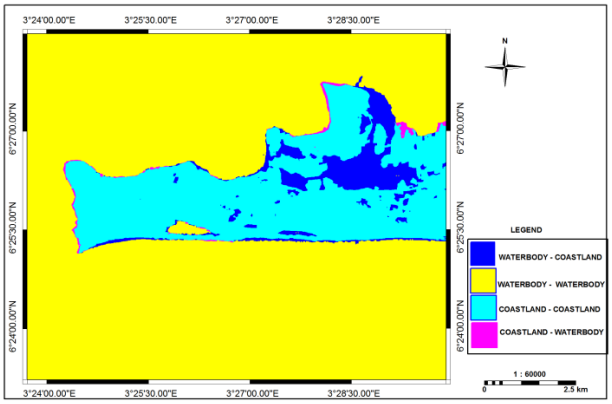

Figure 10: Shoreline position of Eti-Osa (1984 and 2000)

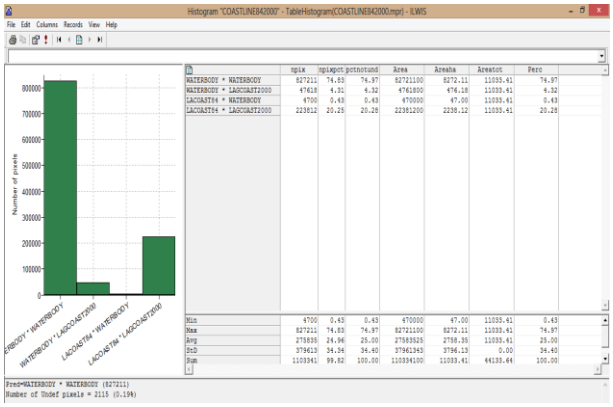

Figure 11: Statistical Results of the positions of shoreline in Eti-osa in the years 1984 and 2000

Figure 12 shows the positions of shoreline in Eti-Osa in the years 2000 and 2011.The Eti-Osa supervise classified Landsat ETM+ showing the shoreline position of the year 2000 was crossed with the supervise classified Landsat ETM+ of shoreline position for the year 2011, to analyze the variation in the shoreline position between these two years. It was revealed that the water body- coastland is the volume of water that have been reclaimed to land between these years, water body- water body is the volume of water that remain unchanged, coastland-water body is the landmass in the coast that has been lost to water body while the coastland-coastland is the amount of the landmass that remain unchanged between these years. Figure 13 showed the statistical results of the classification of the two years. The analysis shows that, between 2000 and 2011, about 490.47 ha (4.45%) landmass was gained from water body, while 114.84 ha (1.04%) of landmass was lost to water body which means that 114.84 ha (1.04%) landmass has been lost to water body. From the analysis, it was discovered that between the years 2000 and 2011, about 490.47 ha (4.45%) of water body was gained (reclaimed) to landmass than the landmass lost to water body. This more gain in landmass between these years may be as a result of the on-going land reclamation exercise in Lagos State especially in Victoria Island Atlantic Ocean and other areas of Eti-Osa by the Lagos State government.

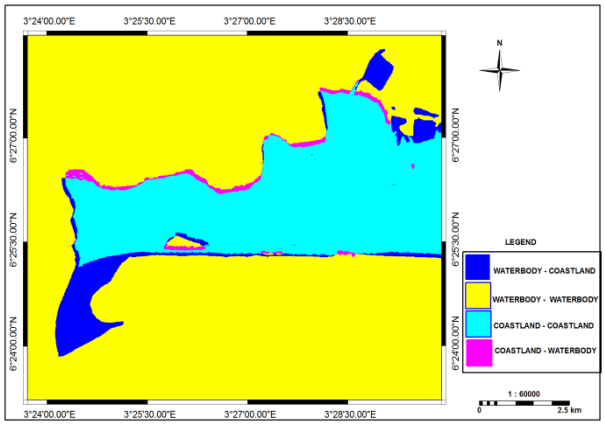

Figure 12: Shoreline position of Eti-osa (2000 and 2011)

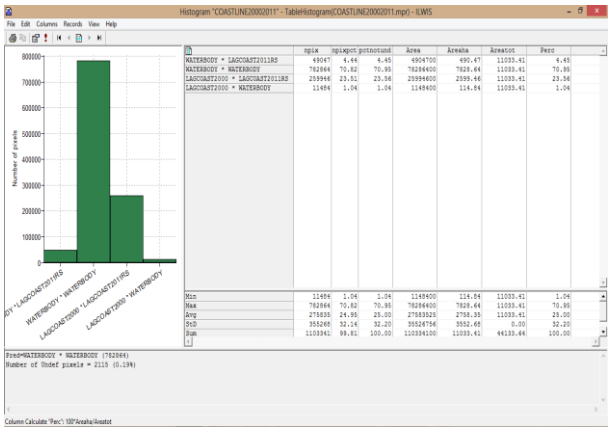

Figure 13: Statistical Results of the positions of shoreline in Eti-osa in the years 2000 and 2011

Table 8 shows the summary of the statistics of the Temporal Changes of Shoreline in the entire Eti-Osa. During the period between 1962 and 1984, the entire shoreline shifted seaward (gain) with 280.36 ha (2.54%) while the shore shifted landward (lost) with about 542.65 ha (4.91%), resulting to shoreline difference of 262.26 ha (2.37%). As a result of this 31.87% of landmass was lost to water body. Between 1984 and 2000, the shoreline shifted seaward (gain) with 476.18 ha (4.32%) while the shoreline shifted landward (lost) with 47.00 ha (0.43%), amounting to shoreline difference of about 429.18 ha (3.89%). As a result of this, 82.03% of land was gained. Also between the years 2000 and 2011, the shoreline shifted seaward (gain) with 490.47 ha (4.45%) while 114.84 ha (1.04%) has shifted landward (lost), resulting to shoreline difference of 375.63 ha (3.41%). As a result of this, about 62.06% of landmass was gained.

From table 8 also, it was discovered that, the shoreline situation was totally different between 1962 and 1984 because during these years, the shoreline shifted landward with percentage loss in landmass of about 31.4%.

Table 8: Temporal Shoreline changes in Eti-Osa between 1962 and 2011

Periods	Advanced (Gain) (ha)	Advanced (Gain) (%)	Retreat (Loss) (ha)	Retreat (Loss) (%)	Change Diff. (ha)	Total Change (ha)	Total Change (%)	% Change
1962-1984	280.36	2.54	542.65	4.91	262.26	823.01	7.45	-31.87
1984-2000	476.18	4.32	47.00	0.43	429.18	523.18	4.75	+82.03
2000-2011	490.47	4.45	114.84	1.04	375.63	605.31	5.49	+62.06

Digital Elevation Model Generation (DEM)

Figure 14 is the Digital Elevation Model (DEM) map of the study area. This map is generated from the contour map of the study area, and it shows and determines the flood plain. Figure

14 shows that the Elevation range of the study area is between 0-16.667m.This reveal that the height of the study area above the sea level is between 0-16.669m. Lagos is a State below the sea level and constantly being threatened with the challenge of climate change and ocean surge (Punch Newspaper 23rd September 2014),

The implication of this is that, the area is a flood plain, which makes it prone to incessant flood hazard due to the fact that the height of the area above the sea level is low. Victoria Island is between the height of 1.1m and 4m above the sea level, this height value is low and insignificant, which means that everywhere in this area is liable to coastal flooding, because water level can rise anytime thereby flooding the entire parts of Victoria Island especially during the raining season.

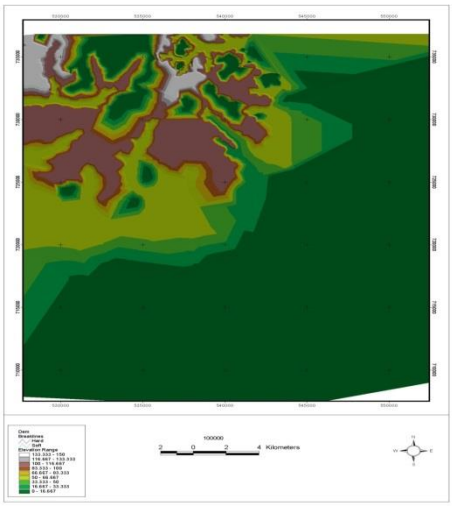

Figure 14: Digital Elevation Model (DEM) of Victoria Island and its Environs

CONCLUSION

The study has highlighted the problem of coastal flooding and shoreline changes in Victoria Island in Eti-Osa Local Government Area of Lagos State and its implication on the environment and the people of the area. Coastal flooding in the study area revolves around poor refuse disposal practice, encroachment on flooding, heavy rainfall, blocked and narrow drainages, indiscriminate waste disposal, lack of adequate set back from oceans among others.. It was also discovered that the inhabitants living in the floodplain lack waste disposal thereby forcing them to dump wastes in drainage channels. The digital elevation model (DEM) map of the study area reveals that the study area is between 0-33.33m while the surrounding area is higher between 116.667-133m. The Elevation range revealed that about 90% of the study area is between the heights 0-16.667m while the surrounding area is higher; this revealed the reason for the incessant flooding in Victoria Island.

RECOMMENDATIONS

This study has established that there is high correlation between coastal flooding and shoreline changes. The GIS analysis has also revealed that the topography of the study area has a role to play in the areas that are susceptible to coastal flooding. The land-cover map of the study area also shows floodable and swampy areas. Based on these findings, the study offers the following recommendations:

Construction of standard paved surface and drainages in the study area will help to combat flood hazard especially in the built up areas. It was discovered that the available drainages in the study area are not wide enough to convey the large volume of water especially during high rainfall. Therefore, standard pavements and drainages are considered as useful options

for combating flooding in the residential, commercial and industrial areas. When these are done, it will prevent flooding, water will move freely to the right channels there by reducing flooding to the minimal level (Olanibi, 2014).

Government should come to terms with its duty of enforcing environmental laws. Pollution should never be encouraged indirectly by bearing full cost of waste management. People should be aware of their social responsibility of caring for the environment. Part of the means of achieving this is charging a fee for wastes generated to complement the waste management efforts of government. Drainage ditches should be cleared regularly to allow unrestricted storm water passage.

There is a need for interdisciplinary cooperation at all governments' levels for a co-ordination of sectorial policies regarding environmental protection, physical planning, land use planning, agriculture, transport and urban development, and a co-ordination regarding all phases of risk management, risk assessment, mitigation planning and implementation of measures.

All envisaged measures concerning flood prevention and protection should be compiled in a comprehensive action plan covering up to several decades. An integrated action plan for reducing flood damage must draw long-term conclusions for preventive action in water management, land use, settlement policy and finance.

Flood maps should be used for the reduction of damage potential by integrating its outputs into spatial planning and emergency planning. Both type of utilization requires that the flood hazard / zoning / risk Increase coastal edge elevations through the Construction of Hard and Soft Structural Engineering Options to Prevent Coastline/ Shoreline Change maps should include the worst-case scenario as well.

ABSTRACT

In Nigeria and in most African countries, the desire to own a house is an indication of social and economic status that constitutes one of the strongest incentives for saving and capital formation. Since finance is an important determinant of success and failure of housing ownership, it therefore becomes very necessary to identify viable sources of funding that can promote house-ownership. This paper examined the activities of Cooperative Societies in the promotion of house ownership in Nigeria with a focus on Akure, the Ondo State capital. The study identified all the registered Cooperative Societies in Akure. Four (4) different sets of questionnaires were designed and used in the collection of data from the four (4) identified research target population. These are chairmen, and members of the registered Cooperative Societies, Ondo State Ministry of Community Development and Cooperative Services; and House-Owners in Akure metropolis. The data were subjected to statistical analysis. The findings revealed among others that majority of the House-Owners in Akure were not members of Cooperative Societies. However, all members of Cooperative Societies in one form or the other invested loans secured from the Cooperative Societies in housing and housing-related projects. This calls for strong advocacy to promote increasing enrollment of membership in Cooperative Societies among urban residents in Akure with a view to promoting house-ownership.

Keywords: Akure Nigeria, Cooperative Society, House-ownership, Housing

INTRODUCTION

Housing is not only a basic human need, it constitutes a vital component of man's welfare, life sustenance and survival. In the hierarchy of man's needs, housing has been ranked second to food. It has a profound influence on the health, efficiency, social behaviour satisfaction and general welfare of the community. Housing has a significant role to play in the individual, local and national economy. In most cases, it constitutes the first major capital investments and life ambition of individuals (Bello, 2003). The desire to own a house constitutes one of the strongest incentives for saving and capital formation (Ozo 1990, Olujimi 2008a). The purpose of this paper is to examine the activities of Cooperative Societies in Akure, the Ondo State capital as a typical Nigerian urban centre with a view to promoting house-ownership. The hypothesis on the lending policy of the Cooperative Societies was formulated and tested. Thus,

$H_{01:}$ The lending policy of Cooperative Societies in the study area is not in favour of housing construction.

$Ho_{1:}$ The lending policy of Cooperative Societies is in favour of housing construction.

The results of the analysis are reported in the research findings as contained in the paper.

LITERATURE REVIEW

Housing Problems

Housing problem is a global phenomenon confronting developed and developing, rich and poor nations. Habitat (1990) stressed that in all countries, regardless of the average standard of living, there is a large section of the population that cannot afford what could be regarded as an adequate or standard housing. Therefore, a substantial part of the population has to live

Olujimi, J. A.; Bello, M. A.; Fashina, T. O.; Ojo, B. & Rotowa, K. (2016). Analysis of Activities of Cooperative Societies and House-Ownership in Nigerian Cities: The Case of Akure. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1342-1350

in accommodation that is severally substandard (Agbola, 2005). Nigeria is not exempted from this phenomenon. The manifestation of these housing problems are in form of overcrowding, homelessness, substandard housing, slum and squatter development. Other housing problems manifest in form of high rent in the housing market, inadequate mortgage finance and inaccessibility to mortgage loans. These have cumulatively resulted to a low home-Ownership rate of 25 percent in Nigeria, which is lower to that of Indonesia (84 percent), Kenya (73 percent), and South Africa (56 percent) (CAHF, 2015).

Alternative Sources of Housing Finance

Prior to the colonial era, many methods of housing finance were adopted in Nigeria. Amongst these were Village Development Scheme, Social Club Contributions, Loans from Traditional Money-Lenders and others. Olujimi (2008b) has confirmed that all these methods were initially successful in the provision of funds for housing and its delivery in the traditional setting. However, with the growing complexity in economic activities, these financing methods faded away and were replaced with more modern forms of financing. These modern forms of financing are regarded as the formal sector that comprises of institutions operating within the guidelines stipulated by the federal government (Nubi, 2000). The formal sector includes the Federal Mortgage Bank of Nigeria (FMBN), Commercial Banks, Insurance Companies, and recently added to the list is the Pension/Provident Funds Administrators.

The saving culture and habit particularly among the average Nigerians is fast becoming low. Many got their savings trapped in the distressed Banks for years without being adequately compensated while the on-going revelations of alleged gross mismanagement levied against most Managing Directors of Banks in Nigeria are making customers and investors to lose confidence in the banking sector as reliable source of housing finance. Furthermore, the statutory conditions attached to lending for housing financing in the sector are mostly not within the reach of most prospective home-owners (Arewa, 2007;). Recently, Zanin (2016) specifically confirmed that high mortgage cost has reduced affordable housing development; yet housing is a basic need of man. All these constraints call for the re-visitation of the informal sector; of which cooperative society constitutes a main pillar.

Cooperative Society and Housing

The existence of Cooperative society dates back as far as when human beings have been organizing for mutual benefit. Tribes were organised as cooperative structures, allocating jobs and resources among each other, only trading with the external communities. Cooperative Societies like other business organizations are established to perform certain tasks. It can be classified according to king (2002) into four broad categories such as service, purchasing, marketing and processing associations. In all the four categories, the activities of Cooperative Societies can be linked directly or indirectly to housing. The benefits of cooperative societies to membership among others include; access to quality supplies and services at reasonable cost; increased clout in the marketplace; share in the earning of cooperative business; enhancement and protection of local economy; and provision of monetary loan for re-investment into many other sectors such as housing.

It is certain from the above exposition that in Nigeria, housing shortage exists and Nigerians deserve to live in liveable accommodation. One of the hindering factors in the realisation of this intention is non-availability of funds to embark on individual housing project(s). The peculiarities of cooperative societies provide a stable platform to pool substantial funds together that could be mobilised for housing provision. The question is, can cooperative societies provide leverage for housing delivery through house-ownership? This paper provides answer to the question using Akure as a case study.

AKURE: THE STUDY AREA

Akure is a traditional Nigerian city and like other traditional Yoruba towns in the country, it existed long before the advent of the British colonial rule in the country. Akure is located between latitude 6^0 $95^1$and 7^o 15^1 North, and longitude 5^o 14^1 and 5^0 40^1 East of Greenwich Meridian. It occupies about 35 square Kilometres of land. Akure is about 700 km South-west of Abuja, the Federal Capital of Nigeria (see Figures 1).

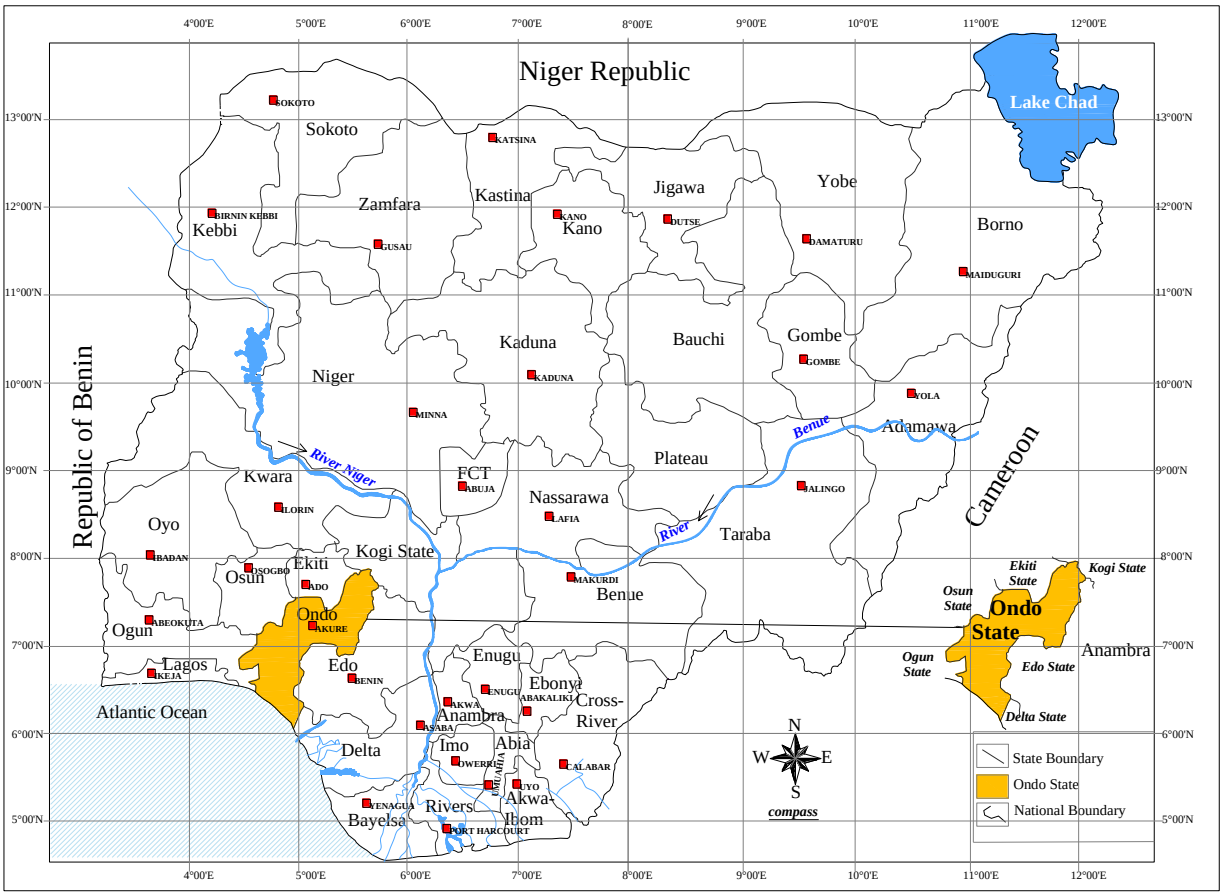

Figure 1.1: Map of Nigeria: Showing Ondo State in the National Setting
Source: Ministry of Works, Akure (Reproduced in AutoCAD by the Authors), 2012

Akure was originally the headquarters of Ondo province until 3rd February, 1976 when its status changed to a State Capital of Ondo State and coincidentally the Local Government Headquarters of Akure South Local Government Council. This led to a phenomena change in the political, social, economic and administrative roles as well as the population of the town. The increased relative political influence of Akure as a state capital and local government headquarters since 1976 have greatly promoted its rapid growth and increased socio-economic activities resulting in its spatial expansion from an area of about 16 squares kilometres in 1980 to about 30 square kilometres in 2000 (Ministry of Works, Lands and Housing, 2000); and at present, it occupies about 35 square kilometres.

The population of the city grew from 38,852 in 1952 to 71,106 in 1963. Its population was estimated to be 112,850 in 1980 (DHV, 1985); and 157,947 in 1990 (Ondo State of Nigeria, 1990). The 1991 national population census however, puts the population of Akure at 239,124 and its estimated population in 1996 was 269,207 (NPC, 1996). However, with the use of 3.5 percent as the growth rate, and the population was projected to 2012 by the time the surveys for this study were conducted at 459,716 persons. The increasing population had not been adequately housed because of the shortage in the supply of housing units to cope

with the housing needs (Olujimi, 2008b). This has been responsible for the shortage of residential accommodation which correspondingly led to skyrocketing of rent for the available residential properties most of which are devoid of necessary infrastructural facilities.

METHODOLOGY

Data collected for the study were from primary and secondary sources. The primary data were sought from the field surveys conducted through the administration of questionnaire designed for each of the research target population. These are the Presidents of the registered Cooperative Societies; members of Cooperative Societies; House-Owners in Akure, and the Akure Zonal Officer of the Ministry of Community Development and Cooperative Services. Only 95 of the registered societies were viable and strictly operating within Akure metropolis. Fifty percent of the 95 registered Cooperative Societies which is 47.5 (i.e. 48) registered Cooperative Societies were randomly selected for the study. However, when the questionnaire for the Cooperative Societies was administered on the 48 randomly selected societies, only 38 of the societies responded.

In each of the selected Cooperative Societies, 5 members were randomly selected for the study since only 38 societies responded; this amounted to a total of 190 members for the administration of the questionnaire for members of Cooperative Societies. Only 179 of the copies of the retrieved questionnaire were usable for the final analysis. The remaining 11 copies were either wrongly filled or inadequately filled to convey any meaningful planning information.

For the conduct of House-Owners' survey, all the residential buildings in Akure metropolis were considered. The peculiarities of house-ownership in Akure made it very difficult to locate or meet owners of residential buildings in their houses for the conduct of House-Ownership Survey. For instance, many of the residential buildings are non-owner-occupiers because they were either built for rental purpose, inherited by group of surviving children, or purchased from the original owners.

Therefore, a systematic random sampling method was used in the conduct of House-Owners' survey; and one (1) residential building in every 30 residential buildings in each of the zones was selected and the owner of the residential building was picked for the administration of the questionnaire. In situation where an owner was not located in a selected residential building, such building is subsequently substituted with any of the 30 residential buildings. Overall, 212, 249, 163, and 59 House-Owners were selected in the core, transitional, peripheral and government Estates' residential zones correspondingly and administered with House-Owners' questionnaire.

The total number of questionnaire administered was 683 on the sampled House–owners in Akure. For the administration of the questionnaire meant for the Ondo-State Ministry of Community Development and Cooperative Services; the Zonal Office of the Ministry in Akure South Local Government area was contacted. By the operational modalities of the office, it is closer to the Cooperative Societies in Akure and their members. The requested answers to the questions in the questionnaire were adequately supplied. The secondary data were materials on the research subject obtained from published and unpublished sources.

The processing of the primary data was carried out through the use of computer, using the Statistical Package for Social Sciences (SPSS) version 8. The analysis was done at different levels and Chi-square analysis was used to test the formulated hypothesis.

FINDINGS AND DISCUSSION

House Ownership in Akure

In this study, the ownership of houses was reported among the cooperative members and non-cooperative members. Home ownership in Akure metropolis can be divided into whether they are members of a cooperative societies or non- members of cooperative societies. A total of 683 house-owners were selected for the survey exercise. In all, 30.2% of the respondents i.e. house-owners were members of cooperative societies while 69.8% were non-cooperative members (see Table 1).

Table 1: Distribution of House Ownership by Cooperative and Non-Cooperative Membership in Different Zones in Akure

Residential Zones	Cooperative Members (n=206)		Non Cooperative Members (n=477)		Total (n=683)	
	Fr	%	Fr	%	Fr	%
Core	82	39.8	130	27.3	212	31.0
Transitional	61	29.6	188	39.4	249	36.5
Peripheral	44	21.4	119	24.9	163	23.9
Government Estates	19	9.2	40	8.4	59	8.6
TOTAL	206	30.2	477	69.8	683	100.0

House Ownership by Cooperative and Non-Cooperative Membership in Different Zones in Akure

Our findings as shown in Table 1 also revealed that members of the cooperative societies constituted the highest proportions of house-ownership (39.8%) that resided at the core residential zone of Akure. The next higher proportion of members of cooperative societies resided at the transitional zone where about 29.6% of respondents were captured in the survey. In addition, 21.4% of cooperative members resided at the peripheral, others (9.2%) resided in the government estates that dotted the metropolis. On the other hand, the highest proportion of non-cooperative members that owned house at the transition residential zone of the metropolis was 39.4%. The core residential zone is the next zone where 27.3% non-cooperative members resided. The third higher proportions of respondents who were non-cooperative members were located at the peripheral zone, where about 24.9% of respondents resided. The least proportion of respondents (8.4%) resided in the government residential estates as at the time of the survey. Overall, the distribution of house-ownership in the study areas showed that 36.5%, 31.0%, 23.9% and 8.6% are correspondingly located in transitional, core, peripheral and Government residential estate zones of the study area.

Year of Construction of the Residential Buildings

In Akure, Table 2 reveals that the highest proportion of residential buildings (57.4%) was constructed between 1 and 5 years ago. This is followed by buildings that were constructed less than one (1) year ago (30.5%). Buildings that were constructed between 6 and 10 years were 5.7%, while the rest of the buildings 6.4% were older than 10 years. In term of their spatial analysis, it was discovered that among Cooperative members, 59.7% of the buildings were built between 1 and 5 years ago. Consequent to this, are buildings that were less than 1year old that constituted about 27.7% of buildings in Akure metropolis. Furthermore, buildings that were between 6 and10 years old were 6.3% and buildings that were older than 10 years were 6.3%. Among the non-cooperative members, the highest proportion of buildings were those constructed less than 5years ago (56.4%). This is closely followed by buildings that are less than 1year (31.7%). The next higher proportion of residential buildings were the ones constructed between 6 and 10 years ago (6.6%) while 6.5% of the residential buildings sampled for the survey were built more than 10 years ago.

Table 2: Year of Construction of Residential Buildings in Akure

Construction Year	Cooperative Members (n=206)		Non Cooperative Members (n=477)		Total (n=683)	
	Fr	%	Fr	%	Fr	%
<1 Year	57	27.7	151	31.7	208	30.5
1 – 5 Years	123	59.7	269	56.4	392	57.4
6 – 10 Years	13	6.3	26	6.6	39	5.7
Over 10 Years	13	6.3	31	6.5	44	6.4

Sources of Funding Residential Building Projects

Funding of housing projects is not restricted to a single source. It is always augmented by other sources. The sources of funding of residential building projects by members of the cooperative societies are shown in Table 3. This reveals that accumulation of funds through personal savings (82%), loans from cooperative societies (100%), and Bank loans (0.97%). Others sources include assistance from friends and relatives (32%), gifts in cash and kind (28.6%) and housing loans from Government establishments (i.e. places of work of the members who are government workers) was 2.43%. It is necessary to note that when all members had the opportunity of obtaining loans from their societies (and they all took advantage of this and obtained loan invested in their housing project at one stage and the other), at least 0.97% still went ahead and took loan from the Bank. The implication of this is that building houses needs much money that the developer may not in all cases source funds from just one source alone; and it also requires a very substantial amount of money.

Besides the fact that non-cooperative members did not receive funds from any cooperative society, sources of funding house construction by them do not differ much from those that were cooperative members. However, higher proportion (93.7%) of non-cooperative members accumulated their housing funds from personal savings. This is followed by 27.9%, those who augmented the funding of their housing construction through gifts in cash and kind, and funds from friends and relatives were 26.6% loans from government ministries and parastatals was 10.5% and while Bank loans was 11.1%. It is necessary to note that among the two groups, higher proportion of the non-cooperative members (11.1%) took loans from the Bank for their housing projects when compared with the members of cooperative that constituted just 0.97%.

Plate 1: One of the Residential Buildings Built by a member in FUTA Staff Cooperative Multipurpose Society Housing Estate in Aule, Akure

Total Numbers of Houses Built with Cooperative Assistance

Overall, 80.1% of the House-owners confirmed that they got assistance from cooperative societies in building one house. The proportion of cooperators that built two (2) houses with the financial assistance of a cooperative society was 11.2% while 5.8% built three (3) houses

and 2.9% built more than 3 buildings through the same approach. This supports the fact that Cooperative Societies provide financial assistance to members towards encouraging house-ownership among members.

Table 3: Sources of Funding Residential Building Projects in Akure

Sources of Funding	Cooperative Members (n=206)		Non Cooperative Members (n=477)		Total (n=683)	
	Fr	%	Fr	%	Fr	%
Personal Savings	169	82.0	447	93.7	616	90.2
Cooperative societies	206	100.0	0	0.0	206	30.2
Bank loan	2	0.97	53	11.1	55	8.1
Friends and Relatives	66	32.0	127	26.6	193	28.3
Gifts in Cash and Kind	59	28.6	133	27.9	192	28.1
Housing loan from Govt establishments.	5	2.43	50	10.5	55	8.1

Percentage of Total Cost of Building Project Sourced from Cooperative Societies

It is not doubtful that loan obtained from Cooperative Societies was part of the funds used in housing projects by cooperative members. The findings on House-Ownership revealed this fact as indicated in Table 3. Therefore, it becomes necessary to identify the percentage of the total cost of the building which the loan was used to upset by the house-owners. Table 4 reveals that 23.3% of cooperators secured loans running to less than 30% of the total cost of their building project, while 31.1% of the cooperators claimed that between 31 and 60% of the cost of their buildings were sourced through their cooperative societies. This was followed by 45.6 % of the cooperators that confirmed that over 60% of their building cost was sourced from cooperative societies. The implication of this is that all respondents who are members of cooperative societies secured loans (funds) from cooperative societies for their building projects. Again, if more than 45% of cooperators were able to fund over 60% of the total cost of their residential buildings with loans obtained from their cooperative societies, it would not amount to over statement to say that securing funds from this particular source posit a reliable source of housing finance in Akure.

Table 4: Percentage of Cooperative Loan Contribution to the Total Cost of Building Projects

Percentage contribution of cooperatives to total cost of building projects	Cooperative Members (n=206)	
	Fr	%
Less than 30%	48	23.3
31 – 60%	64	31.1
Above 60%	94	45.6
Total	206	100.00

Testing of the Hypothesis

H_{02}: The lending policy of cooperative societies in the study area is not in favour of housing construction.

H_{a2}: The lending policy of cooperative societies is in favour of housing construction.

Table 5: Results of Chi Square Analysis between Criteria for Housing Loan and Number of Members Given Loan

Factors	Calculated χ^2 value	df	p- value	Decision
Members have no existing loan	4.62	3	0.20	Not significant
Members have evidence of land development	4.05	3	0.26	Not significant
Members have certificate of occupancy	4.73	3	0.19	Not significant
Members have collateral	4.05	3	0.26	Not significant

The results of the chi square analysis test conducted between the different criteria which the cooperatives societies followed in approving loans for members and the actual number of members given loans is shown on Table 5. The decision column reveals that none of the

criteria was significantly related to the loans given for housing projects. This is because all the p-values were higher than the 0.05 level of significance at which they were tested in the study. This implies that none of the criteria used by the cooperative societies discouraged members from accessing loans for housing projects. Therefore, the null hypothesis is rejected and the alternate hypothesis accepted which states that the lending policies of cooperatives societies are favourable to members and not a limitation to their accessibility to loans. The leading policies of the cooperative societies encourage and promote house-ownership.

CONCLUSION

The findings of this study had revealed that most of the Cooperative Societies in Akure, Ondo State are viable and they derived their operational funds from salary account of members and membership financial contribution on regular basis. The interest rate chargeable was very low and the conditions for leading are easy to meet by members, thus made access to loanable funds less difficult. This has made funds available for housing construction and housing related projects; thus, promoting house-ownership in Akure city.

RECOMMENDATIONS

i. The formation of Specialized Cooperative Societies should be encouraged, especially Housing Cooperative Associations. The activities of Housing Cooperative Association are essentially designed towards assisting members in the provision of their own houses at avoidable cost. These amongst others include ensuring easy accessibility of members to loanable mortgage funds at drastically reduced interest rates; provision of buildable residential plots (that are free from encumbrances) at avoidable cost to members; provision of building materials at control prices; and assist members in the processing or securing land titles, and building plans approval.

ii. Cooperative societies in their operational activities should emphasise on integrity, vision, dedication, perseverance, and openness as a pre-requisite for people aspiring to leadership positions in their societies. This is to ensure sustainability in the management of the affairs of their different Cooperative Societies with a view to guide against fraud.

iii. Poverty alleviation is a multi-dimensional issue hence, it is imperative that cooperative societies can engage in a wide variety of activities. These activities include: gaining access to markets through the supply and marketing of building materials and household consumable goods. The Cooperative Store located along Ondo road in Akure essentially deals in the sales of drinks and household items. It is therefore suggested that the scope of trading should be widened to include building materials such as cement, plumbing materials, roofing-sheets, paints and tiles among others. Members should be made to enjoy reduced prices, credit purchase facility and soft repayment terms for housing materials purchased in the Cooperative store. Every Cooperative Society should be encouraged to operate Cooperative store facility whenever its capital permits.

iv. In Akure, like other towns and cities in Nigeria, the problem of power supply and distribution is becoming very frustrating. It is therefore necessary to consider the option of promoting green-buildings among members of Cooperative Societies. Green building involves the use of simple technology in providing roofing system that would convert solar energy to power and supply the electricity needs in such residential building. Besides the fact that it reduces cost of power supply to buildings, it also reduces the resulting effect of climate change on the residential environment at the micro-level.

ABSTRACT

Urbanization and increase rate of poverty coupled with the challenges of insecurity in most developing countries have led to increase of crime incidence. This phenomenon is not new to residents of Nigeria cities; it has created unrest and great burden. Consequently, this calls for the development of new approaches to tackle crime incidence in cities. This study therefore focuses on the application of Geographic Information Systems (GIS) as a tool for mapping out the area liable to crime in the core area of Akure, Nigeria. The study employs the use of secondary data. Secondary data includes: literatures, journals and crime incidence reports gotten from internet, archives and Nigeria Police Force (NPF) respectively. Both spatial and statistical analyses were carried out using the appropriate tools such as Neighbourhood and Correlation Analysis respectively. This study revealed that the transport route cutting through Akure metropolis is prone to crime activity. Finally, the study recommends that police officials should be trained on how to use GIS to fight crime.

Keywords: Akure metropolis, Crime, Mapping, Poverty and GIS

INTRODUCTION

The traditional and age-old system of intelligence and criminal record maintenance has failed to live up to the requirements of the existing crime scenario. Manual processes have neither provided accurate, reliable and comprehensive data round the clock nor does it help in trend prediction and decision support, asides resulting to lower productivity and ineffective utilisation of manpower. The solution to this ever-increasing problem lies in the effective use of Information Technology (IT) to crime management especially in the cities.

A crime is an international act or omission in violation of criminal law, committed without defence or justification and sanctioned by the state as a felony or misdemeanour (Reid, 1991). Crime is largely an urban phenomenon peculiar to cities, but the specific urban area dimensions of the social processes that are connected with crime have been seriously understated in much recent criminological work (Baldwin and Bottoms, 1976). Urban crime is a composite and multi-dimensional phenomenon which includes behavioural, physiological, managerial, and spatial factors and other various scopes. Correspondingly, Sutherland, Cressey and Luckenbill, (1992) affirms that the study of crime in its various scopes is a vital area of interest to different groups of people. Sociologists and criminologists believe that crime results from societal anxiety. They associate crime with socio-demographic factors, indicating that the rates of crime in any urban neighbourhood are highly influenced by demographic and socio-economic contexts such as income, ethnic composition, youth concentration and level of education and a host of others without any regard for the spatial configuration of the settings of crime (Reith, 1996). Crime, in the social and legal framework, is the set of facts or assumptions (causes, consequences and objectives) that are part of a case in which they were committed acts punishable under criminal law, and the application of which depends on the agent of a sentence or security measure criminal).

Crime has serious negative effects on societies in both developed and developing countries of the world. Fear of victimization, loss of life and assets, drop in income, unemployment, displacements, evictions, emotional depression and diversion of investment and development funds towards security cost are all impacts of rising incidences of crime in our societies. Despite huge investments in social interventions and crime prevention measures all over the

Olajuyigbe, A.; Omole, K.; Bayode, T. & Adenigba, A. (2016). Crime Mapping and Analysis in the Core Area of Akure, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1351-1358

world, the crime problem is still unresolved, as crime rate around the globe continues to escalate due to increasing growth in poverty and the inequality in urban neighbourhoods, manifest through the proliferation of slums and unplanned urban areas in towns and cities. Crime presents a major challenge for the social, economic and physical development of cities and towns all over the world. Hence, the need for more advanced way, technology and methodology to combating crime in which application of GIS will help a great deal through crime mapping.

Crime mapping is an integral and an essential part of crime monitoring, control and management (Alex and Kate 2011), and Geographic Information System (GIS) plays an important role in crime mapping and analysis. Response capabilities often rely on a variety of data from multiple agencies and sources. The ability to access and process information quickly while displaying it in a spatial and visual medium allows agencies to allocate resources quickly and more effectively. In the 'mission-critical' nature of law enforcement, information about the location of a crime, incident, suspect, or victim is often crucial to determine the manner and size of the response. In addition, Yeung, et al (2007), also emphasised that GIS software helps co-ordinate vast amounts of location-based data from multiple sources. It enables the user to stack layers of data and view the data most critical to the particular issue or mission. It is used world over by police departments, both large and small, to provide mapping solutions for crime analysis, criminal tracking, traffic safety, community policing, Intranet/Internet mapping, and numerous other tasks (Johnson, 2000). Crime analysis involves the collection and analysis of data pertaining to a criminal incident, offender, and target. Crime analysis can be used to evaluate the effectiveness of programs such as community policing and crime prevention, develop policy through research, justify budget requests, and help identify or define a problem (Philip, 1999). Geographic Information System (GIS) and Remote Sensing (RS) provide the medium for the integration of spatial data. GIS and remote sensing have been widely recognized as an effective tool for planning and decision-making tasks. They allow for effective storage, manipulation and analysis of geographical data (Michalak, 1993; Trotter, 1991).

In a strict legal definition, however, a crime is a violation of criminal law which in most societies can be defined broadly as any 'act or omission forbidden law on pain of punishment' (Carvell and Swinfen, 1970). The cost of crime is another aspect relating to urban violence. Two costs of violence can be identified; these are monetary as well as non-monetary otherwise referred to as social cost (Agboola, 2001). Perceptions of crime are not determined by an objective indicator of the degree of injury or damage but by cultural values and power relations (UN, 1995).

In Nigeria, a good number of facts and incidents aid and abet the awareness of crime rate, analysis and mapping. The awareness that crime is not evenly distributed across cities, but often concentrated in certain areas has been the focus of crime study since 1940s, thus given prominence to environmental criminology as a field of the study of the influence of situational factors (social and physical) on crime and travel behaviour of criminals across urban neighbourhoods (Herbert, 1989, Davies et al, 2007). Crime mapping and analysis is a relatively new area with the origin in United State of America and spreading to the United Kingdom in the recent times. Little or nothing had been written about the effectiveness of crime mapping and analysis generally in Nigeria and in particular to the security maintenance and functionality in Nigeria.

Research evidence suggests that both physical and social conditions of the environment may influence crime incidents and make certain neighbourhoods crime prone and others less crime prone thus generating different patterns of crime and crime analysis travel across a city

(Greenberg, Rohe and Williams, 1985; Newman, 1976; Formosa, 2010). The geography of crime with its emphasis on mapping and spatial analysis has emerged in recent years as a growing area of research. However, 'cartographic criminology' involving the production of maps indicate the distribution of crime is found not enough for the modern day crime analysis, rather, the requirements today involves the need to explore the relationship between socio-spatial phenomenon and crime pattern through a more robust spatial and statistical analysis tools present in the modern day Geographic Information System (GIS) and Remote Sensing (RS) (Herbert, 1989)

The immediate response of most people to crime is fear. Although several factors have identified as the cause of fear in relation to crime, one general feature of crime is that high level of fear are not only dependent on actual personal victimization. A study confirmed that there is little difference in the levels of fear of crime between victims and non-victims. In essence, the high level of fear of crime perceived by the residents may not necessarily match the risk of personal victimization. A comparison of the historical situation with the present suggests that recent interest in crime mapping is likely to have a more substantial and lasting impact on crime prevention theory and applications. A review of literature shows that a combination of different physical and social variables may impact crime at various stations in a specific area, neighbourhood or regions. Researchers have argues that defensible space characteristics of residential apartment design (such as lighting, fencing, specific security hardware, and open design that allows opportunities for surveillance) can discourage crime activities (Harries 1971).

This research further shows that the urban characteristics of neighbourhoods are important for crime. Particular land uses (e.g. schools, bars, stores, and abandoned buildings) have been found to attract more crime in their vicinity (Block and Block, 1995 and 2000; Byrne, 1986; Greenberg, 1986). The presence of physical disorder and incivility, signified by deteriorating building stock and public environments, with concentration of graffiti and litter is also likely to have an impact on neighbourhood crime (Perkins et al. 1993; Skogan, 1990).

As previously noted, researchers have also hypothesized that compositional characteristics of the neighbourhood surrounding densely populated area, income levels, age, educational level, and unemployment level of residents have a likely correlation with crime operations. A violent crime or crime of violence is a crime in which the offender uses or threatens to use violent force upon the victim. This entails both crimes in which the violent act is the objective, such as murder, as well as crimes in which violence is the means to an end, (including criminal ends) such as robbery. Violent crimes include crimes committed with weapons. With the exception of rape (which accounts for 6% of all reported violent crimes), males are the primary victims of all forms of violent crime.

Spatial or geo-information in the form of maps, plans, aerial photographs, satellite imageries among others have always formed the physical base on which settlements development planning is undertaken. It has earlier been emphasized that the ability of cities to manage urban growth is increasingly dependent on timely access to spatial information and the competence of turning these data into information to support decision-making. The rapid advancement and proliferation of GIS has increased interest in crime mapping and analysis due to its ability to aggregate different data sources and converting them into useful information in understanding and predicting a pattern (Longley and Clarke 1995, Bowers and Hirschfield 1999). Furthermore, the analytical application of GIS and RS can be used in either an exploratory or confirmatory capacity.

Crime mapping is a term that has been used for the past few years to refer to research analysis using GIS in a law enforcement setting. Crime analysis mapping is used to describe this

process because using a GIS to analyze crime is not just the act of placing incidents on a map but also of analysis (Racheal, 2001). It is also the process of using a geographic information system in combination with crime analysis techniques to focus on the spatial context of criminal and other law enforcement activity. Maps offer crime analysts graphic representations of crime-related issues. An understanding of where and why crimes occur can improve attempts to fight crime. Mapping crime can help police protect citizens more effectively. Simple maps that display the locations where crimes or concentrations of crimes have occurred can be used to help direct patrols to places they are most needed. Policy makers in police departments might use more complex maps to observe trends in criminal activity, and maps may prove invaluable in solving criminal cases (Johnson, 2000). To this end, this paper demonstrates the effectiveness of GIS to crime mapping in the core area of Akure, Nigeria.

MATERIAL AND METHODS

The Study Area

The study area falls within Akure south, the capital of Ondo State, Nigeria. Akure is located between between latitude $7^0 17'$ N and longitude 5^0 4' E with a coverage area of 318.0 km^2. Akure is about 370m above the mean sea level. Akure is bounded to the South by Idanre; to the East by Owo and to the North by Ifedore Local Government Area. The easy access and geographical centrality of Akure to these neighbouring towns have enhanced the growth prospects of the city. Okoko (2002) asserted that, this influx was necessitated by the development attracted to the state capital. With the presence of government seat in Akure, job opportunities, provision of community facilities such as roads, water etc and social facilities such as hospitals, schools, markets etc precipitated the migration of youths from the surrounding towns/settlements for job opportunities among others, leading to increase in population. In 2006, the population of Akure was 387,100 (NPC, 2006). However, the population of Akure is estimated to be 1.8million by 2015. This growth will be as a result of industrial growth; its classification as among oil producing state and millennium development city. Akure falls within the tropical rain forest region of Nigeria where rain fall is high. The mean annual rainfall is about 250cm, the atmospheric temperature ranges between 28°C and 31°C and a mean annual relative humidity of about 80 per cent (Ajibefun, 2014).

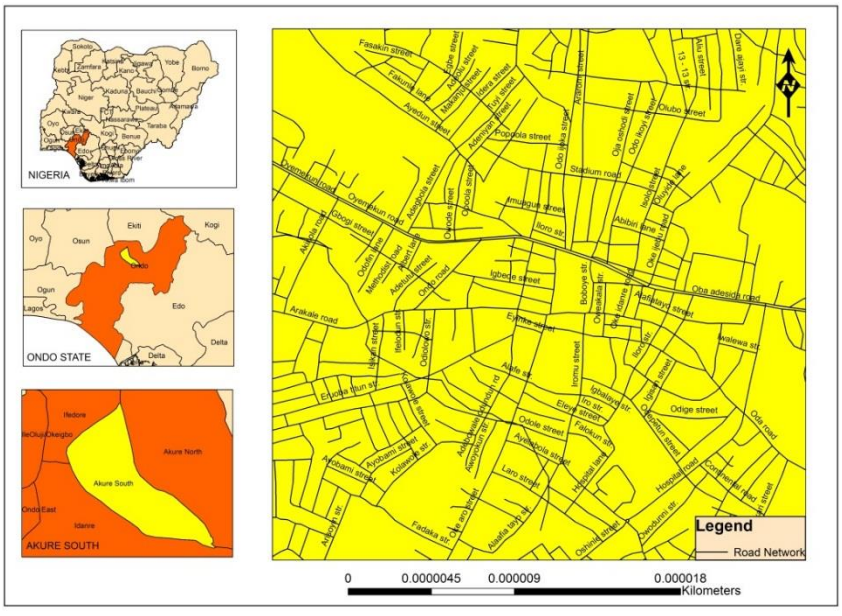

Figure 1: Study area map

The Data Base

This study is descriptive in nature, involving the use of secondary and primary data with the integration of Geographic Information System techniques. Secondary data used for the study were sourced from journals, archives, library and institutions. They include: analogue maps of the study area, crime data in the region from the Police Headquarters and Crime Reports. Primary data which include field data was gotten with use of Global Positioning System (GPS). The data were analysed and presented by the use of maps to explain the distribution of crime incidents in the study area. The software used for data analysis include: ArcGIS 10.0, CrimeStat III, Global Mapper 13.0, Map Source, Transfo (used for converting geographic (angular) coordinates to UTM coordinates).

Analysis using Geographic Information System (GIS)

For this study, GPS Garmin 76 was employed to obtain co-ordinates of major landmarks in the study area in other to register these landmarks; which comprises of police stations, banks, markets, liquor stores, and place of worship. The crime data gotten on field through GPS were transferred into Microsoft Excel and imported into ArcGIS 10 for geocoding. Advanced spatial analysis such as hotspot and black spot analysis using Geostatistical Analyst which includes Inverse Distance Weight analysis, Kriging and Cokriging.

Geostatistical Analyst provides tools that make the best prediction possible by examining the relationship between all the sample points and producing a continuous surface of crime concentration, standard errors (uncertainty) of prediction, and probabilities that critical values are exceeded. This analysis tool bridges the gap between geostatistic and GIS. Examples of geostatistical operations includes: Inverse Distance Weighing (IDW), Kriging, Kernel Kriging, Cokriging etc. They are all interpolation techniques.

ANALYSIS OF FINDINGS AND DISCUSSION

As asserted earlier, IDW was adopted for this study to interpolate the data gotten through the GPS. From the analysis as shown in Figure 2, the study revealed that the intensity of crime is on the increase along the major transport route cutting through Akure metropolis, and also to some specific areas such as Post-Office, Oke-Aro, Odo-Ikoyi and Isolo etc. This is as a result of the poor policing and concentration of activities in these areas. From the study, it was also revealed that police protection with respect to crime and violent act is poor taking into consideration the affected areas in the study area. The ineffectiveness of the police with regards to the respondents view was paramount around various strategic centre of attraction such as the God's Plaza (Nao Supermarket), LASCO, First Bank, WEMA Bank, Ricobin House, BIZ Leonac Mega Plaza etc and even to some interior part of the Akure city core.

From the result of analysis using the cokriging factor, the multiple datasets to investigate cross-correlation and autocorrelation, shows that analyzing of multivariable proves to be a useful way of deducing crucial factors. The combination of these variables (gang activity in the area, paramount property crime and paramount personal crime) shows that the flux of crime in the study area is at a peak level. The major event areas are carried out along the Oba Adesida road and gradually reducing to the exterior part of the Akure Metropolitan core.

Police security management in the area is grossly below average. From the analysis, the respondent strongly believed that police security management is rather poor as the Force does not have sufficient manpower and combating factor to keep the study area healthy from the unrest of crime and violent act.

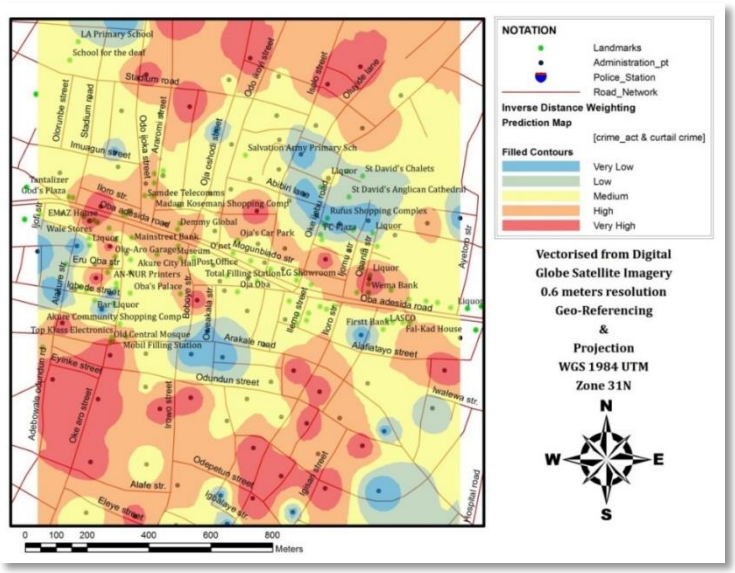

Figure 2: Map showing geospatial analysis of level of crime in the study area

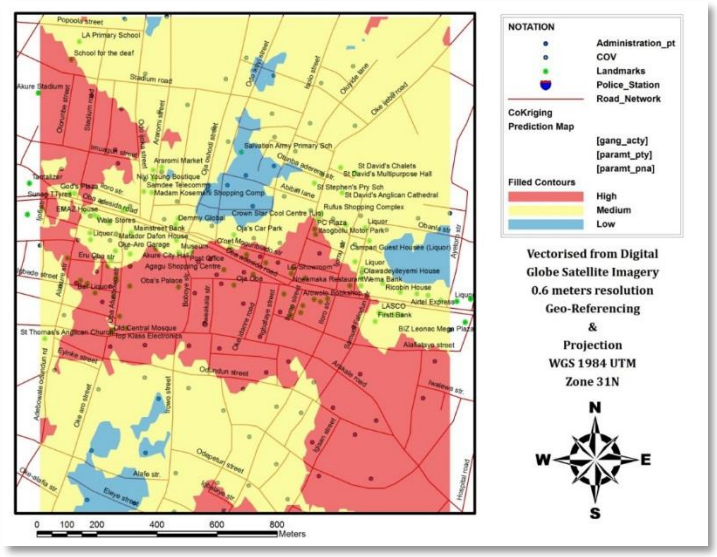

Figure 3: Geospatial analysis of gang activity with respect to property and personal crime

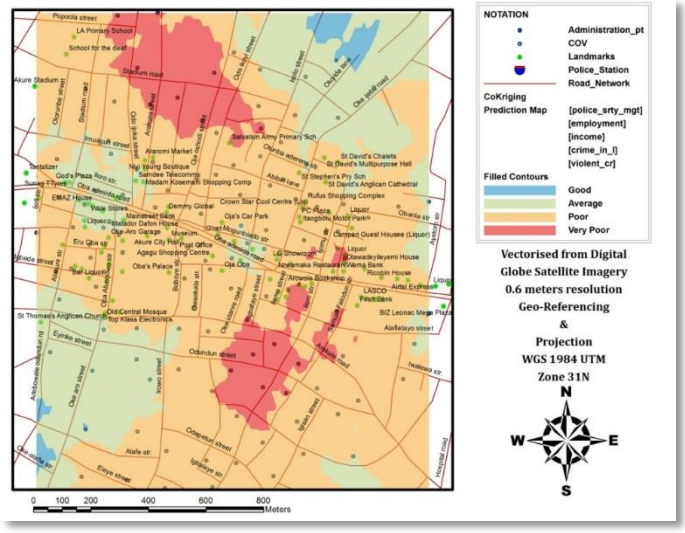

Figure 4: Map showing geospatial analysis of police security management in the study area

RECOMMENDATIONS AND CONCLUSION

This study is based on crime mapping and analysis in Akure city core centre. The occurrence of such activities must be curtailed through a viable planning to increase the security apparatus of the state capital. Again, the police force has not being able to apprehend the occurrence of criminal activities in the study area due to weak capacity. From the field survey, it was revealed that the crime activities are more dominant in some part of the city core compare to others. This study has been able to develop crime database system that could increase security around the Akure city core. Such system will achieve greatly in the detections of hotspots and black spots, generation of maps indicating neighbourhoods that lack security facilities, knowledge of crime pattern and occurrence, crime prediction among others. This system will not only assist Ondo State in crime reduction but other states in the country if adopted.

Based on the findings, the study recommended that the state government promptly embark on the provision of security in the state capital. This is an urgent need in the study area because the reoccurring events of criminal acts are unending. The government should recognise the importance of life and property to economic growth. This can be actualize if the government should invest adequate funds in the Nigerian Police Force including capacity training programme and mind-set change as a means to curtailing crime activity in the state capital. There should be constant police patrol in the city core. Recruitment of man power into police force should not be based on the need for employment at all cost, but on the passion and desire to be a protector of the safety of the people.

ABSTRACT

Public infrastructures are the basic facilities and services essential to both rural and urban societies, economic and social development. The aim of this paper is to examine the problems associated with management of public infrastructure in Ondo West local government, Ondo State. The objectives were to identify the various types of public infrastructure available in Ondo west local government, the agencies in charge of the management of these public infrastructures focusing on the procedural approaches used and also the problems associated with management of infrastructure. Data was selected using stratified sampling method and selection made from the surveyed political wards and the agencies in the study area. Random sampling was adopted to collect data and information from the households and from the officers of the agencies. 250 questionnaires were structured on the socio-economic characteristic of respondents at the five surveyed wards and agencies. It was revealed that lack of maintenance culture was a major problem associated with the deterioration of the available public infrastructure. The management agencies also do not have sufficient staff strength to carry out the necessary monitoring of the infrastructure. The paper recommends that beneficiaries as well as concerned agencies of public infrastructures should be enlightened on the benefits of maintenance of public infrastructure. Also a monitoring committee should be set up to monitor various public infrastructures so as to ensure adequate maintenance on the part of the agencies and finally the issue of staff strength should be addressed as more qualified persons are to be employed.

Keywords: Management, Public infrastructure, Maintenance culture, Monitoring, Ondo state

INTRODUCTION

The state of civilization of the inhabitants and the efficiency of workers within an area is reflected by extent to which their neighborhoods have been provided with infrastructural facilities. The performance or effectiveness of an infrastructure depends on the nature of their management (Obateru, 2003). Public Infrastructure by definition are the basic facilities and services essential to both rural and urban societies, and to economic and social development. The

Infrastructure include transportation facilities, telecommunication facilities, water supply, po wer supp ly, waste and sewage disposal facilities, education, health and recreational facilities, Housing, schools etc. The growth of urban economy and population has rapidly increased the demand for urban infrastructure; the management of urban infrastructures in Nigeria cities presents a frightening picture of decay, obsolescence and acute shortage (Babawale, 2004). To complicate the problem of inadequate infrastructures, new development has dominated the attention of our planners and decision makers, giving no serious thought to maintenance of the existing facilities. Consequently, over utilization of some of the existing infrastructures leads to poor or loss of value among other effects. Infrastructure refers to our national physical assets, which are the basic structures and facilities necessary for a country or organization to function efficiently. The management of these assets which include; transport, water, electricity, etc, is to preserve the new state and good appearance of the facilities as far as it is economically viable and practicable so that it can effectively serve the purpose for which it was built (Omuojine, 1997). One of the factors that militate against effective management of infrastructure is poor maintenance culture as most infrastructural facilities

Aluko, E. A. & Olanibi, J. A. (2016). Problems Associated with the Management of Public Infrastructure in Ondo West Local Government Area, Ondo State, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1359-1368

deteriorate rapidly due to over utilization. According to Environmental Watch (2007), it is critically explained that nonchalant attitude of people towards maintenance of Infrastructures is a problem. The wrong attitude of beneficiaries to maintenance of infrastructure reflects situations of non-challancy to public infrastructure. Increase in reported cases of vandalism of facilities such as telecommunications and electricity power infrastructures has been recorded in Urban centres (Akuruju, 2004). Another critical problem confronting effective management of infrastructures is lack of adequate fund and materials, projects have been abandoned due to insufficient funding while the responsibilities for maintenance of the existing facilities have in many cases been neglected (Babawale,2004). Therefore, this study examines the various problems associated with the maintenance of public infrastructures in Ondo West LGA, suggesting possible measures that can be put in place to improve the maintenance of the public infrastructures.

The aim of this study is to examine the problems associated with the management of public infrastructure in Ondo West Local Government Area, Ondo State, Nigeria. The objectives of the study are to identify the available infrastructures in the study area as well as identifying the agencies responsible for the management. Also to examine the procedures for managing the available infrastructure focusing on the various problems that could be associated with the management of public infrastructure in Ondo west Local government Area.

THE STUDY AREA

The present Ondo West is generally bounded in the North by Bolorunduro, in the East by Idanre, in the West by Okeigbo, and in the South by Igunshin. The town is situated in the West of Ondo State, Nigeria, lying between Longitude 4.83^0E and Latitude 7.1^0N. Ondo West has the second largest city which is Ondo town in Ondo State with 288,868 populations (NPC, 2006). It hosts Adeyemi College of Education, and Wesley University of Technology and other Educational institutions. Popular Health Facilities are the State Specialist Hospital, Wole Ayo Hospital, Emmanuel Clinic etc. National Union of Transport Workers is the popular union in charge of Transportation facility in the study area while for the Telecommunication facility, MTNNigeria, GLOng, Etisalat, Airtel and NIPOST are available.

LITERATURE REVIEW

Omuojine (1997) described infrastructure as "the stock of fixed capital assets in a country for example roads, railways, airports, waterways, hospitals and telecommunication network. All these with the attendant transportation network, electricity supply, Telephone services and wholesome water supply and medical services invariably constitute infrastructural facilities. Obateru (2003) elaborated on the meaning and scope of infrastructure, which according to him is "synonymous with public utilities, community facilities and services". Akubueze (2004) asserted "infrastructure refers to our national physical assets, which are the basic structures and facilities necessary for a country or organization to function efficiently, for example; building, transport, water, energy resources and administrative systems.

From all the definitions, one can see that infrastructures refer to the basic facilities and services essential to institution, economic and social development. They constitute the main fabric of what may be called institutional physical system linked to property development and use. Infrastructure management means the work necessary to preserve its finishes and fittings, in its near initial state so that it continues to provide the same facilities and amenities at it did when it was first created. In this sense, management implies the renewal of infrastructure components through repairs, servicing, replacement, decoration and cleaning (Akubueze,

2004). Infrastructure management is the practice of coordinating the physical workplace with the people and work of the organization. Aulua (1991) writing about poor management of public infrastructure, gave appointment of wrong managers by government to run affairs of her infrastructures as one of the problems associated with management of public infrastructures in Nigeria.

Public Infrastructure in Nigeria

Public infrastructures are mainly government owned facilities charged with responsibility of providing services that are public interest. In Nigeria, public infrastructures include; transportation facilities, electricity supply, water supply, healthcare, telecommunication, etc. each of these facilities is established by the government, hence the extent of their operation and ownership of property are subject to control by the government. According to William (1989), the major concern of public infrastructure is to provide vital services for people's welfare and progress and to accelerate development. The origin of public infrastructure in developing countries like Nigeria dates back to colonial period when many European nations utilized public corporations as an arm of their government for seizing foreign territories (Okpata 2004). The Infrastructural report of Nigeria just like any third world country is nothing to write home about. The infrastructure situation is in a sorry state both quantitatively and qualitatively (Oyedele, 2006). Most infrastructure are now decayed and need repair, rehabilitation or replacement. The management of the various infrastructure will ensure its efficacy as well as prolong its life-span, therefore, it is essential that appropriate mechanisms are put in place to ensure the efficient output of these infrastructure.

Types of Infrastructure

Infrastructure is a complex field with so many different components under it; but all of them can be categorized into two main types of infrastructure which are hard and soft infrastructure. The hard infrastructure includes; telecommunication and communication infrastructure which helps to convey information, ideas, decisions, messages from one place to another, from one individual or group to another individual or group of individuals or from one country to another. Transportation infrastructure aids movement and transportation which is limited to roads transportation in the study area. Linchfield (1974) asserted that roads are routes, which are primarily used for carrying traffic. Most intra-city, inter-city and inter-state roads are in need of repairs, while most village roads especially in the study area are almost impassable. Electricity infrastructure is one of the most important infrastructures, as its importance cannot be overemphasized; its presence is normally felt in all fields of human endeavor. Educational infrastructure is provided to aid learning and knowledge; it includes facilities for elementary schools (Nursery/Primary), Secondary Schools through Tertiary Institutions (Universities, Polytechnics and Colleges of Education) to support a good standard of education and training. Health facility is another crucial infrastructure of any economy, its primary mandate is to provide health care services to the people of the state through the management of secondary health facilities.

Soft infrastructures are the framework required to keep and maintain the different institutions which includes both the physical and the non-physical assets. Examples of physical assets are the buildings that house the network and the equipment used to maintain the institution. The non-physical assets are the software and programs, the governing rules and regulations, the financial system, and the organisational structure. In essence, the soft infrastructure embodies the system of delivery of services to the people.

Agencies Responsible for the Management of Public Infrastructure in Nigeria

Nigerian Communications Commission (NCC) is independent regulatory body for managing the Nigeria Telecommunications Industries. Other agencies are: Post Office, Nigerian

Television Authority (NTA), Federal Radio Corporation of Nigeria (FRCN), Nigerian Broadcasting Commission (NBC); MTN Nigeria, Glong; etc. The Nigerian Electricity Regulating Commission (NERC) is an independent regulatory body with authority for the regulation of the Electric Power Industry in Nigeria**.** The agency responsible for the management of Ondo State Electricity supply is Benin Electricity Distribution Company (BEDC). Also, responsible for the management of transportation infrastructure in Nigeria is the Federal Ministry of Transport, it coordinates road, rail, marine and air transport. The mandate, policies, program and budgets of the ministry are implemented through the various agencies at the ministry which include Nigeria Union of Road Transport workers NURTW. The ministry responsible for the management of health facilities in Nigeria is the Hospitals Management Board (HMB). Its primary mandate is to provide health care services to the people of the state through the management of secondary Health facilities. The agency responsible for the management of educational infrastructure is the Ministry of Education; it is the government body that directs education in Nigeria. It performs its functions through the State Universal Basic Education Board (SUBEB), Teaching Services Commission (TESCOM).

RESEARCH METHOD

The type of research design employed in this study is survey design. The study population in this research work includes the general public and agencies in the twelve (12) political wards of Ondo West Local Government Area, with population size of 283,672populations(NPC, 2006). As a result of the wide coverage of the study area, the field survey is limited to the five (5) most populated political wards that have touches of development by the state government and the public sector. These political wards include wards 3, 6, 7, 9 and 10, all with population of 160,979. Average family size in Nigeria has been estimated at 7 (Fasakin, 2006). This implies that, there are about 22,997 households in the five (5) sampled wards. In order to arrive at a manageable sample size in each ward, the below equation was used.

$$\frac{\text{Ward population}}{\text{Total Population}} \; x \; \frac{\text{Sample Size}}{1} \; \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (1)$$

Therefore, 230 households and 20 officers from the agencies were sampled, making a total of 250 questionnaires administered. Information on infrastructure provision and problem were sourced in the study area.

Essentially, the sources of data for this research were both primary and secondary data. The primary data were obtained by personal observation and the administration of multiple-choice questionnaires. Stratified sampling method was used to select the surveyed political wards among the identified political wards and the agencies in the study area, while random sampling was adopted to collect data and information from the households and from the officers of the agencies. 230 questionnaires were structured on the socio-economic characteristic of respondents at the five surveyed wards and agencies. A total of: 39, 45, 47, 45 and 54 households were randomly selected at wards3, 6, 7, 9 and 10, respectively. This was based on the level of their awareness and experience on infrastructure provision and problems. 20 copies of questionnaires were administered on the officers at the agencies in charge of infrastructure provision and management in the study area. This is to ensure that adequate information that pictured the level of development was collected. Therefore, in all, 250copies of questionnaires were administered, representing 1% of the sample size. The secondary data were obtained from textbooks, project dissertations, seminar papers, journals and research materials on infrastructure development in different part of the world. Useful information was obtained from internet and relevant agencies connected with management of Infrastructure in Ondo West Local Government Area.

Descriptive statistics was used to analyze the data collected in the course of the research. Tables and chart were employed to present the magnitude of occurrences of the variables that were obtained.

DISCUSSION OF FINDINGS

Socio-Economic Attributes of Respondents

Table 1 shows that age group 31-41years were the predominant respondents during the field survey. This is perhaps the most active age group of the population. Similarly, table 2 examines the educational background of the respondents and reveals that 42.4% of the respondents holds NCE/ND certificate, 34.4% holds Primary/ Secondary schools certificate and 21% holds B.SC/HND certificate. Table 3 shows that only 39.2% of the respondents are civil servants, 16% are students while others (44.8%) are self-employed. Table 4, shows the gender composition of respondents in the study area. According to this figure, 53% are males. The implication of this is that male dominates the sampled respondents.

Table 1: Age structure of Respondents

Age of Respondents (Years)	Frequency	Percentage
10-20	28	11.2
21-30	52	20.8
31-40	125	50.0
41and above	45	18.0
Total	250	100.0

Table 2: Education of Respondents

Education Status	Frequency	Percentage
BSC/HND	53	21.2
NCE/ND	106	42.4
Primary/Secondary	86	34.4
None of the above	5	2.0
Total	250	100.0

Table 3: Employment status of Respondents

Occupation of Respondents	Frequency	Percentage
Civil servant	98	39.2
Trader	58	23.2
Artisan	35	14.0
Student	40	16.0

The Infrastructure Available in the Study Area

Figure 1 shows the respondents' rating of the available infrastructures in the study area. It revealed 37% of the respondents opined that education facilities have the highest frequency in the study area. The agency responsible for the management of Education facility is the ministry of Education performing its function through the Teaching service commission (TESCOM) in Ondo Town. Electricity facility has the 2nd highest frequency with 30% of the respondents with this opinion. The Nigerian Electricity Regulating commission (NERC) is

the regulatory body for Electric power supply in Nigeria, however, Benin Electricity Distribution company (BEDC) is the agency responsible for the management in Ondo town. 14% of the respondents were of the opinion that transportation facilities has 3rd highest frequency and the agency responsible for the management of transportation infrastructure in Nigeria is the Federal Ministry of Transport performing its functions through Nigerian Union of Road Transport Workers in Ondo town. Nigerian communications commission (NCC) is the regulatory body for managing the Nigerian Telecommunication industries, performing its duties through the postal Agency, Nigerian Television Authority (NTA), MTN Nigeria, Glo NG etc.10% opined that telecommunication facilities are available in the study area and finally 9% confirmed the availability of health facilities. The ministry responsible for the management of health facilities in Nigeria is the Hospital Management Board (HMB), providing health care services to the state through the management of secondary health facility. From the above analysis, it was revealed that education, electricity, transportation, telecommunication and health facilities are the available infrastructure in Ondo West Local Government. The implication of this is that, no nation can survive without necessary infrastructure, this is supported by Olaseni and Alade (2012) that, road, electricity, health, education, and communication infrastructures have profound effects on the economic development of a nation.

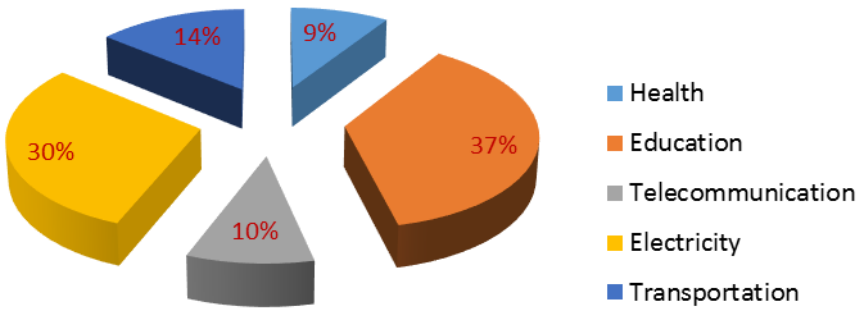

Figure 1: Available infrastructure in the study area

Problems Associated with the Management of Public Infrastructure

FERMA is charged with the responsibility of maintenance of Federal roads in Nigeria, the state and local government roads are not given the needed attention as its maintenance is left to the State and Local government accordingly. This is corroborated by the report of African Development Bank ADB (2010) that if the entire networks of the state and local government are in good condition, annual review and periodic maintenance would be about US200million and US550million respectively.

Another problem identified is that road design standards have not kept pace with increasing traffic volumes and vehicle weights and poor axle load control that is causing significant damage to the existing road network, lack of road markings, safety barriers, and signage that are contributing to the high accident and casualty rate on all roads (Oladele 2013). Administrative management of transport routes slow the movement of goods and people and raise transport costs. Many of the observed shortcomings in the urban transportation system in Nigeria stem from sector management weaknesses (Edema 2010). Nigeria is characterized by the absence of a planned and effectively integrated multi-modal transport system that incorporates rail and water transport, where applicable, to complement road transport on which there is over-dependence. There does not appear to be a well-articulated policy and strategic framework for the urban transport sector. Institutional responsibilities for urban

transport development and service provision among various agencies are fragmented at the three levels of government with no coordinating framework. (ADB, 2010)

The power sector has also been characterized by a high degree of operational inefficiency and under-pricing. As of 2005, only 64 percent of billed revenues were collected. Distribution losses were as high as 30 percent, compared to best practice levels of 10 percent. Tariffs covered about 28 percent of the costs of power supply. In 2005, Nigeria's residential power tariff was around US$0.03/kWh – among the lowest in Africa – and well below the average of US$0.16/kWh found in African countries predominantly reliant on thermal generation technologies. (ADB 2010)

Faced with the challenge of providing electricity and thus improving the economy with all its concomitant social and economic benefits, governments since 1999 have initiated a number of interventions, many of which have failed in implementation due to inadequate planning and the absence of crucial technical support. There is no doubt that there are sufficient domestic resources to meet the power needs of the nation. These resources include oil and gas, coal, substantial hydropower capacity and other forms of renewable resources. The exploitation and utilization of these resources have been hampered, like other aspects of national development, by the grossly inadequate indigenous technical capacity and poor governance in the sector and lack of long range planning. (ADB,2010)

Despite spectacular development over the last decade in terms of communication, a deep digital divide continues to separate Nigeria from more advanced economies in the world. Nigeria ranked a low 13th among the 29 Sub-Saharan Africa countries included in a recent survey. The divide is especially deep in terms of the quality of ICT-related infrastructure, affordability of ICT and the availability of ICT-related skills. With mobile telephony subscriptions of 55 per 100 persons, Nigeria ranks 122 among the 142 countries surveyed. Access to other technologies is limited: only 15 percent of households have a personal computer and only 9 percent of households have internet access (ADB, 2010).

Edeme 2010, opines that infrastructure development management in Nigeria suffer from capital flight, capital sink and capital stagnancy. A lot of materials and managerial services are procured outside the country, the contracts are full of loop-holes that allow leakages of funds. In some cases, there is over-design for the designers to earn more professional fees which are percentage of the contract sum. Capital stagnancy due to abandoned projects is also very rampant. The appropriate designs that will ensure value for money are not adopted. The finance not adequate is procured at high interest rates and financial management is lacked by most Nigerian contractors. The technology of construction is scarce and the management of infrastructure is lacking. The maintenance culture of Nigerians is poor thereby allowing most projects to decay (Oyedele, 2012).

Data sourced also revealed that major problems confronting infrastructure in the study area is not far- fetched from the foregoing discussions.

Table 5 shows the respondents opinion of problems confronting infrastructure, six majors problems were identified and they are lack of adequate funding (27.6%), poor maintenance culture (22.8%), lack of quality materials (17.2%) and wrong selection of contractors (15.2%) as problems confronting infrastructural development in the study area. Others problems are nonchalant attitude of people and lack of expertise. This is in tune with Oyedele(2012) that, poor maintenance, nonchalant attitude of the people, corruption and dearth of visionary leaders are the major challenges facing infrastructural development in Nigeria. Based on these, some policy recommendations were put forward to address these issues in order to

improve the provision and management of infrastructure in Ondo West Local Government Area.

Table 5: Problems Confronting Infrastructure in the Study Area

Problems	Frequency	Percentage
Poor Maintenance Culture	57	22.8
Nonchalant Attitude of People	33	13.2
Lack of Adequate Funding	69	27.6
Lack of Expertise	10	4.0
Wrong Selection of Contractor	38	15.2
Lack of Quality Materials	43	17.2
Total	250	100

RECOMMENDATIONS AND POLICY GUIDELINES

There is an increasingly clear understanding within Nigeria that sustainable improvements in urban mobility cannot take place without the implementation of proactive policies in favor of public transport development.

Many of the observed shortcomings in the urban transportation system in Nigeria stem from sector management weaknesses. Nigeria is characterized by the absence of a planned and effectively integrated multi-modal transport system that incorporates rail and water transport, where applicable, to complement road transport on which there is over-dependence. There does not appear to be a well-articulated policy and strategic framework for the urban transport sector.

Thus, the performance of government depends on the role assigned to the state, the competence of public agencies and the extent to which there is an enabling environment that facilitates and encourages growth promoting activities by private citizens and honest behavior by public officials (Anyanwu,1998).The federal government has appropriated more powers to itself than it can cope with. With about 52% allocations in a three-tier government structure of federal, state and local governments, the federal government is leaving the state with lesser fund for projects.

Therefore, four requirements of any physical infrastructure projects are: design, finance, technology and management. The appropriate designs that will ensure value for money should be adopted. The finance that is not adequate and procured at high interest rates should be reviewed. Nigerian contractors should not be lacking in financial management. The technology of construction should be updated and the management of infrastructure improved upon. Awareness on the importance of maintenance culture by Nigerians should be promoted thereby not allowing most projects to decay.

Stemming from the foregoing, the following recommendations are put forward based on findings on the management of infrastructure in the study area in order to keep the public infrastructure in good condition of functionality:

i. There should be proper maintenance of the available infrastructure, the beneficiaries of public infrastructures should not handle them carelessly but regard them as their own properties which should not be allowed to degenerate, vandalized or stolen. Adequate planning and maintenance scheduling should be done by managing agencies for the various facilities, this would prevent breakdown of facilities.
ii. A monitoring body or maintenance committee for the various infrastructure such as the Federal Roads Maintenance Agencies (FERMA) and its supporting agencies, The Nigerian Electricity Regulating Commission (NERC), Hospital Management Board (HMB), Ministry of Education through its various agencies and the Nigerian communication commission through the various communication agencies should be

adequately equipped financially and with experts to monitor and manage the infrastructure. The issue of inadequate man-power should be addressed by employing qualified and competent people in the agencies in charge of infrastructure management. This will enhance or promote proper inspection of the infrastructure and it will also reduce the burden on the present staff.

iii. Provision and maintenance of infrastructure should be funded adequately; this can be done by releasing adequate fund for the provision of standard and efficient infrastructure. There should be more provision of management instrument for efficiency and the available instrument should be put in good condition for effectiveness.

iv. Quality materials should be used during construction process and there should be proper monitoring of the contractors and others involved in infrastructure provision, this will ensure durability of provided infrastructure.

CONCLUSION

Different government policies in Nigeria have led to infrastructure decay, which has brought about poor erratic power supply, inefficient communication, poor road connectivity, inadequate output by health officials and a deteriorating education system resulting in stagnant economic performance (Bureau of Public Enterprises BPE 2003, Edame & Effiong 2013). Various action plans to improve the living standard of the populace through provision of infrastructure has been put forward: Transport, Electric power and access to energy (rural electrification), information and communication technologies etc (ADB,2010). However, these plans have failed to meet its objectives due to unstable budgetary allocation, underfunding of the projects by government, maintenance inefficiency, poor knowledge on appropriate technology for development, outdated design structure of projects, Finance, corruption etc (Olufemi, 2012) A cursory look at Ondo west local government area would reveal a spectacle of derelict public building and infrastructural facilities. It is therefore, essential for Nigeria (Ondo West LGA) to carry out administrative reforms and management of the infrastructure (Edame, 2013). In fact the ever-increasing population of urban migration has over stretched the available infrastructure beyond limit thereby. There is persistent inadequate supply of basic infrastructure. It is also imperative that a comprehensive planning and management strategy is adopted to ensure that the inadequacies in the areas of provision and maintenance of urban infrastructures are corrected.

ABSTRACT

Efficient management of its refuse is one of the major indices for assessing the level of development of a developing-nation. Inefficient management of refuse poses great threats to public health and the environment. High solid waste generation is linked to economic development, unsustainable use of rapid industrialization, urbanization, and non-existing or poor waste management strategy. Open and indiscriminate dumps threaten environmental safeguards; they can pose major public health hazards and environmental pollution, especially the urban areas. This study investigates environmental impact of indiscriminate disposal of solid waste and its consequent effects on aesthetical value of Okitipupa in Ondo State, Nigeria. A total of 370 copies of a questionnaire schedule were administered in selected locations within Okitipupa metropolis based on systematic sampling technique. In-depth interviews (IDIs) of 70 selected residents/respondents were also conducted while tables and figures presented the findings of the study. It was observed that indiscriminate dumping of refuse causes environmental hazards including flooding (due to the blockage of main drains and sewers), and obnoxious odor (due to decay). It also destroys the aesthetical value of the entire environment. This study, therefore, recommends public enlightenment programs e.g. health education and the use of effective waste-management strategies in achieving an enduring aesthetics in the urban environment.

Keywords: Aesthetic Value, Solid Waste, Urban Environment, Waste-disposal Management

INTRODUCTION

The socio-economic development of any nation depends much on the sustainability of the environment. Akinbode (2002) opined that environment implies all external factors, living and non living materials with social and economic condition for sustainability. Therefore, indiscriminate refuse dump by anthropogenic practices is globally known to impact negatively on the environment. The disposal and management of solid waste is a globally challenging issue especially in developing countries due to its adverse environmental effects. Ayuba et al (2013) observed that mankind depends on the environment to sustain lives and that solid waste is one of the three major environmental problems, including flooding, and desertification, that are often considered life threatening.

Waste is rubbish or materials that are not needed and are economically unusable without further processing. It can also be described as any substance which constitutes scrap material or article, which requires to be disposed of as broken and worn out. It is an inefficient, or other unwanted, surplus substance arising from application of any process, or any substance. Olanipekun and Oyeniyi (2007) asserted that refuse are unwanted, discarded, non-liquid material emanating from various human activities at home and work-stations, such as paper, animal- droppings, carcasses, cellophane, bags and leaves, empty sachets, bottles, empty cartons in (market-places), abandoned automobiles (on public roads and industries), toxic industrial- waste, agricultural waste etc. Okecha (2000) described solid waste as comprising all waste arising from human and animal activities that are normally solid, mostly discarded as useless or unwanted. It is an unofficial index of prosperity. It can also be a major problem to human life especially where it is not well managed.

The problem of solid waste disposal in urban centres in developing countries is a major concern to government and this problem has become worrisome in Nigeria where municipal

Adelakun, A.; Adegunloye, O. & Adebusoye, A. (2016). Effect of Infrastructure Provision on Residential Property Values in Ijaiye Housing Estate, Lagos, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1369-1379

waste generation is always on the increase because of rapid population expansion growth and socioeconomic factors (Omole and Alakinde, 2013). Kenneth and Huie (1983) classified solid waste principally as garbage, ashes and rubbish. The garbage includes varying organic matters resulting from preparation and consumption of food. Ashes include remains of cooking and heating processes while rubbish may be papers, rags, wood, leaves and other non-biodegradable materials such as glass, metals and polythene materials. Sharma, (2009) classified solid waste as garbage which includes man-made waste from food; and rubbish comprising non-biodegradable or non-decomposable waste either combustible (such as papers, wood and cloths) or non-combustible (such as metals, glass, ceramics and polythene). Ashes comprise of the residues of combustible solid fuels, while large waste are made up of demolition and construction debris and trees, dead animals and, lastly, sewage treatment comprising of the materials retained on sewage-treatment screen, settled solid, and bio-mass. The current state of plastic-bag and polythene-waste pollution in Nigeria, and most especially in Okitipupa, is alarming. Several environmental impacts, including blockage of waterways and choking of animals, soils and mosaic litters of pure water sachet in the landscape requires urgent attention (Ogwo et al., 2013). Indiscriminate disposal of refuse is a situation where refuse is dumped in any environment or place whether at home, schools, streets, or market place and not minding the environmental risk-factors that are likely to follow. Ekpu and Archibong (2007) opined that the high rate of refuse generation by people, both in rural and urban areas is a direct reflection of the inefficient ways materials and energy resources are being used. Nearly every human activity creates refuse, which may be difficult to get rid of, especially with the careless attitude of some residents to sanitation. Lucas and Gilles (2006) asserted that the indiscriminate habit of refuse disposal has significantly affected environmental cleanliness and, in turn, bred environmental risk-factors affecting the health and well-being of the people.

In many developing countries, solid waste disposal sites attract, scavengers and small children which is the sources of contamination due to incubation and proliferation of flies, mosquitoes, and rodents. They, in-turn are disease transmitters that affect the population health, which has its organic defense in a formative and creative state. The said situation produces gastrointestinal, dermatological, respiratory, generic, and several other kind of infectious diseases (Salami, 2010). Open dumpsite in developing urban cities involved indiscriminate disposal of waste. They are uncontrolled and therefore pose major health threats which affect the landscape of urban cities (Sood, 2004). The UNEPA, (2006) stated that waste that are not managed properly, especially solid waste from households and the community, are a serious health hazard and lead to the spread of infectious diseases. The report further stated that unattended waste lying around attract flies, rats, and other creatures that, in-turn spread diseases such as Lassa fever.

The present situation in Okitipupa, as in other urban areas of Nigeria, portrays the situation analyzed above. However, empirical observation reveals that the Niger Delta Development Commission (NDDC) donated some Dino refuse disposal trucks to the Local Government Area and is being managed by both the Sanitation and the Local Government Environmental Protection Agency (LGEPA) Departments in the LGA where Environmental Officers are in control. This arrangement, however, failed and took a new turn due to the inefficiency of the officers, insufficient trucks, poor maintenance culture, inadequate funding, greed, indiscipline, illiteracy and unconcerned attitude of both the public and the officials that led to the ineffective waste management in the study area. Therefore, this paper, sort to present findings on the environmental and health impacts of indiscriminate solid waste disposal and its consequent effect on human and the environment in Okitipupa metropolis in Ondo State,

Nigeria, and, also make suggestions on appropriate waste disposal methods and management to avert further deterioration of the environment.

LITERATURE REVIEW

Sources of Refuse

The daily output of waste can be linked with the levels of urbanization/industrialization, living standards, dietary habits, and life styles of people living in an environment. Waste can be classified, based on its generation, its origin and sources. Oyediran (1997) asserted that waste is generated from domestic, agricultural, and industrial sources. The commercial sources of refuse generation include:

i. Domestic refuse; b) Refuse collected by the street cleaning services or scavenging,
ii. Stable litter-animal droppings and left-over animal feeds; d) Market refuse,
iii. Industrial refuse or inert materials, and, f) Sewage sludge.

Methods of Refuse Disposal

For a healthy environment, waste disposal method is very important depending on the types of wastes being generated, its volume, and the choice of disposal techniques. Professionalism is required in the selection of waste disposal sites as domestic waste could be highly polluting (Lucas and Gilles, 2006).

The main waste disposal methods are:

i. **Incineration:** Burning or incineration method is adopted where there is no adequate collection services and where refuse content is low and always at a localized level. Burning has a lot of disadvantages because of its close proximity to domestic dwelling. It could create fire risk in addition to producing atmospheric pollution. It could be very dangerous to asthma patients because of its obnoxious odor and choking effects.
ii. **Composting:** This method is adopted where waste product contains high organic matter. Composting is a method of combined disposal of refuse and “night soil” or sludge.
iii. **Indiscriminate Dumping:** Refuse is dumped in low lying areas as an easy method of disposal of dry refuse. This method entails exposing refuse unduly to flies and rodents; such that it becomes a nuisance from the smell and unsightly appearance. Another major problem arising from this method is that the loose refuse can be dispersed by winds and carried by rain as run-off; and dumped in the drainage system to contribute to the pollution of surface and ground-water. This method is considered the most unsanitary method that creates public-health hazards, a nuisance and severe pollution of the environment (Park, 2007).
iv. **Manure pits:** This method of refuse-disposal is quite effective and simple though adopted mostly in the rural areas. It is by digging ‘manure-pits' by individual householders. The garbage, cattle-dung, straw and leaves could be dumped into the manure-pits and covered with earth after each day's dumping.
v. **Burial:** Nwankwo (2004) discovered that burial of refuse is a method suitable for small camps.

A trench 1.5m wide and 2.0m deep is excavated and after each day, the refuse is covered with 20cm to 30cm laterite and compacted. However, both burial and manure-pits are not good methods of waste-disposal for inorganic or non-bio-degradable waste such as plastic waste.

Impact of Indiscriminate Refuse Disposal

The blockage of drainages by debris moved from refuse dumps by runoff during storm is the major cause of flood in most cities. Toyobo et al., (2013) observed that empty sachet water disposed in gutter caused blockage of drainages which constitute to the level of flood during heavy downpour, and this is the characteristics feature of Broad Street especially Ebute area. Apart from the physical damage caused by roadside disposal of solid waste to the environment, studies have shown that most of the synthetic or non-biodegradable materials which are disposed in these open roadside dumps contained some harmful chemical elements which have their origin in the decomposing high refuse dumps that dot the entire landscape. Iguisi et al (2001) also observed that several chemical elements have their origin from the decomposing high refuse dumps in the urban area.

Olokor (2001) asserted that the impact of indiscriminate disposal of refuse has been a worrisome health issue for quite some time now. One aspect of the problem is the fact that the cause-effect relationship takes a long time to establish. In some cases, the effects are spontaneous and are seen immediately while in many other cases it is not as direct. The environmental risk-factors attached to indiscriminate refuse disposal can cause mild to moderate illness, and at times, severe illness that can lead to death. There can also be the outbreak of epidemics like cholera, typhoid fever, and other diseases, in severe forms, causing death, especially in children aged 0-15 years, whose immunity is not as strong as that of the adult population. Some risk-factors of indiscriminate refuse disposal include:

i. Breeding of arthropod-borne-diseases which carriers can transmit diseases as malaria, viral encephalitis, typhoid, paratyphoid fever, diarrhea, dysentery, cholera, gastro-enteritis, amoebiasis, conjunctivitis, sleeping sickness, relapsing fever, scabies, filariasis, enteric pathogens, etc. (Park, 2007)
ii. Breeding of flies: As the organic portion of solid waste ferments, it gives rise to the breeding of flies which can deposit polluted materials on the skin or on food or other objects thereby contaminating it. Huge piles of refuse can constitute nuisance and an unsightly scene especially when dumped in strategic places like motor parks, market places or on the streets causing offensive odour and health hazards. (Alakija, 2002).
iii. Refuse dumps give rise to smog and air pollution when burnt openly. Discharge of carbon monoxide by industries, domestic combustion of coal, wood or oil, open burning of refuse, incinerators, pesticide spraying, wind borne dust, fungi, moulds, bacteria and nuclear energy all contribute to air pollution (Ayodele, 2007).
iv. Fire Disaster: Unguarded burning of refuse or indiscriminate throwing of cigarette stubs into refuse dumps may cause fire disasters which can lead to serious devastating effects on human life. Also fire may break out from the methane gas from the organic matter in refuse piles destroying lives and properties. (Lucas and Gilles, 2006).

Achalu and Achalu (2004) found that blockages in drainages caused flooding and hinder the free-flow of erosion, while Moronkola (2003) claimed that indiscriminate dumping of refuse gives rise to offensive odour. On environmental accidents, Ajayi (2004) asserted that if an environment is polluted with filthy items such as broken bottles and heaps of hazardous objects, children and adults can be injured from the materials and, if not quickly attended to, can lead to tetanus infection, which, in turn, can kill the host. Poor environmental sanitation according to Nwankwo (2004) is the indiscriminate disposal of refuse that often constitutes serious threats to human health and the achievement of healthy environmental sanitation. According to Bassis (2004) serious and devastating outbreaks of diseases and epidemics have been regularly associated with the indiscriminate dumping of refuse.

RESEARCH METHOD

The Study Area

Okitipupa metropolis is situated in the southern senatorial district of Ondo State, Nigeria. It is located between Longitudes 4035' and 5050'E and Latitudes 6025" and 6025' N within the tropical rainforest zone of Nigeria (Figure 1). It has a population of about 233,565 (NPC, 2006) with a current estimate of about 400, 00, and, it covers a land area of about 636sq km.

Okitipupa, the erstwhile headquarters of Okitipupa Division but now comprising of Okitipupa, Irele, Ilaje, and Ese-Odo Local Government Areas (LGAs), is now the headquarters of Okitipupa LGA in Ondo State. It is bounded in the North by Odigbo LGA and on the East by Irele LGA, South by Ilaje/Ese Odo LGA and in the West by Ogun State. The inhabitants of the LGA are mainly Yoruba of the Ikale ethnic group. The Local Government Area can boast of many big towns and villages like Okitiupa, Ilututu, Ode-Aye, and Igbotako. The people are mainly urban dwellers and no matter where they go to farm, they still come back to base. Okitipupa is the headquarters of the LGA, while other towns include Aye, Ikoya, Ilutitun, Iju-Odo, Igbotako, Erinje, Igbodigo, Ayeka, Erekiti, Iju-Oke, Igodan, Okunmo, Omotoso, Ayetoro, Wakajaiye and Mile 49 along Lagos–Benin Express way. Aside from the agrarian occupation of the inhabitants of the LGA, other economic activities involve agricultural production and trading-wholesale and retail as well as providing services in, financial institutions, hotels and restaurants.

Methods of Data Collection

The data used for this study were derived from both primary and secondary sources. The primary data were collected from direct interviews, personal observation, and responses to a Questionnaire schedule administered on the respondents/residents. The secondary data were drawn from previous studies done on the research topic and collated, from books, journals, library-search/archives and the Internet.

The sample for the study were residents randomly selected from four areas; namely Broad Street, Ikoya Road, Erinje Road, and Sabo. The respondents from the sampled households in all the areas were selected using a systematic sampling technique based on interval of five. The Questionnaire Schedule designed for the study contained questions for probing into the method of waste disposal used, general aesthetics of the area, and effects of indiscriminate dumping of refuse in the area.

In each of the areas sampled, 100 copies of the Questionnaire schedule were distributed randomly in each of the four sampled areas, making a total of 400. 370 were duly completed and retrieved while 20 were not returned and 10 others were invalid. The response Rate of 92.5% is good enough for the data to be reliable. Site-visits were also undertaken in order to identify indiscriminate waste dumps and access the general aesthetic quality of the areas. Data obtained, were presented in tabular form for clarity and easy understanding and analyzed by descriptive statistics. 70 in-depth interviews (IDIs) were also conducted on some residents in the area; to complement the quantitative data from the Questionnaire Schedule. The qualitative data generated through the IDIs were transcribed and reported verbatim.

RESULTS AND DISCURSIONS

Socioeconomic Characteristics of Respondents

Table 1, in the appendix, shows that majority 29.73% of the respondents attained the primary-school level of education and 23.24% had vocational education while 21.62% attained the level of higher education. Whereas 17.30% attained the secondary school level of education and 8.11% had no education. The table also shows that, majority of the respondents 37.30% were not employed and 32.43% engaged in civil service jobs while 10.81% were

self-employed, others, being 12.97% and 6.49%% respectively, embarked on small scale faming and trading. The implication of this is that most of the respondents engage in all sorts of street trading and small scale enterprise such as hawking, and pure water production/sales as a source of income and livelihood. Some of the residents living close the dumpsites became scavengers collecting solid wastes such as cans, metallic objects, plastics, in order to make a living. Direct handling of solid waste, especially Health Care waste mixed with domestic waste can lead to increasing risk of infection most especially the scavengers. The activities of street traders and market women cause littering of solid waste on the streets and drains thereby destroying the aesthetical values of the environment. The degenerating influence of flooding due to blockage of drains and water ways also leads to overland pollution that drains into the streams or river bodies, which led to infrastructure degeneration.

Types of Waste Generated by Respondents

Table II, revealed that paper and water nylon 27.56% are the commonest generated wastes in the four areas of study, followed closely by food remnant and vegetables 22.70%; clotting materials/foot ware 14.05%; metal scraps/bottles/plastic 12.97% while wood/saw dust, electronic gadgets and other wastes represents 11.89%, 6.48% and 4.32% respectively. The mixed biodegradable and non-biodegradable waste dumped by the road side has negative impacts on the general environment. Some of these solid wastes are been washed by rainstorm into drainages/gutters that were made for free flow of water and end up blocking them preventing easy flow of water and subsequently lead to flooding of River Oluwa/Yewa banks and even people's home along the bank.

Sources of Waste

Sources of solid waste generated by the respondents as indicated in Table III, shows household waste as the highest with 59.4%, while educational establishments and commercial waste takes 15.13% and 13.0% respectively. Industrial waste accounts for 4.90%, agricultural 5.40% and others 2.17%. The biodegradable solid waste in Okitipupa are mostly consumable materials such as kitchen remains, discarded food items, yard wastes, pieces of cloths and discarded cartons that were used for packaging. There are several heaps along the roads with no special organized system of solid waste collection. The residents confirmed that the wastes are either incarcerated at the site or left to rotten and sometimes evacuated during the monthly environmental exercise.

Disposal Methods used by respondents

The Disposal methods of solid waste adopted by residents in the study area are unsatisfactory. The preference of educated people to adopt better methods of waste disposal could be higher than illiterates. It is obvious from the table that people who throw refuse on open land and drains are uneducated. Table IV, shows that 24.32% of the residents prefer to dispose their refuse in any thereby bush and 17.18% in any open spaces thereby constituting nuisance to their immediate environment. Waste Management Authority Dino-bin type of waste disposal method 13.51%. This method has constituted a serious nuisance in the environment because of the nonchalant attitude of the Waste Management Workers. The study also confirmed that, waste evacuation is not regularly done because it takes more than a period of one month to evacuate waste deposited in Dino-bin by the Waste Management Authority. This automatically leads to overflow of waste in the bin which results into spreading of waste along the streets in most cases. It is also a source of transmissible diseases because majority of the respondents either throw their waste on land around the bin, drains or the streets thereby constituting health hazard to the immediate environment. Only a small proportion 3.95% of the respondents deposits their waste in bins and bags from private refuse disposal companies where they can be transferred to dumpsites outside the living environment.

Furthermore, from the total of 70 in-depth interviews (IDIs) conducted, responses on the types of solid waste generation and disposal, revealed household waste to be the major waste generated in the study area, followed by industrial waste, and some biomedical waste. The reason given for high generation of household was the rapid urbanization and industrialization of the study area. This is in line with the findings of Oyediran, (1997) who linked waste with the levels of urbanization and industrialization in living environments. To buttress this, one the respondents Mrs. 'Akin'60 year old trader stated that;

> "I*t was not like this when l was growing up, Okitipupa was not as busy as this and people did not use to throwing dirty anyhow as at then"*

Moreover, on the question of solid waste disposal in the study area the in-depth interview conducted shows that respondents disposes their waste in nearby bushes, open-spaces and only few people employ the skeletal services provided by the Waste Management Authority, while others burn their solid waste and dumps theirs in the drainages, gutter/river. This environment according to the household residents especially those who are living very close to the dump sites complained about the smelly and filthy nature of their environment that also constitutes nuisance to the aesthetical value of the environment. When they were asked for the reasons for indiscriminate solid waste disposal, many of them claimed they do not have a standard or approved refuse disposal. Among those who claimed to dispose their refuse in bushes and rivers were further asked on why they refuse to make use of the Okitipupa Waste Management facilities. All respondents interviewed complained that there are no standard waste management techniques in place in Okitipupa. Mrs 'Ago', aged 40, a teacher, said;

> *"Even around the premises of the local-government Secretariat where one of the Waste Management Authority Dino-bin type of waste disposal method is placed is full of refuse waste littered on the ground, where then is the waste management/facilities?If the local government claims they have waste management they should start with their environment"*

General overview of the environment

From Table V, household residents, especially those living close to the dump site are the most hit of the impact of refuse dumpsite, they complained that the dumpsite near their home is the major cause of sicknesses within that environment. As indicated in the table, 37.30% argued that their surrounding are dirty, 42.70% of the respondents claimed their surrounding are smelly, while 20% said their surrounding are filthy.

Similarly, the result of the complementary in-depth interview conducted revealed that the respondents, argued that their surrounding are smelly, filthy and dirty and that some of the wastes from the dumpsite overlap their houses causing environmental discomfort in the environment. Apart from the fact that waste disposal bins were not provided by the Local Government Authority to willing homes, it was further reported that they are no waste disposals facilities even in market places. The market is littered with waste and the marketers either dump their waste in the gutters/drainages or drop the waste on open spaces (the multi-billion naira ultra-modern market is now a ghost of itself). Another respondent 'Mrs. Ige' aged 35 trader in the market claimed that;

"Since we do not have any standard disposal, we dump our waste in the gutters/drainages so that when rain falls it will help us flush them inside the river especially river Yewa and Oluwa".

When they were further asked on what to do about indiscriminate waste disposal, many of the respondents admitted that they are aware of the implications of indiscriminate dumping of waste, like drainage blockage, flooding, underground stream or water pollution and infrastructural degradation with its attendant health hazards. And they agreed that they are ready to pay a little token if there are standard waste management facilities. They also suggested that isolated waste dumpsite should be provided or marked out by the Local government administrators as a 'drop off location', to enable individuals deposit their waste.

Impacts of Indiscriminate Refuse- dump

The impacts of inappropriate disposal of solid waste are quite numerous to be mentioned. Table VI, shows that, 26.49% of the respondents agreed that indiscriminate refuse dump causes flooding, 27.57% said it causes pollution while 22.16% and 23.78% agreed that it causes erosion and infrastructural degradation respectively. The implication of this is that indiscriminate refuse dump could cause health deterioration, accidents, destruction to the landscape, and other environmental pressures. UNEPA, (2006), further confirmed that waste that are not managed properly, especially solid wastes from households and commonly, are a serious health hazard and lead to the spread of infectious diseases. The report further stated that unattended waste lying around attract flies, rodents and other creatures that, in turn spread diseases. The mountains of refuse dump which decorate the major roadsides in Okitipupa serve as good hideout for rodents and snakes. These rodents are known to be vectors of the deadly "Lassa fever" and the snakes are also known to be poisonous reptiles. Also the biodegradable wastes serve as good breeding grounds for mosquitoes. These spread various diseases like cholera, typhoid fever, malaria and yellow fever. It therefore impacts negatively on the health the residents and also destroys the beauty of the environment.

Respondents' view of Indiscriminate Refuse Dump

As reported in Table VII, majority of the respondents 38.90%, were not satisfied with the indiscriminate waste disposal. About 30.30% had no idea of the consequences of the effects of dumpsites. Only a few of the respondents 11.40% whose refuse are being evacuated by private waste management companies seem to be satisfied with the system. On the environmental aesthetic and quality, majority of the respondents confirmed it as being filthy and dirty.

CONCLUSION

The study examined the consequences of indiscriminate solid-waste disposal by households in Okitipupa and environment. Results from the analysis of the data reveal that both far-away and nearby respondents suffered from related-diseases due to the location of dumpsites closer to their houses. This study further reveals that the indiscriminate dumping of refuse on road-sides and in any open space in Okitipupa often result in drainage blockages, flooding, underground stream or water-pollution, and infrastructural degradation with its attendant health hazards. It was also noted that the extent of air and water pollution is worst in the raining season as a result of offensive and disease-carrying odor, as well environmental decay during the dry season. The smoke from the burning of refuse in the dumpsite is a major source of air-pollution that causes asthma and chest pain.

The study therefore concludes that dumpsites should be properly located away from houses and properly managed to minimize its effects on the environment. People need to be educated by health motivators about the effects of dumpsites on their health, therefore, for a sustainable management of waste the study emphasizes the need for a frequent and adequate publicity and environmental health enlightenment to ensure healthy environment. The study further suggests the need for the introduction of an environmental management strategy (by

means of legislation) with clearly defined objectives such as the introduction of waste disposal bin, regular environmental sanitation period, more Dino-bin, adequate funding of waste disposal equipment, introduction of permanent dumpsites outside the residential area, that can be articulated into one holistic approach to achieve a cleaner and healthier environment with good aesthetics value.

ABSTRACT

The study examines the effect of infrastructure provision on residential property values in Ijaiye Housing Estate. It assesses the level of satisfaction of occupiers with the maintenance of the infrastructure and the effect of the services on the residential property values in Ijaiye Housing Estate, Lagos, Nigeria. Structured questionnaire were administered on one hundred and twenty five (125) respondents for the study. Data collected were analyzed using descriptive (frequency distribution tables and weighted mean score) and inferential (multiple regression analysis) statistics. Findings revealed that parking space is the most adequate of all the infrastructures in the estate, while security and water supply were somewhat adequate. Also, the occupants are satisfied with the maintenance of water supply above other infrastructures, while electricity is the least maintained. Furthermore, the results of the regression analysis shows that all the infrastructural facilities, except type of security outfit and parking garage, have significant effects on the values placed on residential properties in the estate. The R^2 Statistics is 0.553, which is significant at 0.000 levels. It is therefore recommended that the available infrastructures in the estate should be adequately maintained in order to keep the functionality and further enhance the value of the residential properties in the estate.

Keywords: Infrastructure, Provision, Residential, Property, Value

INTRODUCTION

Over the years, infrastructural provisions have been played down by all levels of government (Federal, State and Local) perhaps because they are largely ignorant of the fact that a major determinant of property values is the availability of infrastructures (Odudu, 2003). The provision of infrastructural facilities is of high importance in every country because of its contribution to the economic development of a nation. The efficiency of any form of human activity system, including urban area, largely depends on the provision of efficient infrastructure and services (Babarinde, 1998). The quality and coverage of infrastructure services have a major impact on living standards and economic growth, yet it is estimated that two billion of the world's poor lack access to adequate sanitation, two billion lack access to electricity, and one billion lack access to clean water (United Nations, 2002).

According to Oyenuga (2006), housing comprises of the immediate accommodation, environment and facilities like roads, water, electricity and a host of other facilities that make living comfortable to the dwellers. The World Health Organization defined housing not only in terms of the dwelling units but also in terms of the facilities and services in them. Therefore, urban infrastructure plays an important and indispensable role in the economic, social and environmental aspects of life of any urban setting. The competition for locations with good urban infrastructure usually results in an increase in land and housing values, either sales or rentals (Harvey, 1993). The availability of these basic facilities, public utilities and services in any residential area enable the properties to function properly, efficiently, satisfactorily, and become more marketable. Okoh (2010) discovered that the rental values of residential properties were directly dependent on the level of adequacy and functionality of the facilities available. Ibrahim (2011) is of the opinion that the presence of facilities generates high preference, keen competition for properties and thus high rental values, while

Ezeokoli, N. B. & Nwosu, A.E. (2016). Effect of Infrastructure Provision on Residential Property Values in Ijaiye Housing Estate, Lagos, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1380-1387

absence of facilities results in low patronage, disincentive to people, attraction of poor tenants and consequently low rental values.

However, it is painful to note that the Infrastructural report of Nigeria, just like any other third world country, is nothing to write home about. Research has shown that the housing situation is in a regretful state both quantitatively and qualitatively (Agbola, 1998; Nubi, 2000; Ajanlekoko, 2001; and Oyedele, 2006). Therefore, the government ought to put in place all measures deemed fit to make the environment beneficial for living for everybody. Therefore this paper tends to examine the effect of infrastructural provision on residential property values in Ijaiye Housing Estate, Lagos,

LITERATURE REVIEW

According to Ajibola, Awodiran and Salu-Kosoko (2013), infrastructure network is the very socio-economic climate created by the institutions (public or private) that serve as conduits of trade and investment. Infrastructure does not only affect production and consumption directly, it also creates many direct and indirect externalities. It involves large flows of expenditure, thereby creating additional employment (Oyedele, 2012). Equally, infrastructure can have a significant impact on output, income, employment, international trade, and quality of life. Kumar (2005) observed that the provision of infrastructural facilities in any socio-economic unit whether a nation, region or community could have either a positive or negative impact on property value. For instance, while the provision of infrastructural facilities like good roads network, water and electricity supply, drainage system, good refuse collection treatment and disposal system etc enhances values to unprecedented level, the inadequacy or lack of these facilities will adversely affect value as a paradox.

No matter the level of provision or adequacy of infrastructural facilities in any neighbourhood, maintenance will determine the durability of such. However, maintenance has been a neglected field of technology in Nigeria. Maintenance as a service covers every aspect of the building environment particularly the building assets and infrastructural facilities. Amobi (2006) opined that every infrastructure or equipment requires being maintained to remain in functionality and in up-to-date standard. Buildings and infrastructures are the nation's most valuable assets, providing people with shelter and facilities for work and leisure. Therefore, maintenance starts the day the contractor leaves the site, having completed the project. For instance, Olujimi (2010) observed that the level of deficiencies and the degree of deterioration of infrastructure in Nigerian urban centres is becoming more alarming and worrisome due to the inability of the public sector to meet up its social responsibilities to the people. This problem is pronounced in the old, indigenous core areas of the cities and low income areas. However, maintenance aims at retaining components, equipment as well as the entire structure at specified level of performance.

Residential property is considered a basic necessity of life – the third after food and clothing. The fact remains that unlike food and clothing, real property is difficult to acquire. Its importance can be seen in the vital roles it plays in socio-economic and psychological development of individuals, states and nations. Most often, when people talk of the factors affecting rental values of residential properties, the most commonly discussed factors are location, quality of building, demand and supply rate as little or no regard is given to public facilities. Ajibola et al. (2013) observed that whereas location is important in relation to proximity to the target market and sources of supplies; conditions and facilities (infrastructure) are important in relation to attracting optimal rentals. According to Johnson, Davies and Shapiro (2005), infrastructure is one of the determinants of property value, the presence of which leads to appreciation in property values and vice versa. Whereas Hammer,

Booth, and Love (2000) are of the opinion that good and adequate infrastructure is central to property values. This shows that a neighbourhood may have infrastructure that are not adequate to serve the residents. However, when there is adequate and functional infrastructural facility such as accessibility, water and electricity, a residential user may be prepared to pay a high value for a property depending on his consideration for such basic facilities (Harvey, 1993).

THE STUDY AREA

Ijaiye Medium Housing Estate Phase 4 is the fourth phase of the Lagos State Development and Property Corporation (LSPDC) plan that was executed over 20 years ago. The phase of the LSDPC housing project is aimed at providing premium housing qualities and facilities for the medium income earners in Lagos state. It was built between the years 1986 and 1987 as a result of the housing problems in Lagos State. The estate is well laid out with a peaceful and beautiful serenity. LSDPC Medium phase 4 has just one major road, which serves as the entrance and exit point to and from the estate. Most of the links within the estate are parks, one can hardly find streets. Examples are Cactus Park, Lilly Park, peacock road, Eagle Park, Robin Park and so on. The type of houses and structures found inside LSDPC medium phase are flats of a storey building and bungalows. Also, the estate is provided with various infrastructural facilities which make the estate functional such as electricity and water supply, Drainage channel and Recreational facilities, Street lights and community hall, health facilities, Security and Transportation.

Table 1: Operationalization of Variables

Variable code	Definition of variable	Measurement scale
Independent Variables		
PWS	Power Supply	1, if stable and 0, if erratic
WRTS	Mode of Water Supply	1, if Water running 0, if otherwise
SECTY	Type of Security Outfit	3, if Independent Security 2, if Local Vigilante group 1, if No security Operation
WSDP	Waste Disposal System	3, if Disposal by Gov't Agency 2, if Individual disposal at dump site 1, if by Burning
DSTH	Distance from Health Facilities	Actual (Km)
DSCHL	Distance from Schools	Actual (Km)
RDNET	Type of Road Network	3, if tarred 2, if Graded but not tarred 1, if Ungraded
PRKG	Type of Parking Garage	3, if In-built 2, if Open garage 1, if No garage
Dependent Variable		
RENTV	Rental values	Actual Amount (₦)

METHODOLOGY

The study was carried out in Ijaiye Housing Estate, Lagos having eighty three (83) blocks of housing units in the estate comprising of eighty (80) blocks of 4 no. 3 bedroom flats in each block and 3 no. bungalows. Thus, the sample frame for the entire residential properties in the estate is three hundred and twenty three (323). Therefore, 2 units of the 4 no. 3 bedrooms flat in each block were assessed for the study giving a sample size of 160 no. 3bedroom flat and 3no.Bungalow in the estate. This represents approximately 50% of the total flats in the estate.

One hundred and sixty three (163) structured questionnaires were administered on the occupants of the housing estate, out of which 125 (representing 77%) were retrieved and used for analysis. Descriptive and inferential statistical methods were adopted for the analysis of the data obtained from the field survey. The descriptive statistics involves the use of frequency tables, weighted mean score and standard deviation. The weighted mean score on a 5 point likert scale was used to assess the level of satisfaction of the occupiers with the maintenance of the residential properties in the study area.

The regression analysis was used to measure the effect of the infrastructural facilities on the residential property values in Ijaiye housing estate.

$RV = a + b_1X_1 + b_2X_2$ ----------$+ b_nX_n$

Where, RV = Rental Values

a = constant

b_1-b_n= coefficient of the independent variables

x_1-x_n= the infrastructural facilities

FINDINGS AND DISCUSSIONS

This section deals with the presentation of the data obtained from the field survey. It discusses the objectives of research and employed the methodology put forward in the previous section in attaining the goal of the research.

Table 2 revealed that most of the respondents have been in occupation of the property for more than 5 years. This implies that most of the respondents have resided in the estate for a considerable period of time. This could be as a result of the infrastructural facilities in the estate, the rent paid for accommodations in the estate and/or the fact that some of the properties are owner occupied. Agbola (1997) and Megbolugbe (2007) opined that infrastructural facilities in a neighbourhood help in boosting the healthy life of the residents. These often cause residents to desire for and/or retain accommodations in the neighbourhood notwithstanding the rent they pay. Also, most of the residents, by virtue of the years they have spent in the estate, have adequate knowledge of the state of developments in the estate.

Table 2: Period of Occupancy

Period(Years)	Frequency	Percentage
1 – 2	5	4.00
3 – 4	11	8.80
5 – 6	52	41.60
7 – 8	12	9.60
9 – 10	17	13.60
Above 10	28	22.40
Total	**125**	**100.00**

In order to examine the adequacy of infrastructural facilities in Ijaiye Housing Estate, the respondents were asked to rate level of adequacy of a list of possible infrastructural facilities as reported in Table 3. On a 5-point rating scale, '5' is used to denote very adequate, while '1' is used to denote the not adequate.

Table 3 showed the adequacy of the available facilities provision in the estate. From the table, Parking space with the mean score of 4.14 was ranked as being adequate in the estate. Security and water supply with mean scores of 3.93 and 3.70 respectively ranked 2nd and 3rd indicating that they are adequate. However, other infrastructures like, recreational facilities, electricity etc are not adequate as their mean response was less than 3.50. The mean response of between 2.50 and 3.49 indicates that the respondents are undecided or indifferent in their response. These services are available in the estate, but they are not adequate enough to meet

the demand and desires on the residents. The implication of this is that things other than infrastructural facilities such as low rent and owner occupation etc might have kept the residents in the estate, because facility provision is an essential part of any housing provision within a neighbourhood.

Table 3: Adequacy of Infrastructural Facilities Provision

Facilities	VA (5)	A (4)	U (3)	LA (2)	NA (1)	WMS	Rank
Parking Space	83	17	0	15	10	4.14	1st
Security	7	111	0	5	2	3.93	2nd
Water Supply	33	62	0	20	10	3.70	3rd
Road Network	30	55	5	15	20	3.48	4th
Waste Disposal	21	28	0	57	19	3.26	5th
Recreational Facilities	17	30	2	63	13	2.80	6th
Electricity	16	31	1	52	25	2.69	7th
Drainage System	10	27	4	59	25	2.50	8th
School	10	40	5	28	12	2.34	9th
Estate Hall	10	11	4	38	71	1.53	10th
Health Facilities	0	9	0	15	101	1.34	11th

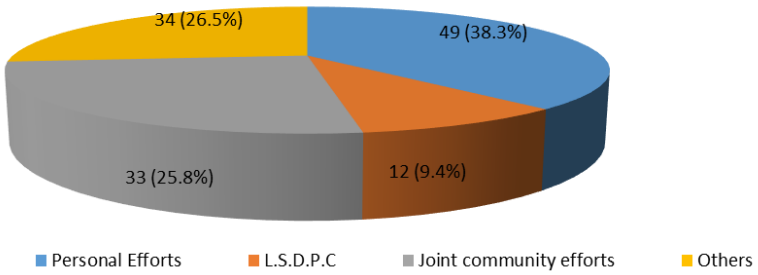

Fig 1: Mode of Maintenance of the Infrastructural Facilities

Fig 1 shows the mode of maintenance of the infrastructural facilities in the estate. It can be observed that that funds employed for the maintenance and sustenance of infrastructures within the estate are those realized majorly through personal and joint community efforts. This reveals the fact that the public sector, as noted by Olujimi (2010), has left their responsibility to the individual community and residents. Ijaiye estate, if care is not taking, might degenerate into slum in the nearest future unless there is a conscious effort by the government to revamp its maintenance level.

In order to examine the level of satisfaction of respondents with the maintenance of infrastructural facilities in Ijaiye Housing Estate, the respondents were asked to rate their satisfaction on a 5-point rating scale, where '5' is used to denote 'highly satisfied', while '1' is used to denote the highly 'dissatisfied'.

Table 4: Level of Satisfaction with the Maintenance of the Infrastructure

Facilities	HS (5)	S (4)	LS (3)	D (2)	HD (1)	WMS	Rank
Water supply	70	10	10	25	15	3.80	1st
Recreational Services	33	55	17	15	5	3.77	2nd
Parking space	49	25	19	12	20	3.57	3rd
Security	38	4	70	5	11	3.50	4th
Drainage	18	53	25	19	10	3.40	5th
Waste disposal	25	19	50	21	10	3.22	6th
Road network	31	16	28	30	20	3.06	7th
Estate Hall	15	32	19	40	19	2.87	8th
Communication	10	27	4	59	25	2.50	9th
School	17	11	23	24	50	2.37	10th
Health facilities	15	35	7	23	12	2.32	11th
Electricity	5	5	4	101	10	2.15	12th

Table 4 shows the level of satisfaction of the respondents with the maintenance of the infrastructural facilities provision in the estate. The result shows that the respondents are satisfied with water supply, recreational services, packing space and security in the estate as these ranked 1st, 2nd, 3rd and 4th with mean scores of 3.80, 3.77, 3.57 and 3.50 respectively. They are less satisfied with maintenance of the drainage system, waste disposal, road network and estate hall with mean scores of 3.40, 3.22, 3.06 and 2.87 respectively, while they are dissatisfied with communication system, school, health facility and electricity supply. The finding shows that the intervention of government is highly needed in the estate to save it from deterioration. These facilities are basic to human function and health, thus they ought to be working very efficiently.

Table 5: Model Summary of Effects of Infrastructural Facilities on Residential Property Values

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.743[a]	.553	.507	61236.65590

Table 6: Analysis of Variance of Effects of Infrastructural Facilities on Residential Property Values

	Sum of Squares	Df	Mean Square	F	Sig
Regression	361298717412.058	8	45162339676.507	12.044	.000[b]
Residual	292494386036.218	78	3749928026.105		
Total	653793103448.275	86			

In Table 5, the value of R (0.743) shows that there is a strong relationship between the dependent variable and the predictor variables, while the coefficient of determination i.e. the R^2 statistics is 0.553 indicating that 55.3% of the variation in the dependent variable (Rental Value) can be attributed to the independent sampled variables (infrastructural facilities). Also, the computed F statistics (F = 12.044) in Table 6falls in the rejection region. The data provides that at least one of the model coefficients is non-zero and this is significant at 0.000 levels. This shows that the model can be used to predict the rental values in Ijaiye residential estate, Lagos.

Table 7: Regression Coefficients on the Effects of Infrastructural Facilities on Residential Property Values

Impacts	Unstandardized Coefficients		Standardized Coefficients	T	Sig.
	B	Std. Error	Beta		
(Constant)	464174.036	70666.908		6.568	.000
PWS	56790.259	19415.610	.289	2.925	.005*
WRTS	107144.379	27411.217	.336	3.909	.000*
SECTY	37783.137	21564.308	.217	1.752	.084**
WSDP	59453.947	20707.228	.401	2.871	.005*
DSTH	-32931.650	8832.707	-.372	-3.728	.000*
DSCHL	32972.368	9095.536	.344	3.625	.001*
RDNET	-57486.121	20841.482	-.381	-2.758	.007*
PRKG	-9765.969	13125.906	-.074	-.744	.459

*Significant at 0.05
**Significant at 0.1

Table 7 shows that six (6) of the variables were absolutely significant at .05 levels and these variables are power supply (PWS), Mode of water supply (WRTS), waste disposal system (WSDP), health facilities (DSTH), distance from children school (DSCHL) and type of road network (RDNET) and thus have effect on the rental values of the residential properties in Ijaiye housing estate. Whereas type of security outfit (SECTY) can be said to be significant at 0.1 levels, type of parking garage (PRKG) is not significant in predicting changes in the dependent variable the model. From the findings, a unit change in power supply from stable to erratic will result in approximately ₦56,790.00 change in the rental

value of the property. Since majority of the infrastructural facilities under study are significant to the model, the finding supports the works of Hammer, Booth, and Love (2000) and Johnson, Davies and Shapiro (2005) that infrastructure is a major determinant of and central to property values. McNeil and Dollery (1999) is of the view that as infrastructure works, productivity and labor increase; when it does not work, economic renewal can be postponed or even halted. Also, the provision of infrastructure in residential property would continue to attract prospective tenants and therefore increase property values. Thus, serious attention should be paid to these infrastructures as the value of both lives and properties depend on it.

Thus, the model; $Y = \alpha + \beta_0 + \beta_1X_1 + \beta_2X_2 + \ldots + \beta_nX_n + e$; can thus be re-written as

RENTV = 464174.036 + 56790.259PWS + 107144.379WTRS + 37783.137SECTY + 59453.947WSDP - 32931.650DSTH + 32972.368DSCHL - 57486.121RDNET - 9765.969 PRKG.

CONCLUSION

Infrastructure is an important element of a good living environment hence, this study examined the effect of such infrastructural provision on residential property values in Ijaiye Housing Estate, Lagos State. The findings suggest that various infrastructural facilities are available in the estate. The various infrastructures available in the study area include water supply, electricity, road networks, waste disposal, drainage system, health facilities, security, parking space, school, estate hall and recreational facilities. It could be concluded therefore that the required infrastructure for good living environment is available within the estate but not in good state of repair, which was the reason why the residents are not satisfied with the level of maintenance of the infrastructures. However, the study revealed that not all the facilities are significant in influencing property's rental value in the area. Facilities such as power supply, mode of water supply, waste disposal system, distance from health facilities, distance from children's school and type of road network are significant, while type of security outfit and type of parking garage are not. Therefore, it is recommended that facilities within the estate need serious upgrading to further enhance the living conditions of the residents and the rental values of the properties. Provision of infrastructures is capital intensive, and funds realized for infrastructural service maintenance may not be adequate, hence the need for Public-Private participation.

Appraisal of the Geographical Influence of the Cocoa Products Limited, Ile-Oluji as a Regional Agro-Pole in Ondo State, Nigeria

Akinbamijo, O. B.[1] & Adegboyegun, K.A [2*]

[1& 2] Department of Urban and Regional Planning, Federal University of Technology Akure, Ondo State
[*] adegboyegunkemisoye@gmail.com

ABSTRACT

The Cocoa Products Limited, Ile-Oluji (CPL) as a firm, buys raw cocoa beans and processes it into value-added forms such as cocoa powder, cake, butter and liquor which sell locally and internationally. The CPL requires large quantity of raw cocoa beans for production hence buys cocoa beans from across the cocoa producing areas within the state. These are largely from Ondo, Idanre and Ile-Oluji. This study explores the geographical influence of the CPL as a regional agro-pole in Ondo state. Two management staff were interviewed at the CPL using purposive sampling, seventy farmers, sixty Sub-buying Agents (SBAs) and six Licensed Buying Agents (LBAs) were interviewed across the three towns which constitute the region of study using the simple random sampling with Tipett's table of random numbers as a guide for selecting the sample. Using the Statistical Package for Social Sciences (SPSS) for analysis, the study discovered that the demand of the CPL for raw cocoa beans has a large impact on the quantity of raw cocoa beans produced by the farmers as well as that bought and sold by the SBAs and LBAs in the region of study thereby creating job security and enhanced opportunities. The study therefore recommends that the CPL be seen as a regional agro-pole whose influence cuts across several towns and villages.

Keywords: Agro-pole, Cocoa beans, Cocoa Products Limited, Region, Value chain

INTRODUCTION

Industrialization refers to the presence of industries in an environment, according to Basorun (2003), it is a government development policy rooted in both national and regional plans and is in most cases tailored towards effective use of both human and natural resources available within a community, state or a nation. Industrialisation has been seen as a veritable channel of attaining the lofty and desirable conception and goals of improved quality life for the populace; this is because industrial development involves extensive technology-based development of the productive (manufacturing) system of the economy. It could be seen as a deliberate and sustained application and combination of suitable technology, management techniques and other resources to move the economy from the traditional low level of production to a more automated and efficient system of mass production of goods and services (Ayodele and Falokun, 2003). Against this background, however, industrialisation seems to be central to economic growth and development.

In many developing countries, industrialization has become an increasingly valuable tool towards achieving rapid and sustainable economic growth as well as a more balanced regional development; this is as a result of the high potential which manufacturing activities have in generating externalities that would have a widespread effect across sectors of the economy through production linkages. The main objective of regional development is to have a strong economic flavour through the achievement of high growth rates and the efficient utilization of resources (Glasson, 1978 in Basorun, 2008). Basorun, (2008), citing Hall (1992) opines that other possible objectives of regional economic policy includes: improving the efficiency of industry, raising the level of gross regional product per work or per head of total population, improving the distribution of regional income and many other variants.

Economic activities are characterized by their pronounced tendency to cluster in space, the presence of factors such as raw material sources, cheap labour availability, market potentials,

Akinbamijo, O. B. & Adegboyegun, K.A. (2016). An Appraisal of the Geographical Influence of the Cocoa Products Limited, Ile-Oluji as a Regional Agro-Pole in Ondo State, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1388-1395

nodal points on transport networks and the like usually tend to attract different industrial activities thus aiding the clustering of activities in an area and this in turn is a factor that brings about regional development.

From the planning view, cocoa production in Ile-Oluji is a development indicator that can generate the driving force for the economic growth of Ile-Oluji and the interdependencies among cocoa firms in the cocoa industry (and other sectors of the economy). It is a vital feature of the industrialization process in the town and this is a tool for regional development in Ondo state with the cocoa industry as the significant attribute and the Cocoa Products (Ile Oluji) Limited (CPL) the reference point to which other Cocoa based firms are linked. This study explores the geographical influence of the CPL as a regional agro-pole in Ondo state with a view to promoting regional development by examining if there are any viable trade links between the CPL and the farmers in the region as well as if the existence of the CPL in the region has any effect on the quantity of raw cocoa beans produced by the farmers in the region.

STUDY AREA

The Cocoa Products (Ile-Oluji) Limited located in Ile-Oluji, Ile-Oluji/Oke-Igbo local government of Ondo state, Nigeria is the most prominent industrial outfit in the Local Government Area.

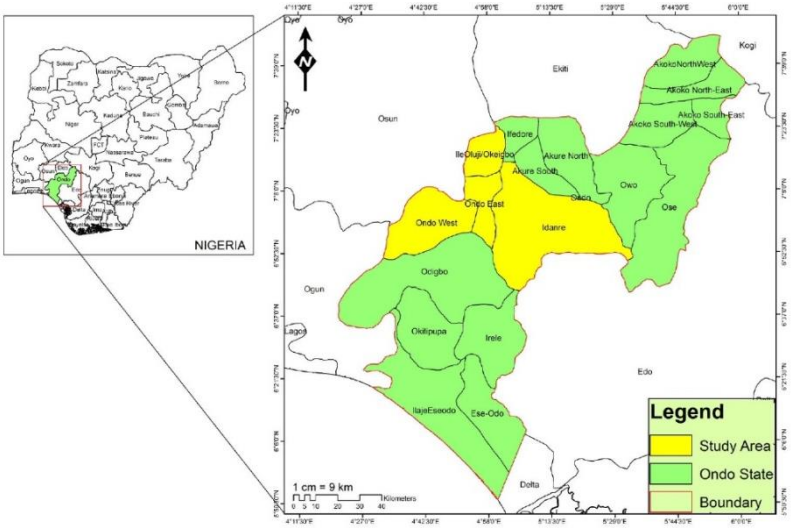

Fig. 1: Map of Nigeria showing Ondo State and Map of Ondo showing the region of study
Source: Akure south Local Government secretariat (Updated, 2009)

The CPL is one of the three first generation Cocoa Processing companies in the country established in Nigeria between 1964 and 1991; it was incorporated as Ile-Oluji Cocoa mills on 1st of April 1980 and was commissioned on May 31st, 1984. The company was designed to process raw cocoa beans into semi-finished edible products of cocoa butter, cocoa liquor, cocoa cake and cocoa powder with an initial installed capacity of 30,000 tonnes of raw beans per annum based on a projected 100 tonnes of cocoa beans per 24 hour day of 300 – day year to produce (a) 8,000 tonnes of cocoa butter (b) 7,000 tonnes of cocoa liquor (c) 7,200 tonnes cocoa powder (d) 2,000 tonnes of cocoa cake hence buys cocoa beans from across the cocoa producing areas within the state; largely from Ondo, Idanre and Ile-Oluji as shown in figure 1 above.

The influence of the CPL extends beyond Ile-Oluji its host community to farmlands in Idanre and Ondo town, the scope of this study is therefore limited to the CPL and the cocoa based firms who supply raw cocoa beans to the CPL within the three towns.

LITERATURE REVIEW AND CONCEPTUAL FRAMEWORK

Literature Review

Regions are not arbitrarily defined or demarcated areas but are defined on the basis of some significant attribute(s). The Microsoft Encarta Dictionary (2009) defines it as a large area of land that has geographical, political or cultural characteristics which distinguishes it from other areas. According to Langdon in Basorun, 2008, regions are artificial constructs used by planners to divide the world into sections which can be compared with other units. Okafor (2004) opines that regions have common attributes and in the regional planning context, these attributes could be unemployment, agricultural output, industrial output, school enrolment, infant mortality and so on. Three types of region are recognised in literature, these are: homogeneous region, functional region and programming regions. The region of study in this research is a functional region and it is defined by interactions and flows between the CPL which is located in Ile-Oluji and the surrounding cocoa based firms (LBAs, SBAs and farmers) located in Ile-Oluji, Ondo and Idanre with which linkages exist. The common attribute that defines this region is the production of raw cocoa beans.

Adeoye, (2005) in a study on the industrial development and trade in Nigeria reports that theoretical and empirical studies on industrialisation and globalisation in Nigeria have focused mainly on sources of industrial growth and the linkage effects of different sectors of the economy. Among these studies include that of Ohiorhenuan (1978) who attempts at clarifying the concept of industrial linkages *vis-a-vis* the developing economies as against the developed economies; in line also with this is the study conducted by Olofin and Iyaniwura (1983) which was to attempt at ascertaining the degree and nature of the inter-sectoral relationship existing in the Nigerian economy before the emergence of the oil as a dominant sector using the measures of direct and indirect dependence. Falokun (1996) in a similar study discusses ten key sectors of the economy that the government can stimulate through its export diversification and expansion programme in order to bring about rapid industrial transformation of the economy were identified. The study findings however show that the economy is still largely dependent on the external sector for the supply of intermediate input.

For the case of South Korea, Park in Bing Zhang and Junhai (2003) argued that polarized regional economies with a diversity of industries, information, and technical workers generate innovative firms and spin-offs, which, in turn, encourage further growth. He further noted that vertical disintegration and the clustering of small plants increase the productivity of labour-intensive industries and that subcontracting is an important organizational strategy for lowering wages and deflecting industrial disputes. Similar arguments have been made for the case of Taiwan, where subcontracting networks and cluster-based manufacturing were found to be important strategies for increasing the competitiveness of firms, Bing Zhang and Junhai (2003).

In a study of the semiconductor industry in Southeast Asia, Scott, 1987 in Bing Zhang and Junhai (2003) showed that production units in Manila's semiconductor complex in the mid-1980s were clustered close to one another and were intricately linked to minimize transactions costs. Similarly, in 1994, he demonstrated as stated in Bing Zhang and Junhai (2003) that the gem and jewellery industry of Bangkok has been able to thrive on the basis of its vibrant transactional networks, its low wages, and the skilful political manoeuvring of its representatives.

Conceptual Framework

One of the basic concepts adopted for this study is the "agro-pole" which was developed to offer explanations for the significance of a centre in a region. The concept according to

Basorun (2010) is coined from the term "growth pole," and it implies that there is the presence of a center with some indicators of growth (Perroux 1950), a geographical agglomeration of activities according to Boudeville (1966) as well as a center of an activity whose output influences the performance of many other activities in a particular economy (Ivarah 2003).

"Regional agro-pole" in this study refers to a main agricultural core that reflects some features of a central place in a geographical context. In this case, the focus is on a particular activity which is dominant and growth-inducing in a place and the agro-pole is seen in terms of location and influence, which in turn has some spread effect on the whole of a regional economy.

Francois Perroux who propounded the growth pole theory in 1950 was concerned about the phenomenon of economic process of structural change that accompanied the rise and fall of industries on others within the economy. He was of the belief that spatial as well as industrial development which are indicators of growth do not appear everywhere and all at once but in points or development poles with variable intensities spreading along diverse channels and both with varying degree of terminal effects to the whole economy. These points are referred to as growth poles. Viewing the growth poles as centres of activity interrelationship within any region, Perroux was of the opinion that such focal points attract centripetal forces and emit centrifugal forces as development in terms of business or commercial ventures and sub-sectors of the economy appear functional.

According to Ugwu, 1992 in Basorun, 2003, of importance in the analysis of growth pole are two terms, these are: linkage and innovation. Perroux's concept of propulsive industry (as well as the related idea of a key industry) invokes inter industry linkages – when an industry defined as a propulsive industry expands its outputs, it induces major expansion in the outputs of other industries in the industrial system.

The Cocoa Products (Ile-Oluji) Limited is seen as the propulsive industry in the region which invokes inter industry linkages in the region, an increase in the output of the CPL will bring about an increase in the output of the firms that are linked to it and this is a tool for the development of the region.

RESEARCH METHODOLOGY

Three sets of questionnaires and one interview guide was used to obtain data from the population audiences of the research; at the CPL, two management staff were interviewed; one set of the questionnaires was administered to the six (6) Licensed Buying Agents (LBAs) across the three towns in the region of study; the remaining two sets of questionnaires were administered to the farmers and Sub-Buying Agents (SBAs) who sell raw cocoa beans to the LBAs respectively taking a sample of 10% out of the total number. Table 1 below shows the breakdown of the sample frame and size of the SBAs and farmers respectively.

Table 1: Table showing the breakdown of the sample size of sub-agents and Farmers

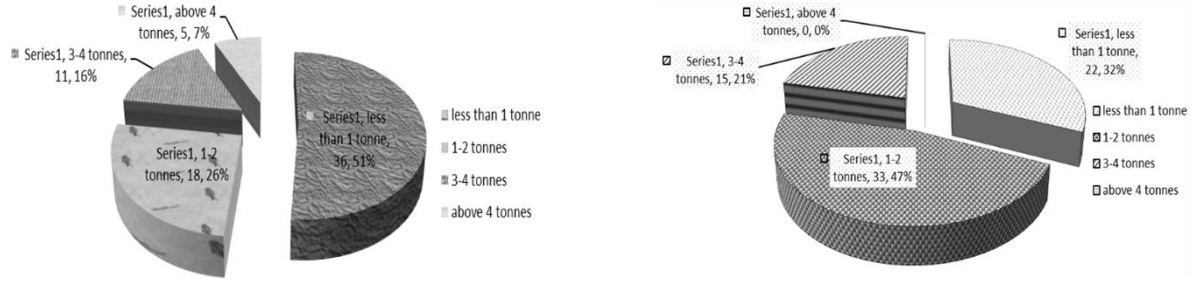
LOCATION OF LBA	LBAs SAMPLED	NO. OF AGENTS	10% OF AGENTS	NO. OF FARMERS	10% OF FARMERS
Ile-Oluji	LBA 1	200	20	100	10
Ile-Oluji	LBA 2	150	15	100	10
Ondo	LBA 3	20	2	200	20
Ondo	LBA 4	120	12	100	10
Ondo	LBA 5	60	6	100	10
Idanre	LBA 6	50	5	100	10
TOTAL		600	60	700	70

The sampling techniques used for the interview and administration of questionnaire is; purposive sampling at the CPL; total census for the LBAs and; the simple random sampling technique for the farmers and SBAs with the Tipett's table of random numbers as a guide for selecting the sample. Analysis and presentation of data was done using the Statistical Package for Social Sciences (SPSS) and Microsoft Excel.

FINDINGS AND DICUSSION

Quantity of Raw Cocoa beans produced by the Farmers yearly

Analysis of the research revealed as shown in figure 2a below that 51% of the farmers produced less than 1 tonne before the existence of the CPL in Ile-Oluji, 26% produced between 1 and 2 tonnes, 16% produced between 3 and 4 tonnes while the remaining 7% produced above 4 tonnes.



a: Before the Existence of CPL b: After the Existence of CPL

Fig. 2: Quantity of raw cocoa beans produced by farmers yearly before and after the existence of the CPL in Ile-Oluji

Findings reveal as shown in figure 2b above that 47% of the farmers sampled produce 1-2 tonnes of raw cocoa beans yearly, 32% produce less than 1 tonne and 21% produce 3-4 tonnes. It may be seen from the analysis when comparing figure 2a and b that the farmers produced more raw cocoa beans after the establishment of the Cocoa Products Limited in Ile-Oluji than before it was established, It may therefore be inferred that the existence of the CPL in the region has a positive effect on the quantity of cocoa produced by the farmers.

The set of people that the farmers sell their raw Cocoa beans to

It was discovered during the course of the research that before the existence of the CPL, farmers sold their cocoa through the cocoa board which was in operation at the time as the cocoa board served as the sole buyer and exporter of all cocoa beans and products. This posed as a major problem to the cocoa farmers because the prices of beans and products were fixed at the beginning of a trading season and farmers only received small fractions of the terminal market price and in most cases they were delayed but shortly after the existence of the CPL, the cocoa board was dissolved and transaction of cocoa beans and products became easier and this enabled LBAs to be able to function better and also brought about the introduction of SBAs.

The farmers sampled sell the cocoa they produce either to SBAs or LBAs and few of them sell to other farmers. It was discovered that 54.3% of the farmers sell to SBAs, 34.3% of them to LBAs while the remaining 11.4% sell to other farmers who may need more to meet up with the requirement from the agents that buy from them. It can be seen from the analysis above that the existence of the CPL in Ile-Oluji makes cocoa trade easier and more profitable for the farmers.

Quantity of raw cocoa beans supplied by the SBAs to the LBAs

Before the existence of the CPL in Ile-Oluji, the SBAs were not in operation, the LBAs at this time buy cocoa directly from the cocoa board but when CPL was established and the

board was dissolved, there was a need for an intermediary between the LBAs and the farmers who would be able to gather raw cocoa beans for the LBAs in order for them to be able to meet up with the requirements of the CPL. Figure 3 below shows that 33% of the Sub agents supply above 100 tonnes of raw cocoa beans to LBAs yearly, another 33% supply 26-50 tonnes, 17% supply76-100 tonnes and the remaining 17% supply less than 26 tonnes. It may be inferred from this that there is a viable trade link of cocoa from the farm gate to the CPL through various intermediaries such as SBAs and LBAs.

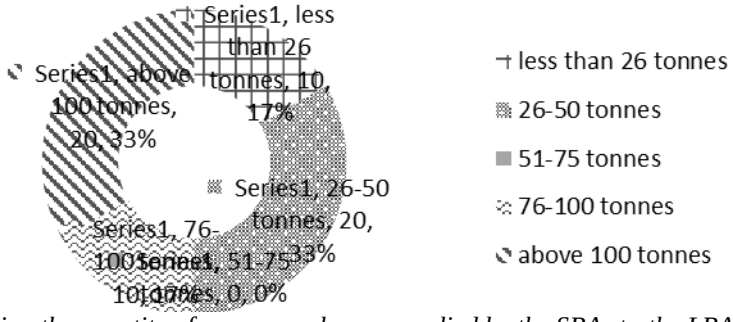


Fig. 3: Chart showing the quantity of raw cocoa beans supplied by the SBAs to the LBAs yearly

Total quantity of raw cocoa beans that the LBAs supply to the open market yearly

It was discovered during the course of the research that all the LBAs that supply raw cocoa beans to the CPL entered into the business after the existence of the CPL in the region, none of them was involved in cocoa business before the existence of CPL. Analysis of findings on the total quantity of raw cocoa beans that the LBAs supply to the open market on a yearly basis and revealed that 33.3% of the LBAs supply between 1000 and 1999 tonnes of raw cocoa beans to the open market yearly, another 33.3% supply between 2000 and 2999 tonnes, 16.7% supply between 3000 to 3999 tonnes and the remaining 16.7% of the LBA's supply 4000 tonnes and above.

Percentage supplied by the LBAs to the CPL out of the total quantity supplied to the open market yearly

Figure 4 below shows the percentage of the raw cocoa beans that the LBAs supply to the CPL out of their yearly supply to the open market and it reveals that 33.3% of the LBAs supply between 21 and 40% of the total quantity of cocoa they supply yearly to the CPL while 16.7% supply each between 1-20%, 41-60%, 61-80% and 81-100% respectively. It may be inferred from this analysis that the CPL takes most of the cocoa beans that the LBAs supply and this means that they supply more to the CPL than other cocoa firms.

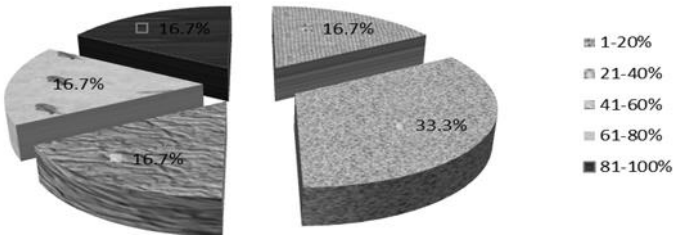

Fig. 4: Chart showing the percentage of raw cocoa beans supplied by the LBAs to the CPL out of the total quantity they supply yearly

Quantity of raw cocoa beans required by the CPL monthly

From the interview that the researcher conducted with the management staff of the CPL, it was discovered that the Cocoa Products (Ile-Oluji) Limited requires a lot of raw cocoa beans for their production and sometimes buy as much as 80 tonnes of raw cocoa beans at once, on a monthly basis the company purchases about 800 to 1000 tonnes of raw cocoa beans, this

translate to about 9600 to 12000 tonnes of raw cocoa beans yearly. The result of the findings however reveals that the quantity of raw cocoa beans supplied by each of the LBAs yearly is not sufficient for the CPL

SUMMARY OF FINDINGS

i. None of the LBAs can singly handle supply the CPL with the cocoa they require yearly so the CPL has to buy from as many of them as possible, it may be inferred from this therefore that the rate at which the CPL patronizes the LBAs is high and can lead to other LBAs joining the business in order to meet the required quantity of cocoa need by the CPL which will make job opportunities available for people in the region.
ii. The quantity of raw cocoa beans supplied by each SBA to the LBAs is also not sufficient to meet the requirement of each of the LBAs which is as a result of the need of the CPL.
iii. The raw cocoa beans produced by individual farmer is not sufficient enough to meet the needs of the CPL, this may be the reason why the sub agents have to buy from a lot of farmers in order to be able to gather a considerable amount of raw cocoa beans. This may serve as a form of encouragement to the farmers to produce more raw cocoa beans. It may therefore be said that the existence of the CPL in Ile-Oluji has an effect on the quantity of raw cocoa beans produced by the farmers in the region.

CONCLUSION AND RECOMMENDATION

The purpose of industrial development of any region is to provide opportunities of better living and employment to the people. The agglomeration of various firms within a region is bound to affect the economy of the region positively. The study revealed that there is a positive difference between production of raw cocoa beans before the inception of the CPL and after its inception and that the existence of the CPL in the region also led to the establishment of various cocoa firms which are linked to each other thereby making job opportunities available to individuals; (LBAs and those working in their firms as well as SBAs and farmers), the following recommendations are therefore made:

i. Government should provide incentives such as timely procurement of adequate supply of necessary cocoa production inputs and introduction of improved mechanized farming systems to attract youths into cocoa farming and provide subsidies such as access to loans, chemicals and fertilizers to farmers.
ii. Stakeholders such as the CPL to develop initiative programs to assist the farmers so that they can increase productivity. This may be done by encouraging the farmers to produce more with the assurance that they would buy all the cocoa, there should be a form of interaction with farmers, provision of things like fertilizers, store houses among other initiative programs.
iii. The CPL should also seek to employ more LBAs to supply them with raw cocoa beans, as this will give the CPL better opportunity to have access to raw cocoa beans for processing and also increase competition amongst LBAs thereby making them strive for excellence and better quality of cocoa.
iv. In furtherance to the problem of insufficient supply of cocoa beans as discovered in the research, this study is recommending that the CPL embark on extensive plantation agriculture solely funded or in public-private partnership schemes.

There is therefore a need to see the CPL as a tool for regional development and government as well as other stakeholders should invest in the CPL to give it a face lift and also bring it up

to begin to produce at its initially installed capacity of 30,000 tonnes of raw cocoa beans yearly as against its present production capacity of 12,000 tonnes of raw cocoa beans yearly

ABSTRACT

Infrastructure facilities refer to those basic services without which primary, secondary and tertiary productive activities cannot function. Infrastructure plays an important role in effective service delivery and enhances quality of life. Most developing countries are faced with the challenge of inadequate infrastructure. The aim of this study is to investigate the challenges posed by inadequate infrastructure facilities in Akure with a view to recommending sustainable solutions. The scope of this study is limited to road network, street fabrics and street trading, it also accesses how they affect the city vista. Qualitative and quantitative research methods is adopted for the study, data were collected through 160 questionnaire interviews, facilities survey as well as physical observation were carried out for the study. Challenges of Inadequate infrastructure, such as lack of streetlights on major roads, feeder roads and congestion of vehicular movement especially at peak periods of the day were noticed in the study area. This has resulted into inconveniences for the inhabitant. This paper gives an overview of the status of infrastructure in Akure and its effect on city vistas and recommends the provision of adequate infrastructure and improvement of the existing ones.

Keywords: challenges, city vista, infrastructure, services, service delivery

INTRODUCTION

The escalating rate of population growth with inadequate infrastructure poses great challenges on the city outlook. Cities all over the world attract large number of people primarily for economic growth. The desire to work and live in the cities is enormous while the needed infrastructure for a healthy and satisfying which are not usually met, or inadequate. Sanni and Hashim (2014) conclude that adequate infrastructure enhances social and economic development of any nation.

Most cities in developing worlds are faced with inadequate infrastructure facilities as a result of population increase, which posed a lot of challenges on the inhabitants of such cities. Olotuah, (2005) observed that the rate of urbanization bringing about massive movement of people from rural to urban area in Nigeria has led to environmental problems characterized by inadequate supply of water, lack of drainage facilities, problems of refuse disposal, poor road conditions, erratic power supply and unbalanced economy .

Infrastructures facilities such as road networks are constructed in the city centre but in most cases they are inadequate to meet the volume of traffic, they are not well constructed and they lack regular maintenance Alabi and Ocholi (2009), noted that in Nigeria there are inadequate infrastructural facilities in terms of quality and quantity as compared to other developed countries. Also collaborating this assertion, United Nations (2012) said that cities continue to be challenged by shortages of affordable housing and basic services, traffic congestion, and declining infrastructure.

Infrastructures are the physical facilities that enhance society functionality, they are facilities put in place by the Governments and managed by them. Nubi (2003) opined that the three tiers of government federal, state and local are to make provision of these services in the urban centres and constitutionally, local government councils are responsible for the

Adegunloye, O.O. & Folorunso, C.O. (2016). Challenges of Inadequate Infrastructural Facilities on City's Vista in Developing Countries: The Case of Akure, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1396-1404

construction and maintenance of some categories of roads, street drains, installation of street lighting and waste disposal.

Fawehnimi (2003) describes infrastructure as a social services derived from public works and for public use. Osaisoje and Aidelunuoghene (2012) in Mabogunje (1976) refers to infrastructure as basic services without which primary, secondary and tertiary productive activities cannot function. Infrastructures include all public services from law and order through education and public health to transportation, communications and water supply.

Infrastructure is said to enhance not only decent living in cities centre of developing countries but also for city beautification and economic gains Arun and Owolabi (2014) opined infrastructure as facilities needed for economic activity these include power, water supply, roads network and sewage. Ojiefo and Urhoghide (2011) highlight the key role play by infrastructure in economic development and growth. The challenges posed by inadequate infrastructure has affected how the city vista is been view. Ibrahim and Bello (2015) observed how inadequate infrastructure has rendered the city unattractive. Gbadegesin, Oladokun and Ayorinde (2011) noted that expansion of cities has resulted in traffic congestion, where resident use lengthy time to travel to work, and time wasted and this have made urban centres to be unsafe for people and less attractive.

Infrastructure have shifted from physical facilities such as roads, water supply, power, sewage system which are called public utilities but now includes infrastructure such as telecommunication and information.. Infrastructure is broadly refer to all basic inputs and requirement needed for functioning of the economy and can be categorised into social and economic infrastructure. United Nation (2011). Economic infrastructure include utilities (power, gas, water, sewage and sanitation), public work (road and drainage) and transport (railways, waterways, airports and urban transport system) while social infrastructure include services such as education, health and recreation.

The study is investigating three variables as it affect city vista

i. Road network
ii. Street lighting and
iii. Street trading

City can be characterised into demographic or functional definition Massey, Allen and Pile (1999) said the city constitute the physical features, human experience and urban image. City life is distinct as a result of its luxury, poverty, amenity and pollution, tradition and innovation, drudgery and novelty, order and disorder, thrill and spills. City features are the physical features such as house, housing estate, streets, shops, hotels, hospital, museums, traffic, libraries, cathedral, restaurants and so on. City experience differ from person to person, it varies depending on the part of that city in which the person or group is located. City life is distinctive because it is bigger and with more activities. City could be for pleasure, for home, for work, for administration and government. The vista of the city are very different as seen by a holiday makers, city dwellers all have different view of how the city looks like.

The rapid growth of urban centres has been attributed to traffic congestion within the city cities experience traffic congestion at peak periods constantly with long queues of vehicles. Most road network in cities can no longer cope with the volume of traffic plying the road daily Ogunsanya (2002). Population increase and inadequate infrastructures in cities leads to traffic congestion Varaiya (2005) noted that traffic congestion in most urban centres is as a result of limited infrastructure. Osaba (2012) revealed that the traffic congestion leads to time delay as a result of inadequate parking space, traffic signs/signals and indiscipline.

Congestion on roads can be caused by non adherence to road traffic regulation by motorist, Asiyanbola, Osaba and Adewale (2012) attribute lack of discipline and recklessness among motorist as a factor responsible for traffic congestion on roads. Osaba (2012) revealed that the traffic congestion leads to time delay as a result of inadequate parking space, traffic signs/signals and indiscipline.

The rate of high number of motorist plying the roads and has subsequently increase the volume of traffic in urban/cities is cause by increase in urban population, a lot of problem are associated with traffic congestion as asserted by UNCHS (1993) that travel speeds in cities are decreasing and the travel environment for pedestrians and people-powered vehicles are deteriorating in developing countries, due to the inefficiency of the entire road transport system, also Ibrahim et 2015 noted that traffic congestion are as a result of on-street parking, street hawking and narrowness of the road. .Fadairo 2013 also noted that poor driving habits, weather condition, absence of traffic light and/ warden, work zones, road side parking, are some of the causes of traffic congestion.

Street defines the circulation pattern within the city, trading is the activity of buying and selling, Adepeju and Oluwole (2012) described street as an element of the built environment. Omosegun (2015) described street as any commercial activity undertaken beyond confined premises or secluded working environment such as sidewalks, street pavement, major transport hubs and other public area.

Street trading is an informal employment basically for economic gains, people desire to make a living engages in street trading, street trading are common at road intersections, traffic light points and traffic holdup. Street trading or hawking constitutes a nuisance to the city vista and it leads to traffic congestion on our road, road accident, and waste travelling time.

The aim of this study is to investigate the challenges posed by inadequate infrastructure facilities on city vistas in Akure with a view to recommend a sustainable solution. The objectives are to access the existing condition of infrastructure in the study area and access the impact infrastructure plays on city vista.

RESEARCH LOCATION

The study is located in Akure. Akure is a city in the South Western region of Nigeria; it is the capital of Ondo State located on the intersections of Latitude 7^{o} 17^{1} North of the equator and Longitude 5^{o} 14^{1} East. Akure is a medium-sized urban centre and became provincial headquarter of Ondo province in 1939. Akure being the state capital with its inhabitants engages in different activities. Akure is located within the tropical rain forest vegetation where rainfall is common for 8 months of the year. Akure is an agricultural trade centre popular for yam, cassava, corn and palm oil. The study is limited to road network at Oda junction along Igbatoro road, street lights along Ilesa road and street trading at North gate of Federal University of Technology, Akure all in Akure, Ondo State, Nigeria.

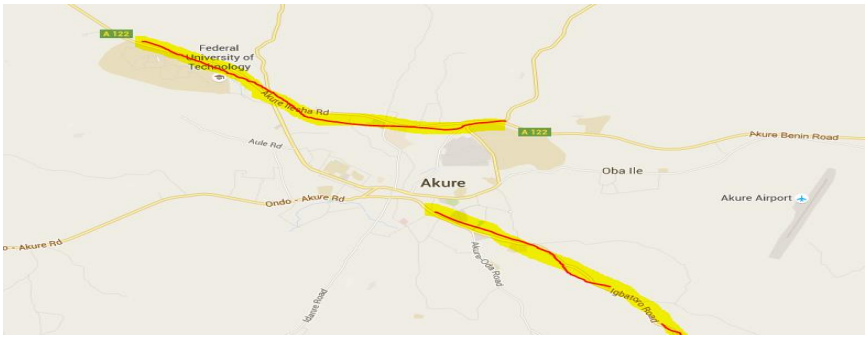

Figure 1: Map of Akure showing the study area
Source: *www.googleearth.com*

METHOD OF STUDY

The research method employs descriptive findings obtained from questionnaires which were administered to residents of Oda and Igbatoro road, Oyemekun and Ilesa Garage road and federal University of Technology, Akure all within Akure. The sample population were selected by simple random sampling in such a way that every individual in the study has an equal chance of being included in the survey. Questionnaires for this study were designed to obtain data on the state of physical infrastructural facilities; while a reconnaissance survey purposely meant to familiarize the researcher with the study area and their physical environment.

The sample populations were professionals in built environment, residents, road users and traders in the study area. The questionnaire probed into the availability of infrastructural facilities, condition of the infrastructure, and their management. The general variables associated with this study are: Electricity, Drainage System, Roads Network, travel hour and commercial or shopping complex

In each of the three area visited, about 55 questionnaires were distributed to randomly selected residents and average of 45 were retrieved in each of the area and a total of 135 questionnaires were validly completed and returned and were used for the analysis. Site visits were also undertaken in order to assess availability and quality of infrastructural amenities within the study areas. For the purpose of this study, the infrastructures such as Road, Drainage, shopping centre and road width were classified into good, fair and bad based on the users' perception of their functionality.

The research design objectives are to:

i. identify the condition of physical infrastructure,
ii. investigate how infrastructure affect the city vista,
iii. the present state of the city

The data sources that was used for this study was derived from both primary and secondary sources. The primary data was collected from direct interviews, personal observations and responses to structured questionnaires administered to the residents. The secondary data was collated from previous work done on the subject matter, including books, journals and visits to libraries and the internet. The empirical research in this paper focuses on existing situation in the study area, the road network at Oda junction along Igbatoro road, the street lights along Ilesa road and street trading at North gate of Federal University of Technology.

RESULTS, FINDINGS AND DISCUSSIONS

The socio- economic characteristic of the respondents in Table 1 revealed that 61% were males while 39% were females. in terms of age distribution about 7.4% of respondents were aged 25 and above, while those who were aged 26 to 50, and those who were 50 years and above were more of adult dependent respondents. The marital status revealed that about 68.8% of the respondents were married, 8.9% were single and about 8.9% were divorced/ separated and widowed. The result shows that more than half of the respondents are male, adult and married.

Occupation analysis in Table 2 shows that 45.1% of the respondents were Civil servants, 46.67% are businessmen and business women, while about 8.89% are in other Jobs. Most of the respondents are both civil servants and business men and women and are on the road daily for work and to improve their economic activities.

Table 1: Socio-economic Analysis of respondents'

Socio-economic characteristics		Frequency	Percentage
	Male	82	60.74
Sex	Female	53	39.25
	Total	**135**	**100.00**
Age	Under 25yrs	10	7.41
	25yrs-35yrs	37	27.4
	36yrs-45yrs	56	42.0
	46yrs-50yrs	22	16.29
	50yr+	10	7.40
	Total	**135**	**100**
Marital status	Single	12	8.9
	Married	93	68.8
	Divorced/separated	12	8.9
	Widowed	18	13,3
	Total	**135**	**100**

Table 2: Distribution of Respondents by Occupation

Occupation	Respondent	Percentage
Civil servant	61	45.1
Businessmen/women	63	46.67
Others	12	8.89
Total	135	100

Analysis of Monthly Income

table 3 shows the level of monthly income of respondents, 11.85% of the respondents earns N10,000 or below, 40% of the respondents earns N10, 001-N50,000.39.25% earns N50,001-N100,000 and 8.89% earns N100,000 and above. The result shows that majority of the respondents earns between N50,001-N100,000 which mean they are middle income earners.

Table 3: Level of monthly income

Rate	Respondent	Percentage
N10,000 or below	16	11.85
N10,001-N50,000	54	40.0
N50,001-N100,000	53	39.25
N100,001 & Above	12	8.89
Total	135	100

Analysis of Means of Transportation

Table 4 revealed that 9.52% use private vehicle, 19.04% of the respondents disposes uses public means of transportation, while 14.07% uses motorcycle popularly call Okada and 2.2% use other means of transportation. The result therefore shows that many of the respondents have private vehicle and this will subsequently increase the number of vehicles plying the road daily especially at peak period of time.

Table 4: Means of transportation

Types	Respondent	Percentage
Private vehicle	76	56.2
Public transport	37	27.4
Motorcycle(Okada)	19	14.07
Others	3	22
Total	135	100

Analysis of Travel Time

Table 5 shows 41 respondents that is 30.37% use between 5minutes and 3omintyes to travel or get to their destination, 54.07% travels for between 31minutes and 1 hour and 11,11% and 4.4% travel between 1 hour and 2hrs and 2hours and above respectively as travel time. The

result shows that many of the respondents spend between 30mins-1 hour to get to their destination as a result of the traffic congestion they experience daily.

Table 5: travel time/ hour(s) to work place

Time(Mins/ hour)	Respondent	Percentage
5mins-30mins	41	30.37
31mins-1hour	73	54.07
1hr-2hrs	15	11.11
Above 2hrs	6	4.4
Total	135	100

Analysis of Business Venue

Table 6 shows categories of business venue of the respondents. 11.11% that represent 15 respondents have their business located in s shopping complex, another 11.11% respondents engages in an in-house business, about 24.44% have their business location inside the container/ on street Kiosk. 18.5% of the respondents engage in street hawking and selling in traffic and 17.17% has no business. the result revealed that many of the respondents sells on street, in traffic or hawking and they constitutes to the poor view of the environment by taken advantage of the traffic for their trading activities.

Table 6: Business venue

Categories	**Respondent**	**Percentage**
In shopping complex	15	11.11
In house	15	11.11
On-Street Kiosk/Container	33	24.44
Mobile trading	8	5.92
Street hawking/selling in-traffic	25	18.5
No business activities	34	17.17
Others	5	3.70
Total	**135**	**100**

Analysis of Road Condition

Table 7 analysed the condition on the road into categories to find out from the respondents if there are drainage on the roads, if the width (wideness) of the road is adequate and if there is pedestrian walkway by the road. 46% said the drainage is bad, 40%aid fair and14.07% said good, 60.74% said the width of the road is inadequate, 30.37% said it is fair and 8.88% said good and lastly 46% said the road has no pedestrian walkway, 41.48% said fair and 13% said good. the result therefore shows that major roads lack proper drainage, they are not wide enough, and as a result of this both pedestrians and vehicular movements are in a chaotic state most especially at peak period of time.

Table 7: Condition of road Infrastructures

Categories	**Good**		**Fair**		**Bad**	
	No	%	No	%	No	%
Drainage on roads	19	14.07	54	40.0	62	46.0
Road width	12	8.88	41	30.37	82	60.74
Pedestrian walkway	17	13.0	56	41.48	62	46.0

Analysis of Street Light Condition

Table 8 revealed the analysis of street light in the study area, 15.55% of the respondents affirms that the street light are working, about 43.70 said they are available but are not working and 40.74 said there are no street light in their area. Many of the respondents pointed out the availability of street light but they are not functioning.

Table 8: Condition of street light

Categories	Respondent	Percentage
Available and working	21	15.55
Available but not working	59	43.70
Not available	55	40.74
Total	**135**	**100**

Assessment of City and Infrastructure

Table 9 shows the analysis assessing the city vistas of the surrounding visa vice infrastructure, 26.66% of the respondents affirms that the view of the city is very poor, 37.77% and 26.66% said the city vistas is poor and fair respectively, while only 7.40% said good and only 1.48% said very good. The analysis revealed the condition of the environment and how the city is been view by the respondents, where many of them affirm that the city vista is poor.

Table 9: city vistas / infrastructure

Categories	Respondent	Percentage
Very poor	36	26.66
Poor	51	37.77
Fair	36	26.66
good	10	7.40
very good	2	1.48
Total	**135**	**100**

Plate 1: shows hawking on major road, a constant view at FUTA North gate, depicting a ugly environment at the entrance of the University

Plate 2: Shows Street trading

Plate 3: shows road side trading

Plate 4: shows trading in traffic

CONCLUSION

The city vista has changed as a result of inadequate infrastructure leading to traffic congestion as shown in the study. Economic activities on major roads in form of hawking and street trading in traffic have affected the view of the city and its aesthetic value. Street trading activities also contribute to the litter of the surroundings and can also result into accident. Lack of street light on major roads was It is important that the three tiers of Government implement the recommendations in this paper for a sustainable and attractive city.

RECOMMENDATIONS

The paper investigates the challenges posed by inadequate infrastructure and how it affects City vistas. The paper recommends the followings, expansion of road network into more than 2 or 3 lanes to accommodate the population increase so as to reduce traffic congestion, the construction of an alternative road to reduce the pressure on Oda-Igbatoro road junction. The use of traffic control devices and road signs to provide necessary information to warn road users and regular maintenance of street light along Oyemekun-Ilesa Garage road.

Lastly, the paper recommends the deployment of law enforcement agencies on major roads to curb motorist excesses and adequate provision of pedestrian walkway where necessary to deal with these challenges.

ABSTRACT

Residents' participation has become a topical issue in housing development research. Thus, residents' willingness to participate in the provision and maintenance of infrastructure in their neighbourhoods especially in developing countries like Nigeria is essential because it creates an avenue for accountability and also enables them to develop a strong sense of attachment of community with their neighbourhood. This study examines the level of residents' participation in the provision and maintenance of infrastructure in two selected estates; Alagbaka and Ijapo housing estates in Akure, Nigeria. Primary data were collected through the use of structured questionnaires and direct observations of infrastructure within the residential neighbourhoods. The data were analysed using descriptive statistical tools and categorical regression was used to predict participation in the study area. The paper identifies education, income, tenure status, length of residence and household size as predictors of participation in infrastructure in the study area. The paper concludes by providing implications to improving neighbourhood revitalization through residents' participation in infrastructure provision and maintenance.

Keywords: Infrastructure maintenance, Infrastructure provision, Residential neighbourhoods, Residents' participation

INTRODUCTION

The existence of infrastructural facilities in a residential neighbourhood is essential because in conjunction with the house itself, they make living in housing environments possible for residents. It would be absurd if a house is designed and constructed without its concomitant infrastructure and services such as roads, water supply, electricity supply, drainage, etc. Housing, as defined by Federal Ministry of Works and Housing (2002) refers to the process of providing a large number of residential buildings on a permanent basis, with adequate physical infrastructure and social amenities, in planned, descent, safe and sanitary neighborhoods to meet the basic and special needs of the population. Housing is a residential environment which man uses for shelter and the environs of the structure required or designed for his physical and mental health as well as his social wellbeing (Omole, 2001). As averred by Adegun (2011) housing embraces all infrastructure, services and utilities that go to make a neighbourhood environment to become livable. From the above definitions, it is palpable that housing comprises of the house and its concomitant infrastructure. Housing infrastructure is an important aspect of housing development due to the fact that the house cannot stand alone; it requires basic services and infrastructure to be able to perform its functions.

Mallo and Anigbogu (2009) defined neighbourhood as residential area in a particular location of a city. Thus it is an area in a city where people live and a community can be formed amongst themselves. According to Local Government Commission (2015) community change processes affect residents, first and foremost; therefore they should be allowed to help shape such changes. This is one of the main reasons behind the notion of resident participation in housing development. Therefore, it is necessary that residents of housing

Fakere, A. A. & Ayoola, H. A. (2016). Residents' Participation in Infrastructure Provision and Maintenance in Residential Neighbourhoods in Akure, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1405-1412

neighbourhoods participate in the planning, provision and maintenance of such infrastructure. Resident participation as claimed by Leung (2005) is an aspect of community development intended at increasing involvement of residents in housing development, management and community building. Janine (2006) stated that the lack of appropriate residents' participation in housing infrastructure development will result in failure to establish an authentic and empowering people centred development. This is predicated on the fact that people should be at the centre of developments in order to ensure that such development meet their identified needs. Thus, such identification of needs should not be done through abstraction because only the people that have such needs and who the developments are meant for can state them actually.

Okoye (2014) observed that despite the fact that public housing estates in Nigeria which are government initiated and managed should be a model of housing provision especially in basic infrastructure facilities, this is not so due mainly to problems of low quality facilities and lack of maintenance culture. This according to the study results in high level of dissatisfaction by the public housing residents. The strategies implemented to produce what can be considered a successful resident's participation is an aspect not thoroughly considered in the development process (Janine, 2006). This is evident in situation where development authorities attempt to provide and maintain infrastructure in neighbourhoods without trying to identify from the resident what actually are their needs. In such cases, what will be provided is assumed and might not necessarily meet the needs of the resident users in such neighbourhoods.

Thus, this study therefore focuses on discovering the sources of provision and maintenance of neighbourhood infrastructure in Alagbaka and Oba-Ile housing estates in Akure, Nigeria. Both of these estates are government owned public housing estates located in the city and it is necessary to discover whether the government authorities involve the residents of these estates in infrastructure planning, provision and maintenance. The aim of this study is to therefore highlight the significance of the participation of residents in these residential neighbourhoods in Akure, Nigeria. The main objectives of this study include: assessment of the residents' willingness to participate in infrastructure provision and maintenance; appraisal of the existing levels and modes of participation; evaluation of outcomes of existing participation and identify if the socioeconomic characteristics of the respondents influences their participation.

LITERATURE REVIEW

Nature of Resident Participation in Infrastructure Provision and Maintenance

Who decides what, for whom, is a central issue in housing and human settlement (Sanoff, 2000). Bovaird (2007) asserted that traditional conceptions of service planning and management are outdated and require revision to account for coproduction (resident participation) as an integrating mechanism and an incentive for resource mobilization; a potential that has been greatly underestimated. Olotuah and Aiyetan (2006) believed that, for housing provision to be sustainable in Nigeria, cognizance must be taken of the bottom-up participatory approach involving genuine local participation by people at the grass root level. Resident participation in housing infrastructure requires that the development authorities carry the local residents along from the planning stage through to the implementation stage. It takes the notion that one size does not fit all and therefore that every neighbourhood have their unique requirements that can be different from others.

Housing should be a planned environment with the provision for critical condition for the physical, psychological, social and economic well-being of human beings (Taiwo and Arayela, 2010). Participation in infrastructure management is a process whereby people – as

consumers and producers of infrastructure services, and as citizens influence the flow and quality of infrastructure services available to them (Schubeler, 1996). As such Arnstein (1969) ladder of citizen participation helps to explain the levels of participation of residents in housing development. Thus, on the ladder, the degree of participation of residents should be based on the peculiar situation of the particular project. However, there is need for transparency and trust in the whole process if success is to be expected of the project. According to Harris (2000), a socially sustainable system must achieve distributional equity, adequate provision of social services including health and education, gender equity, and political accountability and participation. Therefore if resident participation in infrastructure is properly carried out, it should lead to certain benefits that can be derived from the process.

Benefits of Resident Participation in Infrastructure Provision and Maintenance

One of the most important objectives of economic development is the improvement of production capacity and welfare through the availability of sustainable and reliable infrastructural facilities (Obiegbu, 2008). In other words, the benefits of having adequate and satisfactory neighbourhood infrastructure cannot be overemphasized. Therefore, resident participation due to its potential to improve this should be integrated into housing policy and monitored during execution of housing projects. Several researchers have highlighted the benefits of resident participation in housing development.

LGC (2015b) stated the benefits of public participation in community planning to include: enhancement of the quality of planning; avoidance of contentions between interested parties; ensuring swift and efficient project implementation; ensuring that good plans remain intact over time; foster a sense of community and trust in the government. Social equity, the fulfillment of basic health and educational needs, and participatory democracy are crucial elements of development, and are interrelated with environmental sustainability (Harris, 2000). LGC (2015b) affirmed that in the long run, programs and projects that develop from an informed public, guided by professionals, are likely to be more creative and locally appropriate than those where the public is excluded from the planning process. Therefore, public participation is vital to the processes of community design, planning, and development (LGC, 2015a). This collective approach to development will also create a sense of belonging among the residents and this is beneficial to the government due to the trust they have from the residents.

Therefore, to ensure that both government and resident communities grow closer to each other, the aspect of decentralization of power must be considered especially for infrastructural service provision (Nhlakanipho, 2010). This aspect is very vital because such approach empowers the residents and ensures that the government schemes are successful in achieving their set goal. Hence, it is expedient that residents be involved in the planning, provision and maintenance of neighbourhood infrastructure. Also, if the people are allowed to participate, it can help strengthen the community and ensure such infrastructures are protected; thus enhancing its durability.

As asserted by LGC (2015a) Community involvement and resident participation in infrastructure planning may be more time- and resource-intensive than entirely “top-down” planning, but they present the following important benefits:

a. Ensuring the retention of good plans and policies over time, through the development of a long-lasting and stable constituency.
b. Reducing the likelihood of contentious battles over density and land use, which have eclipsed the equally important considerations of context and fit. Proactive planning that incorporates meaningful public involvement increases the likelihood of a project’s success.

c. Speeding the development process and helping prevent costs associated with public opposition.
d. Increasing the quality of planning, by combining the insights of an informed citizenry with the guidance of professionals.
e. Enhancing the relationship between citizens and government. Local and regional governments become more open, responsive and effective, eliciting increased trust and sense of ownership on the part of citizens.

Improvements in infrastructural services can have the positive effect of increasing household's real income and quality of life (Okoye, 2014). Similarly, Omole & Rotowa (2010) averred that human health, security, educational and employment opportunities coupled with quality and efficient housing system are essential for economic growth and prosperity. Hence, the proposed projects have the potential to employ some of the residents of the neighbourhood; and this creates a win-win situation for both the residents and the development authority. Thus, there are several benefits to resident participation in infrastructure development, and especially in developing countries like Nigeria, this approach needs to be widely practiced.

METHODOLOGY

The study employed the survey method. A structured questionnaire was designed to elicit information on the level of participation of residents of two public estate, Ijapo and Alagbaka housing estates in Akure, Ondo State. The questionnaire consists of two parts. Part A deals with the socio-economic characteristics of the respondents while Part B deals with the residents' perception of participation in infrastructure provision and maintenance. In administering the questionnaire in each estate, the systematic sampling technique was used. On the main street in each estate, the first house was randomly chosen, with subsequent units at an interval of every third building. Due to the nature of the research one adult household head was administered questionnaire in each household visited. A total number of five hundred and forty-five (545) household head collected the questionnaire. Four hundred and fifty five (455) questionnaires were returned and analysed with descriptive analysis and categorical regression analysis.

RESULT AND DISCUSSIONS

Residents' perception of importance of participation

The study investigated the importance respondents attached to participation in the provision and maintenance of infrastructure within their estate. The result of findings (Table 1) shows that the highest percentage (69.9%) of the respondents ranked participation important, (9.5%) also ranked participation as fairly important. A few of the respondents (20.7%) rated participation to be of no importance. The result indicates that citizens are aware of the importance of participation in neighbourhood development.

Table 1: Level of importance of participation

Importance of participation	Frequency	Percent
Very Unimportant	49	10.8
Not Important	45	9.9
Fairly Important	43	9.5
Important	105	23.1
Very Important	213	46.8
Total	455	100.0

Willingness to participate

Willingness to participate is an essential tool in measuring how well citizens want to be part of what goes on within their neighbourhood. Resident's willingness to participate (Table 2)

shows that the majority (77.1%) of the respondents are willing to participate in the provision and maintenance of estate infrastructure while a few of the respondents (9%) are not willing to participate. The remaining (13.8%) of the respondents are fairly willing to participate. The result indicates that not only do the residents consider participation important; they are also willing to participate in the physical development of their estate.

Table 2: Willingness to participate

Willingness to participate	Frequency	Percent
Very unwilling	12	2.6
Not willing	29	6.4
Fairly Willing	63	13.8
Willing	230	50.5
Very willing	121	26.6
Total	455	100.0

Willingness to pay for infrastructure

Peoples' willingness to pay can be used to measure how valuable a commodity is to them. The result of finding (Table 3) shows that an over whelming majority (80%) of the respondents are willing to pay for infrastructure while (9.4%) are not willing to pay for infrastructure development in their estate. The result indicates that estate infrastructure provision and maintenance is indeed important to the residents. This result further confirms Whittington, Lauria and Mu (1988) opinion that if people are willing to pay a certain cost of a particular service, then it is a clear indication that the service is valued and therefore will most likely be used and maintained.

Table 3: Willingness to pay

	Willingness to pay	Frequency	Percent
Valid	Very unwilling	12	2.6
	Not willing	31	6.8
	Fairly Willing	48	10.5
	Willing	242	53.2
	Very willing	122	26.8
	Total	455	100.0

Evaluation of residents' participation in the provision of infrastructure and maintenance

The result of findings (Table 4) to investigate how well residents have participated in the provision of infrastructure in their estate shows that only a few of the respondents (23.1%) ranked participation high in their estate while (39.8%) rated participation to be low or no residents participation in the provision of neighbourhood infrastructure. However a sizeable percentage of the respondents (37.1%) rated participation to be moderate in the estate. The result shows that there is a reasonable level of residents' participation though not strong in the provision and maintenance of the existing infrastructure in the estates.

Table 4: Participation in infrastructure

	Participation	Frequency	Percent
Valid	No participation	104	22.9
	Low participation	77	16.9
	Moderate participation	169	37.1
	High participation	105	23.1
	Total	455	100.0

Residents' participation in neighbourhood infrastructure

The respondents were asked which of the neighbourhood infrastructure they have participated in. The result of findings (Table 5) shows that residents participated more on neighbourhood

security (54.7%) and power supply (33.1%) within their estate. There is however a very low level of participation in the provision and maintenance of other infrastructure in the estate. The reason for this could be because they are more capital intensive and they may need support from the government.

Table 5: Neighbourhood infrastructure residents participated in

Neighbourhood infrastructure	Frequency	Percent
Security	249	54.7
Waste management	23	5.1
Roads	13	2.9
Electricity Supply	151	33.1
Water supply	8	1.8
Drainage	3	.7
All of the above	4	.9
No Idea	4	.9
Total	455	100.0

Levels of participation

Respondent's level of participation was investigated in the study. The result of findings (Table 6) indicates that participation was higher (43.3%) at the street level than the neighbourhood or individual (house) level. Participation at the neighbourhood level (36%) was also considered to be higher than that of the house level (20.7%). The result of findings shows that respondents preferred to contribute to the provision and maintenance of infrastructure close to where they live than in the whole estate. The implication of the result is that people are more willing to contribute to infrastructure in which they have direct access to and are more likely to benefit from.

Table 6: Levels of participation

Level of participation	Frequency	Percent
Individual (house)level	94	20.7
Street level	197	43.3
Estate community level	164	36.0
Total	455	100.0

Means of Participation in the provision of infrastructure

The result on residents' participation in estate infrastructure development (Table 7) indicates that majority of the respondents (63.1%) participated through payment of estate levies and voluntary donations to the estate, while (7%) of the respondent participated in provision of labour and man power and (4.4%) participated by educating other residents of the estate. Only 12.6% of respondents participated in decision making, planning and execution.

Table 7: Means of participation

Means of participation	Frequency	Percent
Financial participation (donations and levies)	287	63.1
Intellectual /decision making	23	5.1
Project planning & execution	34	7.5
Provision of labour /man power	32	7.0
Education of estate residents	20	4.4
All of the above	3	.7
No Participation	46	10.1
Total	455	100.0

Stages of participation

The preferred stage of participation (Table 8) shows that the highest percentage (27%) of the respondents wants residents to participate in the project planning while (25.3%) want to be involved in project execution. Also (20.2%) of the respondents preferred residents participate

by given regular feedback and (9.2%) residents should participate by collaborative funding of infrastructure in the estate. A few of the respondents (9.2%) also believes respondents should take part in policy making. The result implies that at all levels of infrastructural provision; the residents will like to be carried along.

]*Table 8: Stages of residents' participation*

Stages of Participation	Frequency	Percent
Project planning	123	27.0
Project execution	115	25.3
Regular feedback from residents	92	20.2
Financial participation only	28	6.2
Policy making	43	9.5
All of the above	54	11.8
Total	455	100.0

Predictors of Participation

In search for explanation for the level of participation in the estates, categorical regression was done. The result as shown in (Table 9) yields R2 = .160. This result indicates that there is a relationship between the dependent variable (level of participation in the estates) and the independent variables (residents' social economic characteristics). The analysis of variance (sum of square = 72.628; df = 17; p≤ 0.005) confirms the significance of the relationship.

Table 9 : Predictors of participation

	Standardized Coefficients		df	F	Sig.
	Beta	Std. Error			
Gender	-.056	.046	2	1.521	.220
Age	.084	.054	2	2.458	.087
Highest level of education	.132	.047	2	7.835	***.000
Monthly income	-.149	.050	2	9.012	***.000
Tenure status	.274	.055	1	24.562	***.000
Length of residence in the estate	-.202	.051	2	15.809	***.000
How long will you stay in the estate	.078	.051	1	2.299	.130
Household size	.129	.047	3	7.684	***.000
Marital status	.057	.051	2	1.242	.290

***** significant predictor variables**

The results indicates that five variables of residents' socioeconomic characteristics namely, education (p≤0.005), income (p≤0.005), tenure status (p≤0.005), length of residence in the estate (p≤0.005) and household size (p≤0.005) were significant predictors of participation. As indicated in the (Table 3), gender, age marital status and how long respondents will stay in the estates are not significant predictor of participation. Out of all the variables that are significant predictors of participation, length of residence in the estate is the strongest predictor of level of participation (Beta = -.202).This is followed by monthly income (-.149), Tenure status (.274), education (Beta = .132) and household size (.129) as the least significant predictor.

The result implies that socioeconomic status of the respondents contributed to their level of participation in the provision and maintenance of estate infrastructure.

CONCLUSION AND IMPLICATIONS OF THE RESULT

Participation in neighbourhood infrastructure was found very important (69.9%) among the residents of the estates and a very high percentage (77.1%) of the respondents showed willingness to participate in the provision and maintenance of public infrastructure. Willingness to pay for infrastructure was also investigated to know the value residents attached to infrastructure in their estates, majority of the respondents (80%) are willing to pay for the estate infrastructure. This indicates they value the infrastructure and will maintain it.

Despite their willingness to participate, only a few of the respondents (23.1%) rated participation high in the provision of estate infrastructure. The residents and estate residents association participated majorly in contributing fund regularly for security in the estate and maintenance of power supply equipments in the estate. The paper has revealed respondents' attitudes towards participating in infrastructure projects in the estate, 63.1% of the respondents participated by paying levies and donations towards infrastructure while the others contributed in the planning and execution of projects. The respondents however preferred to be involved in both decision-making process and the financing of the estate infrastructure. The study also suggested that some socioeconomic variables like education, income, tenure status, length of residence in the estate and household size were significant predictors of participation.

The study therefore concludes that government should ensure that residents are part of the entire process of neighbourhood development right from the inception to the project execution and completion. They should also allow for feedback on projects implemented towards the physical development of neighbourhoods. Participation enhances trust and sense of belonging to a neighbourhood which also translate into residents' attachment to their neighbourhood and therefore wanting to contribute to the total development of their neighbourhood.

ABSTRACT

This study looked at the influence of neighbourhood physical characteristics on sense of community in poor residential neighbourhoods in Akure, Nigeria. Previous researches on sense of community have suggested a number of interrelated components, which were integrated into this research: the social characteristics of the neighbourhood, the physical infrastructure and the socio-economic characteristics of the residents. Four specific residential neighbourhoods in the core of Akure were selected for the study, 532 questionnaires were successfully administered and analysed with frequency distribution and categorical regression analysis. The regression analysis confirms a significant relationship between neighbourhood physical characteristics and sense of community (Adjusted R2= .136, sum of square = 63.444; df = 24; p 0.000). The results indicates that nine variables of neighbourhood physical characteristics namely, physical condition of the residential units, neighbourhood environmental quality, health facilities, recreational facilities, shopping centre, educational facilities, power supply, street roads and house type were significant predictors of residents' perception of sense of community. Sense of community was also found to be influenced by the socio-economic status of the residents. The second regression analysis model produced a significant relationship between neighbourhood sense of community and resident socio-economic characteristics (sum of square = 33.068; Adjusted R2= .042, df = 11; p 0.000). Socio-economic variables like age, income, sex and education were the strongest predictors of sense of community. The paper concludes that sense of community if well utilised can result into neighbourhood improvement while neighbourhood physical characteristics on the other hand is an essential tool in building strong sense of community particularly in poor residential neighbourhoods.

Keywords: Neighbourhood, poverty, sense of community, social capital, social network

INTRODUCTION

Poor neighbourhoods are places of resources based on the strong social capital and social network embedded in it (Ayoola, 2015). Neighbourhood sense of community is premised on the notion that social networks have value. Social capital is the collective value of all social networks (who people know) and the benefits that arise from these networks to do things for each other (norms of reciprocity). Social networks also reflect the degree of social interaction within communities. When social networks are related to participation, they are often found to be helpful in facilitating participation by bundling individual needs and capacities; in other words, networks allow communal action to take place (Kearns & Forrest, 2000).

The notice of social capital and network has been significant for neighbourhood studies. It has helped to re-focus attention and efforts on the positive aspects of neighbourhoods especially neighbourhoods with high levels of poverty. Social capital is influential and widely accepted as useful, because it is seen as important to economic development (Forrest and Kearns, 2001). The dimensions of social capital can include: empowerment (people feeling listened to); participation (people taking part); associational activity and common purpose (people cooperating with each other); collective norms and values (people sharing common values and norms of behaviour); and trust (people feeling that they can trust their neighbours and organizations in their community) (Forrest & Kearns, 2001). The US Asset-Based Community Development Institute, recommends re-building communities 'from the inside out', maintaining that low-income neighbourhoods are rich in social capital. They argued that

Ayoola, H. A. & Amole, D. (2016). Neighbourhood Physical Characteristics and Sense of Community in Poor Residential Neighbourhoods in Akure, Ondo State, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1413-1421

"everything you need is inside" because low-income neighbourhoods have many more local associations than in some more affluent areas and newer sub-divisions (Benns, 2003).

Research on social capital has shown that people with rich social connections are more likely to have housing, jobs, good health and life satisfaction. However, the benefit derived from social capital depends on the type of social capital and the socio-economic position of people. "For the poor, social capital is not just about how many people you know and how close you feel to them, but where they are located socio-economically" (Warren, Thompson, & Saegert,1999).

This paper examines the relationship between neighbourhood physical characteristics and the sense of community with a view to a better understanding of how the neighbourhoods physical structure has contributed to strong sense of neighbourhood particularly in poor residential neighbourhoods. Galster, (2001), defined neighbourhood as both physical and social unit. It is thus important to view places (especially neighbourhoods) as composites of both the physical and social environment. It is their interaction that creates neighbourhood characteristics; therefore neighbourhood cannot be seen in isolation with any of its attributes missing. The neighbourhood is a context in which socially supportive relationship can be established and maintained (Schwirian & Schwirian, 1993). La Gory, Ward, & Sherman, (1985 quoted in Young, Russel & Powers, 2004) defined sense of community or sense of belonging to a neighbourhood as a complex process involving the objective qualities of the neighbourhood, the physiological state of the person and his subjective definition of neighbouring and neighbourhood. This qualities or factors according to Bolan, (1997) are the environment, emotional attachment to the community and formal participation or involvement in community organisation. Sense of community is an essential tool in measuring the general quality of life among all social classes (O'Brien & Ayidiya, 1991).

The ongoing debate on sense of community and neighbourhood physical characteristics is important for neighbourhood revitalization and improvement. It has helped to re-focus attention and efforts on the positive aspects of neighbourhoods especially in neighbourhoods with high level of poverty. The physical characteristics of the neighbourhood, such as the condition and adequacy of the dwellings and surroundings, may influence the establishment of social ties (Schwirian & Schwirian, 1993). If the physical characteristics of the neighbourhoods are not conducive to establishing contact, then obtaining support may be more difficult (Thompson & Krause, 1998). The physical barriers as well as psychological barriers such as poverty and socio economic deprivation, can further contribute to fewer social networks and norms of reciprocity. The quality of the physical environment could also be a consequence of different levels of social capital experienced in poor neighbourhoods (Araya, Dunstan, Playle, & Thomas, 2006). The high level of physical poverty evident in poor residential neighbourhoods could probably be as a result of low levels of social capital experienced in that area. Poor neighbourhoods with obsolete buildings and poor neighbourhood infrastructure are likely going to affect the sense of community in the neighbourhoods while it is also likely that poor sense of community will lead to poor physical characteristics of the neighbourhoods as residents might have little or no interest in their neighbourhood development. It is could therefore be agreed that the physical and social characteristics of the neighbourhood can both affect each other and effect changes which has impact on the neighbourhood quality.

This study will therefore investigate sense of community in poor residential neighbourhoods with a view to contributing to a better understanding of how the neighbourhood physical environment has helped in creating a feeling of sense of community.

LITERATURE REVIEW

Sense of community

Sense of community can be described as a feeling of belonging and shared interests among members of a community (Farahani & Lozanovska, 2014, Rogers & Sukolratanametee, 2009). McMillan and Chavis (1986) discuss four key elements: (1) membership, which involves the sense of belonging and the emotional safety it provides; (2) influence, reflecting the ability to affect change in each other; (3) reinforcement and needs fulfilment, which refers to the feeling or perception that needs are met through the cooperative behaviours of the group; and (4) shared emotional connection, which individual member's commitment and belief the members of the group share (or will share) life experiences, or history of time and place. Sense of community has been identified as a key determinant of well being and a sense of been part of a readily available social network which one can benefit from (Sengupta, Luyten Greaves, Osborne, Robertson, Armstrong & Sibley, 2013).

Long & Perkins (2007) have argued that social capital is intricately linked to sense of community and that it is often an outcome of social participation. Sense of community operates differently at individual (among neighbours) and community levels to predict informal neighbouring behaviour and citizen participation.

Most researches on sense of community in neighbourhoods have concentrated mostly on neighbourhood social outcomes while relatively few studies have examined the relationship between neighbourhood physical characteristics and sense of community (Farahani & Lozanovska, 2014). It is however observed that the contribution of the neighbourhood physical characteristics in creating sense of community have not been adequately emphasised in most researches in the social science discipline. (Moustafa, 2009; Rogers & Sukolratanametee, 2009; Farahani & Lozanovska, 2014).The physical characteristics of the neighbourhood environment can influence the residents perception of sense of community (Farahani & Lozanovska, 2014).The physical attractiveness of the neighbourhood has also been discovered to strengthen social cohesion (Buckner, 1988). Lockton, (2011), also opined that designed environments influenced people's behaviour in various ways and have also been used in crime prevention or for political reasons.

Sense of community in a neighbourhood is spatially defined, and a well-defined boundary contributes to the connection to a particular place and the sense of community. The use of shared public outdoor space (in the form of natural and semi-developed areas) has a stronger positive impact on sense of community (Kearney, 2006).

There are a lot of other factors that have been documented in the literature which plays significant important roles in sense of community. For example, length of residency (Skjaeveland et al., 1996), homeownership (McMillan and Chavis, 1986) and membership or sense of belonging (Bradsky and Marx, 2001) have all been found to influence sense of community. Neighbourhood sense of community has been found to be beneficial to the general well being of individuals, families and the society at large. It is also assumed in the literature on sense of community that cohesive neighbourhoods are useful in the implementation of social and economic development programs (Moustafa, 2009). This particular study investigates how neighbourhood physical infrastructure and residents socioeconomic characteristics enhance sense of community in poor neighbourhoods.

METHODOLOGY

This study is part of a larger study which evaluated urban poverty in the core residential neighbourhoods of Akure, Nigeria. For the purpose of the study, four poor residential neighbourhoods identified by Olanrewaju, (1990) in the study of spatial distribution of urban

poverty in Akure were purposively selected for this study. The four selected neighbourhoods are Zone 3 of the inner core area (which comprises Araromi, Oja Oshodi, Odo-Ikoyi, Isolo and Ijomu via Oke-Ijebu streets), Zone 1 covers Erekefa/Erekesan market, Town Hall, General Post Office, and Deji's Palace areas, Zone 2 includes Idiagba, Ijemikin, Irowo, Odopetu, Ajagunle areas while zone 4 comprises the other side of Araromi, Odo–Ijoka and Old stadium areas.

The sample size was based on the number of existing buildings in the area since questionnaire administration will be done on one person per household and a household per building. The unit of analysis was the household head in the housing units. Stratified systematic sampling technique was used. Out of a total population of about 2228 housing units a sample of about 25% was selected, and questionnaires were distributed to the household heads of these units. Five hundred and thirty-two (532) questionnaires were returned, and these were subsequently analyzed. The questionnaire was used as the instrument for collecting data. Three types of data were collected. The first was the residents' sense of community. This was done using thirteen variables measured on a 5 points Likert scale. These variables measured social capital, reciprocated exchange, collective efficacy and trust within the housing unit and the whole neighbourhood. The second was the residents' perception of their neighbourhood quality. This was measured also on a Likert scale with fourteen variables. These variables measured the availability of neighbourhood infrastructure and their level of performance. The socio-economic characteristics of residents were also collected and are presented in this paper to further emphasise the level of economic deprivation experienced in the study area. The data collected were analysed using categorical regression model. In line with the aim of the study, two models were examined; the socio-economic characteristics model and the neighbourhood physical characteristics model. In the first analysis, the variables of social-economic characteristics (independent variables) were regressed with neighbourhood sense of community (dependent variable). Similarly, the variables of neighbourhood physical characteristics (independent variable) were also regressed with sense of community (dependent variable)

RESULTS AND DISCUSSIONS

Socio-economic characteristics of respondents

Out of the 532 respondents interviewed (Table 1), half (50%) were males while the other (50%) were females. Also, each active age bracket was well represented. More than half of the respondents belong to the very active age bracket 26-55, this group accounted for the adult and most economically active group. It is however surprising that about a third of the respondents had tertiary education, this shows that poor urban neighbourhoods are not predominantly inhabited by people with low level of education. The employment situation of the urban poor in Akure indicated that majority of the respondents are petty traders or working informal sector of the economy. The income situation of most of the respondents is however embarrassing as about a third of household heads earned below ₦ 10,000 per month (far below the national minimum wage of ₦18,000 per month approved by the federal government of Nigeria for the least paid civil servant), there were also the presence of a few wealthy individuals in the neighbourhood. The neighbourhoods are dominated by rentals (51.5%) and people living freely in family houses (21.5%). The socio-economic status of the respondents is an evidence of a concentration of poverty in the neighbourhoods.

Neighbourhood physical characteristics

In order to evaluate the physical characteristics of poor urban neighbourhoods in Akure, the overall quality of all the neighbourhood housing and infrastructure were examined together, taking into consideration the resident's perception of their housing condition, neighbourhood

infrastructure and amenities. Respondents were asked to rank the quality of their neighbourhood, out of the 532 respondents only 131(26.5%) ranked the condition of the street good while (10%) ranked the residential units good. Percentage of neighbourhood Infrastructure ranked good; health facilities (19.2%), recreational facilities (16%), educational facilities (16%). A low percentage of respondents agreed that neighbourhood amenities are good; electricity (30.4%), pipe-borne water (12.4%), street roads (29.1%), drainage (29.9%) refuse disposal (36.8%) and sanitary condition (24.9%). A closer look at (Table 2), reveals that majority of the neighbourhood infrastructure are poor particularly water supply, recreational facilities, health facilities and the residential units.

Table 1. Socio -economic characteristics of the respondents

Variable	Characteristics	Frequency	%	Total
Gender	Male	266	50.0	
	Female	264	49.6	532
Age	<25	101	19.0	
	26-40	169	31.8

Tenure status	Self Owned	115	21.6	
	Rented	274	51.5	
	Rent free	4	.8	
	Family Houser	137	25.8	532
Length of residency	0-10 years	118	22.1	
	11-20 years	140	26.3	
	21-30 years	125	23.4	
	31-40 years	79	14.8	
	41-50 years	38	7.14	
	Above 50 years	29	5.45	532

Perception of sense of community

Respondents were asked how much they agreed or disagreed with a series of statements about sense of community in their neighbourhood (Table 3). On average, respondents were more likely to agree that neighbours get together to deal with problems in their neighbourhood (72.3%) and that it is a close- knit neighbourhood (68.2%). The neighbourhood has adult that children can look up to (63.6%) and people are willing to help their neighbours (65.4%). In relation to trust and safety, over half of the respondents (54.1%) feels their neighbourhood is safe, (44.9%) agreed that they trust people in their neighbourhood, (42.8%) feel safe in open spaces during the day and (34%) at night. Sense of being part neighbourhood was also positive as (71.6%) of parents relate with each other and (62.2%) feel at home in their

neighbourhood while just under half (43.3%) grew up in the neighbourhood and (48.5%) of the respondent agreed to been proud of living in the neighbourhood.

Influence of neighbourhood physical characteristics on sense of community

The result as shown in (Table 4) yields R2 = .136. This indicates that there is a relationship between the dependent variable and the independent variables. The analysis of variance (sum of square = 63.444; df = 24; p 0.000) confirms the significance of the relationship, although the relationship is weak.

Table 2. Perception of neighbourhood physical characteristics

Neighbourhood infrastructure	Poor N (%)	Fair N (%)	Good N (%)	Missn N (%)	Mean
Condition of street	159(29.9%)	219(41.2%)	131(26.5%)	6(1.1%)	2.08
Condition of the residential units	194(36.5%)	261(49.1%)	64(12%)	10(1.9%)	1.91
Overall environmental quality	163(30.6%)	245(46.1%)	111(20.9%)	13(2.5%)	2.04
Health Facilities (Dispensary, Health Centre, Hospital, etc.)	292(54.9%)	134(25.2%)	102(19.2%)	4(.8%)	1.75
Recreational facilities	335(63%)	106(19.9%)	85(16%)	6(1.1%)	1.67
Shopping Centre	173(32.5%)	176(33.1%)	177(33.2%)	6(1.1)	2.21
Educational facilities	167(31.4%)	197(37.0%)	153(28.8%)	15(2.8%)	2.27
Electricity	140(26.3%)	221(41.5%)	162(30.4%)	8(1.5%)	2.20
Pipe-borne water/ borehole	368(69.2%)	88(16.5%)	66(12.4%)	10(1.9%)	1.62
Street roads	169(31.8%)	189(35.5%)	155(29.1%)	6(1.1%)	2.08
Religious/ Worship centres	62(11.7%)	181(34.0%)	233(43.8%)	6(1.1%)	2.38
Drainage	137(25.8%)	194(36.5%)	159(29.9%)	10(1.9%)	2.21
Refuse disposal	159(29.9%)	170(32%)	196(36.8%)	7(1.3%)	2.36
Sanitary conditions	184(36.4%)	200(37.6%)	133(24.9%)	5(.9%)	2.00

Table 3. Perception of sense of community

Perception of sense of community	Agree (4, 5)	Neutral (3)	Disagree (1, 2)	% misn	Mean (SD)
If there is a problem around here, the neighbours get together to deal with it	385(72.3%)	67(12.6%)	78(14.7%)	2(.4)	3.81
This is a close-knit neighbourhood.	363(68.2%)	99(18.6)	64(1.2%)	6(1.1%)	3.81
There are adults in this neighbourhood that children can look up to	338(63.6%)	105(19.7%)	83(15.6%)	6(1.1%)	3.68
People around here are willing to help their neighbours	348(65.4%)	101(19%)	127(13.9%)	9(1.7%)	3.76
People in this neighbourhood can be trusted.	289(44.9%)	195(36.7%)	84(15.8%)	14(2.6%)	3.47
Children around here have no place to play but the street	245(46.1%)	147(27.6%)	125(13.4%)	15(2.8%)	3.46
The park or open space closest to where I live is safe during the day.	228(42.8%)	200(37.6%)	100(18.8%)	4(.8%)	3.36
The park or open spaces closest to where I live is at night.	181(34%)	151(28.4%)	192(36.1%)	8(1.5%)	3.08
Parents in this neighbourhood generally know each other and relate	381(71.6%)	97(18.2%)	47(8.8%)	7(1.3%)	3.92
I feel at home in the neighbourhood.	331(62.2%)	123(23.1%)	72(13.6%)	6(1.1%)	3.71
I am proud of living in the neighbourhood.	258(48.5%)	140(26.3%)	132(24.8)	2(.4%)	3.33
I have grown up in the neighbourhood.	233(43.8%)	89(16.7%)	204(38.3%)	6(1.1%)	3.09
The neighbourhood is safe	288(54.1%)	145(27.3%)	87(16.3%)	12(2.3%)	3.63

The results indicates that nine variables of neighbourhood physical characteristics namely, physical condition of the residential units, neighbourhood environmental quality, health facilities, recreational facilities, shopping centre, educational facilities, electricity, street roads and house type were significant predictors of residents' perception of sense of community. As indicated in the (Table 4), waters supply, refuse disposal and drainage is not a significant

predictor of sense of community. This may be due to the fact that they are not communal facilities or shared facilities among a large number of people. Out of all the variables that are significant predictors of sense of community, power supply is the strongest (Beta = -.409).This is followed by physical condition of the residential units (-.126) and then by house type (Beta = -.123) and Educational facilities (-.109). The next one is shopping centre (Beta = .169) followed by street roads (.139), health facilities (.099) and lastly, by the presence of recreational facilities or open space in the neighbourhood (Beta = .081) as the least significant predictor.

Table 4: Categorical regression analysis of neighbourhood physical characteristics on sense of community

	Standardized coefficients		Df	F	Sig.
	Beta	Std. Error			
Physical condition of the residential units	-.126	.053	2	5.660	.004*
Overall Neighbourhood environmental quality	.102	.047	2	4.646	.010*
Health facilities,	.099	.050	2	3.897	.021*
Recreation facilities	.081	.054	3	2.268	.005*
Shopping centre	.169	.065	3	6.858	.000*
Educational facilities	-.109	.053	3	4.193	.006*
Electricity	-.409	.060	2	46.836	.000*

House type	-.123	.045	1	7.456	.007*

Dependent variable: sense of community
*$\rho \leq 0.05$

This result implies that neighbourhood infrastructure and amenities would encourage informal contacts which would in turn enable residents to socialise with one another and protect each others interest. This may enhance social trust and reciprocal exchanges that may lead to neighbourhood revitalization. Also, neighbourhood physical infrastructure may encourage residents to develop relationship with their neighbours which may influence attachment with the environment which that may have positive and direct effect on the strength of local social bonds that may also enhance neighbourhood revitalization. Public social infrastructure that is shared was also found to encourage social interaction that may reinforce neighbouring behaviour. The result of findings further supports previous findings that neighbourhood physical characteristics influence residents' perception of sense of community which in turn has the potential to enhance quality of life.

Residents socio-economic characteristics and sense of community

The result as shown in (Table 5) yields R^2 = .062. This indicates that there is a relationship (though weak) between the dependent variable (sense of community) and the independent variables (socio-economic characteristics). The analysis of variance (sum of square = 33.068; df = 11; p 0.000) shows that it is a significant relationship.

The result (Table 5) suggests that four variables of resident's socio-economic characteristics are linked with perception of sense of community. The predictors of sense of community in this model are, sex (.002), age (.004), education (.001) and income (.003). it is however worthy of note that tenure status and marital status does not influence sense of community in this study. A closer look at the result shows that the strongest predictors of sense of community in the model (Table 5) are age and sex followed by income while education seem

to be the least significant. The result however shows that the neighbourhoods can be described to possess a very high sense of community.

In all, the two models supports previous findings about the positive influence of sense of community on the perception of neighbourhood characteristics which in turn can enhance residents' quality of life as well as neighbourhood quality.

Table 5: Categorical regression analysis of socio-economic characteristics and sense of community

	Standardized Coefficients		df	F	Sig.
	Beta	Std. Error

Tenure status	-.041	.044	2	.856	.425

Dependent variable: sense of community

*$\rho \leq 0.05$

CONCLUSIONS

This study highlights the physical and social characteristics of poor urban neighbourhoods in Akure with a view to understanding the impact of the neighbourhood physical characteristics on sense of community and also to further substantiate the fact that sense of community can also be strengthened by the socioeconomic characteristics of the residents. The result of findings shows that the selected four neighbourhoods in the core of Akure are not only inhabited by poor people who earn far below the poverty line, a few wealthy individuals live within the core neighbourhoods. The neighbourhood can also be described physically to be characterised with poor residential units, poor infrastructure and social amenities but also with a positive social capital and sense of community.

This study supports further previous studies (Farahani & Lozanovska, 2014, Wood, Frank &Giles-Corti , 2010, Schwirian & Schwirian, 1993, Araya, Dunstan, Playle, & Thomas, 2006) that sense of community and neighbourhood physical characteristics both affects each other significantly. The findings further shows that shared public facilities are more likely to encourage sense of community while sense of community variables like trust and social cohesion may encourage residents to collectively develop their neighbourhood which may in turn translate to better quality of life for the residents. Strong sense of community could also be part of the reason people stay in poor environments despite the fact that poor neighbourhoods are linked to poor health and crime threats that renders the place unsafe. Nevertheless, given the reality that many residents of poor neighbourhoods will not accept or cannot afford a move, it may be sensible from the standpoint of government and policy makers to focus on programs that can translate residents' positive bonds of sense of belonging to a neighbourhood into place improvements. Future research may therefore consider how neighbourhood sense of community can better be used to combat poverty and also facilitate neighbourhood development.

Issues in Adequate and Quality Housing Provision for Nigeria Urban Residents

Adebayo, M. A.[1*] & Mbazor, D. N.[2]

[1&2] Department of Estate Management, Federal University of Technology, Akure, Nigeria
[*] adebayomaa@gmail.com

ABSTRACT

The need for Nigeria to comply with the Istanbul declaration and Habitat II conference resolutions of 1990 on ensuring adequate shelter for all and making human settlements safer, healthier, livable and sustainable for all citizens particularly the urban residents is advocated in this paper. Housing as a basic need is lacking for a sizeable number of Nigerians. The medium and the low income groups of the population, most of who live in urban areas, suffer severe housing crisis. In cities like Akure, Lagos, Abuja and P/Harcourt, few houses are available for workers in both formal and informal sectors. In highlighting the roles of housing in the totality of man's life, the paper review the past and present efforts by government and private individuals at providing housing in Nigeria, as well as identifying aggregate factors militating against the provision of quality housing for urban dwellers. While enumerating attributes of standard homes, the authors emphasized the need for identifying all technical, Socio-economic, cultural, political and environmental issues relating to good housing provision.

Keywords: Development, Housing, Infrastructure, Quality, Urbanization

INTRODUCTION

In recent times regional environmental phenomena such as rapid population growth rate, industrialization and urbanization occur mostly in developing countries where 75% of the world population lives Hyuwa (2000). Though these processes are welcome development, but inherent in the processes are socio-economic and environmental problems which include inadequate housing supply to match demand, rapid urban decay characterized by dilapidated buildings, emergence of urban poor, rising crime rates, pollution, poor infrastructures, poor Sanitation system, high traffic congestion among others.

This paper therefore dwells on the issues of inadequate housing provision and a number of social maladies associated with the tripartite processes of high population growth rate, industrialization and urbanization.

Definition of Housing

Housing connotes different things to different people at different times. Housing is an inevitable requirement for the survival of man. Globally, the central thing in housing is the "dwelling unit". Broadly speaking, dwelling unit, which may be in the form of a cave, cabin, canopy, house or palace, offers a bundle of services. Housing is a collective term for human shelter. Strictly speaking the dwelling structure, which is legitimately constructed or erected in accordance with approved plan, qualifies for a house or home. Shelter, which is housing is next to food as far as man's hierarchy of need is concerned. The environmental perception of housing is reflected in the view of the Kick lighters (1986) when they describe housing as being more than just a dwelling. Provision of housing is the creation of a special environment in which people live, grow and conduct their day- to-day businesses.

Housing affects the way people feel and act, just as values and personality affects people's choice of housing. People's life and housing are inseparable; hence the term "life space" is sometimes used to describe housing. For the very poor, a house is just a sleeping place. For others, the house may be a place for intense routine activities in which case the house becomes a home.

Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1422-1431

Functions of Housing

The fundamental functions of housing may be itemized as:

i. Protection from vagaries of weather
ii. Security from intruder
iii. Indoor cooking
iv. Sanitary and storage facilities
v. Serving as area for rest and privacy
vi. Provides space for recreation
vii. Prestige and as a means of self actualization/fulfillment

If housing must be described as adequate; it must be good enough in quality as well as being easily accessible to place of work.

Need for Adequate Housing

Nigeria is one of the fastest urbanizing countries in the world (Raji, 2008). The greatest challenge posed by this urbanization is inadequate housing needs due to the high rate of rural urban migration resulting to social, economic, environmental and political challenges.

A recent study on housing situation in Nigeria put existing stock at 23 per 1000 residents, while the housing deficit is put at between 16million and 17million houses, and N65 trillion will be required to finance the deficit at the average of N3.5 million per unit (dailyindependentonline 2015). This amount is about 10 times the 2016 Nigeria proposed budget expenditure.

LITERATURE REVIEW

Past Efforts in Housing Provision in Nigeria

The issue of housing is of paramount concern to government across the globe. Since man went through a transition from primitivism to modernism, the problem of providing adequate shelter for him has been of prime importance. In Nigeria for instance, concerted efforts have been made by the past governments, organized private sectors and individuals towards solving the lingering issue of housing provision.

Pre-colonial Era

Prior to the coming of the colonial masters at the end of 20th century, a communal system of housing provision was in existence in most part of Nigeria. The process involves age grades, friends, and or community members coming together en-mass to carry out the task of building house to the benefiting member, who in-turn provides sumptuous meal to the participants. The process revolves round till every member benefits. This system continues till 1928, and indeed may still be in practice by some communities today.

The Colonial Era

This period spans through 1928 – 1960. Here, the colonial masters began to intervene in the provision of housing in Nigeria particularly during the Bubanic plague in 1928 (NHR 1991). They needed good housing to curtail the incidence of plague that was killing them. This action brought into existence bye-law termed Lagos Executive Development Board (LEDB) which was charged with the responsibility of planning and developing the capital city of Lagos. The scheme was meant for the civil servants who eventually bought the houses through a payroll deduction system.

Post-independence

Several housing provision schemes were introduced after independence to carter for the Nigeria workers. For instance the building society was established and tasked with the responsibility of providing housing opportunities to more Nigerians including those outside

the public sector. The impact of NBS was felt significantly in Lagos, with few people benefiting from outside Lagos. The society could not last for long as it depends wholly on government for its operation.

Other Housing Interventions

Public

According to Fedahunsi (1985), Bodija in Ibadan, Trans Amadi in Port Harcourt and Stander and Taylor Woodrow Estates in Lagos constitute the early efforts made at providing housing for civil servants through the activities of the Regional Town Planning Authorities, Housing Corporation and Federal Mortgage Bank (FMB) which were established to engage in direct housing provision and financing.

From about that same period, involvement of employers in housing their workers was made mandatory by law to reduce national housing problems. Regrettably, in spite of all the efforts made to increase the national housing stock it was discovered that housing problem in terms of quality and quantity kept increasing in the urban communities rather than decreasing.

Considering the prevailing situation, it was obvious that management and strategies for the implementation of housing policy were fundamentally faulty. For instance, in the Third National Development plan, the military government proposed to construct 200,000 units of housing across the nation but by the end of 1980 only about 12 % of the figure was achieved Onibokun (1984). The rate of construction in urban areas hardly exceeded 2 dwelling units per year per 1000 population.

Private

The roles of individuals and corporate entities have been major sustaining factors to housing provision from the onset both in the rural areas as well as in the urban centers. Indeed private sector participatory role has reached such a dimension that it is becoming the most popular source of proving urban housing in Nigeria. Examples of private sector involvement include, Still Water Garden in Lagos, Prince and Princess Estate in Abuja, Brick City Estate Minna, Ijapo estate in Akure to mention a few. Government must find a way of encouraging private developers to boost housing stock for the Nigeria Urbanites. Usman (2000) asserted that if given proper leadership and incentives, the private sector can act as a veritable tool in the socio-economic progress and development of Africa.

Required Standards for Quality Housing Design

Wahab (1985) in reviewing standards for a good home design in Nigeria summarized functional requirements of any building as:

i. Strength and stability to ensure occupants safety;
ii. Structures must be dimensionally stable;
iii. Protection against hazardous weather conditions;
iv. Durability;
v. Thermal insulation;
vi. Sound insulation
vii. Provision of adequate ventilation (cross ventilation design).

While the management requirements must address issues such as.

i. Owner's need/requirement;
ii. Suitable site location;
iii. Good layout;
iv. Maintainability.

The design of a house must provide for the following basic functional areas:

i. The living area;
ii. The bedrooms;

iii. The bathroom;
iv. The toilet room;
v. The kitchen.

Attributes of a Standard House

In addition to the above, the standard homes can be described as those, which satisfy occupancy ratio of 2 or less and fulfills/ or are served with functional infrastructural facilities such as:

i. Access roads and free flowing side drainages:
ii. Portable water supply;
iii. Steady supply of electricity through a well installed and appropriately rated transformer;
iv. Adequate sewage and solid waste disposal systems:
v. Open space for play and recreation;
vi. Safety factor such as adherence to prescribed set back to roads, rail, rivers, or beaches in case of coastal towns;
vii. Education and Health services located in appropriate proximity.

METHODOLOGY

In order to examine the challenges associated to adequate quality housing provision, the study included secondary data. The secondary data involved available housing census data, official documents and other relevant secondary data were obtained from existing literature, books, internet and journals.

RESULTS, ANALYSIS AND INTERPRETATION

The abysmal performance of the National Housing Policy in meeting its set goals and objectives led to a comprehensive review, which culminated in the Housing and Urban Development Policy of 2002. Under the revised National Housing policy during Olusegun Obasanjo regime in 2002, and upon the recommendation of the Presidential Committee on Housing and Urban Development, the Federal Government of Nigeria accepted to adopt a primary goal which was to ensure that all Nigerians own or have access to decent, safe, and quality housing accommodation at affordable cost with secured tenure. As proposed by the Presidential Technical Committee on Urban Development and Housing, the framework for its operation involved restructuring of existing structures and the creation of new ones. These include: National Urban Development Policy of 1997; Land Use Act 1978; Mortgage Institutions Act, 1989(Cap 231); Employees Housing Scheme (Special Provision) Act (Cap 107); and Federal Housing Authority Act, 1990(Cap 136), among others. The housing reforms policy also involved the establishment of the Federal Ministry of Housing and Urban Development in July, 2003 which was saddled with the responsibility of adequately addressing the complex problems of the urban housing sector. It also accepted to vigorously pursue the implementation of a private sector led programme of constructing forty thousand (40,000) housing units per annum nation-wide under the following distribution:

i. 1,000 units in each state of the Federation except Lagos, Kano and River State;
ii. 1,500 units in Kano and River States;
iii. 2,000 unit in Lagos State
iv. 3,000 units in Abuja in addition to restructuring and adequately funding key agencies such as Federal mortgage Bank of Nigeria (FMBN), Federal Mortgage Finance Limited (FMFL) and Federal Housing authority (FHA) with a view to ensuring sustainable provision of the needed housing stock.

Recently, on Tuesday 8th December 2015, the Honorable Minister of Power Works and Housing, Mr. Babatunde Fashola announced that Buhari led government would in 2016 spend N10 billion naira in each of the state of the federation including the federal capital territory to build 40 low income housing estate (Vanguardonline, 2015).

The move was in agreement with the Istanbul declaration (1996) and Habitat II conference where the Global National plans of Action deals with provision of adequate shelter and sustainable human settlements in urbanized world for the next two decades.

Today, the efforts made towards meeting the national housing need has not yielded the desired result as the sector continuously receives low funding. For instance, the 2016 budgetary provision to the housing subsector is ridiculously low compared to the allocation made to other sectors. This is shown on the table below:

Table1: showing budgetary allocation to some selected sectors in Nigeria for 2015 and 2016.

S/N	Sectors	Years	
		2015	**2016**
1	Transport	11.98billion	202billion
2	Interior	143billion	531billion
3	**Works, Housing and Power billion**	**6.2b (housing)**	**433.4**
4	Education	450billion	369.6billion
5	Defence	289billion	294.5billion
6	Health	232billion	221.7billion
7	Ministry of Interior	157.5billion	145.5billion
8	Labour and productivity	8.7billion	500billion

Source: *Budget office of the federation, budget research, 2016*

From the table above, it is observed that N6.2billion was allocated to housing sector in 2015 national budget and N433.4billion was proposed for 2016 budget for works, power and housing sectors. This amount is ridiculously low and will in-avertedly hamper the idea of providing quality housing to Nigerians.

Table 2: Distribution of Housing Units Under the National Housing Programme (1994/95)

S/N	State	Targeted unit	Unit completed s/n	S/N	States	Targeted unit	Unit completed
1	Abuja	10,000	1,114	17	Kebbi	5,000	None
2	Abia	5,000	None	18	Kogi	3,000	None
3	Adamawa	3,000	None	19	Kwara	3,000	None
4	Akwa Ibom	2,000	None	20	Lagos	10,000	None
5	Anambra	5,000	None	21	Niger	1,000	None
6	Bauchi	3,000	None	22	Ogun	3,000	None
7	Benue	1,000	None	23	Ondo	3,000	None
8	Bornu	3,000	None	24	Osun	5,000	None
9	Cross River	1,000	None	25	Oyo	5,000	None
10	Delta	5,000	None	26	Plateau	3,000	None
11	Edo	2,000	None	27	Rivers	3,000	None
12	Enugu	3,000	None	28	Sokoto	3,000	None
13	Imo	3,000	None	29	Taraba	5,000	None
14	Jigawa	5,000	None	30	Katsina	3,000	None
15	Kaduna	3,000	None	31	Yobe	500	None
16	Kano	3,000	None	TOTAL		121,000	1,114

Source: Housing Policy Council Report No 3, 1995 and Agbola, 1998 in Shittu and Akande (2010)

Table 2 above revealed that government could only provide less than 1% (1,114 units) of the targeted units of housing (121,000 units) for the year 1994/95. This is grossly inadequate compared to the number of people that are in need of housing.

Poor Environmental and Housing Conditions In Nigeria

Waste generation is a natural by-product of population but absence of effective disposal system results to serious health and environmental problems.

It is estimated that Solid waste generated per home per annum in Nigeria is 20kg, and for an estimated population of 110 million homes, it means that a total volume of 2.2 Million tones of solid waste is generated annually in Nigeria. Out of this figure, only about one-fifth is properly and hygienically disposed. Table 3 below shows estimated volumes of solid wastes produced in states across Nigeria.

Table 3: Distribution of Households by Method of Solid Waste Disposal – National

State	Total	Collected	Buried	Approved	Unapproved	Burnt	Other

Source: Population and Housing Census of Federal Republic of Nigeria (2006)

From the table above, it is observed that the quantity of solid waste deposited at the government approved dump sites was only 20.4%. This shows that 70.6% of solid wastes generated by Nigerians, particularly the urban residents are disposed in a manner other than the approved system.

As long as these generated solid wastes outweighs the rate at which they are properly evacuated and disposed, the quest for the attainment of livable and quality housing environment will remain a mirage for the urban dwellers.

In Nigeria, it is common to find road ways in urban streets either completely or half-way blocked with heaps of solid wastes. In several of these urban centers Agbonoga (2000) noted that the rate at which solid wastes are generated overwhelmed urban administrators' capacity to plan for their evacuation. The negative practice of Nigeria urban residents - dumping refuse into drains with the expectation that rain water will wash them off often results to the blockage of the free flow of storm water thereby causing flooding and in some cases cause liquid wastes to stagnate forming mosquito breeding ground with its attendant outbreak of diseases such cholera, malaria etc. It is also a common thing to note that many urban houses do not have toilet and bathing facilities, this often result to urban dwellers defecating in an open place.

Source: Population and Housing Census of Federal Republic of Nigeria (2006)

From table 4 above, it is revealed that only 11.4% of urban houses built in Nigeria have public water supplied into the houses either inside or outside the houses, thereby leaving

about 89.6% of the houses getting their supply from other sources. This has equally resulted to the outbreak of cholera and other killer diseases.

PROBLEMS MILITATING AGAINST EFFECTIVE HOUSING PROVISION IN NIGERIA

Most of the National Development Plans, NDPI (1962-68) NDPIII (1970-74) NDPIII (1975-80) NDPIV (1981-85) and subsequent rolling plans are well intended to boost housing provision but unfortunately the efforts did not yield much dividend because of numerous obstacles in the way of implementation. The problems of lack of realistic housing standards, overconcentration of policy at the federal level with its attendant bureaucratic impediments, lack of proper maintenance culture have all combined to make the lofty ideals expressed in the plans unrealizable. In addition, the following factors greatly contributed to the failure of the various programmes:

i. Change of governments caused by political instability as witnessed during the military rule often lead to change or abrupt termination of policies and priorities.
ii. Variation in political ideologies among the ruling political parties.
iii. Insincerity of those entrusted with governance, which resulted in the implementation of selfish and hidden agenda;
iv. Financial mismanagement and corruption resulting in overpricing and high cost of housing delivery.
v. Favouritism which sustains wrong hands in jobs as well as propping up mediocrity and production of substandard public infrastructural facilities.
vi. Ethnic-balancing and geographic character at the expense of merit and professionalism;
vii. Cultural factors such as giving chieftaincy titles to people in government thereby promoting undue loyalty and loss of focus;
viii. Absence of appropriate technology and researches in sourcing local building material to bring down costs of construction.
ix. Ignorance and dirty habits resulting in poor sanitation and poor housing conditions:
x. Poor urban infrastructures: such as, faulty transformers, damaged water pipes, sewage and drainage, poor refuse disposal systems;
xi. Over-crowding resulting in rapid deterioration of urban infrastructures apart from promoting immorality among the residents;
xii. Sizeable housing stocks are lost to fire when parts of towns and cities are set ablaze during political, ethnic or religious riot as presently witnessed in the North East region of Nigeria.
xiii. Non –involvement of all relevant stakeholders in the conception, design and implementation of housing projects and
xiv. Paucity of fund due to global recession and drop in the oil revenue among others.

PROPOSED STRATEGIC PLANS FOR ADEQUATE AND QUALITY HOUSING PROVISION IN NIGERIA'S URBAN CITIES

The followings constitute a recipe for effective and efficient housing of Nigeria's teaming urban population:

i. Sustenance of political stability to provide to attract foreign investment. This could be achieved by conceding electoral defeats thereby creating a measure of confidence to the prospective property investors.
ii. Involving all stake holders' such as the Architects, Engineers, Surveyors, Builders and others right from the conception, planning and design stages up to the implementation of housing projects.

iii. Planning and implementation of Rural Integrated Development Programme to sustain rural economy and food production in order to reduce the current influx of rural youths and able-bodied men to urban centers there by reducing undue pressure on urban housing and infrastructures.
iv. Embarking on enlightenment campaign on good health habits and proper method of refuse disposals such recycling;
v. Adoption of pragmatic mode of housing such as provision of site and services schemes, and direct provision of affordable housing by states;
vi. Introduction of clean policy on integrated waste management strategy, which should spell out the responsibilities of institutions and all stakeholders involved in waste generation/management and must be supported by appropriate legislation based on principle of farness and in agreement with Malungu (2000) who remarked that those who generates waste should also have the responsibility for its safe disposal.
vii. Conducting periodic census exercise to determine housing needs of the urban centers, towns and cities:
viii. Encouraging private sector developers in housing delivery, through tax relief, site and services scheme to enable them put greater emphasis on production of affordable houses for the urban poor;
ix. Reversal to the status quo of having a Minister solely in charge of Lands, Housing and Urban Development;
x. Establishment of Research Centers in Nigeria Universities on local building materials aimed at lowering the cost of building construction.

CONCLUSION

Nigeria is endowed with both human and abundant natural resources such as solid minerals, gas, and petroleum, extensive regional setting with high agricultural and tourism potentials. They must all be properly developed to build our economy and provide much-needed fund for provision of adequate and suitable housing for all on sustainable basis. Apart from the central role housing plays in the life of an individual, it constitutes a singular biggest sector next to agriculture that generates the greatest number of jobs for the greater number of people. The newly planned 40,000 housing units per annum by Buhari lead administration should not go down in the way of past plans and projections. They should be materially and financially provided for in the national budget and constructed for physical occupation of the targeted workers and population. If this is done on a sustainable basis, the issue of housing provision in terms of quality and quantity will be achieved in not too distant future.

ABSTRACT

Most often, cities suffer decay for lack of values and maintenance of its immediate infrastructure. The real cause of this decay lies in re-establishing the value that gave the city or a section of the city its life. This study aimed at identifying Ile-Ife inner city problems with the aim of providing information that could inform policy towards the rehabilitation of the study area. A total of 477 household heads were selected for questionnaire administration which targeted the residents and was administered on household heads living in one out of every ten (10) houses located in the identified seven (7) political wards that formed the core area of the traditional city. The results revealed that most of the household size in the study area is between 5 to 9 persons, while most of the buildings in the study area were built between 30 to 40 years ago. Information on housing environment reveal that most of the buildings lacked toilet facilities, majority of the buildings depended on well for water supply and majority of the houses are not accessible by road. Similarly, a high number of the residents disposed waste through open dumps, while close to the average respondents' practiced burning method and the remaining few engaged in central collection. In a nutshell, the study revealed the need to formulate strategy in which decayed inner cities such as the core area of Ile-Ife is revived urgently. This study therefore concludes that inner-city of Ile-Ife needs provision of decent and adequate housing units as well as healthy environment for the dwellers.

Keywords: Decay, Environment, Inner City, Rehabilitation and Residents

INTRODUTION

Rapid rate of urbanisation resulting from rural-urban migration is a major contributing factor to slum development in developing countries (UNCHS, 2003; 1986). Due to the unsustainable planning and management, immigrants tend to congregate and seek accommodation from less desirable areas of the city. Most slums in cities of developing countries including Lagos in Nigeria, Bogota in Colombia and Cairo in Egypt resulted from rapid population increase without a corresponding housing and social services provision (Jerome, 1990; UNCHS, 2003). Also, the fact that emerging new estates and neighbourhoods and the old parts of our cities and towns are turning to slum is evident. This has therefore involved the fact that the Nigeria housing environment needs more than construction of new housing units and accompany infrastructure; it requires the rehabilitation and redevelopment of some of the existing ones (Onibokun, 1985).

The problem of urban centres in Nigeria is that most of them are grown and unplanned. Consequently, this has led to the development of disorganized, overcrowded, declined, dilapidated and blighted areas and then slums in our cities. Urban slums are characterised by deplorable living conditions with poor land use planning, inadequate social services, coupled with high levels of communicable diseases, and exposure to fire outbreaks, floods and violence (Agyarko-Oduro, 2009; Butala et al., 2010).

The deterioration of Nigerian urban centres has been a process, not a willful act that may be corrected on command or legislation. The reality in the big cities in Nigeria such as Lagos, Ibadan, Port Harcourt, Aba and Enugu presents a number of problems that are worth mentioning.

Yoade, A. O. & Olayiwola, L. M. (2016). Inner City Decay and Rehabilitation in Ile-Ife, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1432-1439

These include urban decay, slum, overcrowding and lawlessness which lead to the loss of land and natural resources (Njoku and Okoro, 2014).

Housing, as a substantive unit of the environment is described as a residential environment. This includes the physical structure used for shelter, all necessary services, facilities, equipment and devices needed or desired for the physical and mental health and social well-being of the family and individual (Aribigbola, 2001; Adedeji, 2008; Owoeye and Sogbon, 2012a). The United Nations Ad-hoc Group of Experts on Housing and Urban Development defines it as physical environment in which a family must develop, being the basic unit in the society. Housing, this is often defined as a multi-dimensional bundle of services but comprises a number of facilities, services and utilities which link individuals and his family to the community in which it evolves. It is universally acknowledge, therefore, as one of the most basic needs with a profound impact on the lifestyle, health, happiness and the productivity of the individual (UN Habitat, 2003; Owoeye and Sogbon, 2012b).

Researches have shown that many Nigerian cities are still characterized by filth and squalor, decrepit structures, poor sanitary conditions and poor accessibility, among others. These generalized conditions also apply to the cradle of the Yoruba race (Ile-Ife). Strategies tried to reduce and transform slums in different countries, with varying degrees of success, include a combination of slum removal, slum relocation, slum upgrading, urban planning with city wide infrastructure development, and public housing projects. Studies have shown that challenges of the implementation cannot be over-emphasized, despite the overwhelming aesthetic value, environmental health, economic and social benefits that are expected to be derived from the program, its implementation in African countries has not always been without challenges especially, faced with opposition from inhabitants' disagreement and misunderstanding and even violence between the renewal agencies and the inhabitants in extreme cases.

In furtherance of previous studies on the subject of urban renewal, this study seeks to examine inner city rehabilitation, and on this basis suggest and provide a framework for the implementation of urban renewal programmes in Ile-Ife, Nigeria. Along this line, the study examines the socio-economic characteristics, building and facilities characteristics of inhabitants regarding rehabilitation of the inner-city.

LITERATURE REVIEW

The Inner-City

One important feature of human settlements in many parts of Africa including Nigeria is the notion of the centre. This may be the physical or conceptual geometric centre of group settlements. This according to Davidson (1969), are extant cosmologies and myths in many sedentary societies which point to the relevance of the centre as the mythical source of any story connected with group origins, and linked up with the ancestors to whom supra-sensible intelligence had shown the land and how to cultivate it.

In many societies, the center occupies strategic importance in the spatial scheme of settlements. For instance, in the radial-concentric shape of the Yoruba town particularly as a reflection of its social and political organization, the centre is the most strategic for a number of reasons. It is the magnetic centre of the town, which contains the most important unifying symbols, namely: the palace (Afin), a playground, and all the important shrines and Oba's market (Onibokun, 1985). These features draw (to the centre) all the members of the society in connection with rituals and ceremonies associated with it. The same principle applies to other settlement layouts in many parts of Nigeria. The centre as the spatial and structural core of settlement layouts ought to constitute its most vital point of architectural 'energy' in the

sense that the centre of the town or city ought to provide the conceptual core of architectural planning. When these corporate symbols are designed in response to the demands of design culture, towns and cities may begin to assume a unique character of their own.

While commenting on the issue Dimuna and Omatsone (2010); Omole (2000) and Owoeye and Omole (2012) stated that the haphazard residential morphology of the core has not altered significantly in recent years. The residential environment is "unhealthy" and "filthy". Most of the buildings are structurally and qualitatively deficient; dwellings are chaotically and densely jumbled together while, the few roads that traverse the built-up area are poorly maintained; and basic urban amenities necessary for good health and happy existence sparsely and sporadically distributed. Environment's sanitation is at an appalling level, and machineries of the civic government are perfunctorily operated.

Also, Adeniji (1987) described the inner city areas (core) as homes of the poor and disadvantaged people, including the old, the lonely and the homeless. He therefore concluded that inner city areas as an area characterized by such pathetic social conditions as low income, unemployment, illiteracy and juvenile delinquency, among others.

Jelili et al (2006) examined the planning implications of housing redevelopment in high-density areas of Ogbomoso, Nigeria. In their survey, they highlight the effects of the nature of such redevelopment on the adjoining properties, as well as assess the perceived value of such redevelopment in the area. They recommended a strict enforcement of development control with special emphasis on development permit before the commencement of redevelopment.

Core Rehabilitation

The components of urban renewal include city expansion, redevelopment, comprehensive road development, redesigning and beautification of settlement layout, upgrading of facilities and public goods and services, repair, construction and silting of drainage system within an urban centre, and enforcing slum upgrading and city development (Njoku and Okoro, 2014).

According to Egbu et al. (2014), rehabilitation involves the enhancement of the quality of deteriorating neighborhoods through code enforcement and private actions of the owners. Onibokun (1972) cited in Umunnakwe, (2009) sees rehabilitation as a process of improvement at both micro and macro levels. At the macro levels, it is the process of neighborhood revitalization through the elimination of grossly dilapidated houses, renovation and construction of streets and the provision of infrastructural and communal facilities. At the micro level, it means environmental upgrading of individual housing units. In this case, defective houses are improved upon and made to be conducive to healthy human habitation. It is applicable where the building structures are still in good conditions and can be improved, that is where the squalid condition arose as a result of lack of maintenance. It has though been criticized that full rehabilitation does not replace the main fabric of buildings, and does not significantly improve their life span. The protagonists of this approach recommend it for cities in developing countries, because it is less expensive, less radical and has relatively favorable financial and social implications.

The inner-city of Ile-Ife exhibits these sub-humane conditions, where substandard houses are prevalent in unkempt environments. It is very important that the structures and building as well as facilities characteristics of the core areas are clearly identified. The emerging problem structure will assist in the articulation of adequate rehabilitation for the core areas.

STUDY AREA

Ile-Ife is made up of two (2) Local Government Areas (LGAs), Ife East and Ife Central LGAs, whose headquarters are at Oke Ogbo and Ajebandele respectively. The two (2) LGAs

comprises of twenty one (21) political wards (eleven in Ife Central and ten in Ife-East) in the council areas with the population of 355,818,000 with projected population of over 500,000 by the year 2020 (Federal Republic of Nigeria Official Gazette, 2009). The core, which happens to be the oldest residential portion of the city, consists of the oldest parts of the city. The study area conforms to the general morphology of the traditional core areas of Yoruba cities, with the major elements, which include the palace, the king's market (Oja- Oba) and the seven (7) selected core wards (Yoade, 2013). See Figure 1.

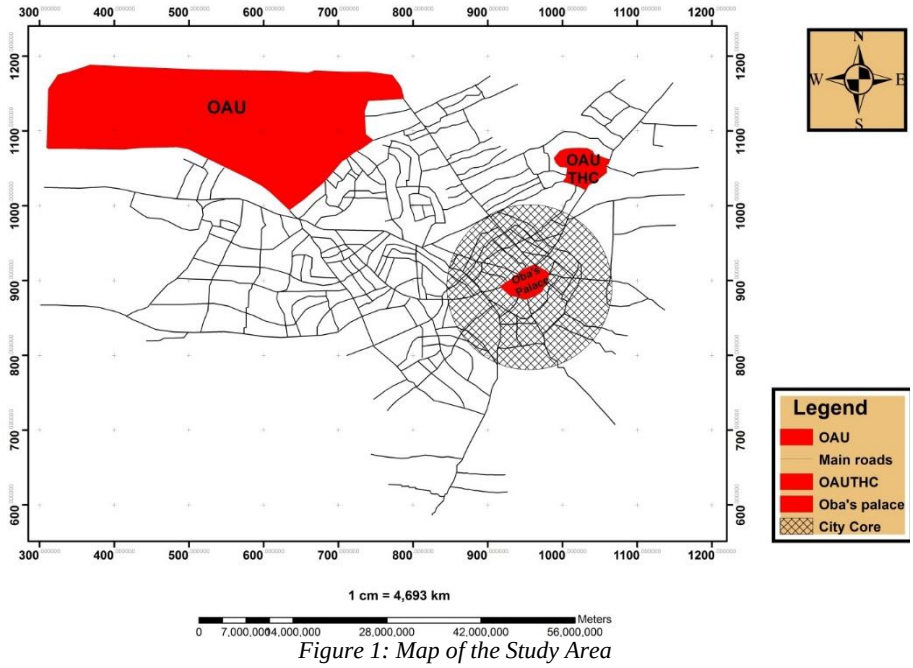

Figure 1: Map of the Study Area
Source: Ife Central Town Planning Office, 2013

METHODOLOGY

Both primary and secondary data were used in the study. The primary data were sorted and gathered using direct observation and questionnaire administration to sampled households in the study area. The copies of the questionnaire, targeted at the residents'; were administered using systematic sampling method on household heads living in one out of every ten (10) houses located in the identified seven (7) political wards that formed the core area of the ancient and traditional city (this represents 10% of the residential buildings in the study area). A total of 477 household heads were selected for questionnaire administration. Meanwhile, only a household was interviewed in each of the building selected. The street guide was well mapped during the reconnaissance survey and pilot study provided a useful direction. Data collected laid emphasis on socio-economic characteristic of respondents, age of buildings, materials and building facilities as toilets, bathrooms and their types, water supply, solid and liquid waste disposal, ventilation, accessibility, pollution, occupancy ratio, land use and disease occurrences. The data collected was compiled, summarized, presented in tables and converted to percentages for easy analysis. Secondary data were sourced from various institutions, base map from ministry of land and physical planning. Also, the population data were obtained from the National Population Commission.

FINDINGS AND DISCUSSIONS

Socio-Economics Characteristics

The result of the finding revealed that a great percentage of contacted respondents (33.5% and 31.4%) had primary and modern school. While 24.3% of the respondents had no formal

education and about 9.2% had secondary school. Just 1.4% of the respondents had tertiary school. The respondents' occupation in the study area established that, closes to two-fifth (32.5% and 31.4%) of the respondents are traders and self- employed respectively. About 13.6% are farmers, 1.5% civil servants, 9.4% artisans and others 11.5%. The study also revealed that it is possible for the level of education and occupation affects the monthly income, as shown in the table 2. Close to two-fifth (35.6%) of the respondents earns below #5,000 while 28.7% less than #10,000. Also, 21% of the respondents earns between #10,000-#15,000, 8.8% earns between #15,000 -#20,000. While a few 5.9% earns #20,000 and above (see Table 1). The finding here revealed that the general income is below the average income level of N10, 000 per month. With this low income distribution, to afford good quality housing, proper maintenance of existing ones and adequate feeding might be very difficult, if not impossible. Besides this, the household level of education is low. Majority of the households were either with primary school leaving certificate of secondary school certificate. This accounts for about 57.8% of the respondents in the study area (See Table 1).

Table 1: Socio-Economics Characteristics

Variables	Number	Percentage
Level of education		
Not educated	116	24.3
Primary school	160	33.5
secondary school	44	9.2
Modern school	150	31.4
Tertiary school	7	1.4

Occupation		
Agriculture	65	13.6
Trading	155	32.5
Civil service	7	1.5
Private employees	150	31.4
Artisans	45	9.4
Others	55	11.5
Total	477	100
Monthly income		
Below 5,000	170	35.6
5,001-10,000	137	28.7
10,001-15,000	100	21.0
15,001-20,000	42	8.8
20,001 and above	28	5.9
Total	477	100

Physical Characteristics

The study revealed that a large percentage 65.2% of the land use is residential, 21.2% are mixed, 0.2 % industrial, 2.9% religious, 8.0% commercial while just 2.5% is institutional. The findings also revealed that more than four-fifth (83%) of the buildings was built more than 30years ago while 8.8% was built between 20 to 30 years ago. Just 2.1% of the buildings was built less than ten years. It was established from the finding that mud is the major material for construction which is 70% while one-fifth (20.3%) is mud blocks. Just 9.6% of the buildings are made of cement blocks. The structural condition of the buildings in the study area is categorized as good, fair or poor. From Table 3, majority 50.3% of the houses are classified as poor, 46.8% are classified as fair and only 2.9% are classified as good. With the foregoing, the rating of the poor and fair conditions of the houses confirms the need of the renewal in the study area (see Table 2).

Facilities and Services

The study revealed that most 87.4% of the respondents depend on PHCN for electricity while few 12.6% source power through electricity. On road condition, more than half of the respondents believed that their road are un-tarred, 42.0% said are tarred while remaining few use footpath. Even those respondents that claimed that their roads are tarred, part of that roads are in bad state. Therefore, the road condition in the area is in bad state which needs urgent attention of the concerned authority. The study showed that most of the total respondents uses pitlaterine, 29.4% of the respondents' uses bucket system while few of the respondents' uses water closet. According to the study majority of the respondents get water through well, 16.0% gets water through tap water while 4.0% get water through bore-hole. Various methods of waste disposal employed by the residents in the study area as illustrated in the Table 3. One major feature of an undeveloped core area is the dirty environment and Ile-Ife is no exception (UNHSP, 2008). 49.1% of the respondent dumps their refuse by the road side due to lack of facilities provided by the Waste Management board, 35.0% practice burning while the remaining 15.9% use central collection and the result of this is that the refuse emits an offensive odor and is quite unsightly and most refuse gets into the gutters and clog them up (see table3). Investigation on drainage condition reveals that 61.0% is in a very poor condition, 22.4% is in a poor condition and the remaining 16.6% is in average condition. This implies therefore that the condition of drainage system in the environment is generally very poor as shown in Table 3. On the state of health facilities in the area; a large number of the respondents are having the facilities either farther away from their dwellings or completely absent within their neighbourhoods. Most respondents indicate non-availability of health facilities while only few are accessible to health facilities in their area (See table 3).

Table 2: Physical Characteristics

Variables	Number	Percentage
Land-use		
Residential	311	65.2
Commercial	38	8.0
Mixed	101	21.2
Institutional	12	2.5
Industrial	1	0.2
Religious	14	2.9
Total	477	100
Age of the building		
Below 10 years	10	2.1
11-20 years	29	6.1
21-30 years	42	8.8
30 years and above	396	83.0
Total	477	100
Material for consumption		
Mud	333	70.0
Mud block	97	20.3
Cement block	46	9.6
Total	477	100
Condition of buildings		
Good	14	2.9
Fair	223	48.6
Poor	240	50.3
Total	477	100

However, the regression analysis computed to investigate the relationship of physical characteristics with the availability of facilities and services show a positive significant relationship of 71.1%. This strong relationship establishes the priority of such factors as

considered in the study to be determinants for good living and aesthetic pleasing environment. The summary is shown in Table 4 below.

CONCLUSION AND RECOMMENDATION

The study established that the deplorable state of the Ife core requires urgent attention to ameliorate the harsh and unhealthy conditions experienced by the slum dwellers as most physical condition, facilities and services are in bad state. Corroborating the study of Ogunleye (2013), the decaying nature of the core areas in Nigerian cities and other developing countries over the last decades has also brought into focus the need for housing researchers and decision makers to develop a better understanding of the structure, operation and dynamics of urban centres. However, it has become imperative to look for the way forward out of the unprecedented growth rate that generated various problems such as lack of inadequate social, medical, educational and recreational facilities, over-utilization of existing inadequate facilities and environmental deterioration.

The study therefore recommends that there is need for provision of adequate housing facilities and healthy environment. In other to achieve this, extensive redevelopment and

rehabilitation programmes should be employed in the study area. Also, Waste Management Authority should be funded more for effective service as well as improved hygienic environment in the area. Furthermore, there is need to rehabilitate some old structures and buildings, upgrading the roads especially the un-tarred ones and damaged roads. It also involves improving the existing infrastructural facilities as well as providing new ones with a view to improving the structural quality as well as to ensure aesthetics pleasing environment.

ABSTRACT

Informal urbanism is the major driver of city development in African cities. In such a scenario where most settlements do not have defined or formal layouts, urban drainage development can become quite a challenge. This paper examines the phenomenon of urban drainage development in Palladan, an unplanned neighbourhood in Zaria, a city in northern Nigeria. The study focused more on the social and environmental aspects of drainage development. This paper adopted a case study, field survey approach. 150 households were selected through systematic random sampling and questionnaires were administered to them to get their opinions on the environmental and social aspects of drainage development in their neighbourhood. Simple descriptive statistics were used to analyze the data. The findings revealed that drainage provision at neighbourhood level is largely subject to individual and communal efforts. There is also no defined drainage hierarchy and connectivity in the area, while solid waste is often dumped in existing drainage. These result in residents experiencing perennial flooding. The paper also found that residents in the area had at one time or the other been involved in drainage related social conflict. On the positive side, most of the respondents were owner occupiers who are ready to contribute and make sacrifices towards drainage development. The paper concludes by suggesting strategies for sustainable drainage development in unplanned neighbourhoods which includes a coordinated collaboration of actors in drainage development.

Keywords: development, Palladan, socio-environmental, urban drainage, unplanned

INTRODUCTION

Informal urbanism is the major driver of city development in African cities. As asserted by Nwaka (2005) "only about 20 – 40% of physical development in Nigerian cities is carried out with formal government approval. The density of development in most unplanned neighborhoods leaves little or no space for the provision of services. In such a scenario where most urban settlements do not have defined or formal layouts, urban drainage development can become quite a challenge. Formal intervention in such informal neighborhoods is usually like 'a drop in the bucket'. As noted by Hall and Pfeiffer (2013) residents of informal neighborhoods usually create local organizations to manage their local environment and urban needs.

The social environment according to Barnett and Casper (2001) refers to the immediate physical and social setting in which people live or in which something happens or develops. In a recent study of informal settlements, Armitage (2011) emphasized the need to cater for greywater (domestic wastewater) in addition to stormwater in high density urban areas. Armitage was of the opinion that high density, unplanned urban areas should be given more serious consideration in the area of adequate drainage provision via pertinent strategies. Jiusto and Kenney (2015) corroborate Armitage's position in their study of a series of small projects in South Africa. Very few studies have focused on urban drainage development particularly in the area of informal urbanism. In the case of Jiusto and Kenney, and Armitage, their studies were based on the South African context where state policy has increasingly

Oladimeji, J. S.; Meshubi, A. O. & Ikpe, E. (2016). Socio-Environmental Dimensions of Urban Drainage Development in Unplanned Neighbourhoods. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1440-1448

embraced upgrading since the advent of full democracy in 1994, though its successful realization on the ground remains challenging. (Graham, 2007). There is therefore a need to examine the socio-environmental dimensions of urban drainage development in other climes such as a Northern Nigerian unplanned neighborhood context.

Informal Urbanism

Informal urbanism is development occurring outside the purview of state planning or administrative systems (Prescott, Vollmer and Heisel, 2013). It should be noted that the development being referred to could relate to the informal economy, and informal housing or built environment. A characteristic of industrializing cities is the presence of both formal and informal settlements. Formal settlements are planned areas with established zoning, infrastructure and municipal services supplied by governments. Informal settlements are areas where residents often lack official property rights (Huchzermeyer and Karam 2006). Werthmann (2014) states that "Informal urbanism ranges from poor rural migrants who build their homes in an emerging community through gradual processes of informal land occupation and consolidation to the developer who subdivides land without complying with all regulations. The informal cannot be simply equated to illegal, since the informal may be the only possible way of urbanization in cities where no other options exist; the informal cannot be equated to inferior or marginal, since there are many examples where informally developed communities become better place to live than dysfunctional public housing projects and housing estates produced by commercial developers. Also, the informal cannot be equated to poor, since increasingly middle class families (even millionaires) find their housing and place to live in non-formal neighborhoods. In fact, as asserted by Hall and Pfeiffer (2013) informal neighborhoods through local self-management and local taxes spent according to local political decisions, spread rapidly through emulation. These areas progressively become middle-class suburbs. Informal urbanism is an urban phenomenon that defies clichés; its only common denominator is its origin." For this paper, informal settlement refers to the unplanned context of urban development, particularly prevalent in the cities of developing countries.

Urban Drainage

'Urban drainage,' is defined by Armitage (2011), as '[including] the removal of all unwanted water from urban areas. Such water includes wastewater – including sewerage and greywater – and stormwater.' As depicted in Table 1.

The responsibility for urban drainage development in most unplanned areas is usually characterized by sharp differences between residents, local authorities, politicians and civil society groups. These tensions are usually exacerbated by severe resource constraints. (Jiusto and Kenney, 2015)

Table 1: Sources and Types of Urban Drainage

Stormwater	Greywater	Sewage
Heavy precipitation	Dishwater	Flooded or clogged toilet blocks
Flooding from higher ground	Bathwater	Night soil
Water accumulation due to poor soil drainage	Laundry water	Private latrines

Source: Adopted from Jiusto and Kenney (2015)

Principles of urban drainage development

According to Tucci (2001), the experience in flood control of many countries has led to the development of some principles in urban drainage management. Although these principles may require some adaptation to the conditions of each country, the principles are listed below:

i. Flood control evaluation should be done in the whole basin and not only in specific flow sections.
ii. Urban drainage control scenarios should take into account future city developments.
iii. The impact caused by urban surface wash-off and others related to urban drainage water quality should be reduced.
iv. More emphasis should be given to non-structural measures for flood plain control such as flood zoning, insurance and real time flood forecasting.
v. Management of the control starts with the implementation of Urban Drainage Master Plan in the municipality.
vi. Public participation in the urban drainage management should be increased.
vii. The development of the urban drainage should be based on the cost recovery investments.

Challenges of urban drainage management in unplanned settlements

Urban drainage development and management in unplanned settlements particularly in cities of developing countries, is fraught with several challenges among which are:

i. Urban development in cities of developing countries occurs fast and unpredictably. Usually the tendency of this development is from downstream to upstream which increase the challenges.
ii. Suburban and risk areas (flood plains and hill side slope areas) are occupied by low income population of unplanned settlements without any infrastructure services.. Spontaneous housing development are on land prone to flooding e.g. Bangkok, Bombay, Guayaquil, Lagos, Monrovia, Port Moresby and Recife; hill sides prone to landslides e.g. Caracas, Guatemala City, La Paz, Rio de Janeiro and Salvador (WHO, 1988).
iii. Local Government and residents of unplanned settlements usually do not have sufficient funds to supply the basics of water, sanitation and drainage needs.
iv. Lack of appropriate garbage collection and disposal decreases the water quality and the capacity of the urban drainage network due to filling. Desbordes and Servat (1988) mentioned that in some African countries there is no urban drainage and when system drainage exists it is filled with garbage and sediments. Tokun (1983) also mentioned this type of problem in Nigeria where the drainage systems are used as garbage collector.
v. There is no prevention program for risk area occupation and when the flood occurs non-returnable funds are given to the local administration to cope with the problem, without any requirement of future prevention programs.
vi. Population, States and Local Governments administration do not have enough knowledge on how to deal with floods using the above principles.
vii. Lack of institutional organization in urban drainage at a local level such as: regulation, capacity building and administration. In Asian cities there is a lack of comprehensive project organization and clear allocation of responsibilities; adequate urban land-use planning and enforcement; capability to cover all phases and aspects of technical and non-structural planning (Ruiter, 1990).

Governance of urban drainage

As depicted in Table 2, Porse (2013) in his study of stormwater governance and future cities, states that, 'while cities with existing infrastructure (developed countries) seek to integrate "greener" approaches, cities lacking existing infrastructure (less developed countries) face stark challenges to expand system capacity and reliability'. These realities show that, while cities in the developed world are aligning with larger regional growth plans to promote smart and sustainable growth via Sustainable Urban Drainage Systems (SUDS), cities in less

developed countries are still befuddled with the task of understanding urban growth patterns and meeting infrastructure needs for industrialization.

Table 2: Urban stormwater management priorities in cities

Goal	Cities with Established Stormwater Management Systems	Cities Lacking Established Stormwater Management Systems
Municipal Management Capabilities	● Meet budgetary requirements ● Satisfy municipal codes ● Meet standards for reliability and performance ● Align with larger regional growth plans to promote smart and sustainable growth ● Engage residents in management programs	● Expand services to keep pace with rapid growth in planned and unplanned areas ● Reduce corruption ● Increase system reliability ● Leverage training and knowledge transfer from external sources to develop internal expertise ● Reduce illegal system draws by residents while also servicing the population ● Secure capital for infrastructure improvements ● More comprehensive planning for long-term growth and urban development
Environment	● Satisfy local, regional and national environmental standards ● Improve local water quality ● Facilitate healthy ecosystems for recreation and economic benefits ● Minimize effects of Combined Sewer Outflows	●Reduce environmental impacts at little cost ●Improve quality of urban runoff ●Expand infrastructure capacity to consider supply, treatment and runoff
Public Health	● Prevent transmission of disease and infections ● Meet public health standards	● Improve system capabilities to reduce disease transmission and ensure clean water supplies ● Promote evacuation during floods
Social	● Enable citizen action and engagement ● Facilitate adoption of Best Management Practices by landowners ● Contribute to regional goals within constraints of social attitudes	● Enable local citizens access to clean water and municipal services at affordable prices ● Understand urban growth patterns and to meet infrastructure needs for industrialization

Source: Adopted from Porse (2013)

Table 2 clearly points out the wide gap existing in drainage governance between cities in developed countries and those of less developed countries. To borrow from Jiousto and Kenney (2015), SUDS and other drainage techniques will simply not work in the context of informal urbanism which is characterized by unplanned settlements unless adapted carefully to their particular social, legal, and environmental realities. Also, without local community consultation, participation and buy-in, most drainage interventions will fail. Lastly, drainage strategies informed by experience and designed explicitly for unplanned settlements are needed to deal with the unique and variable circumstances within these communities, which are often distinctly different even from neighboring communities within the same city.

Aim and Research Questions

This paper examines urban neighborhood drainage development in the social and physical context of unplanned urban development in Palladan. Given the social environment and peculiarities of unplanned neighborhoods, and in the context of the study area, how is the neighborhood urban drainage provided and maintained; what are the challenges of drainage development in such areas? And which strategies are best in promoting urban drainage development in such areas?

METHODOLOGY OF THE STUDY

The Study Area

Palladan is an unplanned but fast growing neighborhood in Zaria urban area of Kaduna state, in northern Nigeria. This fast growth could be attributed to its proximity to two major institutions in Zaria. The first is the Nigerian College of Aviation Technology (NCAT) to the South-west of the area, while the Nigerian Institute of Transport Technology is to the North-west. To the South-east of the area lies Kabama, a planned residential layout adjoining the study area. Palladan is inhabited by a heterogeneous population from several parts of Nigeria, although the larger percentage of residents in the area are indigenes of Hausa/ Fulani origin. The study area is plagued with problems of very poor drainage provision and maintenance; lack of street gutters and culverts, refuse dumping in existing drains, among other urban service problems. The area is generally characterized by haphazard urban development and poor urban facilities and services provision.

Sources of Data, Sampling Techniques and Data Analysis

The study adopted a case study and field survey approach. Primary data were captured via personal observation, semi-structured questionnaires administered to households and also, interviews held with community leaders, officials of the Primary Health Department at the Sabongari Local Government, officials of the Kaduna State Urban Planning and Development Authority (KASUPDA), officials of the Kaduna State Public Works Agency (KAPWA), and officials of the Kaduna State Environmental Protection Agency (KEPA). Secondary data was acquired from Google satellite imagery of the area, web search on urban drainage development, and both published and unpublished literature on urban drainage, informal urbanism and other related works.

The study area has a population of 21,384 and a total of 2,673 households, estimated by assuming a household size of 8 persons per household, given the socio-cultural background of the area *(estimates from the Primary Health Department, Sabongari LGA).* The questionnaires were administered through systematic random sampling within three clusters (*The three wards; Palladan core, Anguwan Fulani, and Layin Zomo; figure 1*) selecting one out of every five households. Kabama Layout was not sampled in this paper because it is a planned layout and the paper does not intend to do a comparative analysis. 150 households were selected, representing 5.6% of the total number of households in the study area. 20 field assistants were utilized in the field surveys and data gathering. Simple descriptive statistics were used to analyze the data gathered and conclusions were subsequently drawn.

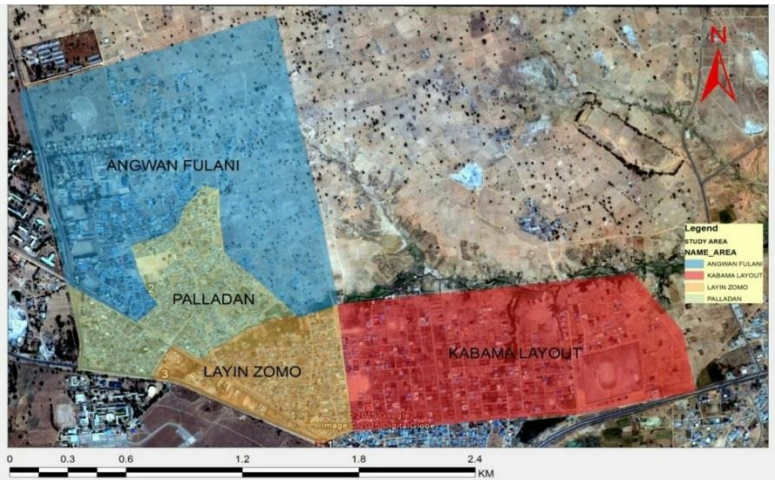

Figure 1: The Wards in Palladan Neighborhood

FINDINGS AND DISCUSSIONS

During the field survey, it was observed that the existing drainage situation in Palladan was grossly inadequate. The nature of housing development in the area leaves little or no space (setbacks) in-between buildings. Even in cases where spaces are left more often than not the spaces are used as passages/footpaths and for refuse/sewerage disposal. This scenario would make drainage provision more costly and difficult. 127 street links were identified during the survey. Out of these, only 61 (48.03%) street links had stormwater drainage provided. As Table 3 depicts, 60.7% of the 61 stormwater drains are improvised hand-dug drains, while 39.3% are lined drains. Also, the neighborhood drainage system is disjointed and not connected to the primary city-wide drainage system (Plate 1 and 2). In fact, even the Zaria Urban Area drainage system lining the primary and district road distributors, lack connectivity and continuity at several points. Moreover, 47 (77%) of the existing drainage in the study area have been converted to refuse disposal points, consequently blocking the drains, impeding stormwater flow and causing perennial flooding in the area during rainfall. It was also apparent from the field surveys and discussions with the community leaders that drainage provision and maintenance in Palladan is largely a community affair. Government intervention has been limited to drains along primary and district distributors. As shown on Table 4, available drains have been provided by either individuals, households, or youth organizations in the study area, usually supported by willing individuals and households.

Table 3: Types of storm water drainage identified in the study area

Types of Drainage	Number of Cases	(%)
Hand dug	37	60.7
Lined drainage	24	39.3
Line and covered drainage	Nil	Nil
Total	**61**	**100**

Table 4: Drainage providers in the study area

Drainage Provider	Number of Cases	(%)
Individuals&households	13	21.3
Local Government	6	9.8
CDAs(Youths)	42	68.9
Total	**61**	**100**

Plates 1 and 2: A stand-alone paved stormwater water drain along Kasuwan Mata street and a blocked drain in the study area

Socio-economic and cultural context of drainage development

From the surveys, 33% of the respondents were found to be indigenes of Hausa/Fulani origin. While the remaining 67% were non-indigenes. This accounts for the significant presence of traditional mud compounds in the area which has implications for drainage and sanitation due to the nature of such housing design and the large number of household members in such a

Hausa/Fulani setting. Most of the residents in the study area fall into the low-income category because out of the 150 households surveyed, 76% (114) earn below 50,000 Naira (about 250 US Dollars) monthly (see Table 5).

Table 5: Income of respondents

Level of Income(In Naira)	Number of Cases	(%)
Below 18,000	57	38
18,000-30,000	15	10
30,000-50,000	42	28
>50,000	36	24
Total	**150**	**100**

This could affect their ability to contribute to infrastructure upgrading in the area. Most of the residents are also literate and educated. 60% have attained unto secondary or tertiary level of education and only 20% are informally educated. This depicts a potential for higher awareness on the health implications of drainage development. The study also revealed that most residents (82%) were owner occupiers' while only 18% of the respondents were tenants, as depicted on Table 6.

Table 6: Tenure status of households

Housing Tenure Type	Number of Cases	(%)
Owner occupier	123	82
Renting	24	16
Leasing	3	2
Total	**150**	**100**

Drainage Induced Social Conflicts

In some cases, while a resident makes efforts to solve his drainage problem, it creates a problem for another neighbor. There was more cooperation in drainage development observed at Anguwan Fulani, towards the North, the area is less dense in development and harbours the more enlightened and middle class residents. The Palladan core and Layin Zomo has more dense development and more drainage conflicts. The field data reveals that out of the 72% who claim to have had drainage related conflicts with neighbors, only 8% came from Anguwan Fulani, while 64% were from the Palladan core and Layin Zomo. This shows that there are more drainage conflicts/challenges in the higher density parts of the study area. Table 7 shows the range of types of drainage related conflicts experienced by neighbors/residents in the study area. Neighbors not cooperating in drainage maintenance (30%) takes the highest number of cases.

Table 7: Reasons for drainage conflicts

Nature of Conflict	Number of Cases	%
Deliberate Blocking of drain passage	39	26
Dumping of refuse	24	16
No Maintenance	45	30
No response	42	28
total	150	100

Failure of Governance Institutions

The Sabongari Local Government Health Department is responsible for ensuring that the existing drains are kept clean by engaging in regular inspections, awareness creation on health implications of environmental situation, conflict resolution on drainage issues, fining of environmental offenders, among other responsibilities. However, the study revealed that the department rarely carried out their responsibilities. Respondents in the study area reported that officials from the local government office are only seen when a resident takes a report to them.

Plates 3 and 4: Hand-dug drains for Greywater in Palladan

The Kaduna Public Works Agency (KAPWA) informed the survey team that no drainage project has been carried out in the study area, and there are no future plans for such. Kaduna Environmental Protection Agency (KEPA) and the Kaduna State Urban Planning and Development Authority (KASUPDA) also confirmed that they were not involved in any form of drainage development initiative in the study area. Therefore most of the existing drains in the area are hand-dug by the residents (Plates 3 and 4).

Potentials for urban drainage development

All respondents (100%) consider drainage development to be important mostly because of health reasons. Although 16% of the respondents were not willing to contribute to drainage development in the area, 84% were willing to contribute financially and through manual labour. Also, studies have shown that secure tenure promotes willingness to contribute to infrastructure development in informal settlements (Choguill and Choguill, 1996). This probably explains the large number of those willing to contribute to drainage improvements. Since 82% of the respondents are owner occupiers in the study area, as earlier shown on Table 6.

CONCLUSIONS AND RECOMMENDATIONS

The study findings in Palladan corroborate the assertions of Jiusto and Kenney (2015), highlighting the reality that governments in developing countries mostly avoid interventions in drainage development in unplanned neighbourhoods. In the Palladan example, it is clear that Government intervention in urban drainage development, when found, largely focuses on city primary drains. This is unlike South Africa where state policy clearly embraces upgrading of informal settlements. It is also clear from the Palladan context that drainage development in Nigerian cities take on a very myopic approach that is still far from the regional SUDS perspective as rightly observed by Porse (2013). This assertion is arrived at because of the disjointed and unconnected existing drainage system observed in the study area. Considering the high incidence of indiscriminate solid waste disposal into open drains in the study area, it is also obvious that until an integrated approach to solid waste and sewerage management is adopted in unplanned neighborhoods drainage development will continue to pose a great challenge. Given the efforts already being made by residents in the study area, more progress can be made in drainage improvement if government institutions can be more committed and offer technical support to communities that are already involved in drainage development.

There is also need for proper public enlightenment and participation in urban drainage management in our cities. This is important, in order to educate people on their roles in achieving sustainable urban drainage systems for city regions.

The study has shown that social and environmental factors shape urban drainage development particularly in unplanned neighborhoods like Palladan. It is clear that the development pattern and social environment will inform the kind of strategies that can be employed in drainage development for specific unplanned neighborhoods. The Millenium Development Goals (MDGs) had a target of improving the lives of 100 million slum dwellers by the year 2020. The task is an arduous one. However, when the political will and right strategies are adopted, incremental upgrading efforts can be made in selected informal settlements to make a difference over time. Governments in cities of developing nations should not view urban drainage development just at the micro-neighborhood level but rather at the macro-regional level where Integrated Urban Water Management (IUWM) and Sustainable Urban Drainage (SUD) considerations are made.

ABSTRACT

In most developing countries today, the provision of housing is grossly inadequate, coupled with the fact that the available housing falls below the standard of appropriate habitable models. This is so despite decades of direct government intervention in the housing sector. It is estimated that more than 50 percent of the urban population in the developing countries lives at the level of extreme poverty. The adoption by the United Nations General Assembly of the Global Strategy for Shelter to the Year 2000 (GSS) in 1988 implied a global recognition of the severity of the housing problem in the developing and underdeveloped countries. There is the need to address these gross inadequacies in terms of quantity and quality of housing provided. According to the Nigeria population census figures of 2006, Nigeria has over 140 million people (currently estimated to be 173.6 million in 2015); placing it as the most populous country in Africa. Many of this population are found living in the major urban centres, with over 70 per cent classified as living under poor and inadequate condition of housing. The paper, using case study approach, explores the issues surrounding the provision of adequate housing in a millennium city of Akure, Nigeria. It made use of data and information collected from both primary and secondary sources. Data were collected through physical investigation of poor inner- city neighbourhoods of the study area; stating some of the findings as framework for the design of future developmental policy. In conclusion, the paper argues for a rethink of policies and increase in investment in the built environment to positively alleviate the adverse housing condition.

Keywords: housing need, human development index (HDI), inner-city neighbourhood, slum, urban poverty

INTRODUCTION

Considering the world population of six billion people, 1.1 billion people fall below the poverty line (Ravallion, 2013; Alkire, Conconi, Robles and Seth, 2015). Half of the people in Sub-Saharan Africa in which Nigeria is one, fall below this poverty line while one third of India are considered poor by this definition (Alkire and Santos, 2014). Poverty is a multidimensional phenomenon; hence it cannot be reduced to a single definition. However, to be able to have a full grasp of the distribution and depth of poverty, it is generally acceptable to evaluate real per capital expenditure on an indicator of welfare (Atkinson, 1999). Hence the need to draw a line that will help to define the cost of living standard below which a person is classified as being poor. Income can be used to draw an absolute poverty line or a negative poverty line can be drawn based on percentages of household at the bottom of the income distribution (Atkinson, Piketty and Saez, 2011). The poor are the most vulnerable of the masses and they often lives in deplorable condition, such as inhabiting ramshackle houses that has no door with leaking roofs (Stokols, Rall and Schopler, 1973). There are categories of poor people that include the not so rich, the moderately poor, the poor and the poorest of the poor. Parental death often thrown children into unwarranted poverty in Africa, hence the orphaned, the internally displaced (due to war, such as in Rwanda genocidal war and Boko Haram terrorist attacks in Northern Nigeria) and abandoned children form special group of the 'vulnerable' amongst the poor.

LITERATURE REVIEW

Factors Contributing to Poverty in the Built Environment

There are three distinct components to the measurement of poverty. First, we have to specify what is meant by 'standard of living'. Second, we have to delineate a critical level of the standard of living below which there is poverty. Third, need to compress information in the standard of living below the critical level into an index of poverty (see figure 1). It has been noticed that what contributed to the underdevelopment of the poor nations is the stagnation of their agricultural output, which has failed to keep up with their population growth rates (Kanbar, 1991; Odeyale, Sodagar, Temple and O'Coill, 2011; United Nations, 2014). The standard of living has increased slowly in poor countries of the world. The gap between the rich and the poor nations due to the gap created as a result of free trade and protection exercised by the developed economic/countries. Factors that contributed to acute poverty in Sub-Sahara Africa, and Nigeria inclusive are identified as follows:

i. Population increases due to lack of birth control, rural urban migration resulting into acute food shortages, high prices of food and services, inflation, poor housing and living condition and high rate of unemployment.
ii. Economic recession with very low price for exports raw material high indebtedness, debt servicing, reduced capital inflow, and imbalance of trade.
iii. Structural adjustment programme introduced by IMF to Nigeria during Babangida era, resulting in reduced government expenditure and high prices of food increasing the poverty of masses.
iv. Political instability and insincerity brought corruption and financial downturn affecting housing and the built environment.

Although Nigeria as a country is blessed with natural resources, it still remains a poor developing country. Gilbert and Gulger (1994) suggested that human development in part of the comprehensive process of societal change. This encompasses the economic, social, moral, physical and financial aspects of the society. Pertinent question to consider is the link between housing condition and poverty and its consequences.

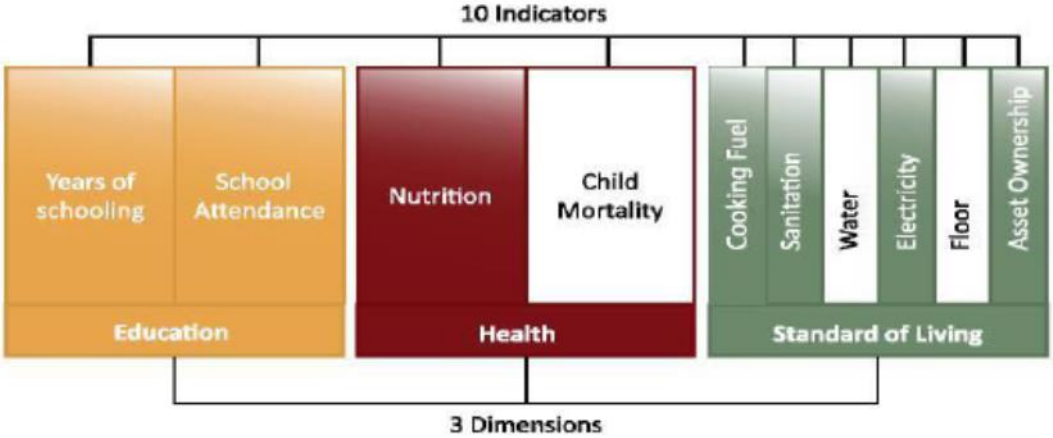

Figure 1: Multidimensional Poverty Index (MPI). Source: OPHI, 2015

There is the need to look at other economic platform in other part of the world, in order to draw out vital lesson for the alleviation of poverty and human development of Africa's most populous country Nigeria. The World Bank criterion for classifying economies is Gross National Product (GNP) per capita. Every economy is classified as low income, middle income (with lower middle and upper middle) and high income. Low-income economics are those with a GNP per capita of $635 or less in 1991. Middle- income economics are those with a GNP per capita of more than $635 but less than $7,911. Lower middle income has

income per capita between $2,555. High-income economics are those with a GNP per capita of $7,911 or more.

Poverty Indicators

These are pointers to the level of poorness of an individual or group of people, such as nutritional, social welfare, economic factors. Examples of such indicators are:

Nutritional Indicators:

This is a measure of both health and wealth. These represent the result of insufficient food intake and/or inadequate access to basic health care. The results of insufficient food intake are stunted growth or severe growth in children below the age of 6, considering the height to age measurement (Roche, 2013; UN-HABITAT, 2003b).

Social Indicators:

As earlier stated, one parameter is not enough to adequately define poverty. Apart from per capital income per month, another strong indicator of poverty is the measure of the effective uses of social services such as (immunization, school attendance, nutrition and access to water) the accessibility and quality of such services e.g. maternal or child mortality rate (Kapoor, 1993; Alkire and Foster. 2011; Cribb, Robert and Phillips 2012).

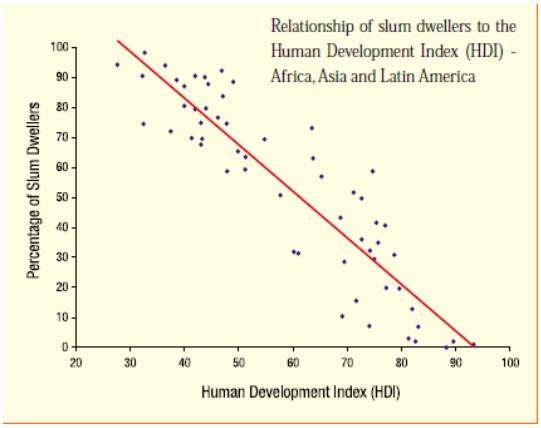

Figure 2: Correlation between Percentage of Slum Dwellers and Human Development Index (HDI). Source: UN-HABITAT (2003a).

Economic Indicators

These refer to the purchasing power of an individual or group of people in a given area. How much do they earn? How much is their expenditure, do they spend a larger amount on food? How much do they spend on education? For instance, considering the example of Uganda, the average of the total population spent an average of 1percent on education and 67 percent in food which is quite high little or within is lest for saving (UNDP, 2014).

Building Traditions, Development of Slum and Housing Problems in Nigeria

Housing itself is influenced by various factors that include social structure, climate, economic growth, technology and culture. The sociocultural heritage and tradition of a people can be observed through the evolutions of its housing forms, pattern and types. Hence, the pattern expressed by the buildings in a community is a pointer to it search for cultural identity and self actualization (Odeyale, 2010). The troubles facing the housing sector in Nigeria are enormous and complex. In Nigerian urban centres, the problem is not only restricted to quantity but also to the quality of available housing units and environment. Severe overcrowding and insanitary physical environment characterize the housing in these urban centres (Olotuah, 2000; 2002); culminating effect of this is the growth of slum areas. The result is clearly revealed in several poverty indices such as growing overcrowding in homes, neighbourhoods and communities; lack of adequate infrastructural facilities and rapidly

deteriorating environment resulting to slum like conditions. For instance, figure 2 provide a window into the relationship between the slum dwellers and human development index.

According to Turnstall et al (2013:5), evidence shows that "poverty affects housing circumstances is stronger than evidence that housing circumstances affect poverty", such evidence is seen in the formation of slum. Slum condition in housing exists when a house or a neighborhood is in poor condition which is generally considered unsafe and not nice to live or be in (Costello, 1987). UN-HABITAT (2009:106) defines slum as "any specific place, whether a whole city or a neighbourhood, as a slum area if half or more of all households lack improved water, improved sanitation, sufficient living area, durable housing, secure tenure, or combinations thereof." It is also an overcrowded area of a city in which the housing is typically in very bad condition (Davis, 2004; see also figure 3 below).

It is often quoted that the economies and societies of the poor countries had been "conditioned" by their relationship with colonial and neo-colonial powers (Deininger and Lyn, 1996; Dollar and Aart, 2002). One aspect of shelter that constitutes serious problem in housing delivery is its affordability to the low income class that forms a large percentage of many nations particularly a developing nation like Nigeria. The factor contributing to housing choice has been attributed to lower incomes, less wealth or less access to credit (typically due to worse employment positions). This led to less desirable or poorer housing conditions than others, including homelessness; and leaving in slum like conditions. The attendant high value of landed property and increasing labour cost in construction, the housing is beyond the reach of the majority of people, hence the springing up of slums and rickety building.

The problem of housing in Nigeria is not significantly different from those of the other developing nations of the world. Research findings have confirmed that there is a drastic housing shortage in Nigeria. Due to upsurge in urban population, the process of urbanization, diversified economic activities, poor management of activities within the framework of the National Development Programme and the heterogeneous nature of the society in urban centres, very many Nigerians cannot find an ideal environment or house (Izomoh, 1997; Odeyale, 2015). Onibokun (1990), estimated acute shortage in housing sector providing the following figures as summarized in Table 1.0.

Table 1.0 Estimated Housing Need between the periods of 1990 - 2020

Income Group	1990	2000	2020
Low-income	8,413,980	14,372,293	39,989,286
Medium-income	7,770,005	13,273,291	33,,573,900
High-income	7,624,230	12,419068	28,548,633

Source: Onibokun, 1990

Poverty and sub-standard housing are closely related (Onibokun, 1985), extreme housing densities coupled with pitiable environmental conditions in which the poor majority lives are characterized by acute sanitary problems and pollution of air, surface water, and solid waste; all pitiable significant conditions of slums (Mabogunje et al, 1978; Filani 1987; Wahab et al 1990). Olusanya (2001) attest to the fact that urban housing problems in Nigeria over the years have acquired an overwhelming proportion that threatens to undermine the very basic fabric of the urban society, underscoring the need for a rethink of policies.

METHODOLOGY

The study made use of data and information collected from both primary and secondary sources. Primary data were collected through physical investigation of poor inner- city neighbourhoods in core area of Akure, Nigeria. The methodology is driven by qualitative approach involving ethnographic field investigation, (with focus on core area of Akure,

namely Erekesan-Erekefa, Idiagba-Ijemikin, and Obanla) and comparing findings with archival documents. Other secondary data includes relevant information from related studies in literature.

DISCUSSIONS AND FINDINGS: STRATEGIES FOR POVERTY ALLEVIATION IN THE HOUSING SECTOR

The World Development Report of 1990 stated that the countries that have been most successful in attacking poverty have encouraged a pattern of growth that makes efficient use of labour and have invested in the human capital manpower especially the built environment. First, those countries gives the poor the opportunity to use their most abundant asset – labour. The second step is to improve their immediate well-being and increases their capacity to take advantages of newly created possibilities (Kapoor 1993; Roche, 2013). If the Nigerian government is to make headway in poverty alleviation, it will have to make policies that will deliver key services to the poor. This will include investing in human capital and ensuring that the poor are able to participate equitably in that growth and make policies that will accelerate economic growth. These must be implemented efficiently, vis-a-vis:

Figure 3: Inner city configuration and ugly face of poverty in housing as exhibited in core-city neighbourhoods of Akure, Nigeria. Source: Author's Fieldwork (2014).

Accelerating Economic Growth and Macroeconomic Stability

The economy of the country in which urbanisation is taking place has been described as stagnant and the growth of industrialization is negligible (Salau, 1992); hence, the need for growth-oriented economic recovery and poverty alleviation. In order to ensure accelerated growth, a concerted effort by the government and private sector is required. This will empower the poor by giving them room to participate and share in the economic growth. This will also be accomplished by the reduction in the income inequality, increase in the standard of living and generation/operation of policies that will enhance labour intensive method of production for the large masses/urban poor by tapping into the rich building tradition. This gives people the opportunity to make long-term investment in any economy.

Non-Governmental Participation (NGO) in Poverty Alleviation

NGO have large experience in poverty alleviation through community self-help projects. There is need for proper coordination between the government and the NG0's for effective poverty eradication and inner city redevelopments to correct city anomalies such as seen in figure 3.

Facilitating High rate of Investment in Infrastructural Development

The need for increase in investment and developing indigenous technology is also observed in the study area. Adequate resource and platform for development of the built environment is a veritable deterrent to poverty, especially in the inner-city. Investment should be encouraged not only for foreign expatriate but local investments in forms of factories and small scale industries should be given room to take root in Nigerian and African economy.

Emphasis on Technological development and technical education

Need to master modern technological system, used in the developed nation of the world. There is every reason, for a "huge" technology transfer from the developed nations to the developing ones. This should be given a priority. Rapid growth in the housing sector demand more technical training.

Adequate Role of Information System

The policy makers need to be well informed on the happenings at the grassroots. Development is both bottom up and top-down. Policy makers need to know the need of the people and what impact their policies is having on the masses.

Stemming inflation rates

Government should get firm control over its budgetary spending. The transformation of the agricultural sector is at the heart of feeding the country, to supply food to the market, to produce raw materials and to act as catalyst for small scale industrial growth. The development of indigenous building materials and methods, this will lead to a decrease in the cases of capital flight through foreign exchange.

RECOMMENDATIONS

There are important steps and ways to develop the housing sector and offer required setting for the urban dwellers. Such steps include: the government should de-emphasis the reliance on oil economy through economic reforms in Nigeria, a step the current government is assiduously working on. Encourage technology transfer and training of manpower in modern science and technology. Establish policies and framework to cause the incomes and living conditions of the rural/urban to improve. Empower the masses and to break the shackle and circle of poverty. Eradication of illiteracy and improvement in high rates of literacy and numeracy, those are vital for rapid economic growth. Local investment should be encouraged and small scale industry favoured in policies formulation. Solution to the problem of incessant power outage and development of sustainable or alternative energy sources for the production of industrial scale building materials. The government in Nigeria, both at federal and state level should set up agencies and organs that will oversee wealth creation and job creation. The need to provide basic modern infrastructures in metropolitan centres across the country and natural economic empowerment development strategies should be encourage. The Nigerian government also need to popularise local entrepreneurships among the youth, in order to increase the economic base for wealth creation and sustainable lifestyle. Partnering with international donor agencies and Non-Governmental Organisations (NGO) in the development of rural and urban area in the country will decrease urban-rural migration. This will reduce the pressure on urban infrastructure and mitigate poverty.

CONCLUSION

There is need to strengthen the database and develop a poverty monitoring system which can provide policy makers with regular information in the impact of economic and social policies in the lives of the urban poor. Making land available to the working class and the poor for housing development and encouragement should be given to macroeconomic growth and stability that will revitalize the provision of adequate housing for all.

Infrastructure Management in Peri-Urban Communities of Developing Nations: A Focus on Akure, Nigeria

Olamiju, O. I. [1*] ***& Fasakin, J. O.*** [2]

[1&2] *Department of Urban and Regional Planning, Federal University of Technology Akure, Nigeria*
[*] *olamijuio2013@yahoo.com*

ABSTRACT

Peri-urban communities in developing nations are characterized by non-functioning infrastructure, uncontrolled physical growth, poor building and environmental conditions. As a result of increase in the rate of urbanization especially in cities of developing nations, government must continue to provide infrastructure for more people and in new areas. This paper therefore examines: the management of infrastructure; building and environmental situations in 11 peri-urban communities in Akure, Nigeria. Data were sourced primarily using the questionnaire instrument. The study utilized simple random sampling technique to select 30% of 3,207 dwellings in the communities giving a total sample size of 962. Empirical analysis from fieldwork reveals that, individuals, families and Development Associations (DAs) are substantially involved in the provision and management of infrastructure with limited government coordination. Building and environmental conditions in the communities are very unsatisfactory. A management-cum-institutional framework for effective coordination of activities of all stakeholders is suggested for sustainable peri-urban development in the city.

Keywords: Akure, Developing Nation, Infrastructure, Nigeria, Peri-urbanization

INTRODUCTION

Synonyms of peri-urban areas include: urban fringe, metropolitan fringe, rural-urban fringe, urban-rural interface, the near urban, urban tract, peri-metropolitan, ex-urban, urban hinterland, semi-urban and even sub-urban (Buxton et al, 2006). Peri-urbanization originates from the French word *périurbanization*; used to describe spaces between the city and the countryside, that are shaped by the urbanization of former rural areas in the urban fringe both in a qualitative (e.g. diffusion of urban style) and in a quantitative (e.g. new residential zones) senses (W.J, 2015). Griffiths (2010) defined peri-urban as the rural-urban transition zone where urban and rural uses mix and often clash. In developing countries, peri-urban areas can be broadly characterized as a mosaic of heterogeneous land uses and people but with lack of infrastructure and a deteriorating environment (Olujimi and Gbadamosi, 2007). Most peri-urban areas are sprawled and dispersed development outside of compact urban areas along the periphery of cities, along highways, and along arterial roads connecting a city, due to ad hoc approaches in planning and decision making (Sudhira et al, 2007). Urbanization trend in developing nations has been responsible for influx of population to peri urban zones with its consequent stress on existing infrastructure. This problem is compounded by the actions of individuals, traditional family landowners and landlords associations who are members of Development Associations. These individuals and groups of people are responsible for the management of infrastructure in their various communities.

The management of infrastructure in peri-urban communities of Akure is undertaken without any consideration for collective decision making from the larger community. In the study area, there is a lack of operational coordination among the various individuals, families and Development Associations (DAs). Government involvement in infrastructure provision and management is minimal and in some instances absent. UN Habitat (2003) reported that this trend is detrimental to the larger community by creating environmental degradation, urban sprawl, slum, and diverse natural disasters; and these account for lack of electricity by 50%

Olamiju, O. I. & Fasakin, J. O. (2016). Infrastructure Management in Peri-Urban Communities of Developing Nations: A Focus on Akure, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1457-1468

of residents in Africa while about 30% of the houses are not accessible due to poor street layout.

It is now obvious that provision of infrastructure need a coordinated system of supply and management; through the cooperative efforts of all stakeholders in order to ensure a balanced city form and image. Oyesiku (2002) observes that, in physical planning, a rational decision about the use of land is necessary so as to ensure that, services are available, accessible, convenient and efficient. The paper, therefore, examines the role of individuals and families in the provision and management of infrastructural facilities such as roads, drainages and electricity in peri-urban communities of Akure and its resultant effects on both the building and immediate environment.

A SUMMARY OF EXISTING LITERATURE

The provision and management of infrastructure in Nigeria are largely in the hands of the public sector (Adewusi and Akinbogun, 2010). Soyido (1998) reported that the reduction of infrastructure investments over the years coupled with the other factors endemic to the Nigerian public institutions, such as, wastages, mismanagement, fraud, lack of maintenance policies and inept leadership have led to the collapse of most infrastructure in Nigeria urban areas.

Mabogunje (1999) observes that, Nigerian cities are dirty, most insanitary, minimally aesthetically pleasing, least safe and secure and most poorly managed in the world. Adewusi and Akinbogun (2010) concluded that the state of infrastructural facilities in Nigeria is dismal: roads are in very advanced state of disrepair and the maintenance of drainages is completely neglected resulting in poor economic development, frequent accidents, environmental hazards, discouragement of investors and decline in quality of life among the citizenry. FRN (1992) reports that infrastructure in most Nigerian cities are grossly inadequate, erratic and unreliable.

The Asian Development Bank (1997), notes that, peri-urban areas in large and medium cities in Latin America, Asia and Africa are likely to experience huge population growth in the coming years. The effect of this growth is stress on already inadequate infrastructure and aggravated poverty of the population. In Latin America, cities of Mexico and Sao Paulo are losing population in their most important central areas, while distant suburbs (*Peri-urban areas*) experience strong demographic increases (Salas, 1994; Torres, 2002). Haroldo (2008) observes that peri-urban areas in Latin America are not only typically ill-regulated and distant from key employment hubs, but also present appalling sanitation conditions and significant environmental problems, including deforestation and pollution of rivers and streams. The author concluded that in order to tackle peri-urban issues, the quality of government information systems and their data on low income settlements must substantially increase.

In Ghana, the supply of water in the peri-urban zones of Accra is hampered by narrow diameter of pipelines which could not carry the amount of water demanded (Yankson and Gough, 1999). Owusu and Asamoah (2005) concluded that most peri-urban areas of Kumasi do not have basic infrastructure to support sustainable living; this has been attributed to: lack of infrastructure policy and poor funding of infrastructure by SHGs among others.

In Kenya, community-run small-scale water systems play a critical role in supplying and improving access to water services in peri-urban and rural areas. This is largely because municipally-owned water services providers currently supply only 25 per cent of the country's population and 39 per cent of the population within their service areas (World Bank, 2011).

Meera, Purushotthaman & Brook, (2003) concluded that most Indian cities experience infrastructure provision in the form of widened highways in the city core; while the infrastructure problems of peri-urban communities around the cities are not being addressed. For instance most un-tarred roads become blocked during the rains as well as the clogged up sewers, which are not being attended to by any government agency.

In Akure, the focus of government in infrastructure development is on the city core at the expense of the peri-urban areas. Individuals, families and development associations are left uncoordinated by appropriate government agencies to provide infrastructure for roads, drainages, water and electricity. This trend has been responsible for poor street layout, drainage system and associated flooding hazards (Olamiju, 2014).

In summary, the trend in peri-urban communities in Latin America, Africa and Asia is similar: infrastructure problem is very rife; government neglect of infrastructure development is acute; problem of long commuting distance due to poor land use planning are prevalent and; stress on available infrastructure owing to rapid urbanization is ubiquitous.

DATA AND METHODS

Research Locale

Akure is the local government headquarter of Akure South Local Government Area (ASLGA) and the capital city of Ondo state of Nigeria. It is the major town in ASLGA which, situates 204 kilometres east of Ibadan, capital of Oyo state; 186 kilometres west of Benin, capital of Edo state and; 311 kilometres north-east of Lagos (see figure 1).

Since the creation of Ondo state in February 1976, the population of Akure has been growing at an alarming rate. Akure had a population of 38,852 in 1952 which increased to 71,106 in 1963 giving rise to a growth rate of 5.5% per annum (Olanrewaju, 2004). According to the 1991 census count, the population of Akure was 239,124 which was projected by the National Census Board to 269,207 in 1996. The current estimated population of Akure at the annual growth rate of 3.18 is 413,060 (NPC, 2006).

Basically, Akure has an agrarian economy with prevalent low productivity. DPA (1980) observes that, the major industrial activities in Akure are saw-milling and furniture making. Due to its weak economic base, there is high unemployment, low per capita income and poor standard of living, all affecting negatively, the ability of the populace to support urban utilities, municipal services and community facilities.

The land use pattern in Akure is a replica of most traditional *Yoruba* cities which have the Oba's palace, the city market, and the traditional place of worship at the centre of the town. The share of population living in Akure urban areas increased from 20.2 per cent in 1971 to 23.7 per cent in 1981 and to 26.1 per cent in 1991 (Okoko, 2004). Population growth, rise in household income, subsidization of infrastructure investments like roads, ineffective land-use, excessive growth, social problems in central cities and poor land policies are taken to be the main causes of sprawl in Akure (Tofowomo, 2008).

This study looks at private residential layouts in Akure located at the peri-urban zones - a transitional environment of mixed land uses between the city's continuously built up area and its rural hinterland where economic and social activities are directly affected by the expansion of the city (Nwafunpe, 1994). Akure has expanded beyond its original extent in 1980 when a Master Plan was prepared (Figure 1). Figure 2 is the street guide map of Akure showing the peri-urban zones (the direction of the city's expansion) as identified for the purpose of this study. The zones contain residential layouts from which samples of houses were taken.

Peri-urban zones are usually characterized by infrastructure under severe stress as a result of rapid growth in population, inadequate supply of housing units, and improper coordination of physical development (Olujimi and Gbadamosi, 2007). In addition, DPA (1980) reveals that, the existing layouts in Akure were developed contrary to planning regulations, lacking essential facilities such as schools, clinics, play areas, markets, library, places of worship, police post and postal agencies among others. This situation explains the planlessness of land use in Akure and the prevalence of private administration of modern day residential layouts.

Data Base Description

Data was collected through the instrumentality of a structured questionnaire. The simple random sampling technique was used to select 30 percent of houses from 11 peri-urban communities due to homogeneity characterizing the study area (See Table 1)

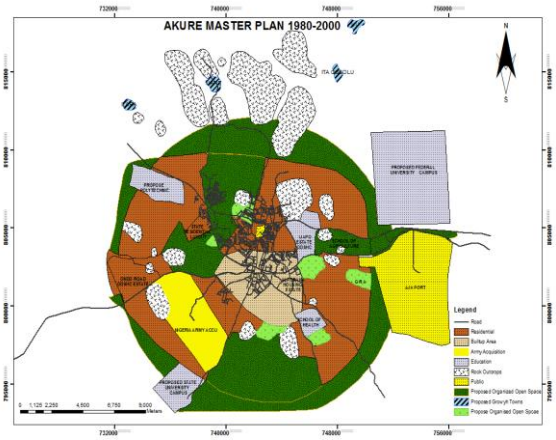

Figure 1: Akure Master Plan (1980-2000)
Source: DPA, 1980 (digitized in AutoCAD by the authors)

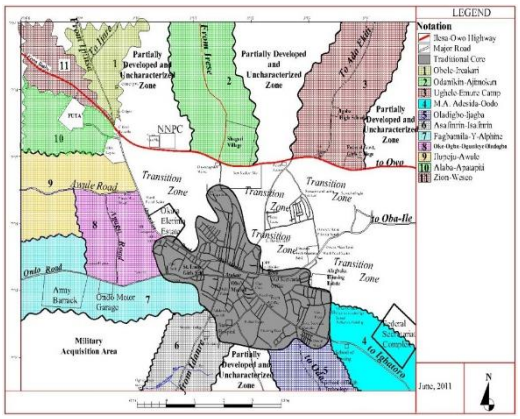

Figure 2: Peri-urban Zones in Akure, Nigeria

Table 1: Sampling in Peri-Urban Zones of Akure

Peri-Urban Zones	Population, (NPC, 2006)	Total Number of Buildings	30 Percent of Buildings
Obele-Ireakari	1,642	59	18
Odanikin-Ajimokun	15,400	550	165
Ughele-Emure Camp	4,835	173	52
Adesida-Oodo	5,052	180	54
Oladigbo-Jigba	1,125	40	12
Asafinrin-Isafinrin	1,958	70	21
OkeOgba-Ogunleye	7,951	286	85
Familugba-Yeosta	24,360	870	261
Ilupeju-Ifelere	2,143	77	23
Alaba-Apatapiti	21,840	780	234
Zion-Wesco	3,480	124	37
Grand Total	**89,810**	**3,207**	**962**

A smaller sample of 5 percent was considered valid and reliable by Ojo (2005), while a 7 percent sample was used by Fasakin (2000) to obtain acceptable results in the study of commercial motorcycles in the transport system in Akure. Houses and people were selected in the sample corridors at regular intervals during the field survey. Table 1 shows sampling in peri-urban zones in Akure. Out of the total number of 962 questionnaires administered, 959 of them were retrieved in useable form giving a 99.97% response rate.

DISCUSSION OF RESULTS

Provision of Infrastructure and Basic Services in Peri-urban Communities of Akure

From Table 2, it is obvious that, 43.6% of respondents believed that, individual landlords were responsible for the provision of infrastructural facilities, while 26.8% admitted that, the families who own residential layouts in the communities were responsible. Twenty-five percent (25%) of respondents said that Development Associations (DAs) were accountable, while only 4.1% held that, it is the government that provides infrastructure in the communities.

Table 2: Sources of Provision of Infrastructural Facilities in Peri-urban Communities of Akure, Nigeria

Source	Frequency	Percent
Individuals	418	43.6
Family Members	257	26.8
Development Associations	240	25.0
Government	39	4.1
Total	**959**	**100.0**

It is apparent that, the involvement of individual landlords and families as well as youths', tenants', and landlords' associations is substantial. An immediate implication of this is a resort to self-help provision of infrastructure that is not coordinated by planning agencies. Interactions with the Development Control Department (DCD) in Akure, confirmed the prevalence of individuals in the provision of infrastructural facilities in the layouts over other sources. In contemporary Nigeria, poverty, corruption in government, lack of environmental consciousness and adequate technology are potent factors responsible for inadequate provision and management of infrastructural facilities in peri-urban communities. Ipso facto, a huge proportion of individuals and families providing infrastructure has led to residential disorderliness in the city. These individuals lack the required environmental education to guide their development efforts. While government at the local or state level provides infrastructure, corruption and lack of requisite technology could also contribute to substandard facility provision. With a master plan prepared in 1980 which lapsed in 2000, Akure lacks good frameworks and policies to guide infrastructure development. The city keeps on expanding haphazardly at the mercy of unprofessional and uncoordinated developers, with un-tarred roads, substandard electricity, haphazard water supply and poor drainage. Efforts of DAs compliment those of individuals in the provision of infrastructural facilities. At present, there exists no coordinating agency for the supervision of the providers of infrastructure in Akure. Adeniyi (2011) concluded that the absence of land use information to guide rational urban development, has led to adoption of personal discretion in city development.

A meager 4.1% of respondents attributed the provision of infrastructural facilities to governments. Some government parastatals such as Power Holding Company of Nigeria (PHCN), Water Corporation and Local Government Councils occasionally visit residents to collect rates on facilities put in place by citizens. This may have accounted for the few who felt that government has anything to do with facility provision and management in the city.

Management of Infrastructural Facilities in Peri-urban Areas of Akure

Table 3 shows the structure of management of infrastructural facilities in peri-urban areas of Akure where 41.3% of respondents stated that individual property owners in the communities are responsible for the management of roads. About 6.1% said family land owners are answerable, while 37.3% and 15.3% attributed facility management to DAs and government respectively. Cumulatively, over 75% of respondents held that individuals, families and DAs are mostly responsible for the management of roads in the communities.

Construction and management of roads are capital intensive. It is however implausible that the onus of road maintenance should shift to individuals and families. The net result is rapid deterioration and even disappearance of poorly constructed roads in residential neighbourhoods in the communities.

As for drainages, water supply and electricity, over 43.9%, 48.8% and 36.7% of individuals in the communities are responsible for facility management respectively. The proportions of respondents stating that families are responsible for the management of these facilities are 6.4%, 10.7%, and 5.4% respectively; while 39.2%, 11.3% and 36.3% attributed management to DAs.

Table 3: Management of Infrastructural Facilities in Peri-urban Areas of Akure

Infrastructure	Managers/Providers								Total	
	Individuals		Families		Development Associations (DAs)		Government			
	Freq.	%	Freq.	%	Freq.	%	Freq.	%	Freq.	%
Road	396	41.3	58	6.1	358	37.3	147	15.3	959	100
Drainage	421	43.9	61	6.4	376	39.2	101	10.5	959	100
Water Supply	468	48.8	103	10.7	108	11.3	280	29.2	959	100
Electricity	352	36.7	52	5.4	348	36.3	207	21.6	959	100

A typical road/drainage facility in the study area is shown in Figures 3 and 4. The drainage facility in Figure 3 varies in quality, width and depth from one building to the other. At certain places, the drainage is covered while at some other places it is left open. In Figure 4, there is no drainage facility on both sides of the road; a building was constructed across the road causing an abrupt dead-end street. This trend is as a result of poor land use planning and lack of coordination of infrastructure provision and management in the city

Figure 3: A Typical Road/Drainage Facility in Peri-urban Communities in Akure, Nigeria

Figure 4: Abrupt Dead-end Road due to Poor Management of Infrastructure

The results show clearly that, individuals, families and DAs are mostly involved in the management of infrastructural facilities in peri-urban areas of Akure, while the involvement of government is limited. The minimal involvement of government is partially due to the operation of few public residential estates (3 in number) to which government is more committed. Government does not see its social responsibility in managing community facilities for social and good governance. Due to this fact, there has emerged a city form, characterized by an array of unplanned areas and pockets of well-planned and maintained estates.

ENVIRONMENTAL AND BUILDING CONDITIONS IN THE STUDY AREA

The environment and building condition in any community is a function of the nature of infrastructure such as roads and drainages. The residential building condition in the study area was measured using the age of building; type of toilet facility; location of bathroom and kitchen in the building; and type of access to the building, (see Table 4); while the environmental condition was measured using the following variables, namely: waste disposal method, sources of domestic water supply, type of drainage facility, and type of landscape around buildings, (see Table 5).

Building Condition

From Table 4, the mean age of buildings in the study area is 35years. Buildings above the age of 40years constitute about 36% of the total number of buildings. This trend shows that buildings in the study area are relatively old. Majority (45.6%) of respondents use pit latrine; 30.2% defecate in surrounding bushes; just 12.8% uses water closet systems in their houses; while a meagre 6.0% uses bucket latrine. Respondents without any form of toilet facility in their building constitute about 5.4%. This phenomenon shows that over 40% of respondents will end up using surrounding bushes as toilets, thus denigrating the environment.

Bathroom is another crucial housing facility; its availability and location of in a building has its impact on the general environmental condition of that building and the community at large. From Table 4, about 41.1% of respondents have their bathroom located within the buildings, while 34.3% have their bathrooms located outside their buildings. Buildings without bathroom constitute about 24.1%. The implication is that since bathrooms outside the building have no soak-away-pits, the building environment is messed up with bath water constituting blot on the landscape and defaming the environment.

Only 24.7% of respondents have their kitchens located within buildings; 51.7% cook outside their buildings while 23.6% use the building lobbies and verandas for cooking. It is pertinent to note here that those who cook outside use firewood as source of energy, while those who cook at lobbies and verandas use kerosene stove. The implication is that about 50% and 20%

of respondents experience air pollution within and outside the building environment respectively. No safe place!

From Table 4, based on the type and condition of housing facilities in the study area, 3.7% of buildings were considered as 'very good'; 43.9%, 'good'; and 12.5%, 'fair'; while 47.6% and 1.3% as 'poor' and 'dilapidated' respectively.

Table 4: Residential Building Conditions in Akure

Age of building	**Freq.**	**%**
-Below 10 years	128	13.3

Environmental Condition and Urban Basic Services in Akure

From Table 5, it is evident that about 12.2% of respondents use dustbin/controlled tipping for disposing solid waste; while 13.7% dispose refuse through burning. About 50.9% and 23.2% dispose their wastes in dunghills and stream/drainages respectively. From the data presented, it is evident that air/environmental pollution and flooding hazards cannot dissociate from the communities. This trend was documented by Dauda and Osita (2003), Oso and Taiwo (2004), who concluded that considerable percentage of urban waste in Nigeria are deposited along streets, roads/road sides, unapproved dump sites, water ways, and drainages or in open sites. The resultant effect of these 'management' options do not only reduce scenic resources, and environmental friendliness; dump sites are a form of nuisance and breeding ground for

mosquitoes, pests and disease outbreaks such as cholera, diarrhoea etc. (Ulloa et al, 2003; Mosler etal, 2006; Okoya and Ogunkoya, 2009; and Oyelola et al, 2009)

Table 5: Existing Environmental Conditions in the Study Area

-Bare	430	44.8
-Overgrown with Bushes	147	15.4
Total	**959**	**100**

The source of water supply is another variable crucial to the health of residents in the study area. Table 5 shows that residents' sources of water supply include: public tap, 5.2%; closed well, 15.4%; open well, 25.7%; rain, 35.2%; and river/stream/pond, 18.5%. Most residents in the communities got water for domestic uses (including drinking) from open wells, rainfall and river/stream which the WHO/UNICEF (2006) classified as unprotected sources. This trend is dangerous to the health of residents as they are vulnerable to scourge of sicknesses and diseases due to use of poor and sub-standard facilities (Health Canada, 2008).

The availability and type of drainage facility is another determinant of environmental condition in the study area. Table 5 shows that 14.8% and 4.2% of respondents respectively identified concrete block and concrete cast as the type of drainage facility available in the study area; while piped and earth drainages were identified by 2.4% and 46.9% of respondents respectively. A considerable number (31.7%) of respondents said there was no form of drainage facility in their communities.

From the analysis, it is clear that less than 20% of drainage facilities in the study area are in good condition. The remaining 80% is either very bad or not available. The implication is that the area will be susceptible to erosion and flooding hazards which degenerates the environmental landscape.

The type of landscape around buildings was examined as they are fashioned by the character of roads and drainages in the community. A few (9.8%) of buildings were planted with grass and trees; while 30.0%, 44.8% and 15.4% of building surroundings are respectively paved, bare and overgrown with bushes. It is obvious that paved surfaces increase the volume and

speed of runoffs; bare surfaces are susceptible to erosion and; bushes around buildings are breeding grounds for mosquitoes and other dangerous insects and pests. It is therefore apparent that less than 10.0% of buildings in the study area are safe and liveable. The reason for this situation can be found in the words of Ofomata (1984) that the people are passive and apathetic to plans aimed at combating soil erosion; they are unwilling "to adopt the procedures deemed necessary to heal the land". The author concluded that the main reasons for the observed failures of past attempts to combat erosion in residential communities included: lack of communication between the Government and the people; inadequate knowledge of the environment, and exploitative excesses of the people (Ofomata, 2000).

CONCLUSION

Individuals, families and Development Associations have been identified, in this paper, as the sources of provision and management of infrastructural facilities in peri-urban communities in Akure. The facilities examined included roads, drainages, electricity and piped water supply. The sanitary condition of buildings and the environment were equally examined as they reflect the state of infrastructure in any society Eleven peri-urban communities were identified and samples were taken from each based on the number of buildings in them. The simple random sampling method was employed to interview 959 respondents using a structured questionnaire. Results from the data collected show that, individuals and families are majorly responsible for the provision and management of infrastructural facilities in peri-urban communities in the city. The building and environmental conditions in the study area is adjudged to be very poor, which have been responsible for urban sprawl, environmental pollution, deterioration, and general urban decay.

This paper recommends that, for effective provision and management of infrastructural facilities in peri-urban communities of Akure, there is a need for government to see both as a social responsibility. Consequently, government should at least increase its involvement to: 100% on road and drainage because of the huge capital outlay involved and for the sake of uniformity and aesthetics; 60% on water and 80% on electricity provision for the purpose of Private-Public-Partnership; leaving the rest to individuals and CBOs (see Table 3). There is need for a calculated coordination of activities of citizens to concord with development proposals (if any) for the city. This recommendation becomes critical as more than 95% of residential layouts in the peri-urban communities of Akure are owned and controlled by private individuals (Olamiju, 2014).

Specifically, each community in the study area should form a Peri-urban Development Committee (PDC) to be registered with the State Ministry of Physical Planning and Urban Development. Members of the Committee should include selected members of building owners and tenants headed by a Development Control Official from the State Ministry of Housing and Urban Development. The function of this Committee shall be to guide and coordinate the activities of individuals and families embarking on any infrastructural facility development in line with set standards for facility provision and management. This may call for the review of the city master plan and relevant development regulations for Akure.

In addition, there is the need for provision of quality housing and hygienic environment. To achieve this, extensive redevelopment and upgrading programmes through the provision of urban basic services are essential in the communities. Priority should be given to provision of portable water, solid waste disposal facilities, and proper maintenance of drainages. Sanitary inspections should be regularly carried out on provision of household facilities with the enforcement of environmental sanitary laws. Adequate funding should be given to Waste Management Authority for effective service as well as improved health facilities in the

communities. Public enlightenment and Environmental Education (EE) would be necessary to keep the people well informed about the importance of healthy and hygienic environment.

ABSTRACT

Nigerian governments over the years have devised measures in the form of policies and programmes aimed at fulfilling their social contracts with the Nigerian populace by providing basic social services and to generally improve their lots. The study surveyed "Social Studies Teachers' Opinion on Factors inhibiting successful Implementation of Millennium Development Goals (MDGs) in Nigeria". The study used survey research design and utilized 114 male and female teachers as sample for the study basing the decision on Research Advisors' (2006) sample size table. The study employed purposive sampling technique to select the sample. However, the study used questionnaire titled "Teachers Opinion on Implementation Factors on Millennium Development Goals (TOIFMDGs). The study was guided by one (1) objective, answered one (1) question and tested one (1) null hypothesis. The data analysis tools were percentage and frequency counts, mean and standard deviation and independent sample t-test respectively. The study rejected the null hypothesis at 0.05 alpha and 95% confidence level. The study discovered significant difference on account of gender of social studies teachers on their opinion about factors inhibiting successful implementation of Millennium Development Goals in Nigeria. In the light of the findings made by the study, it is recommended as follows; the need for project and programme continuity, planning implementation of home-grown policies that explains the reality on ground in Nigeria, the need to stamp out corruption and mismanagement in the business of governance among others.

Keywords: Factors, Implementation, MDGs, Opinion, Social Studies

INTRODUCTION

The MDGs are a United Nations development strategy that targets poverty reduction in all its ramifications as against prescriptions usually foisted on Nigeria by its development partners that seek growth at the expense of equity and development. The MDGs share the realism that development is about poverty reduction and once the people notice that development is targeted at them, their commitment will become easy to exploit and sacrifice for its success genuinely assured. In this vein, Bello & Suleiman (2011: ix) state that:

> *The Millennium Development Goals (MDGs) comprised eight ambitious goals that were approved by world leaders in 2000. The goals are to eradicate extreme poverty and hunger; achieve universal primary education; promote gender equality and empower women; reduce child mortality rates; improve maternal health; combat HIV/AIDS, malaria and other diseases; ensure environmental sustainability; and develop a global partnership for development. The first seven goals are meant for developing countries while the eighth goal is for the developed countries to meet their obligations.*

In a related development, Imoudu (2012) observes that with the right policies and choices, domestic resources can be more effectively mobilized, capital flight minimized and consequentially, the economy can be strengthened as the capabilities of the people are channeled to the cause of development.

Nigerian governments over the years have devised measures in the form of policies and programmes aimed at fulfilling their social contracts with the Nigerian populace by providing

Salihu, J. J. & Adamu, S. (2016). A Survey on Social Studies Teachers' Opinion on Factors Inhibiting Successful Implementation of Millennium Development Goals in Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1469-1475

basic social services and to generally improve their lots. These development plans ranges from short-term, medium-term and long-term plans. Some of these plans introduced over the years include but not restricted to the following; Operation Feed the Nation, Green Revolution, Mass Mobilization for Social Justice and Economic Recovery (MAMSER), Family Economic Advancement Programme (FEAP), Family Support Programme (FSP), Better Life for Rural Women, National Economic Empowerment and Development Strategies (NEEDS), The Seven Point Agenda, The Transformation Agenda among others. These policies and programmes hardly translate into practical reality as a result of some teething socio-economic and political challenges facing the country over the years.

It has been claimed that Nigeria has often formulated good policies but these get bungled at the implementation stage, Eminue (2005). Universally, Nigeria is widely acknowledged for her effective planning in terms of policies and programmes but the problem has always been the implementation. Some of the Nigeria's policies and programmes have been accused of being imported and therefore lack direct bearing with the reality on ground. Examples of such programmes are the Vision 20:2020, and the Millennium Development Goals (MDGs). Some critics have considered these policies and programmes as diversionary tactics aimed at derailing Nigeria from the current situation and realities on ground by her detractors.

However, despite the skepticism by critics on Millennium Development Goals, quite a number of Nigerians believed that well implemented MDGs will assist in improving the lots of Nigerians. Available literatures have identified some of the problems inhibiting successful implementation of Millennium Development Goals in Nigeria. These challenges facing Nigeria in her quest to attain MDGs are slow growth prospects; resource constraints; lack of institutional reforms; inadequate capacity development; uneven income distribution; global economic situation; lack of political will and commitment to the MDGs; lack of an enabling environment to attract investment and encourage private sector development; and the lack of inclusive growth among others. It is against this background that this study examined the factors inhibiting successful implementation of Millennium Development Goals (MDGs) in Nigeria through the perspective of social studies.

Objective of the Study

The main objective of the study was to examine the Opinion of Social Studies Teachers on Factors Inhibiting Successful Implementation of Millennium Development Goals (MDGs) in Nigeria. The study was guided by the following specific objective:

i. To determine whether gender has influence on Social Studies Teachers' Opinion regarding factors inhibiting successful implementation of Millennium Development Goals in Nigeria.

Research Question

The study was guided by the following question:

i. Does gender affects the opinion of social studies teachers on factors inhibiting successful implementation of Millennium Development Goals in Nigeria?

Null Hypothesis

The study postulated and tested the following null hypotheses at 0.05 Alpha:

i. Gender has no influence on the opinion of social studies teachers regarding factors inhibiting successful implementation of Millennium Development Goals in Nigeria.

METHODOLOGY

Descriptive survey research design was adopted for this study. The survey attempts to examine the existence or occurrence of phenomenon or variable. It is usually employed by collecting

data and describing in systematic manner the characteristic features or facts about a given population from a few people or items considered to be representative of the entire group, Akuezuilo & Agu (2002).

The design corresponded with motives of the study which seeks to examine the Social Studies Teachers' Opinion on Factors Inhibiting Successful Implementation of Millennium Development Goals (MDGs) in Nigeria. The study has the entire social studies teachers in the study area as population. The study was delimited in scope to Zaria Education Zone Kaduna state-Nigeria. The collection and retrieval were done simultaneously. The study retrieved 114 questionnaires that were distributed through purposive sampling technique. The four point modified Likert scale questionnaire titled "Teachers Opinion on Implementation Factors on Millennium Development Goals (TOIFMDGs) was used as data collection instrument. The inferential statistical techniques were used in the analysis of the data. The Mean and standard deviation were used to answer the question raised by the study. Moreover, t-test independent sample statistic was used to test the null hypothesis postulated by the study at 0.05 alpha level of significance.

RESULTS AND DISCUSSIONS

Presented below are quantitative and qualitative answers provided for the question raised by the study. The frequency table, mean standard deviation and standard error were used as statistical tools to answer the question raised.

Research Question 1: Does gender affects the opinion of social studies teachers on factors inhibiting successful implementation of Millennium Development Goals in Nigeria?

Table 1.1: Female and male students view regarding the opinion of social studies teachers on factors inhibiting successful implementation of Millennium Development Goals in Nigeria

Factor Inhibiting Successful Implementation of Millennium Development Goals	Male		Female	
	Mean	SD	Mean	SD
Pervasive corruption	3.56	1.42	4.27	0.99
Lack of policy/project continuity	3.08	1.16	3.16	1.21
Lack of political will and commitment to the MDGs	2.34	1.19	3.19	0.52
Inadequate capacity development	2.94	0.82	2.70	1.02
Non diversification of economy	2.66	1.21	3.24	1.14
Global economic situation	2.81	0.81	2.79	0.82
Lack of institutional reforms	2.79	0.85	2.73	0.80
Lack of an enabling environment to attract investment and encourage private sector development	2.77	0.74	2.34	0.91
Lack of inclusive growth	2.56	0.73	3.19	1.07
Slow growth prospects	2.61	0.91	3.03	0.83
Misplacement of priorities	2.61	0.69	3.00	0.91
Resource constraints	2.68	0.75	2.87	2.56
Uneven income distribution	2.87	0.89	2.43	0.84
Poor and ineffective leadership	3.03	0.90	3.51	1.26
Cumulative mean	**2.808**		**3.03**	

Decision mean 2.50

The table 1.1 above shows the mean opinion of social studies teachers on factors inhibiting successful implementation of Millennium Development Goals in Nigeria. The response of male and female teachers regarding their opinion on factors inhibiting successful implementation of Millennium Development Goals in Nigeria was positive but diverse. This was due to the fact that their cumulative mean responses of 2.808 and 3.03 for male and female teachers respectively were higher than the decision mean of 2.50.

On the other hand, the male respondents' highest mean responses were M3.56 (pervasive corruption), followed by (lack of policy/project continuity) M3.08 and (poor and ineffective leadership) M3.03 respectively. On the part of the female respondents, their highest mean responses were M4.27 (pervasive corruption), (poor and ineffective leadership) M3.51 and non diversification of economy M3.24 respectively.

On the contrary, other items on the questionnaire that were not favoured by the teachers responses were (lack of political will and commitment to the MDGs) M2.34, on the part of male respondents and (uneven income distribution) M2.43, (lack of an enabling environment to attract investment and encourage private sector development) M2.34 for female teachers respectively. This was because their individual mean responses fall below the decision mean of 2.50. The table above shows the response pattern of male and female teachers arranged from highest to the lowest mean response.

Hypothesis Testing

H_{01}: Gender has no influence on the opinion of social studies teachers regarding factors inhibiting successful implementation of Millennium Development Goals in Nigeria.

Table 1.2: Independent t-test statistic on the opinion of social studies teachers regarding factors inhibiting successful implementation of Millennium Development Goals in Nigeria

Variable	Gender	N	Mean	S.D	Df	t-cal.	t-crit.	P (sig)
Opinion of Social Studies Teachers on Factor Inhibiting Successful Implementation of Millennium Development Goals	Male	77	95.8442	9.86096	112	2.172	1.96	0.032
	Female	37	99.8919	8.04081				

P < 0.05, t calculated > 1.96

Table 1.2 shows that significant difference exist between male and female respondents on Factor Inhibiting Successful Implementation of Millennium Development Goals in Nigeria reason being that the calculated p (sig) value of 0.032 is less than the 0.05 alpha level of significance while the calculated t-value of 2.172 is higher than the t-critical value of 1.96 at df 112. The mean scores were 95.8442 and 99.8919 for male and female respectively. Therefore the null hypothesis which states that "there was no significant difference between the opinions of social studies teachers on factor inhibiting successful implementation of millennium development goals in Nigeria" is rejected.

Major Findings

The study discovered the following:

i. There was significance difference between the views of male and female teachers on the factors inhibiting successful implementation of Millennium Development Goals in Nigeria.
ii. Pervasive corruption, lack of policy/project continuity, poor and ineffective leadership were the major factors inhibiting the successful implementation of Millennium Development Goals in Nigeria as identified by male social studies teachers.
iii. Pervasive corruption, poor and ineffective leadership, non diversification of economy were the major factors inhibiting the successful implementation of Millennium Development Goals in Nigeria as identified by female social studies teachers.
iv. Lack of political will and commitment to the MDGs, Uneven income distribution, lack of an enabling environment to attract investment and encourage private sector development were rejected as factors inhibiting successful implementation of

Millennium Development Goals in Nigeria as identified by male and female social studies teachers.

Discussion of Findings

The pattern and nature of policy implementation is said to be the major explanation for the failure or success of any given policy in Nigeria and many African countries. In this regard, Nwankwo and Apeh (2008) opined that the implementation of a policy is the most crucial stage in the policy process as it is at this stage that determines the success or failure of any policy. Similarly, Ikelegbe (2006) and Nweke (2006) noted that many policy failures result from ineffective implementation. The views presented by the above authorities corroborate the findings of this study which identifies lack of project/policy continuity and poor plan implementation as major setback in Nigeria's effort to attained Millennium Development Goals. The problem of poor plan implementation and policy/project continuity not only affects Nigeria as a nation but majority of African countries and the Third World.

In a related development, Egonmwan (1971) opined that implementation in developing countries (Nigeria inclusive) often turns out to be the graveyard of policy where the intentions of the designer of policies are often undermined by a constellation of powerful forces of politics and administration in cooperation with people. Little attention is paid to the subject of policy implementation by policy decision makers while it is often taken for granted that once a policy is adopted by government it must be implemented and the desired goals achieved. The above hitch has often resulted in poor policy implementation, which, in effect, gives rise to implementation gap. There is policy failure when there is a sizeable gap between a policy decision and its implementation.

The Nigeria's House of Representatives some years back has threatened to stop financial allocation to any Ministry or Parasatals that has failed to implement the MDGs (Vanguard 2009). The real challenge that militates against the realization of the MDGs is those of policy implementation because adequate budgetary allocations have been made by the government. Furthermore, the implementation of MDGs has been characterized by deeply entrenched corruption and gross inefficiency, and wastefulness. To buttress the above points of view, the Senate report on MDGs described the MDGs office as a "cesspool of corruption and shady deals, (The Guardian (2009). Corruption has been a major problem because "it makes the country unattractive to investors as it raises the cost and risk of doing business in the country" (UNDP, 2004). In addition, there is the problem of duplication of projects in the same areas by the Federal Government, and multilateral donor agencies. Pervasive corruption tops the respondents' ranking as single most important factor that hinders Nigeria's quest to attain Millennium Development Goals. It must be noted that corruption goes with power and therefore, must be located first within the ranks of the powerful Egonmwan (1991). Since independence, corruption has been a major source of cost escalation of government projects. Government contracts in Nigeria have always been a conduit pipe for making fast and easy money by government officials and contractors through dubious means. Another critical factor inhibiting effective implementation of policies in Nigeria is that some agencies or institutions saddled with the responsibility of implementing given policies do not possess the requisite manpower and financial resources to effectively implement them. On the issue of inadequate resources, for instance, Government, sometimes, do not budget adequately to enable the public bureaucracy properly implement formulated policies, Ikelegbe (2006) and Dick (2003). The current war against corruption by the Buhari/Osibanjo administration has started yielding positive results as sanity in the public and even the private sectors is restoring. The Nigeria's image in the eyes of other countries especially the western world is

improving. There is a slight improvement in Nigeria's ranking on corruption perception index in 2015 compared to 2014.

Another cause of implementation gap is the failure of the policy makers to take into consideration the social, political, economic and administrative variables when analyzing for policy formulation. A policy that runs contrary to the manifesto of the government in power may suffer at the implementation stage because it may lack support, both financial and administrative. Also, failure to take the economic variable into consideration may also spell doom to policy implementation.

Moreover, Egonmwan, (1991: 213) states that apart from the ego problem which sometimes culminates in lack of continuity as explained above, it should be noted that for policies to be successful they should involve target groups and they should allow for participatory system, whereby policy makers plan with the people rather than for the people in meeting their felt needs. Such participation will give the target groups a sense of belonging as well as get them committed to the successful implementation of the policy.

Additionally, Igbuzor (2011) observed that there were capacity constraints by the public sector, private sector and civil society and the challenge of coordination between the three tiers and arms of government as factors inimical to successful implementation of millennium development goals in Nigeria. Another issues that has confronted efforts at development in Nigeria is overconcentration on economic reforms/transformation and neglect of political and social reforms/transformation.

Nigeria tends to over indulged in over ambitious policies either owing to the desire to establish support base and legitimacy for government to bring about economic development or to serve ideological ends. Such policies cannot work as they will lack adequate financial, manpower, technical resources, institutional and organizational capabilities and the necessary political will for implementing such fundamental policies, Eminue (2005).

Indeed, most policy making goals in Nigeria are subordinated to the personal rewards and interests of the political leaders and their colleagues with the result that a policy is judged more on its political merits with the real development need rarely factored into consideration. For these, most policies in Nigeria are either inappropriate or lack well defined objectives and programmes for their effective implementation. In this regard, Okoli and Onah (2002) state that implementation of policies in Nigeria take the form of "learning process" or "trial and error". Indeed, in Nigeria there are usually no comprehensive policy standards and objectives to guide the bureaucracy in its policy implementation activities and procedures, Makinde (2005). Sometimes the implementation guidelines are rarely considered as a result of vested interest and lack of adequate monitoring and evaluation.

CONCLUSION

The study has to a reasonable extent examined the Opinion of Social Studies Teachers on Factors Inhibiting Successful Implementation of Millennium Development Goals (MDGs) in Nigeria and by extension Africa and the Third World countries. So far, the Nigerian government score sheet is unimpressive if situations on ground are anything to go by. The deadline for the attainment of these goals has expired in 2015. The findings indicate some teething issues and problems that hinder Nigeria's effort to realize the MDGs goals in Nigeria. These issues and problems must be addressed tactically and effectively in order to ensure the attainment of other future Developmental Plans likes vision 20:2020 and Agenda 2063.

RECOMMENDATIONS

In the light of the findings made by the study, it is recommended as follows;

i. The need to stamp out corruption and mismanagement in the business of governance in Nigeria. This will go a long way in sanitizing the system;
ii. The need for project and programme continuity. Governments at all levels should as a matter of importance continue with laudable projects and programmes initiated by other governments. Laws should be enacted to enforce project/programmes continuity;
iii. Planning and implementation of home-grown policies that explains the reality on ground in Nigeria should be promoted;
iv. The Nigerian government should strive to diversify it economy. This is because no country can attain development on single commodity.
v. There is the need for Nigerian electorates to set aside all sorts of sentiment and insist on visionary and transformative leaders who have the ideas and know-how to take the country to the Promised Land.

ABSTRACT

In the contemporary world today, a nation develops through the provision and maintenance of infrastructural facilities that facilitate and promotes socio-economic development as well as supports urban and rural dwellers in their production, distribution, and consumption activities. The purpose of the study was to classify the existing infrastructure according to ownership and to assess their conditions. This study adopted the survey research method and used three different questionnaires to collect research data from the authority of the Ekiti South-West LG Council, Community Development Unit in-charge of Community Development Projects in Ekiti South-West LG Council, and the officials of the available 61 (CBDAs) in the study area. The findings revealed that provision of urban infrastructure by the LG Council and CBDAs has helped in enhancing the living conditions of the people to some extent; those infrastructural facilities include: road construction, water supply, electricity power supply, and healthcare centres/hospital. However, the condition of some facilities in the town was dilapidated and had not been adequately maintained, which is affecting the level of patronage of these facilities. The findings among others revealed that the area was faced with the problems of low level patronage of services and infrastructure; inadequate funding resulted into low level of provision of social facilities. The recommendations called for the need to improve infrastructural facilities capacity through provision and maintenance; encourage people's participation in the conceptualization and implementation of infrastructural projects.

Keywords: Community-Based Development Association, Infrastructure, Local Government Council, Provision

INTRODUCTION

The world is increasingly urbanizing and the growth of cities is becoming alarming. A United Nation Report noted that in 2005, the World's urban population of 3.18 billon people constituted 49% of the total population of 6.46 billion. The urban areas are growing fast and, consequently, the urban infrastructural facilities have to meet the needs of rapidly increasing users. These problems of inadequate urban infrastructure are more evident in the traditional core of the cities and other settlements that accommodate the poor (Ayoola and Ogundiran, 2014).

The United Nation report predicted that the urban population would grow to 6.4 billion by 2050, and it also estimated that Africa's urban population at 2025 would be 54 % of the population, while total African population is projected to almost two billion by 2040 (United Nation,2013). In Nigeria, according to the World Health Organization / United Nations Children's Fund, between 1990 and 2004, urban population growth had increased from 35% to 48%, which was estimated at 170 million people in 2014. The increasing level of urbanisation and the inadequacy of urban infrastructure in Nigeria were reported by various urban analysts (Agbola 1994, Mabogunje 2001, and Olujimi 2009). Urbanisation is a global phenomenon and is a process of spatial concentration of urban population. The urban areas and cities serve as the engines of economic development. On the other hand, poor infrastructural facilities provision is evident in most cities in Nigeria and this has a serious effect on the quality of life of the residents. The poor state of most urban facilities has created health, social and economic problems. Okpoechi (2010) has highlighted that a good urban

Okosun, S. E. & Olujimi, J.A.B. (2016). Assessment of Local Government Council and Community-Based Development Associations in the Provision of Infrastructure in Ilawe-Ekiti, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1476-1483

infrastructure does not only improve the general appearance of the cities but also have effects on the mental health of the people who live, work and visit cities.

Infrastructural facilities development is at critical stage in the world today. Countries of the world ensure the provision of infrastructure to improve the livelihoods of their citizen and their qualities of life (Khoza, 2009). Infrastructure plays a key role in both socio-economic and political development and enrichment of living standards. The shift from focus on construction of infrastructural facilities to the delivery of infrastructure facilities drew the attention of so many countries in Africa, particularly, Nigeria to focus on the provision and delivery of infrastructural facilities especially at the local level. A study conducted by Udoh (2010) revealed that less than 40% of the population has access to safe drinking water. Access to infrastructure such as; safe water supply, electricity and roads are necessary to reduce vulnerability and poverty in Nigeria. Urban infrastructural facilities development that need be provided should include among others, good roads, electricity, schools, portable water supply and drainage networks. The depleting conditions of these services in Nigerian urban areas are of great concern to the Local Government Council Authorities, Community-Based Development Associations, and other agencies. Governments have come to term with the LG for the need to be involved in grassroots development. However, the establishment of LG Councils in Nigeria aimed among others to facilitate rural and urban development through infrastructure development and delivery (Sehinde, 2008). The LG Council is statutorily empowered to construct and maintain roads, street lighting, water and drains and provide other public facilities (Federal Government of Nigeria, (FGN) 1999). The recognition and importance of this process is to tackle local socio-economic problems and to manage grassroots development (Wunsch, 2001). Despite these provisions, lack of adequate, affordable and reliable infrastructure services still touches the life of urban and rural Nigerian family everyday, water supply is neither safe nor adequate for their needs, and many roads are impassable. Sehinde (2008) concluded that in Nigeria, the overriding impression is that LG Councils are weak in their response to the challenges posed by the infrastructural development. This has led to self-help programmes through which private sectors are now involved in infrastructural facilities development. The CBDAs form one of the main actors of the Local Economic Development (LED) process. They have been responsible for the provision of communal facilities such as schools, markets, water points, health clinics or health centres and town or community halls. (Emmanuel, 2013). In view of these encouraging roles, this study assesses the effects of the efforts of the LGC and the CBDAs in the provision of infrastructure.

Problem of the Study

Infrastructure facilities play a crucial role in the socio-economic development which supports urban and rural dwellers in their production, distribution, and consumption activities as well as promoting socio-economic development in any area. Infrastructure facilities also play a significant role in the modernization and growth of agricultural productions, incomes and increase in employment opportunities for the inhabitants. Their development is an important tool in the socio-economic development of any given settlement. However among the thirteen (13) natural resources available in the world, Nigeria has twelve (12) of them, yet the country (Nigeria) is still faced with problems of inadequate/lack of infrastructural facilities which have brought about poverty, rapid urbanization and high crime rate. Olayiwola (1998) has confirmed that many people are living below poverty line because they do not have access to basic infrastructural facilities. The provision and maintenance of infrastructure and services is essential for the promotion of the efficient operations of a settlement in safeguarding health, protecting the living environment and enhancing the general standard of living (Soyibo, 1999).

Infrastructure relates to the aggregates of all facilities that allow a society to function effectively. As stated by Okwakpam (2010), human needs are insatiable and the government alone cannot meet them. In recent times, various efforts have been made by government. One of the strategies being employed to enhance development is through grassroots participation in development process. Government has come to terms with the need to partner with the LG Council and CBDAs as agents (or institutions of development) in addressing shortage in infrastructural facilities. In Ilawe-Ekiti, the most prevalent problems are lack of portable water supply, inadequate healthcare facilities, incessant power failure (electricity), inadequate and poor state of the existing schools, and poor conditions of the roads. This study assesses the LG Council and the CBDAs in the provision of infrastructure in Ilawe-Ekiti, with a focus on (i) Water supply (ii) Health care facilities (iii) Electricity, and (iv) Roads. However, the objectives to achieve include:

i. classification of existing infrastructures according to ownership and conditions in the study area;
ii. highlighting the existing functioning infrastructural provided for the people on the basic of wards in the study area.
iii. highlighting the effect of infrastructure on the living conditions of the people in Ilawe-Ekiti

RESEARCH METHODOLOGY

The survey research method was adopted for this study. The target population is classified into four (4) groups; Ekiti South West LGC, Community Development Unit in-charge of community development projects in the area, Community/Quarters-Heads in the study area and CBDAs in Ilawe-Ekiti. A Non-probability sampling approach was employed for use in this study. It is carried out when the researcher is not concerned about the representativeness of sample. In this study a total census (i.e 100% coverage) survey was conducted on all the 61 (CBDAs). Meanwhile, only the President/Chairman/Secretary per CBDAs was interviewed. One copy of the relevant questionnaire was administered to the Ekiti-South West LGC Caretaker Chairman. Also one copy of the questionnaire was designed for the official in-charge of the Community Development Project Unit in the LG Council office was administered to him. Data were collected with the aid of structured-multiple choice questionnaire. It consists of sixty-one (61) questions which were set to elicit specific information from the respondents. This study employed the use of four sets of questionnaire for data collection. In this study, the researchers in conjunction with the three (3) Field Assistants administered the questionnaires. Students from Crown Polytechnic Odo, Ado-Ekiti, Department of Urban and Regional Planning, were used. The data collected from the field were collated and analyzed to give meaningful information. The processing of data was carried out using the Statistical Package for Social Sciences (SPSS) version 19. The analysis of data was done, using frequency count; distribution and such information were presented through the use of tables, and percentages.

RESULT AND DISCUSSIONS

In this section, discussion of the findings were based on the research objectives as follows:

The Existing Roads Constructed in Ilawe-Ekiti

Road construction was mostly carried out by the government while CBDAs involvement and individual efforts on road construction projects were not reflected. Roads were constructed in Aaye, in 1991; Okebedo I, in 1990; Adin, in 1984; Oke-Emo, in 1990; and Okepa/Iro/Okeloye, in 1985. Findings revealed that there were no newly constructed roads in Ilawe-Ekiti. The Government embarked on opening up (i.e. bulldozing) and

rehabilitation/upgrading of roads in the town; however the criteria used in assessing the condition of the roads were based on perception. Findings further revealed that the roads lack drainage and are grossly inadequate.

Table 1: The Existing Roads Constructed in Ilawe-Ekiti as at, 2015

S/N	Wards/Location	Ownership	Length of Road	Year of Establishment	Condition
1	Aaye	Government	-	1990	Fair
2	Okebedo I	Government	1..35km	1990	Bad
3	Adin	Government	-	1984	Good
4	Oke-Emo	Government	-	1990	good
5	Okepa/Iro/Okeloye	Government	0.85km	1985	Fair

The Provision of Water Supply in Ilawe-Ekiti

The analysis in Table 2 shows that ownership of water supply project in Ilawe-Ekiti was by the government, the Community and the individual. Findings revealed the provision of water supply was mostly carried out by the Government and the Community; they provided water supply i.e boreholes in all wards in Ilawe-Ekiti. Provision of water by individuals in the town is limited to wards in Aaye, Okebedo 1, Okepa/Iro/Okeloye, Oke-Emo and Okepa/Iro/Okeloye. Based on the findings, it was revealed that water supply in Ilawe-Ekiti is in a terrible condition and grossly inadequate. However it's characterized by low level of coverage and difficult geology.

Table 2: Existing Sources of Water Supply in Ilawe-Ekiti as at, 2015

S/N	Types	Wards/Location	Ownership	Year of Establishment	Condition
1	Borehole	Aaye	Government	2007, 2009, 2013	Functional
	Borehole		Community	1995, 2012	Functional
	Hand-dug well		Individuals	1999	Functional
2	Borehole	Irorin	Government	1999, 2007, 2000	Functional
	Borehole		Community	-	Functional
3	Borehole	Okebedo 1	Government	-	Non Functional
	Borehole		Community	2008	Functional
	Hand-dug well		Individuals	2010, 2013,2014	Functional
4	Borehole	Okebedo 11	Government	1999	Non Functional
	Hand-dug well		Community	-	-
5	Borehole	Adin	Government	-	Non Functional
	Borehole		Community	-	Functional

The Ownership of Existing Healthcare Facilities in Ilawe-Ekiti

In Table 3 the Healthcare centres/hospital was mostly owned by the government, while few were owned and make provision for by the private individual. Findings reveal that past governors of Ekiti State in Nigeria provided the public healthcare centres/health post and the only general hospital in Okededo II, while the Ekiti South West LG Council is responsible for the maintenance of the government healthcare centres. Further findings reveal that the LG Council is also responsible for the payment of the Government health workers' salaries in the area.

Electricity Supply in Ilawe-Ekiti

Electricity supply (i.e. Transformer) provision is the sole responsibility of the governments; this represents 100% ownership/involvement by the government in power. This is found in Aaye, Irorin, Okebedo I, Okebedo I1, Adin, Oke-Emo, and Okepa/Iro/Okeloye. Other electric power supplements are in the form of power generators provided by individual. As seen in Table 4 electricity supply are present in all wards in the town, The electricity power supply in the town is unsatisfactory as power outages are frequent and the power sector operates well below its estimated capacity. This has made most residents/industrialists to install their own power generator which very few in the community can afford.

Table 3: The Existing Healthcare Facilities in Ilawe-Ekiti, 2015

S/N	Names/Types	Wards/Location	Ownership	Year of Establishment	Condition
1	Health Post	Aaye	Government	-	good
2	Health Post	Irorin	Government	-	poor
3	Health Post	Okebedo 1	Government	-	-

Infrastructural Facilities in Ilawe-Ekiti

The provision of community development projects in Ilawe-Ekiti were carried out through participation/involvement/effort of individual, government and CBDAs. As seen in Figure 1 which shows the existing functioning infrastructural facilities provided for the people in Ilawe-Ekiti, on the basis of wards. Those include; schools, boreholes water supply, electricity supply (transformers), healthcare centres and town halls, all of these facilities were found in all wards in Ilawe-Ekiti. Tarred roads were found in Adin, Okapa/Iro/Okeloye and Oke-Emo, one general hospital in Okebedo 11 and one community viewing centre situated in Oke-Emo,

There is also one bank in Okapa/Iro/Okeloye, four markets were provided in the town, one post office was built in Okapa/Iro/Okeloye by the elite of Egbe Araromi club in 1971 and was the first self-help project not championed by a religious body in modern times which was later handed over to the government. The findings revealed that provision of infrastructure in the study area has helped in enhancing the living conditions of the people in the town to some extends; those infrastructural facilities include: schools, road construction, water supply, electricity power supply, market, bank, and healthcare centres/hospital. Those afore mention infrastructure have the power of attracting investors to the area, which in-turns brings about development/growth to the urban area. However the people in (Ilawe-Ekiti) are smiling and enduring suffering, smiling because there is present of infrastructural facilities and food to eat, enduring sufferings because of the low level of infrastructural services, such as roads, electricity, bank and water which had been overstretched by the increasing population and have affected agricultural production/distribution and employment opportunities of the people in the town. No doubt Ilawe-Ekiti did not enjoy government patronage that commensurate their size and population.

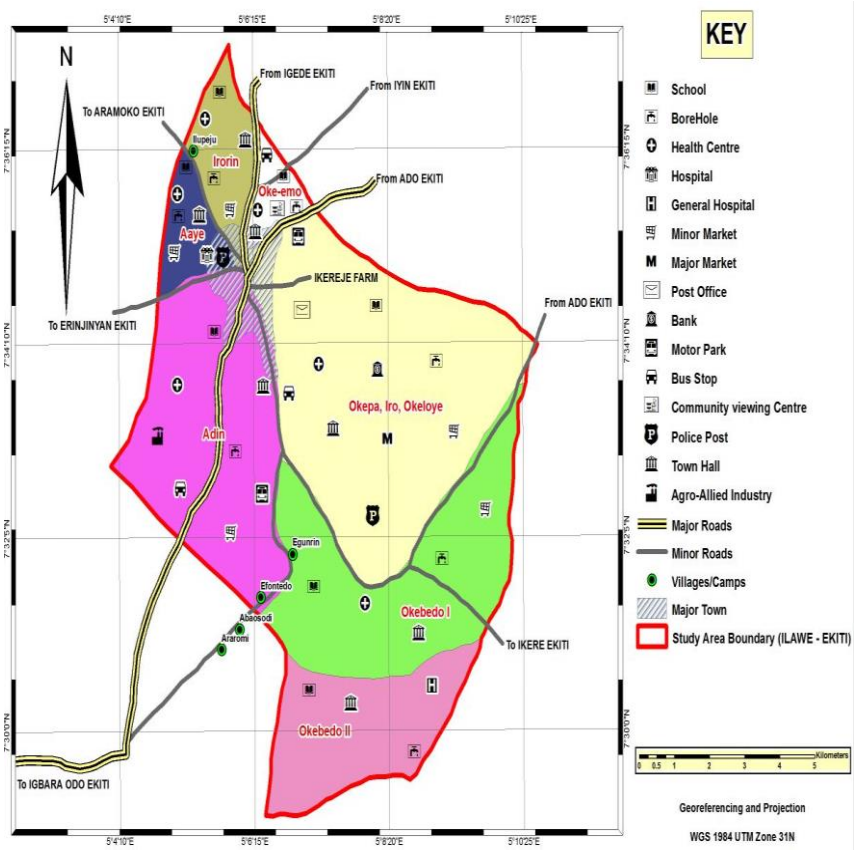

Figure 1: Facilities Map, Ilawe-Ekiti

Effect of Infrastructure on the Living Condition of the People in Ilawe-Ekiti

Table 5 shows the effects of provision of infrastructure on the living condition of the people in Ilawe-Ekiti. The majority of the bore-holes projects are fairly effective; this represents 62.5% while 25.0% attested to the fact that it is highly effective. The majority of the power supply is not effective, this represents 75%, and while those respondents that claimed it was not fairly effective represented 12.5% same percentage with those who claimed power supply project are very effective. The majority of the roads are effective, those are the wards that have tarred roads such as Aaye, Adin, Okepa/Iro/Okeloye and Oke-Emo this represents 50.0% while those roads that are not effective are represented by 37.5% the wards are Irorin, and Okebedo II. The remaining 12.5% attested to the fact that the roads are fairly effective,

was Okebedo I. The healthcare centre/hospital is very effective, this represents about 50.0%. However it should be noted that development in any urban /rural areas of the world can be facilitated and accelerated by the provision of infrastructure. If those social welfare services, such as electricity, potable water supply, healthcare services, roads and educational facilities are not put in place and made accessible in the urban /rural areas; development will be very difficult to come-by.

Table 5: Effect of Provision of Infrastructure on the Living Condition of the People

S/N	Infrastructure	Respondents' Opinion				Total (%)
		Not Effective (%)	Fairly Effective (%)	Highly Effective (%)	Effective (%)	
1	Bore hole	12.5	62.5	25.0	-	100
2	Power supply	75.0	12.5	12.5	-	100
3	Motorable roads	37.5	12.5	-	50.0	100
5	Healthcare centres	25.0	25.0	50.0	-	100

RECOMMENDATIONS

One, people's participations /involvement in the formulation and implementation of policies and projects. People need be consulted to know their needs before projects are initiated for them. Two, encouragement of maintenance culture among target population is inevitable. Infrastructure needs to be maintained as this will prolong its durability and efficiency. Furthermore, considering financial crisis in the LG Councils, the Federal Government of Nigeria should re-route the monthly financial allocation straight to all LG Councils in the federation rather than relying solely on federal allocation that is not enough to provide infrastructure. Also the Government should intensify programme of environmental awareness through the use of community/quarters-heads to compliment efforts of the government officials in the protection and monitoring of infrastructures such as schools, primary healthcare centres, market and roads, in the urban areas. Finally, the office of the community development unit should be equipped with qualified personnel to direct the government efficiently in implementing projects.

CONCLUSION

The present monthly allocation from Federal Government to LG Councils is grossly inadequate; the LG Councils use the money to settle only their recurrent expenditure, i.e pay salaries and allowances of staffs and political appointees. And it is not enough to embark on infrastructural provision; however, the LGC and the CBDAs are good examples of grassroots development. They had shown to be a very useful tool and beneficial both to the government and the community in supplementing government efforts in the urban areas. The availability of infrastructure served as means of reducing poverty, thereby improving the standard of living of the people. Furthermore, the destiny of a great community (Ilawe-Ekiti) lies on the shoulders of the community continues participation/involvement in provision and maintenance of projects, because the government alone cannot provide all their needs.

Spatial Pattern of Public Transport Access Points in the Federal Capital Territory (FCT), Abuja-Nigeria

Oluwole, M. S.

Department of Transport Management Technology, Federal University of Technology, Minna, Nigeria
talkmatthew272@gmail.com

ABSTRACT

The study is aimed at investigating the pattern of public transport access points by commuters in view of the perceived poor public transport access level in the Federal Capital territory (FCT). It provides answer to the question of the pattern of distribution of public transport transit routes, terminals and bus stops in the study area. Relevant data were generated from Google map and field work using the Germin 64x GPS and manipulated on Arc-GIS 9.3 software environment. The result shows that public transport routes, bus stops and terminals were not evenly distributed in the study area and by this reason, most locations have poor access to public transport services within the framework of international standard recommended by World Bank (2000). This is because buffering and Nearest Neighbour Analysis of public transport routes, terminals and bus stops shows high degree of clustering towards the City Centre, a situation which could not have been as a result of random chance. In order to raise the current level of commuters access to public transport service in FCT, it is recommended that bus stops, terminals and public transport routes must be redesigned in line with the current spatial physical development of the FCT.

Keywords: Access, Pattern, Public , Spatial, Transport

INTRODUCTION

Public transport is defined as a system of carrying passengers and or goods for money by private or public operated carriers (Adeniji 1984). It is a means of carrying large number of people 'en mass' as opposed to individual vehicles carrying very few people at a time More narrowly, public transport has been described as a vehicle licensed to provide stage carriers service (Bus and Coach Council, 1984). The need for public transport in globally and locally will continue to grow, the population of people residing in urban areas increased from 13% in 1900 to 40% in 2005. Numerically, this represents a move from 220 million people in 1900 to 3.2 billion people in 2005. By 2011, there were already 480 cities with population in excess of one million as against 80 of such cities in 1950. Currently, more than half of the world's population lives in cities, about three billion people currently resides in urban centres and the figure is expected to rise to five billion in 2050 (Akunnaya and Adedapo (2014). Perhaps, more striking is the fact that most of the population growth in the population growth in the coming decades will occur in low and middle-income countries.

Accessibility has been defined as the ease of getting to a place and as nearness to place or nearness to activities (Richardson and Young 1981). Accessibility has many dimensions (physical, economic and social). In transportation planning accessibility is defined as the ease with which desired destinations can be reached (Niemier 1997). It is a function of land use patterns and of the transport system (Morris, Demble and Wigan (1979), therefore making it an important consideration in the planning and development of policies associated with public transport and in determining land use configurations within urban space management. Public transport commuters seek a convenient access to bus ride between their point of origin and destinations. They neither want to walk very far to get to bus stops/terminals nor wait very long at the bus stop (Faulk, 1990). Added to this, they require comfortable ride at a fare which they can afford (Disney, 1998). The Federal Capital Territory (FCT) Master Plan is premised on sound mass transit system designed to link the city centre at different corridors. The bus system is also designed to provide access to the population, providing for a short

Oluwole, M. S. (2016). Spatial Pattern of Public Transport Access Points in the Federal Capital Territory (FCT), Abuja-Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1484-1491

distance between bus stops of approximately 500-700 meters interval and to be provided with adequate complimentary facilities. Despite the vital role public transport is able to play in an urban area, their services in FCT are frequently insufficient to meet demand and the services that they provide suffer from low output (Ali and Onokala, 2009) making them difficult to access by commuters. The public transport system in the FCT which cater for about 1.4 million commuters (Oniyangi, 2012) is facing numerous challenges despite the effort of Government to improve the system. Beginning from 2007, the traffic and commuting situations in Abuja appear to be reminiscent of the Lagos experience of the 1970's. It is common to see commuters walking over long distance to access public transport transit network, wait longer than necessary at bus stops and, when the bus eventually arrives, the transit time from trip origin to destination is unusually longer than usual and the fare paid is exorbitant for commuters who must make several trips per month. The FCT authority attempts to address the situation through expansion of the two-lane highway that lead to the city centre from the northern end (Kaduna-Abuja), South-Western (Abuja-Gwagwalada) and Eastern (Abuja-Keffi) to six-lanes. How much this has improved commuters' access to public transport in FCT has not been well documented. Murray (2001), opined that for the purpose of ridership forecasting and service performance evaluation, the concept of accessibility in transport planning often only refers to the assessment of transit stops and stations in terms of their catchments potential. There are usually no regards to the destinations and activities that the users can actually reach. The underlying assumption is that, access to the public transport network act as a proxy for access to a range of specific destinations (Kerrigan and Bull, (1992). Studies in this direction will not only help in mitigating the present commuting challenges, but will also form a reliable and objective information source for the transport operation and management, which the FCT Transport Policy admitted will be dynamic and could be subject to change as the city grows and as the commuting pattern is formed over time. It is in the light of the foregoing that this study focuses on the spatial pattern of public transport access points the Federal Capital Territory. This paper therefore answer the fundamental question of what is the average physical distance (in metres) from one public transport access points (public transport routes, bus stop or terminal) to the nearest one and what is the percentage of the total area (in sq/km) covered by the different buffers zones?.

MATERIALS AND METHODS

The Study Area

The Federal Capital Territory is located in the geographical centre of Nigeria. The objective was among others to move the administrative capital to a location that is centrally accessible to and from every part of the federation. The FCT falls within Latitude 07^0 25' N and 09^0 20' N of the equator and longitude 06^0 45'E and 07^0 39'E. With an area of about 8,000 sq/km of which 250 sq km is being developed as the Capital City site, the territory compares in land mass size with the states of Rivers, Enugu, Ondo and Osun while states like Anambra, Ekiti, Lagos, Imo, Akwa Ibom, Ebonyi and Abia are much smaller in size. It is bounded in the North by Kaduna state, on the West by Niger state, on the East and South by Nasarawa and South-West by Kogi state (Fig.1). As the extensive Territory is not intended to become one of the states of the Federation, it has been conceptualized and operationalized as the administrative territory of the country. The Federal Capital Development Authority (FCDA) was established in 1976 as a government parastatal to handle the design, construction and management of the Territory. The territory is divided into six area Councils to differentiate it from states with Local Government Areas. These include Abuja Municipal, Bwari, Gwagwalada, Kuje, Kwali and Abaji Area Councils.

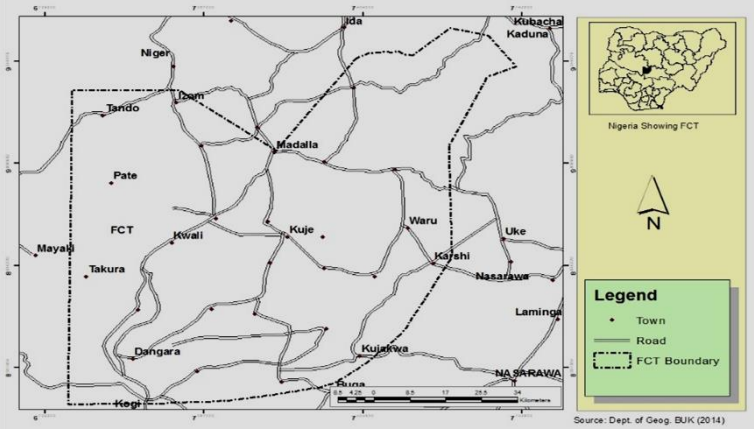

Fig. 1 the Federal Capital Territory

The Data Base

The google earth image was downloaded and stored; the image was zoomed to the lowest level (Scale 1:200) to ease identification of points and locations in the area. The image of the area was saved in JPEG format, while the control points were identified in the field using GPS Germin 76cxs during Ground Truthing Observations (GTOs). A database was developed and used in entering the coordinates of the ten selected control points for the locations of the Bus stops and terminals distributed within the study area. The saved image from the Google Earth was imported into the GIS environment and the selected controlled points were used for geo-referencing with each point registered individually. Image rectification was performed using the Geographical Coordinate Systems in GCS_WGS_1984 and the Datum of D_WGS_1984. Some slight modifications were made on the tie (coordinates) to ensure a good match with the ties on the existing map. This was done with a view to minimizing error during digital projection and transformations. Different symbols were used during the on screen digitization in an Arc GIS 9.3 operating environment. Three main themes namely: the road networks (lines), the built-up area (Polygons) and the bus stops (Points) were used having been initially typed in Microsoft Excel format was later imported into GIS environment. The database includes name of location, address, type of Bus stop and their locations (latitude and longitudes). Three different buffer zones were created in line with the World Bank (2000) guideline to identify areas that are within the different buffer zones and also run the Nearest Neighbour Analysis of the bus stops and terminals.

RESULTS AND DISCUSSION

The distribution of public transport routes, terminals and bus stops with respect to commuters' trip origin and destination are critical to commuter's adoption of the public transport system. The distance of commuter's trip origin and destination to the nearest bus stops/ transit highways is one important element that determines the level of access to public transport service. The spatial distribution of bus stops, terminals and bus routes in the FCT is presented in Fig. 2. The result of Nearest Neighbour Analysis (NNA) on the bus stop and terminal distribution shows a clustered pattern with the ratio value of (R) 0.317272 and the Z-score of -17.33. The significance level ranges between 0.01 and -2.58, implying that there is less than 1% likelihood that the clustering pattern could be the result of random chance. From this result it can be inferred that bus stop distribution within the FCT is not evenly distributed within the settlements and land uses. Some areas in the city centre like Wuse and Garki districts have high clusters of bus stops at short intervals because of the bus route which traverse them, other areas like Asokoro and Maitama have less density of bus stops, perhaps because it is scarcely a public transit routes.

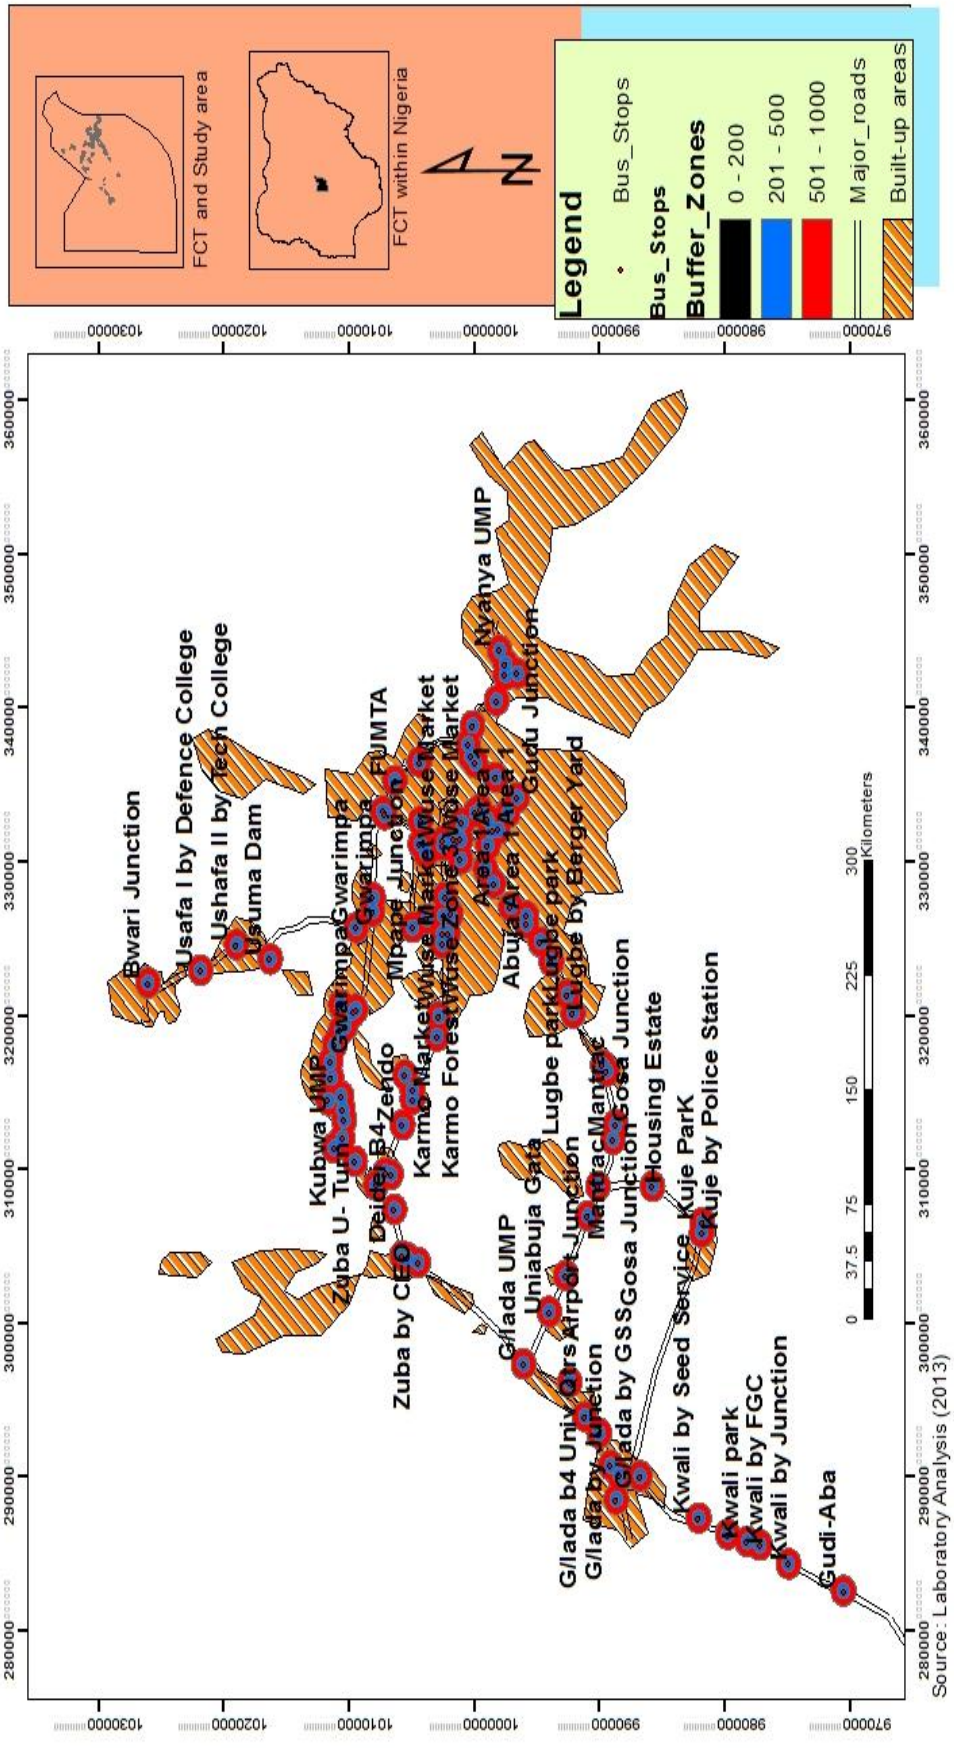

Fig. 2 Bus Stops Distribtuion and Buffering in The Federal Capital Territory

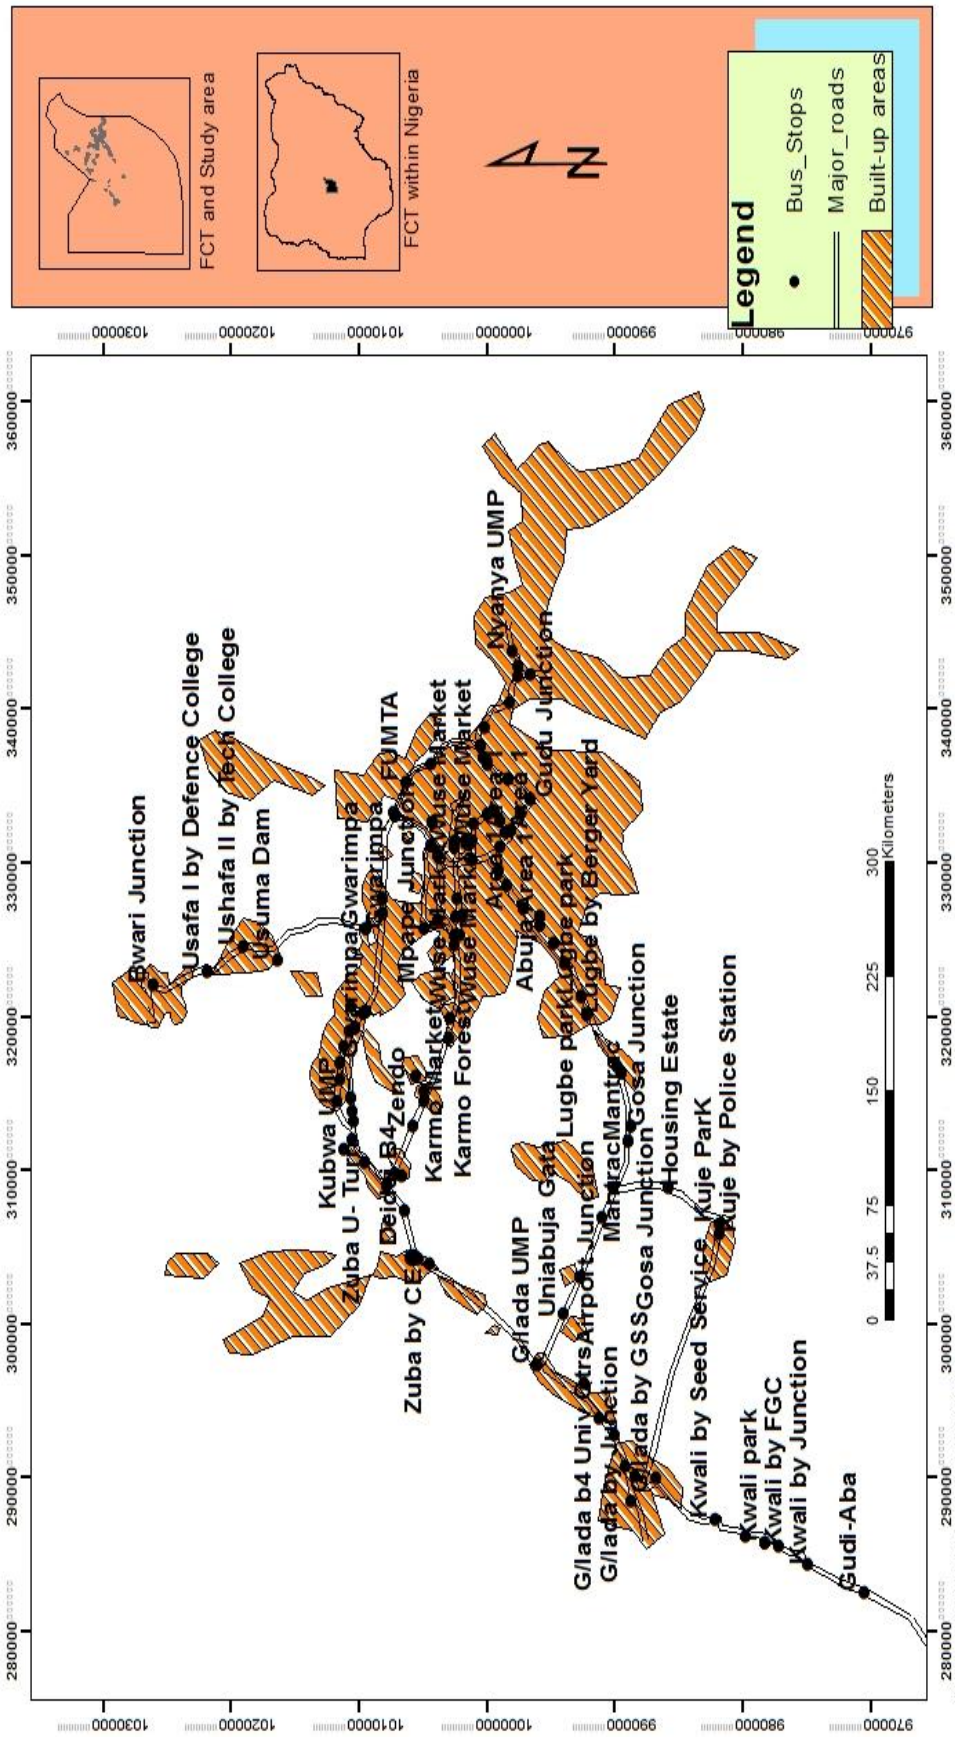

Fig. 3 Public Transport Routes and Bus Stops Distribution in the Federal Capital Territory

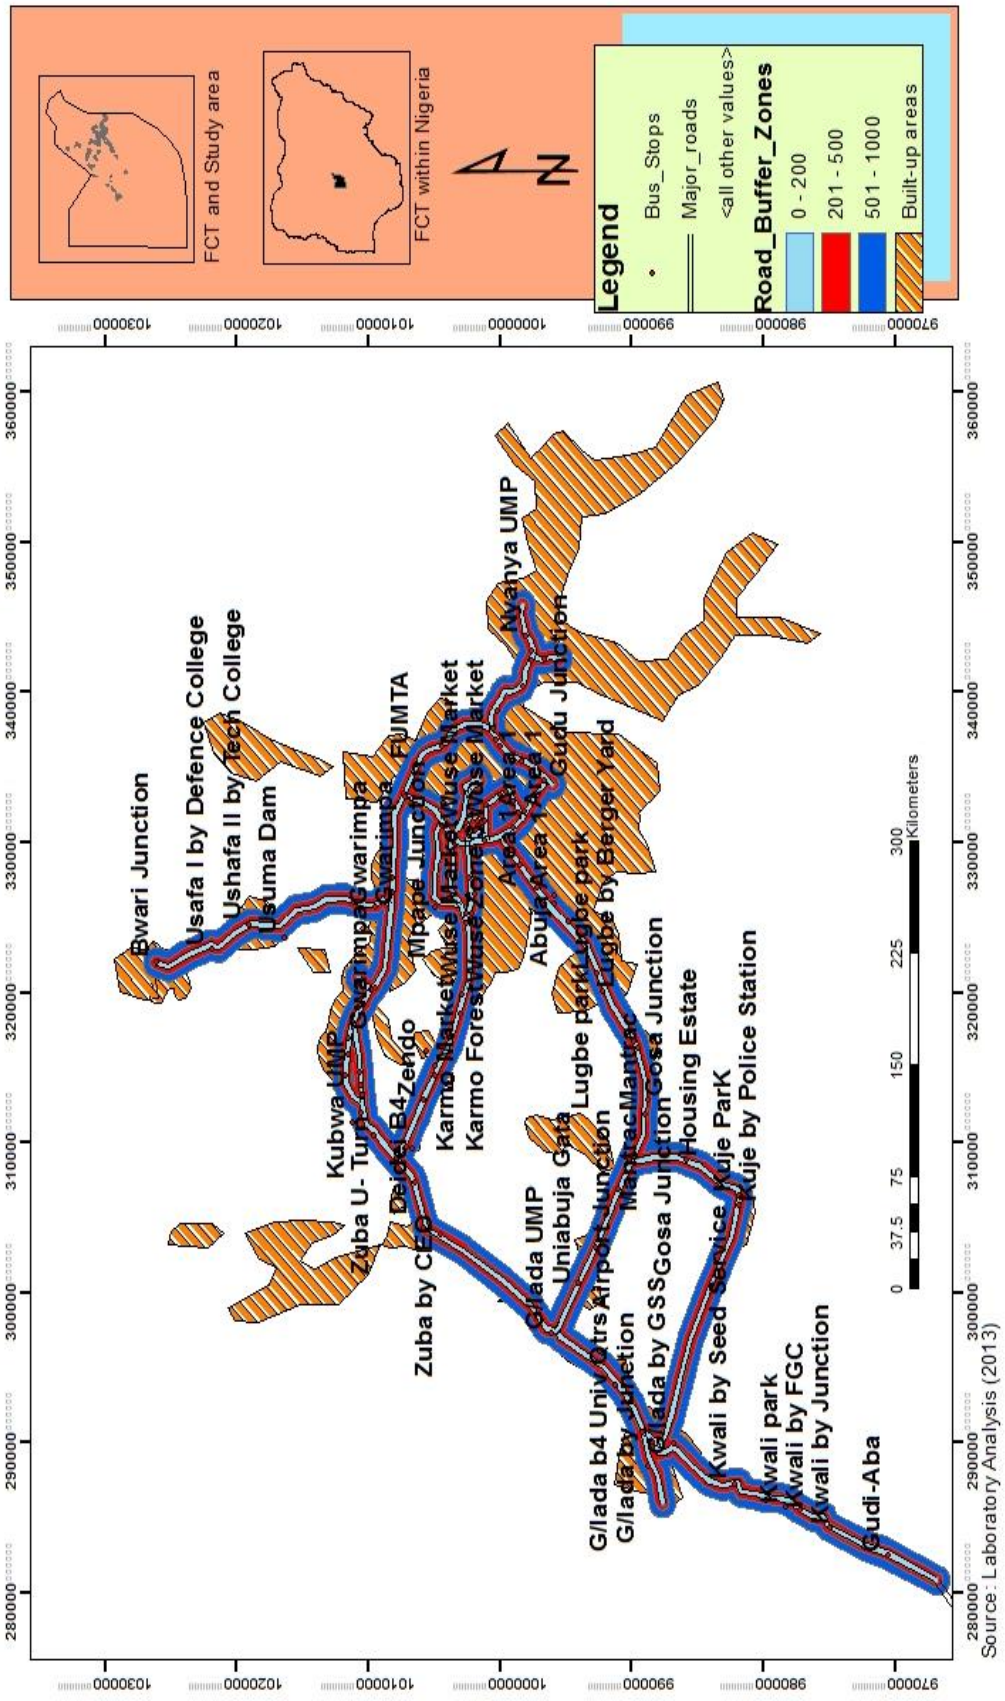

Fig. 4 Public Transport Routes Buffering in the Federal Capital Territory

It is therefore expected that commuters around the Wuse and Garki axis of the City centre will have shorter walking distance to bus stops public transport commuters around the Asokoro and Maitama districts will have longer distance. The evenness of bus stop distribution in satellite towns is worst because of the poor planning implementation and infrastructural provisions. These could create some disincentive to public transport usage. The geographical area in Kilometre Square (km/sq) served by the bus stops/transit highways relative to the size of total size of the settlements was investigated through buffering of the bus stops and transit highways as indicated in Table 1, Figures 3 and 4. Three buffers zone were generated in the categories of 0-200 meters buffers, 201-500 meters buffers and 501-1000 meters buffers based on world- wide averages for dense and less dense urban area (World Bank, 2000)

Table 1 Buffering Statistics for Bus Stops and Public Transport Routes

BufferZones (Metres)	**Bus Stops Area (KM^2)- A**	**% of A**	**Transit Highways Area (KM^2) - B**	**% of B**
0-200	17.529	3.3	62.204	14. 8
201-500	106.787	20. 1	148.974	32.8
501-1000	407.500	76.6	242.475	52.4
Total	**531.816**	**100. 00**	**453.653**	**100. 00**

Source: GIS Laboratory, Geography Department, BUK (2013)

The first category (0-200 metres) indicates areas with very good proximity or high accessibility to bus stops/transit highways, the second level 201- 500 meters buffer shows geographical areas with moderate accessibility to bus stops/transit highways while the third level of 501-1000 metres and above buffers depict geographical areas within the study area having poor access to bus stops and transit highways. Further discussion of the result in table 1 above indicates that about 17.529 sq/km or (3.3%) of the total geographical area of 531.816 sq/km has very good access to bus stops. About 106.787 km/sq or (20.1 %) have moderate accessibility and 407. 500 km/sq or (76.6%) have poor accessibility to bus stops. With respect to public transport routes, about 67.204 sq/km or (14. 8%) of the geographical area out of a total of 453. 653 km/sq have very good access to transit highways.

About 148.974 km/sq or (32.8%) have moderate accessibility while the remaining 242. 475 km/sq or (52.4%) have poor accessibility to transit highways. Generally, accessibility to bus stops and transit highways in FCT is relatively poor as 407. 500 km/sq or (76.6%) and 242. 475 or (52. 4%) of the of the study area have poor access to bus stops and transt highways respectively. Nevertheless, the accessbility level to bus stops in the study area is poorer.With respects to transit highways, about 67.204 sq/km or (14. 8%) of the study area have very good access to transit highways while, about 148.974 km/sq or (32.8%) have moderate accessibility and the remaining 242. 475 km/sq or (52.4%) have poor accessibility to transit highways.

CONCLUSION AND RECOMMENDATIONS

From the foregoing, it is safe to conclude that the distribution of public transport access points in the FCT is uneven and fall short of world standard, this can greatly influence access to public transport service in the FCT, because going by the World Bank standard (2000), no single location in FCT meets all the requirements for high level of public transport access. These findings therefore provide a strong basis for incorporating consideration of public transport accessibility to desirable locations of destination points into the FCT transportation planning and development programmes. In order to improve on the current level of public transport access points in the FCT, it is recommended that, there is the need to redesign a realistic public transport routes, bus stops and terminals across the study area in line with the reality of the current spatial pattern of the FCT. Such bus stops and terminals should be

provided with adequate complimentary facilities like shelters, seats and other infrastructures for commuters so as to ensure that women, children, aged and the physically challenged commuters do not find it difficult to use.

Problems and Prospects of Faecal Waste (Excreta) in Human Societies

Rotowa, O.O.[1*] & Gabriel, E.[2]

[1&2] Department of Urban and Regional Planning, Federal University of Technology Akure, Nigeria
[*] rotowa_2k@yahoo.ca

ABSTRACT

Excreta called faeces are surrounded by taboos, and this explains why attention had been toward its deleterious effects. In Nigeria there are no sewers, hence, sewage is collected through various conservancies and subsequently discharged untreated into rivers, lakes, and sometimes mingled with solid waste. This destroys aquatic life, facilitates the transmission of diseases and has significant economic impact in terms of working days and earnings lost due to ill health. Human excrement is a resource that could be harnessed to promote human livelihood and used as manure and as biogas energy. This paper explores the problems associated with excreta and the benefits that can be derived from it. The paper tries to view how excreta had been turned to profitable material in other parts of the world and how the huge waste generated daily in Nigeria can be recycled and used to enhance livelihood.

Keywords: Biogas, Diseases, Excreta, Faecal waste, Manure

INTRODUCTION

There are no human societies where the act of excretion and its products are not subject to public and private arrangements. Human excrement otherwise known as faces is a contagious waste due to its biological origin. Waste is defined as any unavoidable material resulting from domestic activity or industrial operation for which there is no economic demand and which must be disposed of (Shridar and Hammed, 2014). There are a variety of wastes, liquid or solid, emanating from human activities such as agricultural, domestic or industrial. Wastes may be biodegradable or non-biodegradable, otherwise, hazardous or non-hazardous. Among the liquid wastes, are sullage, sewage, livestock and industrial wastes. Faeces, indeed, is a solid waste. Up to 2008 which was declared as the year of sanitation, social scientist, sociologists, planners and anthropologists had paid little attention to excreta and excreting. In Nigeria, there are no sewers or underground drainage system, consequently, all liquid wastes find their way into water courses. Many public areas lack urinals and toilet facilities, while most schools are devoid of functional toilets.

Waste is generated in Nigeria at the rate of 0.43 kg/head per day and 60 to 80 per cent of it is organic in nature (Sridhar and Hammed, 2014). In the markets, a variety of wastes are generated which include corn cobs, vegetable wastes, packaging materials, etc. Household wastes contain materials such as paper, glass, metal, plastics, and biodegradable materials.Essentially, most of these wastes are not suitable for incineration because of low Carbon/Nitrogen ratio. Paradoxically, these wastes have been found to contain a lot of valuable resources. These include nitrogen, phosphorus, potassium and other chemicals which are useful for fertilizer. (Hammed *et al*., 2011 in Shridarand Hammed, 2014).

Excreta refers to urine and faeces. They form a major health risk due to the presence of pathogens in faeces and the mobility of nutrients and micro-pollutants in urine (Paterson, Mara and Curtis, 2007;Katukiza, Ronteltap, Niwagaba, Foppen, Kanslime, and Lens, 2012). Pathogens are reported to be of faecal origin (Ottoson and Stenstrom, 2003). Pathogens of concern and indicator organisms for faecal contamination include enteric viruses, helminths (internal worms), bacteria, protozoa and faecal streptococci together with *E. Coli.* They are present in wastewater and biosolids contaminated with faecal matter (Sidhu and Toze, 2009).

A child dies every 20 seconds due to lack of access to clean water and sanitation. That is, 1.5 million preventable deaths every year (United Nations, quoted in Jewitt S., 2012). The key

Rotowa, O.O. & Gabriel, E. (2016). Problems and Prospects of Faecal Waste (Excreta) in Human Societies. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1492-1497

cause of these deaths is exposure to pathogens associated with human excreta. About 50 percent of all people in Asia and Africa have no access to basic sanitation and 95 percent of sewage in cities of the developing world is discharged untreated into rivers, lakes and coastal areas, where they destroy aquatic life and reduce the potential of their ecosystems to support food (Watson and Zakri, 2012).

In addition to fouling the environment, it facilitates the transmission of diseases such as typhoid and cholera, thus, having a significant economic impact in terms of the cost of medical care plus working days and earnings lost due to ill health and tourism (WaterAid, 2009). On the economic cost of poor sanitation, it is estimated that every dollar invested in sanitation improvements "generates an average economic benefit of $7" whereas, the economic cost of inaction is astronomic (United Nations, UNDP, 2008).

Nigeria is presently experiencing shortage of electricity, which in most cases is erratic. This is against the backdrop of the fact that most farmers depend on chemical fertilizers for agricultural production. At a population growth rate of 3.18% annually, the collection and treatment of excreta and urine (human waste) is presently a problem. This paper emphasizes that human excreta can be utilized economically for agricultural fertilizer and in the production of biogas as alternative renewable energy. The objectives of this paper therefore are, to highlight on the common types of toilet facilities used in human societies; prospects of human waste; collection and treatment of faecal waste/sludge; and on how human waste is used as a source of energy in many parts of the world.

METHODOLOGY

The methodology is on the review of relevant literature on the.problems and prospects derivable from faecal waste. The study started by considering methods for the collection and treatment of faecal waste. This was followed by considering the prospects of faecal waste. The third aspect of the study, considered how filth can be transformed into fertilizer based on the properties of excreta. The next section was on converting excrement to energy at small and commercial scale. The paper having considered the advantages that other nations had derived from excreta, recommended that Nigeria and other developing countries should treat excreta as a resource.

RESULTS AND DISCUSSION

Collection and Treatment of Faecal Waste/Sludge

In Nigeria, the data from WHO and UNICEF, (2013) showed that the proportion of households with sustainable access to adequate sanitation is about 33%. It implies that around 70% population does not have access to a safe, hygienic, comfortable sanitation that can keep the user and the surrounding environment from contact with human faeces. The system of managing sludge and wastewater in Nigeria is on-site, which include pit latrines, personal septic tanks, pour flush toilet and ventilated improved pit latrine (VIP). Inadequate and poor condition of sanitary facilities expose the people to environmental and health problems. The absence of good water supply and good sanitation predisposes people to ill-health and water- and excreta- related diseases (Evans and Mara, 2011). Not having household-level sanitation facilities means that women and girls are at risk of violence (assault and rape). Particularly when they go out at night, to a communal sanitation facility or to defecate in the open. This affects the personal dignity of women and girls (Evans and Mara, 2011). In addition, women are exposed to 'restricted toileting' which increases the chance of urinary tract infection and chronic constipation as well as causing psychological stress.

Poor sanitation and poor water supply cause disease and death. WHO estimated that poor hygiene, poor sanitation and poor water supplies caused 4% of all deaths in the world and were responsible for 5.7% of the total global burden of disease in 2001. Infant Mortality Rate (IMR) means the number of babies dying before their first birthday, while (U5MR) is the number of children who die before their fifth birthday expressed per 1000 live births. In industrialised countries, the IMR was $5^{0/00}$ and the U5MR $6^{0/00}$ in 2008 (Evans and Mara, 2011). The corresponding figures for developing countries were $49^{0/00}$ and $72^{0/00}$respectively. The main reason why such disparity exists is inadequate sanitation and water coupled with poverty. On account of poverty, people have poor sanitation and water supply, and insufficient food, thus, has a high incidence of excreta- and water- related disease. The major effects are diarrhoea, which kills around 400, 000 adults and norovirus around 200, 000 under 5 yearly. Coupled with the diseases mentioned is stunting or low height for age. Though a manifestation of malnutrition, it is exacerbated by diarrhoea, and further affects a child's verbal fluency, short term memory and speed of information processing (Evans and Mara, 2011).

The World Health Organization (WHO) and United Nations Cultural and Education Fund (UNICEF) JMP (2012), report that the sanitation coverage worldwide in 2011 was 64%. They concluded that the world is not on track to meet the Millennium Development Goals (MDG) sanitation target of 75%, and if current trends continue, it is set to miss the target by more than half a billion people. By the end of 2011, there were 2.5 billion people who still did not use an improved sanitation facility. Though, the number of people practising open defecation decreased to a little over 1 billion, but this still represents 15% of the global population(WHO and UNICEF, 2012). In the developing countries Nigeria inclusive only a minorityis served by piped sewerage systems.

In the advanced countries where water supply and excreta disposal imply pipes beneath the street, this is an advantage. In the context of the developing countries, a fundamental difference can be observed. Water supply means a tap in the street or a pump in the village square, clearly in the public domain. Sanitation on the other hand, means a toilet with an on-site disposal system. Usually, part of the owner's house, built on his land, at his expense and frequently with his own hands. Its use requires a change in some very intimate habits, in the privacy of the home, by all members of the family (Cairncross and Feachem, 1993). Indeed, sanitation facilities are unlikely to be used, still less maintained, unless people want them. As observed by Cairncross and Feachem (1993), health improvement does not motivate many people to install a latrine. Rather, social status and the desire for privacy and convenience are usually the motivating factors. Also, the design criteria for toilets should be a function of the price which the people are willing to pay. Furthermore, new toilets should be a modification of an existing practice or type of latrine. In addition, there must be 'after-installation' services if the technology is to be sustainable.

Pit latrines are the dominant type of excreta disposal facilities in Africa, Asia and Latin America (Mugo, 2006and Katukiza, 2012). The type of pit latrines that are common, includes the traditional ones which are made of wood poles and mud as well as the ventilated pit latrines (VIP). Unlined pit latrines are usually elevated where a high water table exists. In most cases, pit latrines that are available are shared by many households due to high population density and limited space.

The main advantage of the pit latrine is that it does not require water for its functionality. In addition, it can be built and repaired with locally available materials. It also has low capital, operating costs and can be modified to serve user preferences (squatting, anal washing and wiping). Infiltration of the liquid phase into ground water and overflows during the rainy

season from excreta collection chamber have made pit latrine a major cause of ground water pollution (Kalubako*et al,* 2012). Factors that are likely to increase the risk of contamination are: a high level of the water table and flooding during the rainy season as well as poor drainage (Katukiza, 2011).

The major challenge in the usage of pit latrine is the high-user-load and filling rate. Since the municipal councils and the landlords are not held liable for evacuation, the tenants are responsible. The problems are further compounded by lack of accessibility for vehicles coupled with the fact that tenants are not willing to pay for the services of vacuum/vehicular evacuators. In essence, local night –soil and local contractors manually empty the pit latrines. This they do by making a hole in the side wall of faecal sludge chamber. This method poses health risks to the workers and there is no control over the place where the evacuated materials are disposed.

It is therefore suggested that where the pit latrine is to be used, a prefabricated floor should be provided. This is to be in addition to squatting slab or with a seat. This provides the following advantages: the latrine will be structurally safer. Secondly, it will be easier to clean. Also, using the footrests,it will be easier for users to position themselves over the drop hole, so as not to foul it. In addition, the drop hole should have a dimension that is too small for a child to fall into, and is safer and less frightening. The floor should be cemented, this will prevent hookworm transmission. Finally, the toilet should be designed such that it permits a small measure of fly control, through the use of a tight-fitting lid (Cairncross and Feachem, 1993).

For the affluent in developing countries, the flush toilet is used. It is connected to a septic tank that receives grey water that collects and treats the sewage. This system requires water to transport the waste in pipes to a septic tank where it undergoes anaerobic treatment. Depending on the loading rate and effluent discharged into the soak away, it takes about 3 – 4 years to be filled. The effluents from the septic tank are thereafter discharged into a constructed wetland, where they are available. Otherwise, they are discharged to landfills or on open fields far away from settlements. Due to the absence of centralized sewerage, this technology is becoming popular, particularly by the minority with houses that have water connections. In addition, they have the ability to pay for the water, high cost of construction materials and have space for the septic tank and soak away (Katukiza*et al*., 2012).

In recent times, community sanitation blocks using flush toilets and a septic tank are used in urban areas of India and Africa (Mara and Alabaster, 2008). However, their sustainability requires the strengthening of the legal and institutional framework for planning, implementation, operation and maintenance (Katukiza*et al*., 2012).

Prospects of Human Waste

Historically, there has been a long association between excrement and money (Laporte, 2000). This had resulted in widespread "human ambivalence to bodily waste and discontinuity in systems for dealing with them (Laporte, 2000). Invariably, this had succeeded in tempering human attitude towards excreta. Excreta, a combination of human faeces and urine contains nutrients such as Nitrogen (N) – 12g; Phosphorus (P) – 2g; Potassium (K) -3g; Organic Matter – 90g. In addition, between 70 – 80% of the components of urine are Nitrogen (N) and Phosphorus (P) (Herrera, 2003). Except for children, an adult excrete the same amount of nutrient that is taken in, in their diet. This amount, by one person is the same as the amount that is needed as fertiliser to grow the food for that person (Jewitt, 2011). These nutrients are beneficial on land as a soil conditioner and land stabilizer. In spite of the enormous advantages derivable from faecal waste, many still show apathy to it.

Transforming Filth into Fertilizer

A normal stool is 75% water and 25% solid. The colour is brown because of stercobilin and urobilin that comes from bilirubin. The odour is aromatic upon defecation due to indole and skatole products of fermentation and putrefaction in the large intestine. Urine on the other hand, in acidic in term of pH. The colour is amber/straw and it is aromatic upon voiding (Herrera, 2003). In general, the apathy people show to excreta is because of health hazards associated with its improper disposal. Such hazards are: soil pollution, water pollution, food contamination and propagation of flies. The application of excreta to agriculture has been part of agricultural tradition in countries in South Asia like China and Vietnam. There, farmers perceive latrine waste as valuable fertilizer despite the potential health risk and exposure to helminth worm infection. That Human excretions as the best possible fertilizer was first expressed in Pliny's Natural History, Book xxvi (Laporte, 2000 quoted in Katukiza, 2011).

It was about the fourteenth century that attention of scholars was drawn to the relevance of excreta as a resource. An epoch making era was "the symbolic equation of money and shit with the translation of 'Opus ruralism commodorum (1307)' into French in 1532". The work was titled "nuffits comestres et ruraulx". Furthermore, in the nineteenth century, the 'hygienist's movement' in France, rediscovered the value of human waste as a fertilizer (Katukiza*et al.*, 2012). By emphasizing its superiority, they urge agricultural communities to incite growers on the national use of human secretions in their most natural state (Bertherand, 1858, as quoted by Laporte, 2000). In 1918, the discharge of disinfected sewer and cesspit waste out of public streets was denounced by hygienists for squandering a precious resource (Laporte, 2000). In using human excreta as fertilizer, the guiding principles are firstly that, it is the soil that is being fertilized not the plant. Secondly, excreta product should not be used on plants directly, but on the soil in which the plants are grown. Thirdly, urine should be applied in a furrow about 10 cm away from the plants. When properly applied, N. P. K., in human faeces improves soil structure, increases the water – holding capacity and ion-buffering capacity of the soil, and it supports soil microorganisms by serving as an energy source.Finaly, in regions where people are worried about eating food fertilized with human excreta, it can be used for other purposes such as trees, flowers, potted plants, fibre-producing plants and oil-producing plants(e.g. Olive trees).

Converting Excrement to Energy

Human waste is aesthetically unpleasing in terms of odour, and potentially harmful because of the presence of pathogens. Human waste is used as a source of energy in many parts of the world, the global north and south (Jewitt, 2011). For instance, Biogas was used as long as 10 BC to heat bath water in Assyria (Li and Mae-Wan, 2008 as quoted in Jewitt, 2011). Biogas was first produced using anaerobic digester from waste in a leper colony in Bombay in 1859 (GTZ, 2010 as quoted in Jewitt, 2011).Considering the ease of the process and no starter (micro-organism seed) needed in the process of biogas generation, human excreta has similar potential in biogas generation compared to the cattle manure. Human excreta contains: Potasium (8g/kg); Dry mass (216g/kg); nitrogen (11g/kg); phosphorus (4g/kg); moisture content (78%); dry matter content (22%) and pH (7-9). The population of Nigeria is about 170 million presently, with such a high population coupled with a growth rate of 3.12%, she ought to be able to utilize excreta to generate alternative energy. The problems regarding converting human excreta to biogas, include the technology itself and socioeconomic problems in Nigeria.

Methane derived for Biogas is used for A variety of purposes that include cooking and heating gas, electricity, vehicle fuel, and 'mains' gas when processed and introduced into a natural gas pipeline (Jewitt, 2011). In addition, the methanol derived helps to prolong the

storage of fruit and grain by inhibiting metabolism and killing harmful insects, moulds and bacteria (Mae-Wan, 2008 as quoted in Jewitt, 2011).

In term of energy production, China has been in the forefront since the nineteen century, by using Biogas digesters for energy production (Mae-Wan, 2008 as quoted in Jewitt, 2011). As a broader waste management strategy, Biogas units are linked directly to farms, sewage and municipal waste streams (Guardian, 2008). In China, anaerobic digestion is used for managing sewage and livestock waste which currently pollute over 10 million hectares of farmland (Mae-Wan, 2008).

In developing countries, household energy shortages can be addressed through a small scale biogas derived from human and or animal waste thus, providing an alternative to wood or other biomass fuel (Jewitt, 2011). This is particularly important in areas where deforestation is a problem, and the collection of wood fuel is an increasingly difficult and tiresome task. As observed by Mae-Wan (2008), 10 m^3 biogas digester can save 200kg of fuel wood, which is equivalent to reforest 0.26 – 4 ha. The drudgery, of collecting biomass fuel and the 'indoor' pollution can be ameliorated by burning dung-derived biogas as a cooking fuel (Venkataraman, Saga, Habib, Lam, & Smith, 2010).This is because biogas burns without smoke. In essence, women and children are the main beneficiaries of biogas adoption, as they are freed from the hazards and discomfort of cooking over smoky fires, cleaning smoke-blackened cooking pots and disposing animal dung (Shalaja, 2000 as quoted in Jewitt, 2011).

CONCLUSION

The utilization of human excreta for fertilizer and biogas can provide benefits in the areas of environmental and alternative sources of energy. Considering the threat Nigeria faces with her population of about 170 million and a growth rate of about 3.18% the potency of this neglected resource can only be imagined. This technology had been used by countries like China, India, Indonesia, it had proven to be clean and sustainable.

Periodic Market System and Development of Rural Economy in Ijesa Region, Osun State, Nigeria

Faseun, J. O.[1] & Omole, F. K.[2*]

[1&2] Department of Urban and Regional Planning, Federal University of Technology Akure, Nigeria
[*] fkomole@yahoo.com

ABSTRACT

This study examines the impact of periodic market system on rural economic development of Ijesa Region with the view to recommending a policy framework that could enhance the system to accelerate rural economy, growth and development in the region. The region, made up of six Local Government Areas (LGAs), is located in the south-western part of Nigeria. However, the study concentrated on Atakunmosa East, Atakunmosa West, Obokun and Oriade LGAs which are the four rural and semi-urban LGAs of the six LGAs. The remaining two LGAs (Ilesa East and Ilesa West LGAs) are urban; being located within Ilesa Metropolis. Primary and secondary data were collected and complemented with Focus Group Discussions (FGD) and physical observations for the study. The research frames were the periodic markets, the patrons of the market (i.e., the traders and buyers) in the study area. The research instrument used was a three-part structured questionnaire; with Section A generally administered on the patrons of the markets, Section B specifically on the traders and Section C specifically on the buyers. Inventory Schedule for the survey of the periodic markets and Discussion Schedule for Focus Group Discussions were also prepared and utilised. The ten per cent (10%) of the periodic markets and five per cent (5%) of the 487 settlements in the region were randomly sampled for the surveys across the four LGAs. In each sampled market, one in every five traders and one in every five buyers were sampled for survey. The collected data were processed using the Statistical Package for Social Sciences (SPSS) computer software. The result shows that there were differences between in the involvement in periodic market centres and the level of the people's contributions in the market system in the region. This study affirmed that the local economy was being strengthened through the operators of periodic markets in the region. The study recommends a better organisation of the markets and improvement of infrastructural facilities like roads, electricity and potable water to checkmate rural-urban migration which is a bane of rural economic development in the region.

Keywords: Periodic market, rural Economy, rural infrastructure, Ijesa Region

INTRODUCTION

Trading activities are fast replacing agricultural activities as major rural income generating activities in the developing countries [Food and Agriculture Organisation (FAO), 1978; 1998; Goldman, 2000; Lanjouw & Lanjouw, 2001; Reardon, Barrett & Webb, 2001; Haggblade, 2007]. Although a sizeable portion of trading activities has connection with agriculture, trading dominates sources of rural income and its contributing immensely to rural economic development (Faseun, 2014). Many of the trading activities take place in market places on either daily or periodic bases. However, substantial numbers and types of trading activities take place in periodic markets especially in the rural communities. Patronage of periodic markets play significant role in the economy of the rural areas.

Periodic markets are usually arranged in a ring form within close communities in such a way that the major markets in the major settlements within the connected communities are patronised within one or two period. Traditionally, between five and seven major settlements connect to form a market ring (Omole, 2012). Thus, we have markets operating every fourth, fifth or seventh day of the week in the traditional Yoruba communities. However, modernisation has brought in fourteenth-day and monthly market circles in many parts of Yoruba Region. The actual idea behind periodic market is to give enough room and time for local production to build up, so that producers and marketers would have sufficient products to exchange during the market days (Omole, 2014).

Faseun, J. O. & Omole, F. K. (2016). Periodic Market System and Development of Rural Economy in Ijesa Region, Osun State, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1498-1506

Aim and Objectives of the Study

The aim of this study is to examine the periodic market system and its impact on rural economic development in Ijesa Region. To achieve this, the study identified the periodic markets in the study area, categorised the market centres into hierarchical market order, examined the contributions of the markets to the development of the region, examined the hindrances of the periodic markets and assess the impact of the contributions to the rural economy in the region.

The Study Area and Scope of Study

The study was conducted in Ijesa Region located in Osun State, South Western Nigeria. It lies between Latitudes 7^0 17"North and 7^0 50" North of the Equator and Longitudes 4^0 33" East and 5^0 10" East of the Greenwich Meridian. The area falls within the humid tropical region characterised by high temperature and heavy rainfall. The terrain is gently undulating lying roughly between 170 metres around River Oni Valley and 700 metres above Sea Level in the eastern borderland with Ekiti and Ondo States.

Much of the landscape is dotted by steep inselbergs usually referred to as 'Yoruba Hills' particularly towards Ondo/Ekiti boundary. The soils are largely a mixture of sands and high percentage of clays on the surface, under-laid by grey granite in different proportions from one part of the region to another (Peel, 1983; Ekanade, 1984). This makes the area fertile for agricultural practice. This subsequently accounts for the abundant availability of variety of agricultural produce and products at low prices which consequently attract people from far and near to the periodic markets in the study area. The natives are called the 'Ijesas' who are renowned dexterous traders found across Nigeria.

This study is rural area-focussed and case-specific. Therefore, the two City-local government areas in Ijesa Region (Ilesa East and Ilesa West LGAs) were excluded; leaving four Less-City local government areas of Atakunmosa East, Atakunmosa West, Obokun and Oriade which are basically rural and semi-rural (Olayiwola & Aguda, 2009) [Figure 1]

The study identified the periodic markets and rural income generating activities in the study area and assessed the interaction of the activities and the markets and their impacts on rural economic development in the region.

RESEARCH METHODOLOGY

Primary and secondary data were collected and complemented with Focus Group Discussions (FGDs and physical observations for the study. The research frames were the periodic markets, the operators of the market (i.e., the traders and buyers patronising the markets) in the study area. The research instrument used was a three-part structured questionnaire; with Section A generally administered on the operators of the markets (traders and buyers), Section B specifically on the traders and Section C specifically on the sellers. Inventory Schedule for the survey of the periodic markets and Discussion Schedule for Focus Group Discussions were also prepared and utilised.

Ten per cent (10%) of the periodic markets and five per cent (5%) of the 487 settlements in the region were randomly sampled for the surveys across the four LGAs. In each sampled market, one in every five traders and one in every five buyers were randomly sampled for survey. The collected data were processed using the Statistical Package for Social Sciences (SPSS) computer software.

LITERATURE REVIEW AND CONCEPTUAL ISSUES

Rural development is concerned with household income, resource allocation, poverty, and access to basic needs such as health, education and food security. De Janvry, Sadoulet and

Murgari (2002) aver that the heterogeneity with respect to these issues among rural households is germane for the design of rural development strategies. For example, while households that derive their main income from farm activities can benefit from improved agricultural technologies, landless rural households that diversify toward the non-farm sector would generate greater welfare from policies that improve such employment opportunities.

Some scholars see rural development and regional development as synonymous while some separate them. United Nations Development Programme (UNDP) always mention them separately but discusses them together. One of its departments is tagged *Rural and Regional Development Department* which sees rural development and regional as inseparable; and, therefore, has a common comprehensive approach to rural and regional development at the local level by improving local government capacity to plan, identify priorities and deliver results; stimulating economic recovery through entrepreneurial activity, job growth and investment, increasing the competitiveness of local producers and income generation; strengthening local priority infrastructure; delivery of social services to vulnerable populations, and the sustainable use of natural resources and energy efficiency (UNDP, 2012). Rural development is concerned with improving the livelihoods of the population and especially the poor rural households (Datonjo and Chikagbum, 2015).

Omole, Lukman and Bako (2014) described a market as an authorised public gathering of buyers and sellers of commodities meeting at an approved place at regular intervals. Geographical space in a region is an amalgamation of a number of subspaces within the region (Johnson & Wanmali 1981). One of the many ways in which geographical space is divided for the provision of rural services, especially in the developing countries, is through the existence of periodic markets. Marketing, which is the backbone of economic activities, takes place at market centres where goods and services are traded. They are also places of social and cultural exchange.

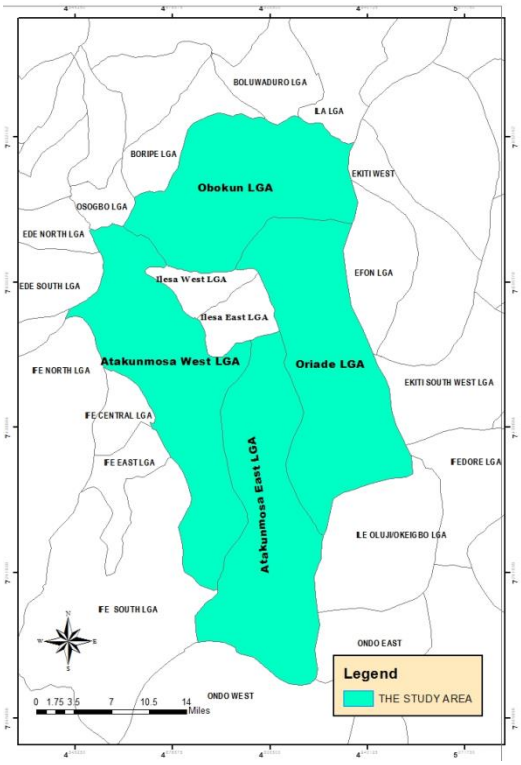

Fig 1: Digitized Map of Ijesa Region Highlighting the Four Rural/Sub-urban Local Government Areas that Constitute the Study Area
Sources: Osun State Ministry of Lands, Physical Planning and Urban Development, Osogbo, 2015.

Market place is the most ideal place for exchange system of goods and services particularly in agricultural societies and market system has come to be accepted as an axiom in modern geography for depicting the regional personality (Singh, 1980). To achieve sustained growth and transformation of rural sector, the market should be capable of handling increased production of commodities. Market place is one of the base and fundamental aspects in marketing geography and performs its predominant role to keep the marketing activities in a dynamic manner by arranging different spatial units into a place. Market centre performs numerous functions not only for the rural but also in the urban areas. With the growing size of market, it becomes more complex and differentiated by increasingly multifunctional process.

Periodic Market system is an arrangement of repeated movement of traders nearer to their customers. Bharathi (2000) asserts that the traders can carry out more efficient trading activities than infrequent movement of individual customers to a permanent market place. A periodic market is a trading market held on one or more days of each week and, most times, on the same days of the week. The market days are at regular intervals. Periodic markets bring extra shopping opportunities to rural residents.

Rural periodic market centres is one way through which development from grass root could be encouraged. Therefore, the role of market is very significant in the enhancement of economic activities for the development of regions. The rural people largely depends upon periodic markets for the sale transactions of agricultural and non- agricultural commodities that takes place in a retailing process at regular interval of a given time and place. These markets are responsible for establishing the links between its surrounding areas and paved the way for establishing the grass root level networking of trade systems throughout the developing world.

The rural markets provide an employment to the workers of unorganized sector and source of livelihood for itinerant traders who purchase the agricultural commodities from different places to sell in periodic markets (Eighmy, 1972). In the chain of production, processing and distribution of goods and services, the market centre has definite role to play as an outlet and inlet centre. Thus, the market centre performs this function for itinerant traders who purchase the agricultural commodities from different places to sell in periodic markets (Eighmy, 1972). The market centres also perform the function of service centres, helping in increasing the socio- economic and political contacts in the vicinity. However, the functions of markets, especially, periodic markets are largely dependent on the threshold population and the location, administrative character and road links between the market and its hinterland.

FINDINGS AND DISCUSSIONS

Findings from the study are presented and discussed below.

Analysis of Market Centres in Ijesa Region

Market centres are major land use and have contributed significantly to the economic and physical development of Ijesa region. Of importance is in the area of land development, employment generation and provision of goods and services among others. Paramount to this study are the types of markets, their spatial distribution and their hierarchical order in the study area.

Market Days and Market Periodicity and their Economic Distributions

Two most popular types of market discovered in the study area were the ‘daily markets, and the ‘periodic markets’. The daily markets hold everyday while the periodic markets hold at

intervals of days. The periodic markets days are arranged in a way that no market day within the same area falls on the same day. The idea behind this, as gathered during field survey, is that market patrons will be able to enjoy activities of each of the markets in the region, if they choose to patronise all the markets in the region. By this arrangement, a sort of 'market ring' is established. For instance, the Atakunmosa Market which is one of the biggest markets in the region comes up at 14 days interval. Within this period, other market centres like the Ijebu-jesa Market (in Oriade LGA) which is a 3day interval/periodic market takes place, while others like the Owena-Ijesa Market in Oriade LGA holds on a several other day. The same pattern of arrangement is found across the region.

Table 1 presents the number of major markets in each of the LGA in the study area. Apart from the fact that some of them make provision for daily needs, hardly would their periodic date conflict with other markets within the immediate and close communities within the region. By this arrangement, 'market rings' are formed for the benefit of all the market patrons and shoppers in the region and even beyond. Interestingly, there is no day a market will not be in operation in the region.

Table 1: Distribution of Periodic Market Centres in Ijesa Region

Local Government Area	Observed Number of Major Market-centres
Atakunmosa west	8
Atakunmosa east	9
Obokun	11
Oriade	3
Total	**31**

Apart from the numbers of market centres listed in table 1, there are other numerous market centres located in rural areas that contribute significantly to the rural economy of the area. Apart from the periodic markets, other non-periodic markets and of different hierarchies are always in operation. It was also discovered that the market centres in fairly big settlements like Ijebu-jesa and Ipetu-Ijesa (both in Oriade LGA) operate as daily markets as well as periodic markets.

Hierarchical Order of Market centres in the Study Area

Settlements were of different hierarchy in terms of land coverage, population, economic activities among others. The pattern of distribution also varies from one local government to another based on the morphology and historical antecedent of the towns. Hierarchically, markets in the study area fall into different hierarchies. Three distinct market orders were identified and categorised. The first order is made up of market centres in the local government headquarters while the second order is made up of market centres in other fairly big settlements. The third order consists of the rural market centres (Table 2 and Figure 2)

The three hierarchies vary in their catchment area, threshold population and the range of available goods and services. The Atakunmosa Market in Ilesa region stands as a rallying point for all other markets within and outside the region. The first hierarchy in the study area is made up of the main markets located in the LGA headquarters of Iperindo, Ijebu-jesa, Ibokun and Osu. The second order markets are located in other fairly populated settlements that are not LGA headquarters. The settlements are Ipetu-Ijesa, Owena-Ijesa, Ifewara, Imesi-Ile, Esa-oke and Okebode. All the other market centres in different village/settlements constitute the third hierarchy (Table 2 and Figure 2). The settlements include Itagunmodi, Iwara, Ilare, Ibodi and Ilaa as shown in Table 2.

Figure 2 shows the distribution of goods in the market system in the region. The market setting operates as a system in which the high order goods (mainly finished goods, 'polished rice' clothing materials, agricultural chemicals, building materials among others) flow from

the 1st order market centre to the 2nd and 3rd order market centres. In like manners, agriculture produce flows from the 3rd order market centres to the 2 and 1st order market centres (Figure 2). The flow of goods in this manner keeps the market system running and impacted on the economic development of the state and beyond. This aids food production, supply of raw materials to feed the local industries and also creating jobs and employment opportunities among others.

Table 2: Market Hierarchy in Ijesa Region

Order/ Centres	Names of Market	LGAs
First Order	Ijebu-jesa	Oriade
	Iperindo	Atakunmosa East
	Ibokun	Obokun
	Osu	Atakunmosa West
Second Order	Ipetu-Ijesa	Oriade
	Esa-oke	Obokun
	Owena-Ijesa	Oriade
	Ifewara	Atakunmosa East
	Imesi-Ile	Obokun
	Okebode	Atakunmosa West
Third Order	Itagunmodi	Atakunmosa East
	Iwara	Atakunmosa East
	Idoka	Obokun
	Ilare	Obokun
	Ibodi	Atakunmosa West
	Ilaa	Atakunmosa West
	etc.	

Hindrances to the Viability of Periodic Markets in the Study Area

The major problem militating against the existence of the periodic markets is that of bad state of roads and poor road connectivity. It was discovered that some of the market centres do not have direct motorable roads linking settlements where market centres are located. This is costly in terms of cost of travel time, time involvement on trips and delay. Due to poor road condition, motorcycles were found to be the major mode of transport to most of the rural markets in the study area.

Another problem is that of unplanned market spaces. Traders and shopper are found displaying their wares in bare floor, while buying and selling are going on in the open air under rain and sun. Store, stall and lock up shops are non-existent in virtually all the third order market centres.

It was also discovered that the threshold population could not sustain the existence of many of the markets. Findings reveal that cultural and historical arrogance was responsible for this type of situation in that each of the sub-regions wants to carve out an empire for themselves without considering the threshold population that will support the demand for the products from the markets.

Contributions of Periodic Markets to the Development of the Rural Economy of the Study Area

Findings show that market centres in the study area have contributed in the following ways:

i. Provision of jobs and employment opportunities for the local populace as farmers and traders in the market centres.
ii. The periodic market brought people from outside the vicinity in which the markets are established, thereby boosting the economy of the area.
iii. Similarly, periodic markets improved cross-fertilisation of ideas from other settlements.

iv. It has also enhanced the flow of goods both inward and outward of the market location such that, what cannot be produced is brought in from another location and the surplus from one area is taken to other areas and lastly
v. It has alleviated poverty among dwellers in the region.

RECOMMENDATIONS

This study recommends that regrouping of villages should be carried out to form 'Local Economic Development Areas' each with one "Central Rural Periodic Market" to be established and managed by the relevant Local Government Authorities. Factors for the regrouping should include socio-cultural affinity and compatibility as well as road connectivity, market connectivity, among others. The Local Government authorities should

be involved in designing and development of rural periodic market using their Urban and Regional Planning Department and Works Department.

There should also be mass rural road development by government. The region is well connected with access roads; but most of the roads are rough and unmaintained by the relevant government authorities.

More periodic markets, which should be regional markets, should be established at Ijebu-jesa in Oriade LGA, Oke-Ibode and Osu in Atakunmosa Local Government Area and Iperindo in Atakunmosa East Local Government Area (Figure 3).

The existing Owena-Ijesa Regional/Periodic Market in Oriade Local Government Area should be relocated to Iyana Reserve – some 2 kilometres to its present choky site towards Ikeji-Arakeji. Figure 4 depicts the Proposed Development Plan for the market at proposed new site.

ABSTRACT

This study investigates Akure urban land use change detection using GIS and RS devises. Efforts were made to examine the direction of which the continuous expansion of the city tends towards. Using Aerial Imagery Overlay (AIO), the pattern of land use changes in Akure and its environs were determined. It focuses on imageries interpolation and overlaying to determine the land use changes, direction and extent of the expansion during the study period. Findings revealed unguided expansion in the growth of the city which affects the pattern of land uses within the city, as well as, in the adjoining settlements. There were incompatible conversions in land uses and undue encroachment into green areas in the adjoining communities. Therefore, the study suggests effective zoning strategy to check the indiscriminate nature of urban expansion whose effects on land use are well prominent in the study area. Adequate monitoring by the Development Control Department and other stakeholders in urban planning is equally suggested to mitigate the incompatible land use changes in the area.

Keywords: Urban Land-use, Change Detection, GIS, Imageries Interpolations, Zoning

INTRODUCTION

Land Use and Land Cover Changes (LULCC) is urbanization induced, which has led to dramatic changes in land use practices (Mirkatouli et al, 2015). Rapid pace of urbanization is believed to be a global problem present in most of the developing countries of the world. Balogun et al (2011) submitted that urban populations in developing countries have grown by 40% between 1900 and 1975; the trend will continue adding approximately 2 billion people to the urban population of the presently less-developed nations for the next 30 years. In similar way, Arnfield (2003) observed that the world is becoming increasingly urbanized with 45% of the population already living in the urban areas in the year 2000. With the projection as at then, half of the world will live in urban areas by 2007. It was also estimated that by the year 2025, 60.0% of the world's population will live in cities (UNPF, 1999).

Akure is not in any way going contrary to this prediction as the population has been more than triple of what it used to be before it became administrative headquarters of the state and local governments. For example, the population was just 71,106 in 1963; but with the influx of public servants into the town due to the state creation of 1976, the population rose to 239,124 by 1991 and 360,268 in 2006 (NPC, 1991 and 2006). Even as at 2010 and 2014, the population was estimated at 413,060 and 476,159 respectively using the 3.18 annual growth rates recommended by the National Population Commission of Nigeria (NPC, 2006).

Globally, land cover is often altered principally by direct human use such as agriculture and livestock raising, forest harvesting and management, urban and sub-urban construction and development. Hardly can we find any vegetation that has not been affected or altered by man in the world (Kufoniyi, 1998; Oyinloye, 2010; Olofin, 2012; Rimal, 2013; Oduwaye, 2013 and 2015). In this regard, about 400,000 hectares of vegetation cover are confirmed to be lost annually (Adesina et al, 1999; Balogun et al, 2011). Due to anthropogenic activities, the earth surface is being significantly altered by man's presence and several activities on earth.

Owoeye, J. O.; Ibitoye, O. A.; Hall, S. & Sinnett, D. (2016). Akure Urban Land Use Change Detection Analysis Using Geographical Information System. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1507-1517

According to Fasal (2000), land transformation has been asserted to be one of the most important fields of human induced environmental transformation. Environmental protection is facing critical challenges due to several factors like increasing population, depletion of natural resources, environmental pollution, unplanned land use and several others. The trust of this paper, therefore, is to examine definite changes that have taken place in Akure urban land use in the past three decades with a view of generating a predictive model for managing the future trend and combating its possible effects.

LITERATURE VIEWPOINT

Several researches have shown that unplanned changes of land use due to urbanization have become a major problem (Zhao, 2003; Nanda, 2005; Balogun et al, 2011). Most land use changes occur without a clear and logical planning and without giving attention to their environmental impacts. Major flooding, air pollution in large cities as well as deforestation, urban growth, soil erosion, and desertification, are all consequences of a mismanaged planning and inappropriate projects' execution without considering their environmental impacts. As observed in Nicholson (1987), the rapid land use changes by the growing population have reduced natural vegetation cover in most countries of the world.

Urban growth observation and management remains a major concern of Geographic Information System (GIS) and Remote Sensing (RS) applications. The duo provides historical vehicle to monitor, determine and evaluate long term changes in land use due to urbanization process. They have been proved to be effective means for extracting and processing varied resolutions of spatial information for monitoring urban growth. According to Masser (2001), the collection of remotely sensed data facilitates the synoptic analyses of earth in terms of system functioning, burbling, and changes at local, regional and global scales overtime. Such data provides import data link between intensive, localized, ecological research and regional, national and international conservation and management of biological diversity (Wilkie and Finn, 1996; Hegazy and Kaloop, 2015).

Land use changes arising from urbanization, housing development, agriculture, and deforestation are some of the contributing factors to land cover changes in Akure. These changes reflect on the population growth, land consumption rate and local climate. Expansion of Akure has resulted not only in depletion of natural resources, but also in deterioration of the environment due to incompatible changes in land use pattern. Agriculturally productive land and forestland are being converted to residential and other private and public uses. Balogun et al (2011) argued that the land use land cover pattern of a region is an outcome of natural and socio-economic factors and their utilization by man in time and space. Hence, the uncontrolled growth of urban development of Akure has adversely affected its ecosystem which has potency to indirectly reflect on weather parameters with eventual local climate modification (Akinbode et al, 2007; Balogun et al, 2009).

Akure is the capital of Ondo State as well as the headquarters of Akure South Local Government Area. Between 1976 and present time, the city has experienced enormous growth and has developed independently of any spatial urban planning. This rapid growth became prominently noticed in the last two to three decades. As urbanized features extended farther from the central areas, lands populated by development are altered in significant ways. From the population figures of past national censuses, the population of Akure increased appreciably from approximately 71,106 in 1963 to 239,124 in 1991 and 360,268 in 2006 (NPC 1963, 1991 and 2006). Since 1976 when the town became the state capital, there have been remarkable changes in its growth and development. Several developmental projects that brought transformation to the physical landscape of the city are very prominent. Oyinloye

(2010 and 2013) specifically observed that the construction of Ilesha-Owo expressway opened up the area for further development. It links the city with the northern and eastern parts of the country. Presently, development and establishment of public facilities are concentrated along this route.

In other to mitigate the negative effects of the city's growth and expansion, there is need for adequate programs and policies that can foster its sustainable development. The essence of this is to encourage and monitor development in a way that it will not damage the environment for the incoming generations. This can only be achieved by taking appropriate inventory of the available resources and planning for their present and future uses. It is on this premise, therefore, that the study is set to investigate the influence of urban sprawl on land use changes in Akure and its surrounding communities.

MATERIALS AND METHODS

The Research Locale

The study centers on Akure city and its immediate environments. Akure is a notable city in the South-western Nigeria which became the capital of Ondo State on February 3rd, 1976. It is located between Latitudes 7^0 15^1 and 7^0 17^1 North of the Equator and between Longitudes 5^0 14^1 and 5^0 15^1 East of the Greenwich Meridian. It is about 204 km east of Ibadan, capital of Oyo state; 168 km west of Benin City, capital of Edo state; 311 km north-east of Lagos; and 323 km south-west of Abuja, the Federal Capital Territory of Nigeria. Akure town spreads over an area of about 15,500 km^2 in about 370m above the sea level. Its population figure by the National Population Census (NPC, 1963) was just 71,106. With the influx of public servants into the town consequent upon state creation in 1976, the population rose to 239,124 and 360,268 in 1991 and 2006 respectively (NPC, 1991 and 2006) with a projection of 476,159 to year 2014 (on 3.18 annual growth rate) when this study was carried out.

The Database

Data collection for this study was essentially through Aerial Imagery Overlay (AIO) with the aid of GIS, RS and personal observations. Other sources include government ministries and establishments for historical milieu of the area as well as base maps and population data used for the study. Internet facilities were equally explored for relevant information. The study area has a total (projected) population of 476,159 in 2014 with a total land expanse of 125,212 Hectares. The main approach used in this study was mainly post-classification comparison analysis of satellite imageries of Akure obtained at different decadal variations. This helps to show the direction and extent of growth in the study area from one period to the other. The studying period span through three decades and is divided as follows: 1985–1994, 1995–2004 and 2005–2014. The land use for the study area is classified into four categories, which include: the built-up area (involving residential, commercial, industrial, recreational and educational land uses); thick vegetation (forested land areas); light vegetation (cultivated land areas), and the water bodies (Rivers, streams, etc).

RESEARCH FINDINGS AND DISCUSSION

Analysis of Land Use Land Cover Classifications (LULCC) - 1986 to 2014

As shown in Figures 4-7; lager proportion (80,796 Hecht) of the study area were covered with thick vegetation in 1986 which accounted for 64.53% of the land area while 37,977 Hectares (30.33%) were cultivated and covered with light vegetation. Only about 5.1% were developed areas which are either residential, commercial, recreational, industrial or educational land uses, occuping just about 6384 Hectare land area. Just about 56 Hectares (0.04%) were covered by water. This situation express the low level of development as at 1986 with a small compact urban area.

In 2002, the percentage of built-up area had increased to 16.63% (20,885 Hecht), cultivated area (light vegetation) also increased to 68,940 Hectares (55.06%) while the area covered by thick vegetation reduced drastically to 32,978 Hectares (26.34%). This shows that much of the thick vegetation were cultivated while some gave way to further development and urban expansion through building constructions and provision of public utilities.

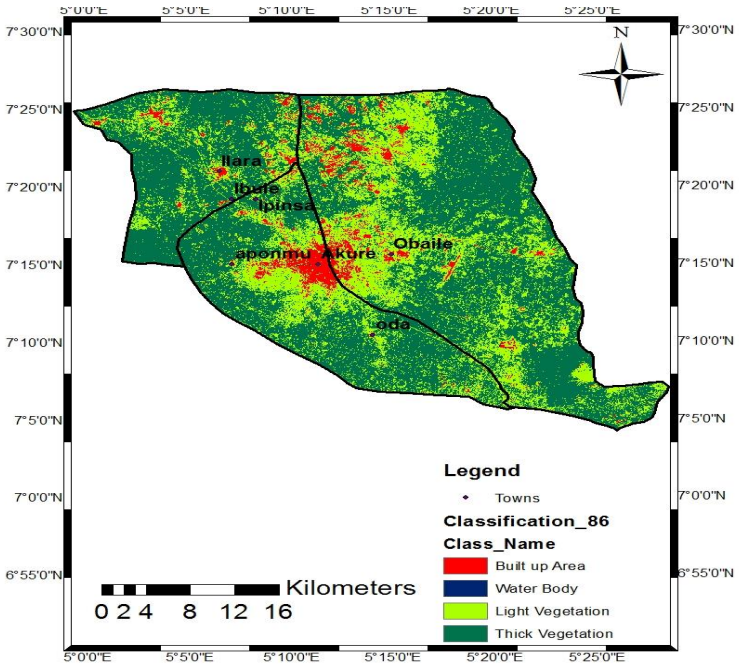

Figure 4: Land Use Classification of Akure as at 1986
Source: Landsat 4 Thematic Mapper (TM) Imagery (1986)

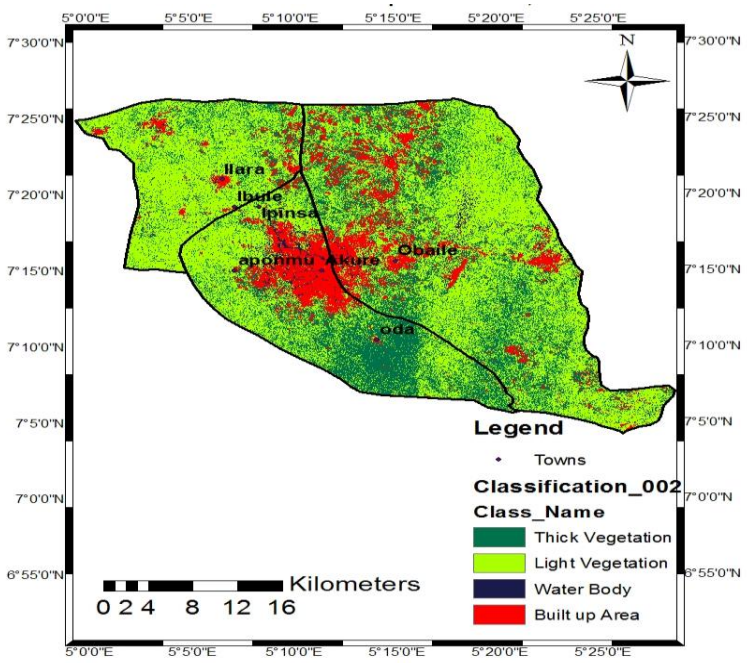

Figure 5: Land Use Classification of Akure as at 2002
Source: Landsat 7 Enhanced Thematic Mapper (ETM$^+$) Satellite Imagery (2002)

In 2007, the built-up area further increased to about 22,985 Hectares (18.36%), light vegetation cover occupied 82,415 Hectare (65.82%) while areas covered by thick vegetation and water body reduced to 19,002 Hectares (15.18%) and 811 Hectares (0.64%) respectively. The land use for the built-up area continue to increase till date while that of thick vegetation, light vegetation and area cover by water reduces.

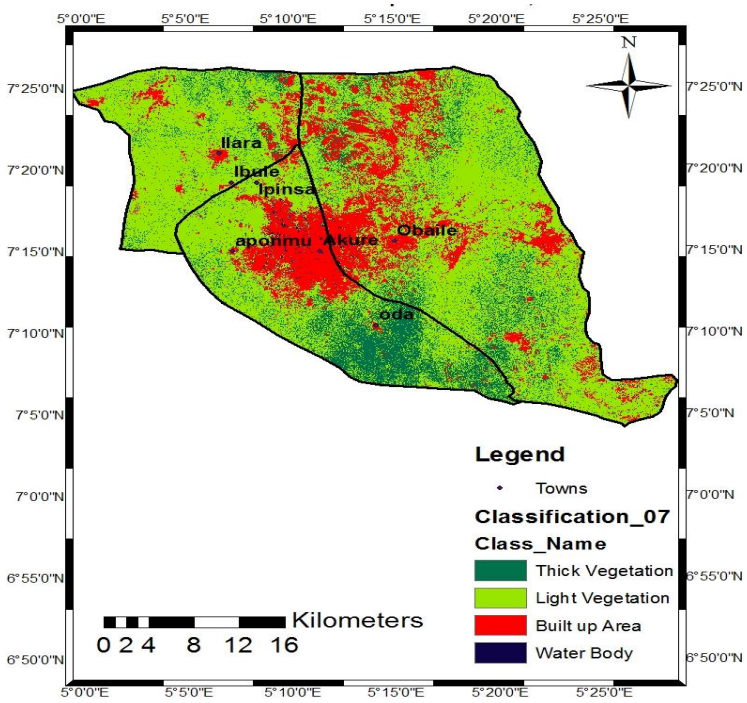

Figure 6: Land Use Classification of Akure as at 2007
Source: Landsat 7 Enhanced Thematic Mapper (ETM$^+$) Satellite Imagery (2007)

In 2014, land use for built-up area increased from 22,985 (in 2007) to 34,303 hectares (27.40%) while light vegetation (the cultivated area) reduced from 82,415 hectares (in 2007) to 72,675 hectares in 2014. The reason for this might be because of drastic reduction in

number of farmers since majority of people working on the farms had been taken over by civilization while some land areas meant for cultivation were acquired for provision of public utilities.

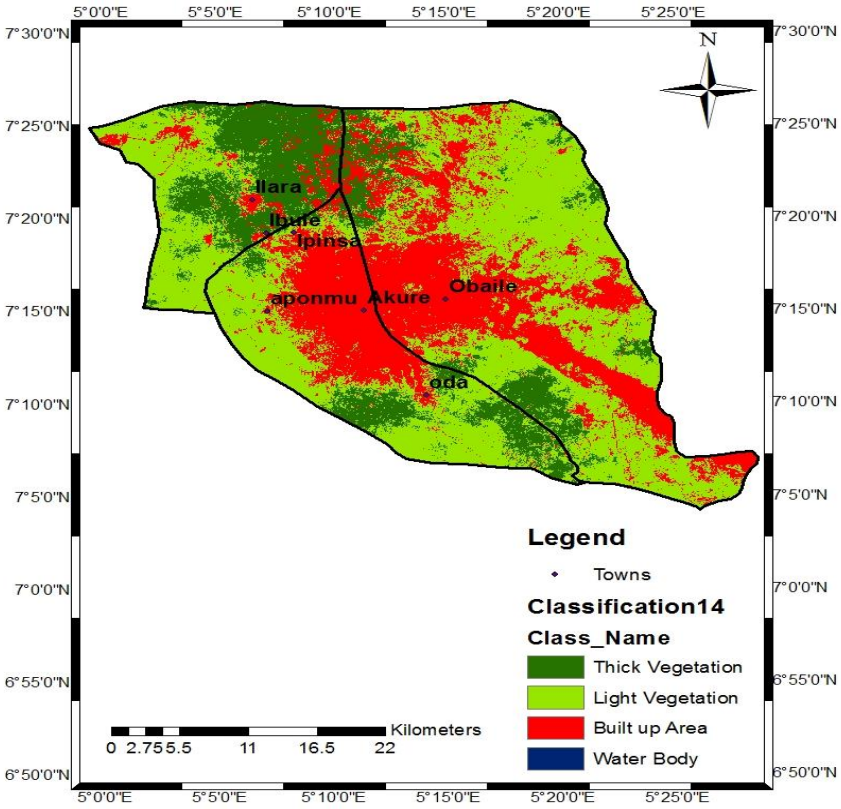

Figure 4.4 (a): Land Use Classification of Akure as at 2014
Source: Landsat Operational Land Imager (OLI) Satellite Imagery (2014)

The inference that can be deduced from this analysis is the rate of urban expansion as illustrated by the trend of increase in the built-up area and light vegetation (cultivated land areas). The drastic reduction in the percentage of area covered by thick vegetation shows there was a phenomenal growth within the studying period. For instance, the built-up area increased by 22.3% between 1986 and 2014 as well as light vegetation (cultivated land areas) by 27.71%. This is likely to be the result of much encroachment into the thick vegetation, rocky and undulating land areas for the purpose of building construction, quarry, blasting and mining activities. Besides, the economic situation in the state around the time (especially, the ealier years of the new millenium) was favourable for individuals, government and various establishments to embark on massive developments. For example, in 2002 (being the beginning of the millenium), various projects were embarked upon consequent upon the discovery that the state falls within the mineral endowed region, which accounted for the tremendous increase in the built-up areas, which result in massive physical expansion of the region. Again, Akure gained much influx of people seeking greener pastures being the state capital while the discovery of bitumen in the state attracted much investors and other immigrants within the studying period. Its administrative status and concentration of establishments like government ministries, several housing estates, Ondo State Oil Producing Area Development Commission (OSOPADEC) secretariat, Federal University of Technology, Akure (FUTA) and lot more were the centre of consideration for the attraction.

Land Use Land Cover Change Detection Analysis for the year 1986–2014

The LULCC of Akure and the change detection analysis for the 1986–2002, 2002–2007 and 2007-2014 are presented in Table 1 and Figure 8. From the table and figure, the percentage

increase of built-up area, light vegetation (cultivated land areas) and water body was higher between 1986 and 2002 than between 2002 and 2007. Percentage difference for built-up area was much more higher between 2007 and 2014 while other land classifications have negative index. Thick vegetation was rapidly depleted and taken over by light vegetation and built-up land uses as indicated by the negative index throughout the studying period. This is an evidence of consistent growth and rapid development witnessed in the city.

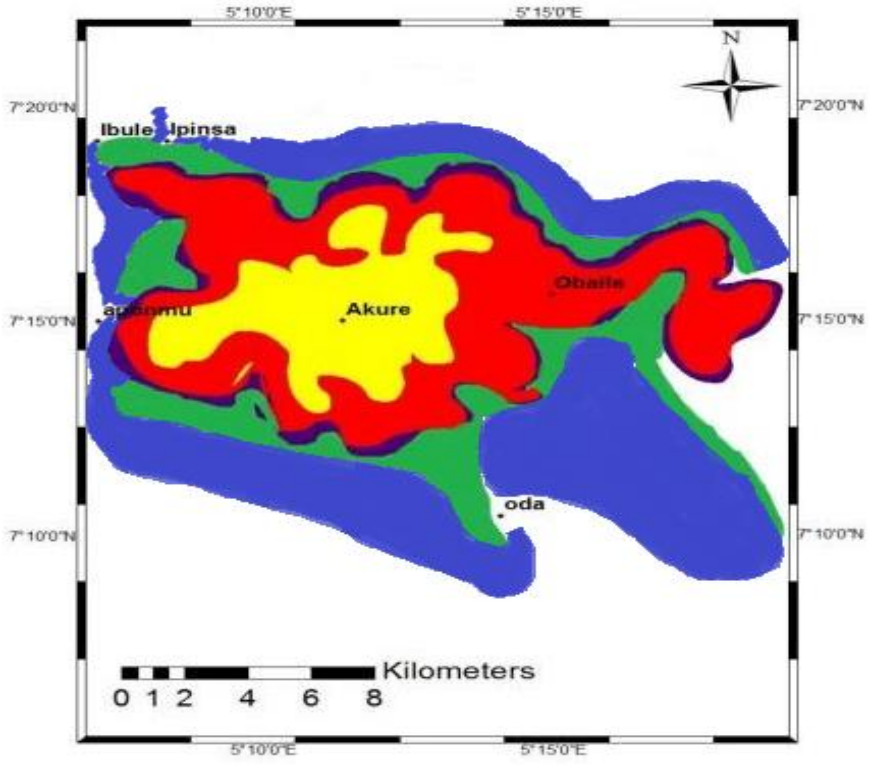
Urban Built-Up Change Detection Analysis and Predictive Model for Future Expansion

The spatial pattern of sprawling in Akure over a period of three decades (1985-2014), as shown in Figures 4-7, express the direction and extent of growth in the period examined. For instance; between 1985 and 2002, the growth navigates towards the northern and the eastern parts of the region more than any other direction. These areas were earmarked for the construction of Government Residential Areas (GRAs) and most of government parastatals and ministries. Besides, the area was the location of Ijapo estate, a notable residential estate in the city which attracted much influx into the area. The construction of Ilesha-Akure-Owo express route which passes through the north-eastern part of the city was another notable factor that play prominent role of attracting people to the area. But the direction of growth thereafter diffused to other directions, probably due to congestion in this area and availability of cheap lands and good topography that favours construction in other parts of the city.

The location of Federal University of Technology, Akure (FUTA) in the north-western part of the city has much influence in attracting huge population of people into the area. Most staff of the institution and students preffer to live close to it, thereby making the growth to be institutional attraction. Currently, the growth around this institution has almost captured Ipinsa and Ibule (the two nearest settlements) as high percentage of students of the institution find cheaper accommodation there as well as cheaper lands for staff and people from Akure to build houses and hostel accommodation for students. This and other important developments that parade the city revealed significant difference in stages of expansion and

land uses within the studying periods. The findings corroborate the work of Oyinloye (2010) and Balogun (2011 who observed significant difference in stages of development and growth in Akure since its inception as a state capital.

The use of GIS to predict future expansion of the study area and possible changes in land uses was modeled to guide policy makers in the management of land use activities in Akure and environs. Based on 3.6% growth rate adopted in Oyinloye (2010) for Akure, the predicting future expansion for the built-up area for a period of 20 years (2014 to 2034) is estimated at 68,793.41 hectares. The pictorial representation is shown in Figure 9. As seen in the figure; there is every possibility for Akure to become a full grown conurbation by 2034 when it would have subsumed many of its adjoining communities.



Legend: 1986 2002 2007 2014 2034

Year of Growth	Growth Area (ha.)	Cumulative Area (ha.)	Percentage Area

Source: Field Survey, 2014

SUMMARY OF FINDINGS AND POLICY IMPLICATIONS

The study gives a clear indication of unguided expansion in the growth of Akure which seriously affects the pattern of land uses in the city and its surrounding settlements. There were incompatible conversions of land uses and undue encroachment into green areas in the adjoining settlements due to favourable economic situation in the state around the period. In the early year of the millenium, Akure gained much influx of people being the state capital;

and most importantly, due to the discovery of bitumen in the state which attracted much investors and other immigrants in quest of greener pastures and job opportunities. Its administrative status and concentration of establishments were the key indices for this attraction. With this, the thick vegetation was massively encroached which consequently gave way to further developments and expansion from the city into various sorrounding communities. Also, the regional setting of Akure has naturally influenced the direction of the expansion. Findings revealed that the city spread out along the fairly flat areas of the north-western part of the city which appear to be more favourable to human settlements. Thus, the expansion first tend towards this direction before it began to diffuse to other areas.

Based on major findings in this study, it has become pertinent to put up some policy recommendations. In the first instance, the unguided nature of Akure urban development whose effects on land use pattern are well prominent in the study area needs adequate attention. The check on this should commence with land acquisition and allocation procedures for various uses so as to guide against incompatible land uses. It is therefore recommended that ministries in-charge of land management should employ resourceful control measures over private and public land uses through effective zoning strategy. In view of this, the Development Control Department (DCD) in the Ministry of Urban Development and Physical Planning should be reinforced with strong tools to carry out their duties, particularly in the area of effective monitoring for sustainable development.

The existing land use in the study area is more of residential, most of which are aged and dilapidated. In some parts of the city, especially at the urban core; most of the old buildings are being removed and changed over to new ones. In the course of changing some of these buildings, the usages are always at variance with compatibility standard. They constitute nuisance rather than complementing the planning and environmental standards. In this regard, it is recommended that adequate monitoring be made by DCD and other stakeholders in urban planning, right from plan approval stage to erection of structures so as to forestall such occurrences with a view to achieve a sustainable and virile livable environment. Besides, property rehabilitation strategy should be adopted on degraded landed properties rather than arbitrary removal and rambling replacements. This should involve improving the existing infrastructural facilities as well as providing new ones with a view to making their services functional and accessible to all and sundry. To reduce the level of encroachment into natural vegetation in the course of expansion, it is also suggested that vertical expansion should be encouraged in the form of story buildings, high scrappers, and the likes. It is believed that this will reduce the rate of land consumption and improve the structural quality as well as adding to the aesthetic value of the environment.

The administration of physical planning in Nigeria was not effective as far as promotion of orderly development of urban and rural communities is concern prior the enactment of Decree 88 of 1992 Nigerian Urban and Regional Planning Law (NURPL). Related programs on physical planning were carried out only on ad-hoc basis. However, the enactment of 1992 NURPL makes provision for improvement of urban area and city sustainability; essentially in part IV section 79-85 of the law. With this, it is expected that cities are to be in orderly shape and made sustainable for human living. But, in reality, this is not so. At local government level, planning is expected to be felt through various planning authorities since it is the closest tier of government to the people. But the authorities are almost become moribund since the mode of planning administration in Nigeria does not allow them to function. It is therefore recommended that the state of local government planning administration in Nigeria be reactivated and made functional.

The existing Master plan of Akure was produced in 1980 and has become inactive, old and superseded. There is need for a more comprehensive one as well as Regional Plan to guide the development and spatial growth of the region. These plans are to be administered by a constituted board which is to be saddled with responsibility to maintain an orderly and aesthetic environment in the region. The board is to be made responsible for the preparation and implementation of planning schemes as well as local, area and structural plans in conformity with the state and regional plans. This will go a long way to assist in regulating land uses for sustainable development in the area.

ABSTRACT

This study analyzes the land use/land cover changes in Damaturu metropolis and obtained the trend from 1986 to 2005. LandSat TM Images of 1986, 1999, and 2005 were used. Built-up lands, agric lands, water body and other lands (vacant) were created as themes in ILWIS 3.4 software. The images were displayed in False Colour Composite (FCC) for a better visualization and identification of the themes created. Training sample sets were collected based on the ground truth data during field checks. Statistical data were later extracted from the classified sample set. Area in hectares for each theme was calculated for each year and the result for each land use/land cover types for each study year was compared. From the result, it was found out that built-up areas have a considerable increase from 37.71 hectares in 1986 to 1062.72 in 2005. It has an annual increase rate of 0.34%. The results also reveal that there is a decrease of 5829.66 hectares of other lands (vacant lands) from 1986 to 2005.

Keywords: Land Use, Distribution, Analysis, Rate of Change

INTRODUCTION

Patterns of land use often lead to changes in land cover. Urban areas develop either through objectively planned areas, guided and regulated by deliberate regulation and control systems, or spontaneous growth through unplanned isolated constructions especially on the city fringes (Lawan, 2014). Human population dynamics largely affect the demand for land in any society. This dynamism leads to scarcity of land and land resources in communities (Isa, 2008).

Ideally, the growth that takes place around the urban areas should be channeled in an orderly manner that can produce an economically efficient, socially and personally satisfying living environment. The direct implication of such population growth is the change in the land use of the region.

Spatial patterns of urban growth over different time periods, can be systematically mapped, monitored and accurately assessed from the satellite data (remotely sensed data) along with conventional ground data (Lata *et al*., 2001). Modelling urban growth provides a "picture" of where this type of growth is occurring, helps to identify the environmental and natural resources threatened by such growth, and to suggest the likely future directions and patterns of the growth. This phenomenon comes with high level population increase in the urban areas as well as consistent decline in economic opportunities in rural areas (Gardner, 2001; UN-Habitat, 2004).

The aim of this study is to analyze the land use changes in Damaturu Metropolis from 1986 to 2005 using satellite images. This can be achieved through the following objectives:

i. Production of three land cover maps of the study area for the year *1986, 1999, and 2005*.
ii. Analyze the produced maps in order to obtain the extent of land use for each year.
iii. To obtain the trend of the land use using the raster approach.

Musa, L. & Zumo, I. M. (2016). Analysis of Land Use/Land Cover Changes in Damaturu, Nigeria: Using Satellite Images. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1518-1522

Statement of the Problem

The daily influx of people into the State Capital has put high demand on land, giving rise to high impacts of land use changes in Damaturu Metropolis. This has translated into socio-economic and political problems, thereby imposing great challenges to the urban planners, city administrators, and the general public.

Scope of the study

The study has focused on analyzing the land use changes in Damaturu Metropolis, Yobe state; and forecast for the future pattern of the land development in the study area.
Thus, the study has limited itself to the Damaturu Metropolis with the geographical location lying between latitude 11º 42'N and 11º 47'N, and longitude 11º 54'E and 12º 02'E.

METHODOLOGY

Data types and Sources: Table 2.1 shows the Data types and Sources.

Table 2.1; Data Source

S/N	DATA TYPE	DATE	SCALE/ RESOLUTION	SOURCE
1.	LandSat ETM+ Image	2005	30m	NASRDA
2.	LandSat ETM+ Image	1999	30m	GLCF(ESDI)
3.	LandSat TM Image	1986	30m	GLCF(ESDI)
4	Ground Control coordinates (GPS of some selected points)	2010		Field Work

Source; Global land cover facility 2009

Materials/Equipment used

The major equipments are used in this study are personal computers (PC) with 250 GB of hard disc space, 2.0 GB RAM with 1.66 GHZ speed; Hp DeskJet F2280 scanner and colour printer. Prominent software packages used for this Study were ILWIS 3.4, and Idrisi32.

Data preparation: LandSat images acquired, topographical maps, image map and the Land use plan of the Town were geo-referenced using the ground control points (GCPs). The root mean square (RMS) error of geo-referencing is approximate 0.5 pixels. The Root Mean Square (RMS) error represents the difference between the original control points and the new control point locations calculated by the transformation process (Isa, 2010). The transformation scale indicates how much the map being digitized will be scaled to match the real-world coordinates.

DATA ANALYSIS

Five themes were created. These are built up lands, forest lands, Water bodies, vegetation/Agriculture and Other lands. The images were displayed in False Colour Composite (FCC) for a better visualization and identification of the themes created. This determines the relative spectral between the bands to identify the different land cover types in the images. Training sample sets were collected based on the ground truth data during field checks. Statistical data were subsequently extracted from the classified sample set.

Calculation of the Area in hectares of the resulting land use/land cover types for each study year and subsequent comparison of the results

Table 4.1 shows the area in hectares and the percentage change for each year measured against each land cover type. Percentage change to determine the trend of change was then calculated by dividing the observed change by the sum of changes multiplied by 100

$$\text{(Trend) percentage change} = \frac{\text{observed change}}{\text{Sum of change}} * 100$$

To obtain annual rate of change, the percentage change was divided by 100 and multiplied by the number of the study year.

Identification of land use changes

From the classified images, the area under the built-up lands, other lands, vegetation – agriculture, and the water bodies were computed and tabulated accordingly, for further analyses.

Table 4.1; Land Use / Land Cover Distribution (1986, 1999, and 2005)

Table 4.2 Land use / land cover change of Damaturu and its environs (1986, 1999 and 2005)

	1986 – 1999		1999 – 2005		ANNUAL RATE OF CHANGE	
LANDUSE/LAND COVER CATEGORIES	**AREA (Ha.)**	**PERCE TAGE CHANGE**	**AREA (Ha.)**	**PERCENT AGE CHA NGE**	**1986 - 99**	**99 – 2005**
	37.71	1	1062.72	9	0.13	0.54
BUILT-UP LAND	1694.34	48	-5829.66	-50	6.24	-3
OTHER LANDS	-1754.28	-50	4620.42	40	-6.5	2.4
VEG.& AGRIC	22.23	1	146.52	1	0.13	0.06
WATER BODY						

The percentage change in the built-up lands between the year 1999, and 2005 (9% as from the Table 4.2) was found to be very much higher than that of between the year 1986, and 1999 (1%). This may suggest that the rate at which the new lands were acquired for development after the state creation is high and this may also be the trend between the year 1999 and the 2005, as there seems to be development expanding towards the outskirts of the city. The following Figure 4.4 shows the gains and the losses in the built-up lands between the year 1999, and 2005 (9%) that indicate some significant differences. This implies that since there is an expansion of 9% from 1999 to 2005, this rate expansion will continue in the next few years and adequate planning towards increasing the distribution of facilities must be done in relation to the rate of growth.

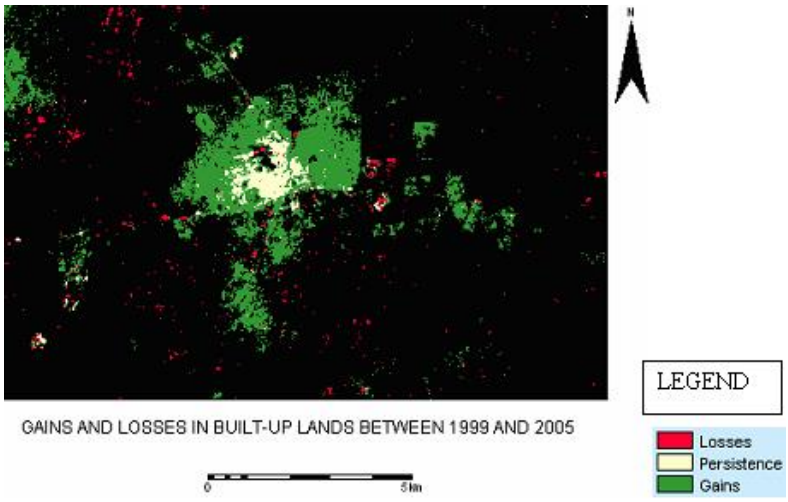

Figure 4.4; Gains and losses in built-up lands between year 1999 and 2005 derive from Idrisi software overly.
Source: Author's Laboratory work, 2013

CONCLUSION

This paper concludes that there is an increase in the usage of land from 1986 to 2005. It was found out that built-up areas have a considerable increase from 37.71 hectares in 1986 to 1062.72 in 2005. It has an annual increase rate of 0.34%. The results also reveal that there is a decrease of 5829.66 hectares of other lands (vacant lands) from 1986 to 2005.

Characterising Peri-Urban Sprawl of a City in a Developing Country: Case Study of Ibadan, Nigeria

***Fasakin, J. O.*[1] *; Dosumu, N. A.*[2*] *& Omole, F. K.*[3]

[1, 2&3] *Department of Urban and Regional Planning, Federal University of Technology, Akure, Nigeria*

ABSTRACT

Peri-urban areas, which may have become the most common type of living and working situation, as well as the dominant urban form and spatial planning challenge in the developing world in the twenty-first century, can be characterized as a heterogeneous mosaic of rural and urban features. Peri-urban areas have some mutually conflicting goals, including housing the neediest immigrants, attracting private capital and provision of un-serviced but affordable plots of land to a significant proportion of the people. It is often a zone of chaotic urbanization leading to sprawl. This study focuses on characterising the peri-urban areas and sprawl of Ibadan, Nigeria. Data for the study were collected through questionnaire administration, Focus Group Discussions, Key Informant Interviews, and direct observations. The following findings came from the data analysis: Ibadan recorded a sprawl of more than quadrupled over a 34-year period (1966-2004); the exponential growth of peri-urban areas in Ibadan was attributed partially to the increase in personal vehicle (cars) ownership by the people; the areas were highly populated by non-indigenes; commercial activities were predominant, although uncoordinated, unplanned and unregulated; and there were varied types of houses, predominantly bungalows, leading to the sprawl. Relevant recommendations sequel to findings include: curtailing the peri-urban sprawl by strengthening the existing Town Planning Authorities; encouraging the inhabitants to provide the necessary in-house infrastructural facilities and creation of enabling environment by the governments; and incorporating peri-urban areas into the ambit of planning and governance.

Keywords: Peri-Urban Areas, Peri-Urban Sprawl, Peri-Urbanization, and Urbanization

INTRODUCTION

Peri-urban areas are grey areas, overtly urban in terms of their economic function and, often, of their physical form; yet they are still rural, for lack of municipal facilities, among others (Storey and Overton, 2003). It can be characterized as a heterogeneous mosaic of rural and urban features. The area, perhaps, may become the most common type of living and working situation in the world in the twenty-first century, thus also becoming the dominant urban form and spatial planning challenge of the twenty-first century (Ravetz, Fertner and Nielsen, 2013). The reality of this is in the developing world (Nigeria inclusive) where peri-urban area is often a zone of chaotic urbanization leading to sprawl. Thus, there could be problems relating to increase poverty, inadequate services, poor housing and environmental degradation in the peri-urban areas, consequently leading to sprawl.

Sprawl, either urban or peri-urban, according to Batisani (2006), refers to a type of spreading suburban development with negative outcomes such as increased commuting time. Urban sprawl has been characterized as a distinct form of dispersed and inefficient urban growth, haphazard in configuration, and highly reliant on the automobile (Hasse and Lathrop, 2003). Peri-urban sprawl is the spreading out of a peri-urban area and its suburbs over more and more rural land at the periphery of the urban area. It usually involves the conversion of open space/rural land into built-up, developed land over a period of time in a rapid and not gradual form.

LITERATURE REVIEW

Urbanization and Peri-Urbanization

Mabogunje (1981, 1985) defines urbanization as a process of human agglomeration in multi-functional settlements of relatively substantial size. Stren (1992) also sees urbanization as a

Fasakin, J. O.; Dosumu, N. A. & Omole, F. K. (2016). Characterising Peri-Urban Sprawl of a City in a Developing Country: Case Study of Ibadan, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1523-1534

set of processes that transform nations through a transfer of production and population from rural to urban areas. According to Sudhira, Ramachandra, and Subrahmanya (2007) it is a form of metropolitan growth that is a response to often less understood implications of technological, economic, social, and political forces and to the physical geography of an area. Thus, urbanization is the process in which the number of people living in urban areas increases when compared to the number of people living in rural areas. A country is urbanized when over 50 percent of its population lives in urban areas. These definitions show that urbanization can only take place in cities or urban centers.

The definition of peri-urban areas, however, could be said to be situational, case specific, cloudy and nebulous at times, since spatially, peri-urban areas change over time. It shows that at times there is no clear divide between peri-urban and urban fringe. Nevertheless, peri-urban has been defined as an interface between the urban and rural spheres, in which activities traditionally classified as "urban" (e.g. industry) or "rural" (e.g. agriculture) co-exist. It has also been seen as the transition zone/area, or interaction zone/area between the urban and rural areas, where urban and rural activities are juxtaposed, and landscape features are subject to rapid modifications, induced by anthropogenic activity. It describes areas that are in transition from strictly rural to urban; the meeting of urban and rural areas (peri-urban interface) with interaction between three systems: urban, rural and natural (Parkinson and Tayler, 2003; Gregory, 2006; Mattingly and Gregory, 2006; SCOPE, 2007; Miljković, Crnčević and Maric, 2012). Peri-urban areas occupy changing spaces on the margins of towns and cities. They were once rural, but are gradually becoming urban due to outward expansion of cities. Therefore, today's rural will become tomorrow's peri-urban, while today's peri-urban will become tomorrow's urban.

While houses and other land uses are springing up daily in the peri-urban areas, with some of the residents taking advantage of these new income-generating opportunities, others who are the original rural dwellers are made poorer by this rural to urban transition (Mattingly and Gregory, 2006). Peri-urban challenges are complex and include spatial, service infrastructure, environmental, economic and social dimensions. Although the factors causing peri-urban growth could be said to be, by no means, confined to the spatially defined peri-urban areas, the complexities extend beyond the spatial manifestations of urban growth. Nevertheless, as cities develop, much of their growth is located in such areas leading to peri-urban intensification. Peri-urban intensification is associated with increases in the amount of activities that take place within the areas. Consequently, peri-urbanization affects a wide range of areas geographically, historically and morphologically. Regretably, these critical areas of land cover change, leading to transformations in the hydrological, ecological, geomorphological and socio-economic systems, are often neglected by both rural and urban administrations.

Peri-urbanization process, according to Rouge, Gay, Landrieve, Lefranc-Morin, and Nicolas (2013), is a combination of three factors:

i. a socio-cultural factor: collective appreciation of a habitat model based on the single-family house and proximity to resources combining the city and the country;
ii. a socio-technical factor: the spread of a new form of mobility, the automobile, which allows for a more marked separation between living spaces and workplaces; and
iii. a socio-economic factor: housing strategies that enable the acquisition of land and development of houses outside the city by a large segment of the population.

Characteristics of Peri-Urban Areas

Peri-urban settlements are usually characterized by high population densities coupled with agglomeration of different social and economic activities associated with inadequate or lack

of infrastructural facilities. Rapid population exacerbates due mainly to un-controlled migration from rural to urban areas leading to increase in economic activities and other changes in edges of urban areas by construction of buildings in hitherto agricultural land, which exert enormous pressure on resources and infrastructure in these areas (Mwesigwa, 1995; Ndezi and Wedgwood, 2001; Maseka, 2001; Bunting, 2002; Cohen, 2002).

Housing in the peri-urban area is characterised by various (mix) land uses, not because of planning strategies, but due to unregulated development. This is the reflection of the diversity of the social, cultural and economic activities that take place within the areas. Such uses include residential, commercial, religious (especially churches and mosques), and industrial, educational and agricultural uses. The benefits of such arrangements notwithstanding, peri-urban areas are characterised by low-income settlements, absences of infrastructure and services, insecure livelihoods with the associated problems of health, safety, noise and air pollution, and poor quality of life.

In Nigeria, like other developing countries, the unplanned growth of the peri-urban areas is aggravated by the absence of land use planning instruments, their execution and control. As a result, most of the peri-urban population live in areas without adequate access to basic infrastructure and social amenities. The dwellers live in sub-standard housing, without secure land tenure rights. Nevertheless, these areas provide opportunities for low and middle income earners to be accommodated and to be house owners.

Peri-Urban Sprawl

Ottensmann (1977) sees urban sprawl as the scattering of new developments on isolated tracts, separated from other areas by vacant land. Lee, Tian, Erickson, and Kulikowski (1998) argue that sprawl is the result of the development process of urbanization, sub, counter, and re-urbanization allowing for urban expansion into rural areas spreading outward in haphazard pattern and consuming more land than is necessary while creating unnecessarily high costs for basic community and social facilities and services. Batty, Xie and Sun (1999) perceives urban sprawl in relation to the contemporary urban growth consisting of three interrelated problems of spatial dynamics: the decline of central or core cities which usually mark the historical origins of growth; the emergence of edge cities which compete with and complement the functions of the core; and the rapid sub-urbanisation of the periphery of cities - core and edge - which represent the spatially most extensive indicator of such growth. Zhang (2001) defines urban sprawl as resulting from poorly planned, large scale new residential, commercial and industrial developments in areas previously not used for urban purposes. Sprawl has also been seen as the spread-out development that consumes significant amounts of natural and man-made resources, including land and public works infrastructure of various types (Transportation Research Board, 2002).

METHODOLOGY

Quantitative and qualitative data for this study came from both primary and secondary sources. The primary data were collected on the socio-economic characteristics of the inhabitants, availability of in-house infrastructural facilities, number of rooms in a house, household size, mode of travel and vehicle ownership, and distances to offices/places of work were also collected. The data were collected with the help of four (4) Field Assistants (FAs). Participatory Rapid Appraisal (PRA) techniques were used to collect the primary data. PRA is a bottom-up approach to development that enables stakeholders express themselves, share and analyze their knowledge. Existing documentations on peri-urban sprawl, housing/settlements, sustainable environment, accessibility to land, infrastructural facilities and their affordability in Nigeria peri-urban areas were reviewed. Tertiary Institutions, Research Institutes and International Bilateral, Multilateral and Development Agencies were

contacted to collect published and unpublished materials. Electronic materials were also sourced from the internet.

The Enumeration Areas (EAs) of the National Population Commission (NPC) were used and 1.3 per cent of these EAs was sampled. EAs are convenient areas subdivided by the NPC during the 2006 National Population Census. The research used simple random sampling technique to select the thirty-five (35) enumeration areas (EAs) in the two LGAs (Oluyole and Lagelu) that were studied. This gave all the 2,700 EAs equal chance of being selected. For the purpose of the household questionnaire administered, systematic random sampling was used in the selection of houses. The process of selection involved random selection of the first (1st) house, while others are systematically selected by a predetermined sampling interval (every fifth house on a street). This involves getting a list of population (N); determining sample size (n); calculating interval (N/n= k); and selecting every k interval after the first (1st) house. Thus, the procedure involved administering the questionnaire on the head of household in every fifth house on a street. The studied LGAs, localities and enumeration areas are shown in Tables 1 and 2.

FINDINGS AND DISCUSSIONS

In identifying the characteristics of the peri-urban areas, there is the need to measure the specific peri-urban areas, which can be done qualitatively and quantitatively. This study looks exclusively at the quantitative measure of the amount of sprawl – the actual square kilometres or hectares of land that are converted to peri-urban use as the city and its suburbs expand beyond their boundaries. Also, the socio-economic characteristics of inhabitants of the peri-urban areas in terms of education, marital status, religion, occupation, and income, among others, are discussed. Figures 1 – 3 show the maps of Ibadan and the two areas in time lapsed view of how the landscapes in and around the city of Ibadan and the two studied areas have changed as a result of development between 1966 and 2004. During these periods, there was rapid deforestation and other issues associated with sprawl, as trees were cut down, roads, businesses, and houses were built. According to the findings of this study, the total area of the

city in 1966 was 7,935 hectares, which grew by 36.58 percent within a 7-year period to 10,838 hectares in 1973. It means the city grew by 2,904 hectares within the period.

However, the growth became phenomenal in the late 70s to early 80s (the oil boom years), increasing exponentially in 1982 to 18,868 hectares, which is 74.08 percent of that of 1973 (with a sprawled of 8,030 hectares over a 9-year period). By 1996, it sprawled with 10,533 hectares to increase to 29,402 hectares (55.8% of 1982 over a 14-year period). By 2004 the growth had reached 42,219 hectares, having sprawled 12,817 hectares (43.5% over a 8-year period). Figure 1 shows the rate of spatial growth of the peri-urban areas of Ibadan. In the 1980s, the Ibadan-Lagos expressway generated the greatest urban sprawl in Ibadan, closely followed by the Eleyele-Dugbe expressway

Rates of spatial growth of Oluyole and Lagelu peri-urban areas of Ibadan were not the same, as shown in Figures 2 and 3, respectively. While the extent of growth between 1966 and 1973 in Oluyole was at an average annual growth of 29 percent, it increased to 35.6 percent between 1973 and 1982. However, it was at its lowest ebb between 1982 and 1996, recording only 16.7 percent average annual growth rate. But between 1996 and 2004 the growth recorded its second highest annual rate of 35 percent (Figure 2).

In Lagelu, the trend differs. There was phenomenal growth between 1966 and 1973, recording more than triple annual growth rate. It increased drastically furthermore to more than quadrupled between 1973 and 1982, before plummeting to about double annual growth rate between 1982 and 1996 (Figure 3). It reduced drastically to 20.5 percent between 1996 and 2004. The growth rate was high immediately after independence simply because the area was highly rural before independence and people only started moving to the area in late 60s and early 70s, coupled with the fact that the period was the oil boom era in the country. The phenomena rate of sprawl witnessed between 1973 and 1982 could also be attributed to the

Lagos-Ibadan (Ojoo) expressway and the Ibadan (Iwo road)-Ile-Ife expressway, which were constructed during this period.

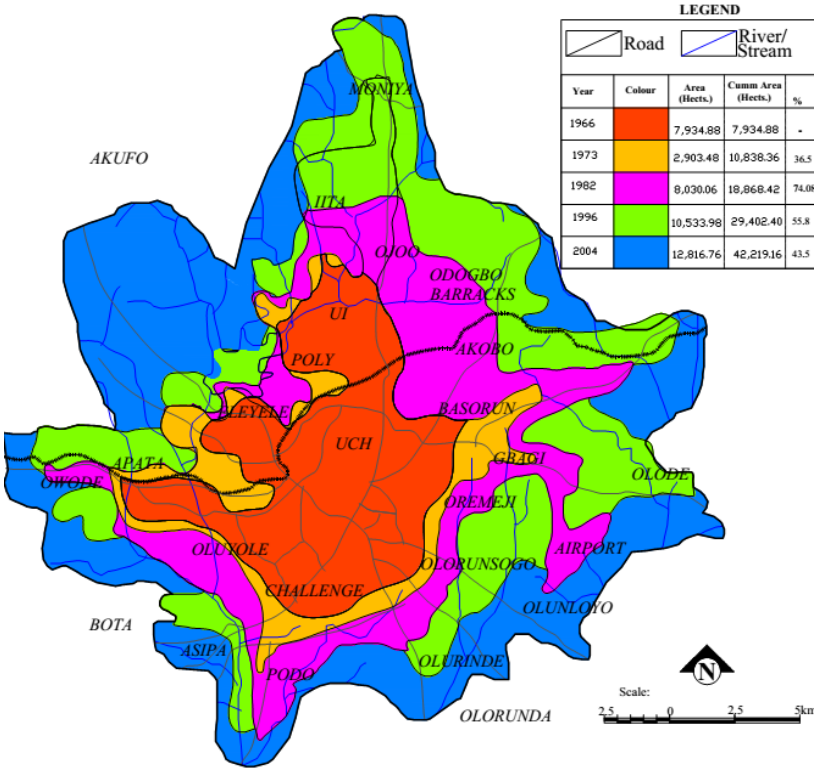

Fig. 1: The Extent of Growth of Ibadan Over a 38-Year Period (1966-2004)

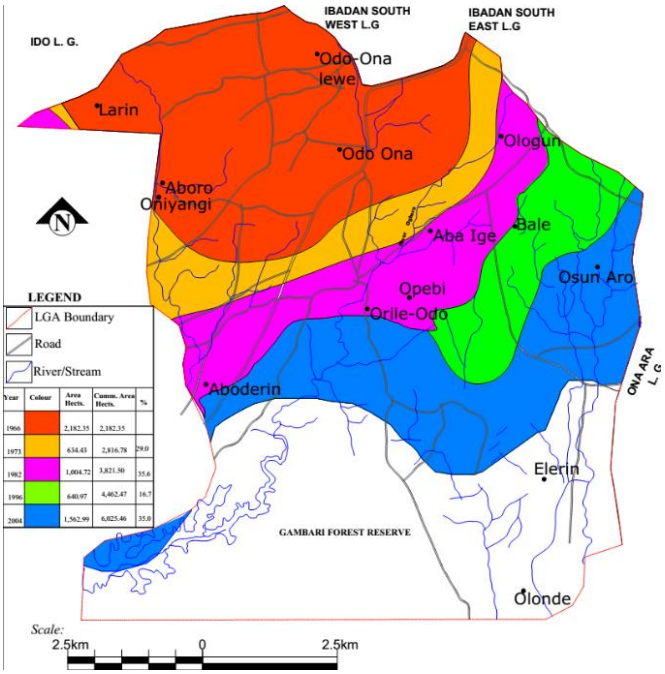

Fig. 2: The Extent of Growth of Oluyole LGA Over a 38-Year Period (1966-2004)
Source: Compilation from Google Earth Timelapse Builder Analysis, 2010

Thus, the trend shows that the population has been moving towards the peri-urban areas as a result of rapid urbanization of the urban area and industrialization of the peri-urban area where land is readily available for various uses. Improvement of public transport, especially road network enabled people to reside and activities to be located more easily outside the

town/city. Figure 4 shows the aerial view of a typical peri-urban sprawl in an enumeration area in Ibadan. From the figure one can see vividly lack of planning and disorganised road network, as well as comatose siting of buildings in the area.

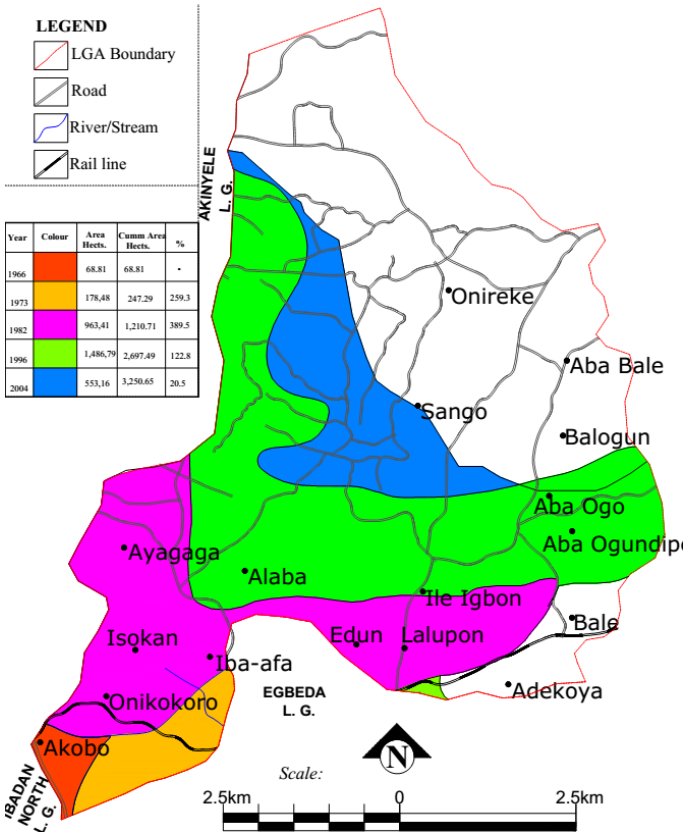

Fig. 3: The Extent of Growth of Lagelu LGA Over a 38-Year Period (1966-2004)

Fig. 4: Aerial View of Peri-Urban Sprawl of Isokan Enumeration Area in Lagelu LGA
Source: Google Earth, 2012

A significant proportion of the residents in the peri-urban areas of Ibadan were involved in either petty trading/small business (37.2%) or artisanal activities (26.4%), as shown in Table 3. There were pockets of retail and artisan shops, as well as commercial activities located sporadically within the areas. This confirms finding of other studies (Mabogunje, 1968; Areola, 1994; Onibokun and Faniran, 1995; Akerele, 1997; Fourchard, 2003) that there was

high level of informal economic sector activities in form of petty trading and petty craft activities in Ibadan.

Table 3: Occupation of Respondents

S/N	Occupation	Local Government Areas				Total	
		Lagelu		Oluyole			
		Frequency	%	Frequency	%	Frequency	%
1.	Farming	12	1.3	59	5.6	71	3.6
2.	Trading/Business	283	30.1	460	43.4	743	37.2

	Total	940	100	1,060	100	1,998	100

The people's involvement in petty trading and other small scale artisanal activities would have an effect on their level of income, which was low. About 43.5 percent of the respondents claimed to make a profit of less than ₦50,000.00 per annum, that is, about ₦4,166.67 per month, while 6.5 percent earned between ₦250,001 and ₦500,000, only 3.8 percent claimed to be earning over ₦1,000,000 per annum (Table 4). It shows that the peri-urban areas of Ibadan were inhabited predominantly by poor people who were leaving below the poverty line, since in the Nigerian context, the national minimum wage is ₦18,000.00 per month or ₦216,000.00 per annum, that is, US $1,309 per annum or US $109 per month or US $3.6day.

Table 4: Annual Income of Respondents

S/N	Income (₦)	Local Government Areas				Total	
		Lagelu		Oluyole			
		Frequency	%	Frequency	%	Frequency	%
1.	< 50,000	385	41.0	480	45.3	865	43.3
2.	50,0001- 100,000	160	17.0	180	17.0	340	17
3.	100,001 - 250,000	75	7.9	110	10.4	185	9.3
4.	250,0001- 500,000	60	6.4	70	6.6	130	6.5
5.	500,001 - 1,000,000	110	11.7	65	6.1	175	8.7
6.	> 1,000,000	60	6.4	15	1.4	75	3.7
7.	No Response	90	9.6	140	13.2	230	11.5
	Total	940	100	1,060	100	2,000	100

A significant proportion (28.4%) of the respondents had stayed in the areas for between 2 and 5 years and between 5.1 and 10 years (22.6%). While 21.3 percent had stayed for less than 2 years, 18.8 percent had stayed for over 15 years. This shows that most of the respondents should have a good understanding of the areas, having being staying there for long prior to the study. About 72.3 percent of the respondents were less than 10 years old as residents in the areas means most of the buildings were relatively new, less than 10 years old. Nevertheless, some of the buildings were not structurally sound. Family landholding was very prevalent in the peri-urban areas of Ibadan, resulting in the indigenous land owners (*omo-oniles*) to be highly influential. Most (45.8%) of the respondents acquired their land, which most often were without any registered title, from the *omo-oniles* and still believed a prospective land owner could acquire his/her land through the same source. Also, a

significant proportion (36.5%) of the respondents claimed to have at one time or the other received threat on their land from the *omo-oniles.*

The types of housing available in the peri-urban areas were bungalows (59.4%), rooming buildings (20.1%), storey buildings (14%), and duplexes (5.5%). Most of the houses being bungalows was adding to the spatial spread of the peri-urban areas of Ibadan, making the growth not to be smart and the entire areas not to be compact. Also, most of the buildings in the studied areas neither have a formal building plan, nor approval by the town planning authority. Such buildings lacked the necessary facilities and infrastructures, such as, toilet, bath, kitchen, as well as water, electricity, among other municipal facilities. Specifically, the finding shows that a significant proportion (36.5%) of the residents had low access to safe/adequate/improved sanitation; still using pit latrine, and practicing open defecation (in fields, bushes, or bodies of water) in the peri-urban areas of Ibadan. These people were putting themselves and others, especially children, in danger of deadly faecal-oral diseases like diarrhea, among others. It should be noted also that some of these houses were being developed installmentally, again, without the necessary in-house facilities. This is s system whereby the owner would complete one or two rooms, moved into the house, while the remaining parts are being developed.

Most of the buildings were rooming, with the modal class of the number of rooms per building being 6-10 (39.5%), closely followed by 4-5 rooms' class (29.5%), while 19.8 percent contained between 2-3 rooms. This frequency of high and varied rooms/building might be due to the varied housing designs or types of houses (bungalows and rooming) constructed within the peri-urban areas of Ibadan. The majority of number of rooms occupied by households in the buildings ranged from 1 to 5. The finding reveals that 41.5 percent of the households occupied 2-3 rooms, followed by 20.5 percent and 20.3 percent households occupying, respectively, less than 2 rooms, and between 4-5 rooms.

Majority of the households (38.8%) consisted of between 2-4 members (Table 5). Following this group were households of 5-7 members with 31.3 percent. While 11 percent were households of 8-10 members, only 9.8 percent had above 10 household members. The single person household recorded only 7.4 percent. The high frequency of low household size recorded in the peri-urban areas might be due to the fact that most of the houses consisted of relatively new and young family formation. Another factor that may be attributed to this is the immediate family structure that is being practiced by significant proportion of the residents of peri-urban areas.

Table 5: Household Size of Respondents

S/N	Household Size	Local Government Areas				Total	
		Lagelu		Oluyole			
		Frequency	%	Frequency	%	Frequency	%
1.	< 2	70	7.4	75	7.1	145	7.3
2.	2- 4	360	38.3	415	39.2	775	38.8
3.	5 – 7	325	34.6	300	28.3	625	31.3
4.	8 -10	105	11.2	115	10.8	220	11
5.	> 10	55	5.9	140	13.2	195	9.8
6.	No Response	25	2.6	15	1.4	40	2
	Total	940	100	1060	100	2,000	100

The exponential growth of peri-urban areas being attributed to the increased in personal vehicles (cars) ownership by the people within the last couple of years was confirmed by this study. Thus, vehicles ownership of the respondents were essentially cars (35.5%),

motorcycles (8.3%), buses (2.5%), and pick up vans (1.3%). Modes of travel for those without personal vehicles included commercial vehicles (49.2%), *okada* (46.7%), trekking (34.4%), and lift (26.3%). The heavy reliance of those without personal vehicles on motorcycles, popularly called *okada* shows the relevance and the growing importance of this mode of travel in the peri-urban areas. This can also be the impact of banning of *okadas* in some cities such as Lagos, Abeokuta and Abuja, which pushed the riders to Ibadan and especially the peri-urban areas of the city.

In providing answers to the question of the distance of the respondents' houses to the central market (Oja-Oba)/ the King's Palace, which was taken as the city (Ibadan) centre, 24 percent of the respondents stated that they lived within 15.6 - 17.5km; 21 - 23.6km (21.9%); 14.6 – 15.5km (21.1%); 11.6 – 14.5km (19.4%); and 17.6 - 20.99km (14.3%). Table 6 shows these distances to the city centre. Thus, it is striking to note that a substantial percentage of the residents had their offices/places of work within the peri-urban areas.

Table 6: Distance to Offices/Places of Work

Distance	Local Government Areas				Total	
	Lagelu		Oluyole			
	Frequency	%	Frequency	%	Frequency	%
< 2Km	435	46.3	570	53.7	1005	50.3
2 – 4Km	165	17.6	140	13.2	305	15.3
4 – 6Km	65	6.9	85	8.0	150	7.5
>6Km	180	19.1	175	16.5	355	17.7
No Response	95	10.1	90	8.5	185	9.3

While majority (55.4%) of the respondents had their offices/places of work located within less than 2kms to their residences (obviously because of the informal employment opportunities in such areas), 19.6 percent respondents' offices were located outside their neighborhoods (more than 6kms), 25.1 percent of the respondents were in between the two extremes, with 16.8 percent (2-4kms) and 8.3 percent (4-6kms), respectively. These distances had an effect on the time spent to travel to these places of work. Since most of the respondents had their offices within the areas, however, mostly they spent less time to travel to such places. Thus 37.7 percent of the respondents spent less than 10 minutes, 28.4 percent spent between 10-30 minutes, 15.2 percent spent between 20 minutes and 1 hour. However, 12.7 percent spent between 1-2 hours, while the remaining 6.1 percent spent over two hours. Those spending more time to travel to their places of work were those working outside the peri-urban areas.

These peri-urban areas lacked designated open spaces and other recreational facilities. Consequently, majority (68.3%) of the respondents claimed to be recreating at home (in form of relaxation), while 29.1 percent were recreating within the communities, in such places as beer parlours and centres for playing game board (ayo olopon) and checkers (draughts). These are traditional games being played at leisure time by the people as revealed through the PRA exercises.

CONCLUSION

In this study, the development of Ibadan, vis-à-vis the peri-urbanization of the city has been examined. The study found out that Ibadan recorded a sprawl of more than quadrupled over a 34-year period (1966-2004). Moreover, the rates of peri-urban sprawl of Oluyole and Lagelu LGAs of Ibadan were not the same. The exponential growth of peri-urban areas in Ibadan

was attributed partially to increase in personal vehicle (cars) ownership within the last couple of years. A significant proportion of adult residents in the areas were involved in either petty trading/small business or artisanal activities, resulting in pockets of retail and artisan shops, as well as commercial activities located sporadically within the areas. The commercial activities were uncoordinated, unplanned and located at irregular intervals within the residential areas. Also, majority of the inhabitants had their offices/places of work located within the areas, which were inhabited predominantly by relatively poor people. The distance of the inhabitants' houses to the city centre (Oja-Oba) ranged from 15.6 to 20.99km. There were varied housing designs or types of houses, with majorly bungalows, leading to the sprawl.

Considering the findings of the research, the following recommendations are necessary:

i. **Regulate the peri-urban sprawl.** Considering the challenge of regulating peri-urban sprawl through the existing weak and ineffective planning instruments, it is being recommended that there should be strengthening of the existing Local Town Planning Authorities through human capital development and procurement of the necessary equipment. This will address the issue of planlessness and uncoordinated growth of the peri-urban areas, thereby promoting smart and compact peri-urban growth.

ii. **Provision of in-house and neighborhood facilities.** The inhabitants of peri-urban areas should be encouraged to provide the necessary in-house facilities, such as safe water and sanitation facilities (toilet and bathroom), kitchen, among others, in the peri-urban areas. Moreover, the government should create the enabling environment for the provision of the essential neighborhood facilities, such as electricity, motorable roads, drainages, culverts, among others.

iii. **Regulate land allocation and acquisition process**. The family landholding system should be regulated and or the land use act of 1978 be reviewed to make land easily accessible to prospective house owners.

ABSTRACT

This study appraises the relationship of rural income generating activities with the prosecution of community development projects in Ijesa Region with the view to proposing a policy framework that can capitalise on the advantages of the connection to accelerate prosecution of community development projects in the region in particular and in Nigeria in general. The region is located in the south-western part of Nigeria and made up of six Local Government Areas (LGAs). This study focused on Atakunmosa East, Atakunmosa West, Obokun and Oriade LGAs which are the four rural/semi-urban LGAs in the region. Data were collected from primary and secondary sources and complemented with Focus Group Discussions (FGD) and physical observations. The research populations were the resident-population and community projects in the study area. The main research instrument used was two sets of structured questionnaire administered on heads of households and co-coordinators of community development projects in the study area respectively. The collected data were processed using the Statistical Package for Social Sciences (SPSS) computer software. The result shows a significant relationship between the people's level of involvement in income generating activities and their contributions to community development projects in the study area. It was revealed that funds for investment constitute a main constraint to the operations of income generating activities in the study area. This study affirmed that the more viable the people's income generating activities, the more their ability to contribute to community development projects. Improvement of access to credit facilities by operators of rural income generating activities through better funding from "sleeping funds" such as pension fund, among others, was recommended. Upliftment of the state of infrastructure, such as markets and roads was also recommended to aid the operations of income generating activities.

Keywords: Community Development, Entrepreneurship, Local Economic Development, Rural Income Generating Activity

INTRODUCTION

Community development is a term coined to denote initiatives and actions taken by members of a community to improve their standard of living. The United Nations defines it as a process where community members come together to take collective action to generate solutions to common problems (Wikipedia, 2015). This involves a set of approaches undertaken by individuals, groups and/or organisations to solve physical and socio-economic problems of their communities.

Significant contributions to community development highly revolve around the financial capabilities of the community members. This talks of level of economic vibrancy of the activities involved in income generation in the communities. Rural income generating activities, therefore, constitute a significant source of entrepreneurial revenue for rural population through rural livelihood diversification. These are assorted wage and non-wage entrepreneurial ventures that produce income in the rural areas for livelihood sustenance of the dwellers and socio-economic upliftment of the area (FAO, 1978).

The study set to resolve the question of whether rural income generating activities have been able to sufficiently empower the residents to contribute significantly to socio-economic and physical development of their respective communities or not. It also set to answer the question of how the level of participation, contributions and involvement of the community members contribute to the social, economic and physical upliftment of their communities.

Faseun, J. O.; Olanrewaju, D. O. & Olujimi, J. A. B. (2016). Community Development Perspective of Rural Income Generating Activities in Nigeria: The Ijesa Region Example. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1535-1544

According to Oyetunji and Ajayi (2014), participatory development is highly essential towards enabling communities to help themselves in development projects in order to have livable communities.

Therefore, the aim of this study is to appraise the impact of the people's involvement in rural income generating activities on their contributions to community development projects in the study area with a view to recommending a policy framework that will strengthen rural income generating activities for community development. It further tested a hypothesis which states that:

H_0: Rural income generating activities do not significantly contribute to community development in Ijesa Region.

H_1: Rural income generating activities significantly contribute to community development in Ijesa Region.

LITERATURE REVIEW

Community Development

Community development reflects a grass-root or bottom-up approach to development; and this is in the purview of Local Economic Development (LED) concept. LED concept is a development approach whereby local endowment is utilised for the socio-economic upliftment of the area where they are endowed; believing that the aggregation of these localised developments will eventually result into a viable corporate regional development (Emmanuel, 2003). People's participation in community development refers to the active voluntary engagement of individuals and groups to change problematic conditions and influence policies and programmes that affect the quality of their lives and the lives of others. It builds strong and resilient communities through the process of identifying and addressing needs, assets and priority investment (Green, 2015). Community development activities may support infrastructure, economic development projects, installation of public facilities, community centres, housing rehabilitation, public services, clearance/acquisition, micro-enterprises, code-enforcement, home-ownership assistance and many other identified needs.

Carletto et al. (2007) affirm that issues about socio-economic development should consider the full range of rural income generating activities (both agricultural and non-agricultural) being carried out by the rural households. This allows for a proper understanding of the relationships between the various economic activities that take place in the physical space and of their implications for physical and socio-economic development of the communities.

Rural income generating activities as a strategic entrepreneurial force for community development

Rural income generating activities constitute the entrepreneurial pursuits of the rural dwellers for livelihood sustenance. According to Jhingan (2011), an entrepreneur is someone who possesses the ability to recognise opportunities for successful introduction of new commodities, new techniques and new sources of supply to run a business venture. Entrepreneurship mobilises other resources to meet unmet market demand (Jones and Sakong, 1980).

Entrepreneurship forms an economic force in rural development; as both have strong inter-link with each other. It is also a strategic development intervention that accelerates development. It provides enormous employment potentials and opportunities and constitutes a central force of economic growth and development; and without it, other factors of development are wasted and frittered away (Acs, et al., 2015). Food and Agriculture Organisation (FAO) arm of the United Nations considers entrepreneurial activities in rural areas as a vital issue in local (rural) and regional development. Local and regional

development cannot be separated from the full range of income generating activities being carried out by rural households. Rural income generating activities have implications for socio-economic growth and poverty reduction which, in turns, dictate the level of achievement of sustainable development.

As part of a community adaptation strategy, rural individuals and families are turning to non-farm income generating activities for subsistence (Jenson et al, 1995; Mencken & Maggard, 1999). Rural households are seizing business opportunities in order to improve their livelihood and create job opportunities for people around them. Many poor rural households maintain diversified set of activities to cope with life. Their activities, in many parts of the world, are the backbones of local economies and employment; producing about 70 per cent of goods for local, sub-regional, regional and national markets (Canzanelli, 2001). There is an increasing awareness in the developing nations of the necessity to strengthen local enterprises to provide answers to unemployment, economic survival and local (rural) and regional development (Emmanuel, 2003, Faseun, 2007).

Since human resource is paramount to local and regional development, the economic capability of people strongly influences people's ability to enhance local and regional development. The level of vibrancy of people's income generating activities has a strong bearing with the level of their contributions to socio-economic development at both local and regional level. Therefore, strengthening income generating activities is directly and indirectly analogous to enhancement of socio-economic development at all levels – be it grass-root, sub-regional, regional, supra-regional and national. It was on the above observation and premises that this study intends to find out whether the activities have significantly contributed to development in the region.

THE STUDY AREA AND RESEARCH METHODOLOGY

The Study Area: Ijesa Region

The study was conducted in Ijesa Region located in Osun State in the south-western geo-political zone of Nigeria. It lies between Latitudes 7° 17' North and 7° 50' North of the Equator and Longitudes 4^0 33' East and 5^0 10' East of the Greenwich Meridian. The region covers six of the 30 Local Government Areas (LGAs) and one Administrative Area political division of Osun State. Two of these LGAs are within Ijesa Metropolis while the remaining four are situated in the rural and semi.-urban areas of the region (Map 1).

The Ijesas are countrywide-acclaimed resourceful and ingenious traders and great farmers especially in tree crops, such as cocoa, kola-nut, palm-produce, plantain and fruits. Local crafts, like mat and cloth weaving, blacksmithing and pottery were popular in the region until the advent of new technologies for the production of such materials.

Research Methodology

The study employed survey method using questionnaire as the main survey instrument. The use of questionnaire was considered appropriate for the study because it allowed interaction with the resident-population in order to obtain their feelings, opinions and thoughts on the subject under study. Two sets of questionnaire were designed to obtain data from the resident-population on their income generating activities in relation to their involvement in community development projects in their respective communities and the CDA administrators respectively. Data were also sourced from primary and secondary sources complemented with Focus Group Discussions (FGD) and physical observations. The research populations were the rural resident-population, the leadership of Community Development Associations (CDAs) and community projects in the study area.

The 487 settlements in the study area were stratified into four Order-Centres (socio-economic activity-zones). Stratified random sampling method was used to determine the sample-size for the surveys across the LGAs and the Order-Centres; cutting through the various CDAs. In all, a total of 65,146 households and 198 functional Order-Centres were identified. Using stratified sampling technique, the household questionnaire was administered on 2 per cent of the households (i.e., 1,303 heads of household), and while the other set of questionnaire was administered on 100 CDAs spread across 10 per cent of the functional Order-Centres (i.e., 20 settlements). Data collected were complimented and supplemented with Focus Group Discussions and physical observations conducted across the region. The collected data were processed using the Statistical Package for Social Sciences (SPSS) computer software.

ANALYSIS AND DISCUSSIONS OF FINDINGS

Assessment of Level of Utilisation of Endowed Resources in the Study Area for Income Generation

Ijesa Region is endowed with many natural resources, such as high quality gold at Itagunmodi, an ancient town in Atakunmosa East LGA, forestry resources and agricultural

resources like cocoa, kolanuts and palm produce and food crops across all the LGAs. The utilisation of these resources provides opportunities for the highly resourceful resident-population to create employment for income generation. Except for exploitation of gold, which is under the control of Federal Government of Nigeria, people are free to legitimately utilise all other resources for income generation. There are evidences of illegal mining and selling of raw gold by families with gold deposit in their landed property.

The field survey, as depicted in Figure 1, shows that 1.8 per cent, 11.8 per cent and 21.2 per cent of the respondents are utilising the endowed solid minerals, forestry resources and farm resources respectively in their respective income generating activities. While 9.1 per cent of the respondents are utilising the combination of solid minerals and forest resources, 6.3 per cent are utilising mineral and farm resources. About 34.4 per cent utilise forest and farm resources and 18.6 per cent utilise all the three types of resources for income generation.

However, 9.1 per cent are utilising other resources sourced outside the study area for their income generating activities.

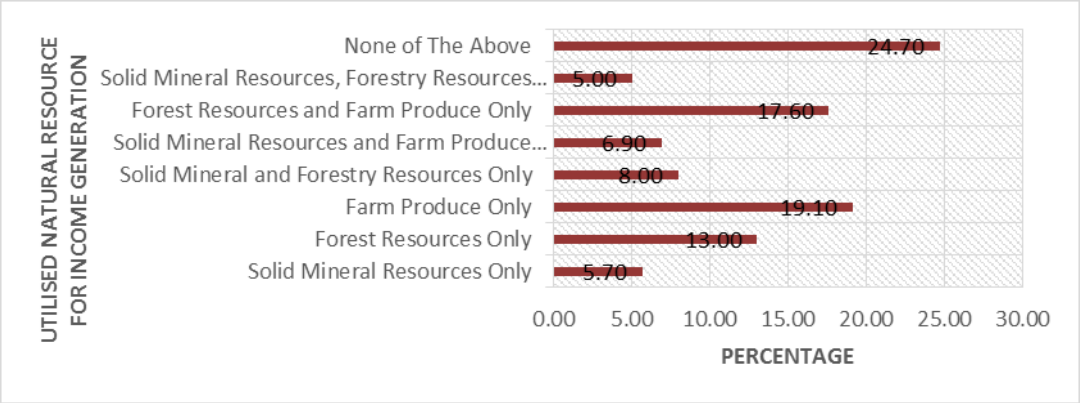

Figure 1: Level of Utilisation of the Endowed Natural Resources in the Study Area for Income Generation
Source: Authors' Fieldwork, 2012

The people are involved in merchandise of finished products such as electronics, cement, canned materials, among others. Some of them are involved in entertainment and hospitality services while others are artisans and craftsmen/women. Survey shows that 90.9 per cent of the respondents are utilising one, some or all of solid mineral, agricultural and forestry resources found in the area for their income generating activities. This shows rural income generating activities highly involve exploiting local resources as sources of employment and agents of local economic development in the study area. This enhances regional economic growth and development.

This implies that rural income generating activities have been able to encourage resource development in the region and assist the residents to make meaningful financial contributions to community development. Survey revealed that substantial numbers of income generating activities in Itagunmodi in Atakunmosa LGA substantially involve gold mining activities (though illegally), agricultural practice and exploitation of forest resources. This inspires and invigorates local and regional economy, growth and development.

A Chi-square test result on the utilisation of endowed natural resources for income generation in the region shows a Pearson Chi-Square value of 0.036 which is less than $\alpha = 0.05$; indicating significant utilisation of these resources for income generation in the region (Table 1).

Table 1: Result of Chi-Square Test on Utilisation of Endowed Natural Resources in the Study Area for Rural Income Generating Activities

	Value	Df	Asymp. Sig. (2-sided)

Association between Population Traits and the People's Involvement in Rural Income Generating Activities in the Study Area

The significance of association between the population traits of the respondents and their involvement in either primary or secondary income generating activities was tested using Chi-Square Test of Significance as depicted in Table 2. Chi-square test of significance possesses the ability to provide insight into the strength of the influence of variables on each other.

As shown in the table, the X2-Calculated Value is greater than the X2-Table Value at 0.05 Level of Significance for all the Degrees of Freedom (df) for all the population traits. This indicates significant associations of population traits of gender, age, marital status, educational attainment, household-size, nativity, employment class and income with the involvement of the people in rural income generating activities as either their primary or secondary employment.

This interprets to mean that the population traits substantially influence the factors that determine the choice of rural income generating activities as primary or secondary employment in the study area. This possibly explains why there are more males in agricultural activities than females and more females in trading than males. This may also partially explain the reason behind the involvement of more males than females in vehicle driving and motor mechanic professions.

Table 2: Result of Chi-Square Test on the Association of Population Traits with the People's Involvement in Rural Income Generating Activities

Population Traits		Gender	Age	Marital Status	Educa-tional Status	House-hold Size	Settle-ment of Origin	Income

Relationship between the People's Involvement in Rural Income Generating Activities and Their Contributions to Community Development Projects in the Study Area

The study shows that 98.5% of the respondent-household-heads claimed that paucity of fund for their activities is their major problem. They complained of inadequate access to loan

facilities and financial grants that should have assisted their operations. This problem, invariably, reduces their contributions to their community development projects.

Due to the nominal nature of the variables, a Point Biserial Correlation test was carried out on the relationship between the people's involvement in rural income generating activities and their financial contributions to community development projects. The result shows that the p-values are less than $\alpha = 0.05$ and positive (0.021; 0.018) for both involvement in the activities as primary and secondary employment (Table 3). This means that there is a significant relationship between the people's involvement in rural income generating activities and their financial contributions to development projects in their communities. This indicates that the involvement of the people in rural income generating activities, either as primary or secondary source of income, is a potent and significant force that propels their contributions of the people to community development projects in the region. This implies that if rural income generating activities are better funded, there is a high possibility of better income for the operators of the activities; and subsequently, the enhancement of their contributions to community development projects.

Table 3: Point Biserial Correlation Test of Involvement in Rural Income Generating Activities and the People's Financial Contributions to Community Development Projects

		Involvement in Income Generating Activities as Primary Employment (RIGAPRY)	Involvement in Income Generating Activities as Secondary Employment (RIGASEC)
Financial Contributions to Community Development Projects (PROJECT-F)	***Pearson Corr.***	0.071	0.089

Test of Hypothesis

Phi-correlation was applied to test the hypothesis that states that:

H_0: Rural income generating activities do not significantly contribute to community development in the study area.

H_1: Rural income generating activities significantly contribute to community development in the study area.

The variables of rural income generating activities used for the test are the activities as primary employment (RIGAPRY) and as secondary employment (RIGASEC), scale of operation (RIGASCAL), types of activities in terms of agricultural, trading and craftsmanship activities (RIGATYPE) and who initiated the activities in terms of individual, group or community (INITIATE). Development was measured with references to the market spread for the products and services of the activities (MARKET) and modes of sales of the products in terms of wholesale and retail enterprises (SALEMODE).

The result of the test shows that all the p-values are less than $\alpha = 0.05$ (Table 4). Therefore, null hypothesis is rejected and the alternative accepted which states that rural income generating activities contribute significantly to community development in the region. All the contributions are positive; though at differing levels of contribution (Table 4).

These findings imply that if the rural income generating activities are enhanced, there will be a significant improvement in the socio-economic development of the region through the people's active involvement in and contributions to community development projects.

SUMMARY OF THE FINDINGS

The summary of the study is that the resident-population of the region is actively involved in income generation with many of them utilising the endowed resources in the area. This empowers them to contribute meaningfully to socio-economic development in their respective communities. This indicates that if the income generating activities are assisted to be more economically viable, the income of the resident-population will be substantially enhanced. The income enhancement will increase their financial capability to contribute significantly to community development projects in the region.

Table 4: Result of Phi-Coefficient Correlation Test on the Contribution of Rural Income Generating Activities to Development in the Study Area

	Phi Coefficient.	Approx. Significance.	Direction & Strength of the Contribution
RIGAPRY * MARKET	0.427	0.000	Positive & Moderate
RIGAPRY * SALEMODE	0.346	0.000	Positive & Moderate
RIGASEC * MARKET	0.525	0.000	Positive & Strong
RIGASEC * SALEMODE	0.286	0.000	Positive but Weak
RIGASCAL * MARKET	0.470	0.000	Positive & Moderate
RIGASCAL * SALEMODE	0.466	0.000	Positive & Moderate
RIGATYPE * MARKET	0.545	0.000	Positive & Strong
RIGATYPE * SALEMODE	0.209	0.000	Positive but Weak
INITIATE * MARKET	0.575	0.000	Positive & Strong
INITIATE * SALEMODE	0.195	0.000	Positive but Weak

RECOMMENDATIONS

Based on this, a policy framework that can capitalise on the advantages of vibrant rural income generating activities to enhance and accelerate initiation and prosecution of community development projects in the region is recommended. The framework should focus on the re-groupings of the weedy activity-groups presently based on individual articles of trade. This is to ensure effective control and management by government for better assistance. The income generating activities should, therefore, be formalised by organising them into registered workable groups based on distinct standard professional status with supervisory agencies at local and state government levels for effective monitoring.

To tackle the problem of paucity of fund, it is recommended that five per cent (5%) of some "national sleeping funds" such as pension funds with the various Pension Fund Administrators (PFAs) and Pension Custodians and "resting funds" in Nigerian Stock Exchange (NSE) should be set aside as loanable funds at a very low interest of maximum of 4% to boost small and medium-scale rural income generating activities.

Also, some high flying companies with a minimum of one billion Naira annual profit before tax should be compelled to be contributing one per cent (1%) of such profits to a special fund strictly meant to service rural income generating activities. Companies such as MTN, DSTV and big other service providers who are making a lot profit in Nigeria should be compelled through the Central Bank of Nigeria (CBN) to contribute to a special fund for the enhancement of rural income generating activities.

There should be reduction in the 20 – 25% interest rate being charged by microfinance banks to about 7%. The banks can do this by accessing resources at 3% interest rate from the earlier recommended specially set aside funds from the 'sleeping funds' and "resting funds".

Specifically, four more regional markets are recommended to be established across the region in addition to Owena-Ijesa Regional Market in Oriade LGA. The recommended locations for the markets are Osu and Okebode (in Atakunmosa West LGA), Itagunmodi (in Atakunmosa

East LGA) and Ijebu-jesa (in Oriade LGA). The new markets along with the existing Owena-Ijesa Regional Market will form a "Regional Market Ring" in the region (Figure 2).

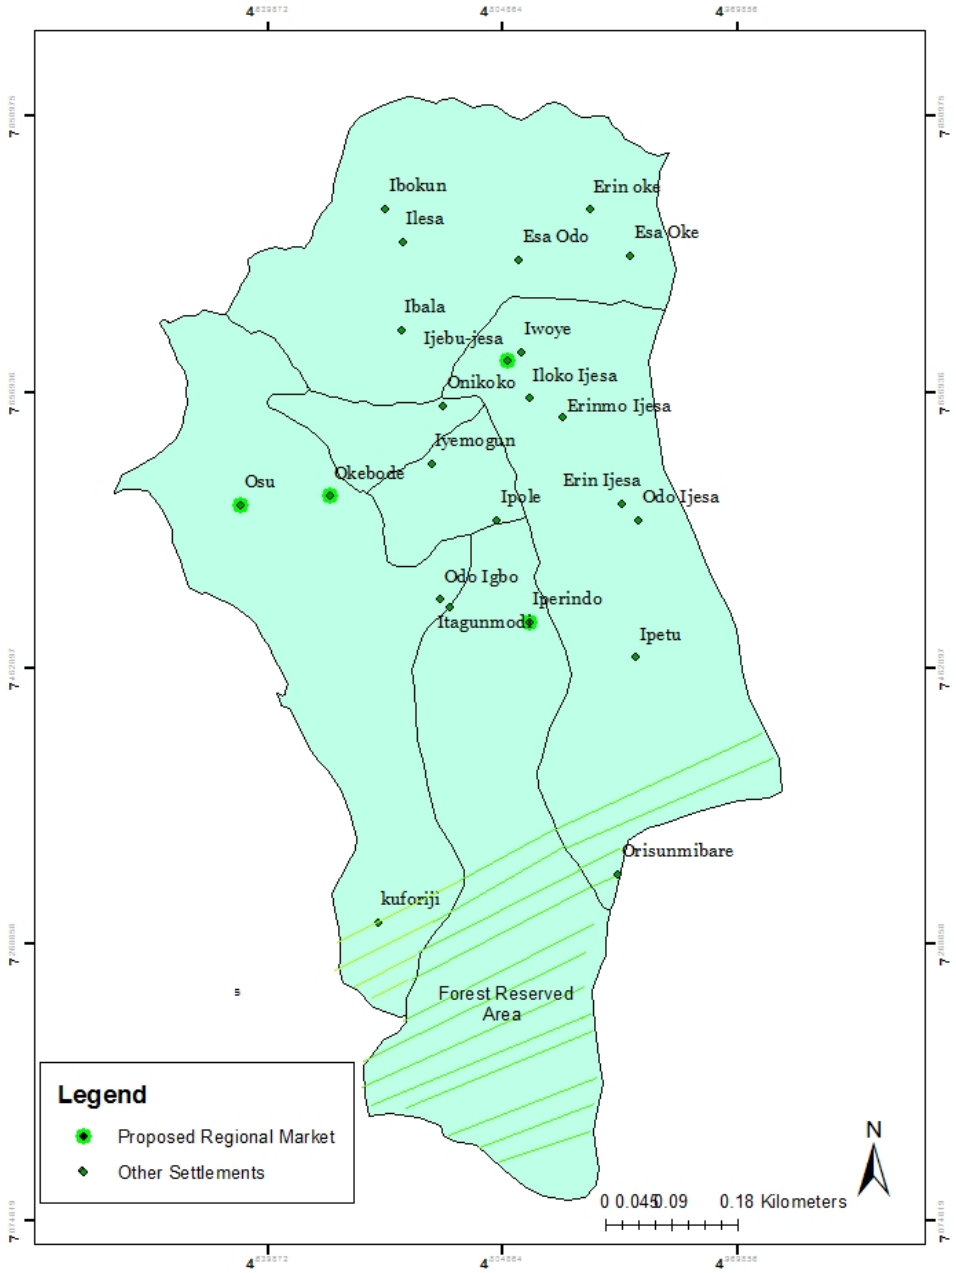

Figure 2: Map of Ijesa Region Highlighting the Locations of the Proposed Regional Markets in the Study Area

CONCLUSION

The level of vibrancy of rural income generating activities taking place in a community determines the propensity of the resident-population to contribute significantly to community socio-economic projects. Therefore, any policy framework that can invigorate the activities is a step towards encouraging the citizenry to be contributors and participants in community projects.

ABSTRACT

High quality road network increases national economic output by reducing trip times and costs, makes road corridor economically attractive and viable. As traffic becomes congested, drivers opt for alternative routes to reach destinations faster. This paper investigates road network connectivity, accessibility and market patronage in Benin metropolis, Nigeria. Stratified sampling technique, questionnaire, physical observation and graph theory analysis were employed for this study. Out of the twenty (20) markets in Benin metropolis, nine (9) of them were selected for the survey. Connectivity and accessibility matrices developed from the road network graph in the study area, reveal some nodal points (markets) and edges (routes). Fundamental properties of the transport network were measured to identify the growth within the network structure and change detection system. Gamma index value of 0.71 and Cyclomatic index (0.7) calculated show strong complexity and high degree connectivity. Yanga Market and Eki-Oba with index 10 were the most accessible nodal points and Eki-Uwa with index 21 as least accessible nodal point. Private cars (42.8 percent) and buses (41.5 percent) were most used transit modes. Market places contribute 90.7 percent to traffic congestion, 4.9 percent indicate that it 'rarely' occurs, while 4.4 percent respondents did not feel any impact of traffic congestion. These values positively influence traffic attraction and circulation with or without intervening opportunities to substitute the need and purpose of trips. The paper recommends identification of alternative routes for none-market destination, mass transit intervention, enactment and enforcement of traffic management laws.

Keywords: Road Network, Connectivity, Accessibility, Market Patronage, Benin Metropolis

INTRODUCTION

The quality of life and economy of any society depend on efficient, comprehensive and coordinated multimodal transport system that provides quick movement of goods and services (Okoko and Fasakin, 2007). Ikegbunam (2014) reports that, transportation system involves the flow of people, ideas, materials, goods and services from one location to another, resulting in spatial distribution of resources.

Transportation, movement and exchange of goods and services are obligatory features of modern life (Umoren et al, 2009) due to their multi-dimensional functions, imperatives of interaction, and its dynamic structure. Road has been described as the life-blood of human civilisation (Sarka, 2013) and social interaction. Economic prosperity in space has been shaped by road networks at intra and inter-regional levels. However, Oyesiku (2002) emphasizes that, the forms and pattern of distribution of structures to promote good health, accessibility, convenience and harmonious land use in an environment are a function of the rights and methods of dealing with land. Therefore, effective urban landuse control and the management of spatial activities in areas with rapid urban sprawl in Nigeria and Benin metropolis in particular, are crucial to tackling land use and transportation problems.

Human settlement is seen to be naturally heterogeneous, but a symbiotic system. One major part of the system is the market place, critically influenced by factors like; mode of transit, socio-economic characteristics of traders, distance, location and range of goods (Omole,

Fasakin, J. O. & Ayo-Odifiri, O. O. (2016). Road Network Connectivity, Accessibility and Market Patronage in Benin Metropolis, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1545-1555

2009). Urban landuses need adequate, convenient and efficient transportation system especially the commercial landuse such as market places. Market place serves as the hub of economic activities of a people and attraction especially from the residential landuse (Ojo, 1966). Therefore, initiating road connectivity to reduce traffic problems in these market areas would attract minimal cost and reduce man hours crucial to urban growth and development.

Availability of a convenient and acceptable location for trading activities as well as proximity to places of activity constitute significant factor in urban development. Adeagbo (2004) asserts that market provides daily reasons for people to meet one another. Similarly, Ratcliffe (1974) corroborates the view that apart from the economic advantages, markets also provide social function as a focus of the community, a meeting place, and generally contributing to the well-being of the society. Commercial activities such as buying and selling are major traffic attractors and circulators, which tend to concentrate more along road corridors for easy access.

Benin metropolis with its well-structured road network, experiences diverse transportation problems, especially easy and quick access to and through market locations. Some of these market places have historical and cultural significance in their locations, which contribute to the high traffic flow around them. The pattern of market distribution influences traffic flow in Benin metropolis, where many markets are located along road corridors. Nwafor (1982) and Eben-Saleh (1999) identify two basic classes of market places as daily and periodic markets. The periodicity (daily or weekly) of market exacerbates the existing traffic situation in the study area. Casual observation reveals that no meaningful attention may have been given to conflict and control of heavy vehicular and pedestrian traffic, especially at the various market locations in the study area.

With enormous traffic problems; uncoordinated traffic management, dwindling government resource allocation to transportation and market infrastructure, there is an urgent need to evolve proactive measures of maintaining free-flow of traffic within and around the market places in Benin City. The paper reveals the role of transportation management agencies and stakeholders, and market operators. Against this background, the paper seeks to investigate the degree of connectivity index of the routes linking the selected markets and also examine the level of accessibility of the selected market places in Benin City.

LITERATURE REVIEW

Road network as one of the oldest infrastructures of transportation, occupies a significant locality in modernisation, sustainable development, and daily activities in ancient and modern times (Al-dami, 2015). Rogers (2003) observes that road network of a high quality increases national economic output, reduces trip times and costs, and makes regions more economically attractive. Omole (2009) reports that market centres are fundamental to the economic, social, cultural, religious and political life of people. Despite poor recognition given to market place development in the post-independence periods, it promotes integration between production and consumption platforms of the economies on which they stand.

Socio-culturally, there is the belief that once information is given at the market place, it would be disseminated with ease to every part of the town by market patrons. Anthonia (1973) points out that, market places are social centres for activities like courtship, visits, exchange of ideas, drumming, and dancing, reuniting and festivities. They also advance economic, cultural and socio-political cohesion for societal development. Traditionally, many ancient Oba (King) palaces were located close to market places, because of the sacred identity attached to market places.

The religious roles of market places especially among the Binis cannot be overemphasized. Oral tradition has it that many market places in Bini were identified as sacred places used for all manner of sacrifices or rituals with associative traditional names. This is said to appease the gods of the land and spirits believed to meet and live on trees at the market centres. However, as orthodox Bini tradition recognises the importance of the market place, so also there the early Christian and Moslem missionaries used as a place for the propagation of the gospel because of her huge population. Olorunfemi (1999) upholds the oral tradition report that in Badagry Nigeria, the first church was built between two public markets, and in Akure, the central mosque is located opposite Oja-Oba. In the same vein, the central mosque in Auchi, Nigeria is sited at the premises of Ughiele market, and The Baptist convention (Church) is located beside Eki-Oliha in Benin City.

Traffic management measure used, organises movement, protects vulnerable road users, and makes best use of existing transportation facilities for safety, smooth traffic flow and re-route where necessary (Ndikom, 2010). On this basis, Litman and Fitzroy (2011) note that mobilizing management is a cost effective safety strategy, but decry that it is seldom implemented. In addition, they stress that, its objectives are to reduce traffic congestion, road and parking cost savings, energy conservation and emission reduction, and improved mobility options for non-drivers. Adeagbo (2004) in his assessment of accessibility opines that whether traditional or modern market, traffic and parking problems in urban markets are prominent in the economic and social development of settlement. The report notes that markets are so important that for any community to develop, availability of a convenient and acceptable location for buying and selling constitute significant factor as well as proximity to places of activity. This strategy Increases traffic flow rate and efficient interaction.

Okoko (2006) posits that Transportation System Management (TSM) concept is a short-term measure to make the most productive and cost effective use of existing transportation facilities, services and modes. TSM is a series of actions embarked upon deliberately to produce shifts in the supply-demand equilibrium of various transportation components. In addition, Fasakin (2000) emphasises that TSM protects pedestrians and encourages invariably the use of Para-transit modes (bicycles and motorcycles).

On the other hand, Transportation Demand Management (TDM) concept reduces traffic flows during peak hours; some of the techniques include car pooling, ride-sharing, and bus priority. IEA National Committee on Transport (1995) sees TDM as intervention to modify travel decisions for a more desirable transport, social, economic and environmentally friendly objectives to reduce adverse impacts of travel. Ohiaegbunem (2007) and Ndikom (2010) identify Contemporary transportation management options as road pricing, fuel taxes, ride sharing (mass transit), and traffic rules and regulations. Others are; traffic segregation, traffic restraint, bus priority, one-way scheme, parking management and landuse option. TDM is a reaction against continued large scale provision of road infrastructure to foster efficient mobility, environmental attractiveness, social equity, and effective utilisation of existing facilities.

STUDY AREA

Benin City is located between Latitude 06°19'N and 06°21'N, and Longitude 05°34'E and 05°44'E. It is situated in the south-south geo-political zone of Nigeria at an elevation of 77.8m above sea-level. Benin is a pre-colonial city, the capital of the defunct Mid-West and Bendel States, and the present Edo State. It is under laid by sedimentary formation of the Miocene-Pleistocene-age often referred to as the Benin formation (Odemerho, 1988). The city is located in the humid tropical rainforest belt of Nigeria with a population of 1,086,882 (NPC, 2006) and a projected population of 1,336,056 by 2012 at 3.5% growth rate.

Rainy season in Benin begins in March/April and ends in October/November. Rainfalls are of high intensity and usually double maxima with a dry little spell in August regularly referred to as 'August Break'. Apart from demographic transition, Benin City has witnessed, rapid territorial expansion due mainly to rapid rural-urban migration as well as tourist destination for bronze casting and the great Benin moat. Property developers have erected structures in different parts of the city and often without strict adherence to town planning regulations (Godwin et al, 2011).

The term "Edo" refers to place, dialect, language and people of Bini. Individuals from the Bini Kingdom call themselves "Oviedo" or "Ovioba". The Bini Kingdom was redefined (by the British) after the restoration of the monarchy in 1914 and limited to the new Benin Division (comprises of Binis).

METHODOLOGY

This paper focused on road network connectivity, accessibility and market place patronage in Benin metropolis. The scope therefore, demanded data set that requires variables on connectivity, accessibility, range of goods, mode of transit, and traffic impedance in Benin metropolis. Structured questionnaire was designed to elicit information from the target population who are traders (buyers and sellers) and households around the selected market places, road users (drivers) and government agencies.

Markets were selected for the study by stratified sampling technique based on the following criteria: geographical location, periodicity (daily or weekly) of the market, historical and cultural significance, Central Business District function (location within the CBD), and traffic confluence. Legal stall owners (sellers and buyers), and road users (private and public drivers) were interviewed. Others were the Nigerian Police; Edo State Traffic Management Agency (EDSTMA), and Oredo Local Government Council. Appendix 1 shows the road network map of the study area, and the selected market places identified by their traditional names. Inventories on road conditions, range of goods, and nature of traffic and patronage level were carried out. Models on connectivity, accessibility indices, and distances matrix were developed to explain the inter- and intra-markets linkages.

Precisely, out of the twenty (20) market places identified, nine (9) of them representing 45 percent were surveyed and questionnaire administered on market patrons. Data were collected at specific places and periods to meet targeted respondents. Questionnaires for traders and road users were administered in the afternoon, when many respondents had settled down for business, while Government agencies questionnaires were administered during office hours (8am to 4pm) on week days. Out of the Thirty-five (35) field assistants recruited, two (2) were assigned to each of the selected market place and road, nine (9) to EDSTMA, four (4) to the Nigerian Police and the other four (4) to Oredo Local Government Council.

Graph theoretic analysis was used to examine the road network and reveal the degree of connectivity and accessibility of nodes (market places) within the network of roads in the study area. The road map was converted to linear graph regardless of the width, standard and quality of the roads. Each market was rated according to its level of connectivity and accessibility using the shimbel index matrix, and the number of routes required to connect a market with other markets in the network through the shortest path was identified.

RESULTS AND DISCUSSION

Findings from the study are discussed under subheadings which include market location and range of goods and services, mode of transit, traffic congestion, and traffic impedance. Others

are road connectivity and degree of market patronage, and accessibility and level of market patronage.

Market Location and range of goods and services

Omole (2005) reports that the range of goods and services is average maximum distance a prospective consumer is willing to cover in order to consume a good or a service. Computation of the distances between the selected market places was done using Shimbel connectivity matrix shown in Table 1. At the ring road (Oba Ovoranmwen square/king's square) where the Oba palace is located, Eki-Oba and Yanga market, which are closest to market patrons are located 189m apart.

The study revealed that, the location and shape of Yanga market and Eki-Oba places conform to Walter Christellar's hexagonal principle that says, each market place serves six other markets (Figure 4) of the same number of smaller centres (central place theory) respectively. The remaining seven (7) out of the selected nine (9) markets do not conform, because of the intervening market centres that break the hierarchical principles among the market places.

Market Location and Modes of Transit

Safety and timely arrival at one's destination are factors of an effective transportation system. Inefficient transport mode and paucity of infrastructural facilities affect the sustainability and patronage of market places. Where these challenges abound, traffic congestion is likely to set-in, especially, when the carriage-capacity of the dominant operational transport mode is low. Figure 1 shows that 42.8 percent of the respondents used private cars to and from the market, while mini-buses and taxi accounted for 41.5 percent and 9.8 percent. About 2.5 percent of the respondents used foot and keke-NAPEP (National Poverty Eradication Programme) to market respectively, while 0.9 percent said they used trucks. The number of private cars used was quite high, considering the occupancy capacity of private and taxi cars with not more than four (4) passengers on board, whereas a bus would conveniently carry between eight (8) to eighteen (18) passengers on a trip. This implies that the traffic problem experienced in the study area is exacerbated by increased use of private cars and taxi cars.

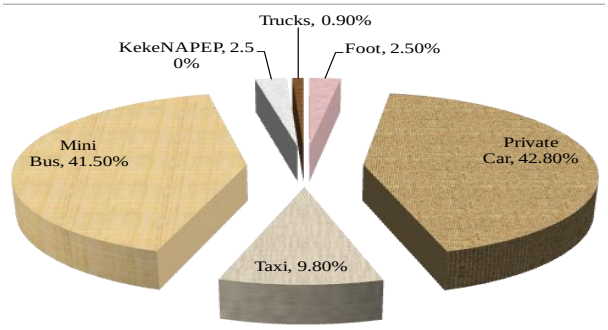

Figure 1. Modes of Transit of Respondents to Mark
Source: Fieldwork, 2013

Market Location and Traffic Congestion

On the possible influence of market location on traffic congestion in Benin metropolis the respondents were of the view that, the location of market was responsible for 38.3 percent of daily traffic congestion experienced in Benin metropolis, while 34.9 percent believed it was responsible for traffic congestion six (6) days of the week. Other respondents observed that, traffic is witnessed once a week (14.4 percent), 4.9 percent indicate that it 'rarely' occurs, while 4.4 percent respondents did not feel any impact of traffic congestion (Figure 2). These responses confirmed the contribution of market location to traffic congestion in the study area. The divergent views of respondents are perhaps based on the periodicity of the selected market and nature of markets (types of goods sold in the market), especially, for the 17.4

percent who observed that, traffic congestion is experienced once a week. Similarly, a negligible 4.4 percent do not feel the impact of traffic congestion, whereas a total of 95.6 percent established the presence of traffic congestion at one time or the other in Benin metropolis in terms of traffic intensity and duration.

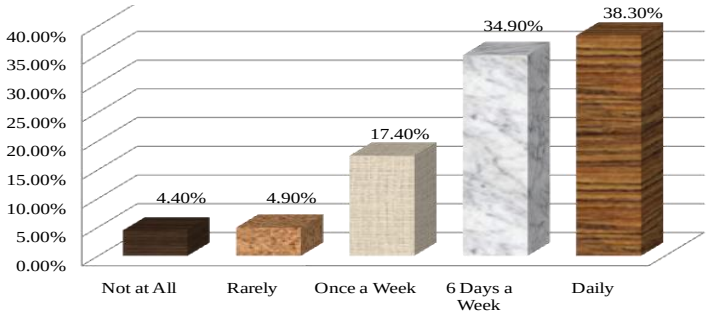

Figure 2: Market Location as a Source of Traffic Congestion in the Study Area
Source: Fieldwork, 2013

Market Location and Traffic Impedance

Figure 3.1 (a&b) showed the traffic situation along Television (T.V) road (between Eki-Oliha and Eki-Uwa). Two markets are located on this route; Eki-Oliha is a daily market known for the sales of traditional items and other commodities and Eki-Uwa (a specialized daily market) is known for the sales of bush meat. Street parking and trading, and alms begging impede free flow of traffic on this route. Potholes, absence of designated motor parks, and open drains were other factors inhibiting traffic flow along this road.

Figure 3.1 (a): Television (T.V) road

Figure 3.1 (b): Television (T.V) road

Figure 3.2 (a&b) reveals the condition of traffic along Oba (Eki-Oba) market road. Eki-Oba and Yanga markets located around the city centre (Ring road) are held daily; all manner of goods are sold in Eki-Oba, and fresh sea-foods are sold in Yanga market about 189m away. Indiscriminate street trading and parking, abandonment of motor parks, activities of revenue collectors and uncontrolled human interference with vehicular traffic were visible impediments to traffic flow on this road. Others include poor traffic management measures and solid waste deposits on walkways encroaching drive ways.

Figure 3.2 (a): Oba market road

Figure 3.2 (b): Oba market road

Road Connectivity and Degree of Market Patronage

Table 1. Shimbel Binary Connectivity Matrix (One Step or Direct Link)

Edges Nodes	1	2	3	4	5	6	7	8	9	Total Index
1. Eki-Uwa	0	1	-	-	-	-	-	-	-	1
2. Eki-Oliha	1	0	1	1	-	-	-	-	-	3
3.Yanga Market	-	1	0	1	1	-	1	1	1	**6***
4. Eki-Oba	-	1	1	0	1	-	1	1	1	**6***
5. Eki-Osa	-	-	1	1	0	1	1	-	-	4
6. Eki-Ogiso	-	-	-	-	1	0	1	-	-	2
7. Eki-Edo	-	-	1	1	1	1	0	-	-	4
8. Eki-Agbado	-	-	1	1	-	-	-	0	-	2
9. Vegetable Market	-	-	1	1	-	-	-	-	0	2

Sum = 18 *Source: Author's Fieldwork, 2013*

A connectivity matrix developed from the road network graph (Figure 4) shows the number of other nodal points (markets) to which a particular node (market) is directly linked; the node with highest number of points is said to be most connected. From Table 1, the most connected markets were Yanga market and Eki-Oba with index of six (6) each. This means that each of the markets have direct link with six (6) other markets. This is followed by Eki-Osa and Eki-Edo with four (4) direct links each to other markets. Similarly, Eki-Oliha has direct links to other three (3) markets. In addition, Eki-Ogiso, Eki-Agbado and Vegetable market have two (2) direct links respectively to other markets, while Eki-Uwa has only a direct link with Eki-Oliha.

The diagonal was coded zero (0), because it represents single origin-destination trips thereby making origin-destination trips redundant. The matrix is rarely concerned with the number of ways a location is connected to itself; no trip along the diagonal is coded one (1) since it takes at least two (2) steps to return to the origin. The non-diagonals zero cells are coded as null in the matrix because one represents one step or direct connection.

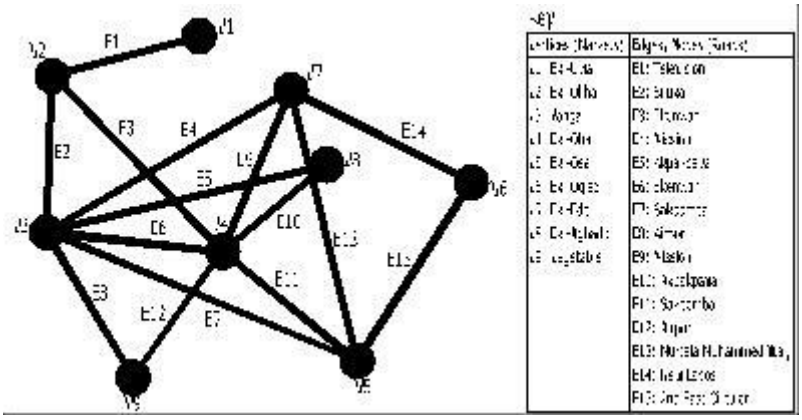

Figure 4: Road Network Graph Analysis of the Selected Markets
Source: Fieldwork Analysis, 2013

Nagne et al (2013) and Al-dami (2015) postulate that, the fundamental properties of a transport network are measured by Alpha index, Beta index, and/or Gamma index. For extraction of connectivity index, it requires a road network (edge) and junction (vertex). These indices are useful to identify the growth within the network structure and also for change detection system.

Figure 4 shows the graph connection irrespective of road grade linking the selected markets under investigation in the study area. Thus, given the number of selected markets in the study

area as nine (9), it is therefore possible to study the affected markets graphically. Nine (9) vertices (**v**)/nodes, and fifteen (15) edges (**e**)/routes/links were found in the study area. To estimate the degree of connectivity, Gamma index (γ) was adopted and the completeness of the network verified with Cyclomatic Index (μ).

Gamma index (γ) is a ratio of actual number of edges to the maximum possible number of node in the network (Al-dami, 2015), but the value is greater where the network is well connected (Nagne et al, 2013). Its value ranges from 0.0 (showing no connection between nodes) to 1.0 (maximum number of connections with direct link to all nodes).

$$\text{Gamma index } (\gamma) = \frac{e}{3(v-2)} \quad (1)$$

γ = Gamma index, e = number of edges (links/routes), v = number of vertices (nodes)

Given that; γ =?, e = 15, v = 9; Substituting into equation (1)

$$\gamma = \frac{e}{3(v-2)}$$
$$= \frac{15}{3(9-2)}$$
$$= \frac{15}{21}$$
$$= 0.71$$

From the Gamma index (γ) analysis, a value of 0.71 (71 percent) was calculated. This value implies that the road networks are considered to have a strong complexity and high degree of connectivity in the study area. This therefore, positively influences traffic attraction and circulation with or without the substitute of intervening opportunities for the purpose of trips.

The completeness of the connectivity network of the selected markets in the study area was evaluated using the Cyclomatic index (μ), given as;

$$\mu = e - v + 1 \quad (2)$$

Where; μ= Cyclomatic index, e = number of edges, v = number of vertices

μ =? e = 15, v = 9; Substituting the values into equation (2); μ = e - v + 1, μ = 15 - 9 + 1, **μ =**

The implication of equation (2) analysis is that, the network is highly developed with short route connectivity. This is because, 70 percent of the selected markets network have developed itself to have shortest possible routes in relation to other markets with 30% in the study area.

Accessibility and Level of Market Patronage

Table 2. Accessibility Matrix Representing Shortest Route in Number of Steps

Edges Nodes	1	2	3	4	5	6	7	8	9	Nodes Index
1. Eki-Uwa	0	1	2	3	3	4	3	3	3	21
2. Eki-Oliha	1	0	1	1	2	3	2	2	2	14
3.Yanga Market	2	1	0	1	1	2	1	1	1	**10***
4. Eki-Oba	2	1	1	0	1	2	1	1	1	**10***
5. Eki-Osa	3	2	1	1	0	1	1	2	2	13
6. Eki-Ogiso	4	3	2	2	1	0	1	3	3	19
7. Eki-Edo	3	2	1	1	1	1	0	2	2	13
8. Eki-Agbado	3	2	1	1	2	3	2	0	2	16
9. Vegetable Market	3	2	1	1	2	3	2	2	0	16

Sum = 168 *Source: Author's Fieldwork, 2013*

The accessibility index matrix (Table 2) reveals that nine (9) nodes (markets) are in the network of roads in the study area. This measure represents the arrangement of links between the markets (Figure 4) and the number of steps taken from one market to another. From the matrix, a cell value indicates the number of inter-nodal link, while zero (0) represents no link. However, the distance between pairs of nodes (markets) is expressed as the number of intervening links along the shortest path that connects them.

From Table 2, the most accessible nodal points are Yanga Market and Eki-Oba with index of ten (10) each. This means that each of the markets requires ten (10) intervening links (steps) from other markets in the network. Yanga Market and Eki-Oba located (189m apart) at the core of the central business district (King Square) are most accessed, patronized and populated with human and vehicular traffic. The index value is a measure of accessibility in terms of the total number of shortest links (steps).

Eki-Osa and Eki-Edo have index of thirteen (13), Eki-Oliha has index of fourteen (14), while Eki-Agbado and Vegetable Market have index of sixteen (16). Similarly, Eki-Ogiso (New Market) had an index of nineteen (19), and the least accessible market is Eki-Uwa with the highest index of twenty-one (21). This implies that, the lower the index value, the higher the accessibility; and the higher the accessibility, the higher the level of patronage (human and vehicular traffic), with the tendency to impede traffic flow as well as generate congestion in the study area.

SUMMARY AND CONCLUSION

This study highlighted the challenges of road network connectivity and accessibility, and their implications on market patronage in Benin metropolis. It has identified high rate of traffic congestion repeatedly caused by incomplete road connectivity, poor accessibility, eroded road surfaces, and street parking and trading. Others included activities of revenue collectors and EDSTMA staff, and poor enforcement of traffic regulation mechanism as critical issues in the study area. Graph theory, physical observation, and structured questionnaire were adopted to elicit information for this study. Also used was stratified sampling technique based on criteria of geographical location, market periodicity (daily or weekly), historical and cultural significance, Central Business District function (location within the CBD), and traffic confluence.

The results of the graph theory-base study showed that, although good road network connectivity existed among the selected market places, it was 30 percent incomplete. Eki-Oba and Yanga market were found to be most accessible and patronised because of locational advantage at the city centre (Kings'/Oba Ovoranmwen Square). Private cars and mini-buses were the most used mode of transit, while trucks were lowest.

RECOMMENDATION ON POLICY GUIDELINES

This study advances some recommendations in the light of the findings for sustainable traffic management system (STMS). All the access routes should be rehabilitated as possible alternative to bye-pass market places for none-market trips; Television road where Eki-Oliha and Eki-Uwa are situated and 2nd East Circular road where Eki-Ogiso and Eki-Osa are located should be reconstructed. Provision of traffic signals, street graphics and furniture along the market roads; motor parks for private and public vehicles should be provided in all the markets to prevent street parking.

Vertical and horizontal expansion of the market stalls using planning techniques and architectural design scheme is highly necessary to accommodate traders who display their wares on walkways. Pedestrian bridge should be constructed between Eki-Oba and Yanga

market which are 189m apart, within the city core which are most connected, accessed and patronised. Legislative empowerment for the enforcement of traffic management laws and measures would breed discipline among road users and facilitate high traffic flow rate. Effective planning of the market place as a city node and development centres should be taken seriously prior to its physical development, in order to prevent slum and blight in the built environment where these markets are situated.

Assessment of Local Government Council and Community-Based Development Associations in the Provision and Maintenance of Educational Facilities in Ilawe-Ekiti, Nigeria

Okosun, S. E.[1*] & Olujimi, J.A.B.[2]

[1&2] Department of Urban and Regional Planning, Federal University of Technology, Akure, Nigeria
[*] okosunsenator@gmail.com

ABSTRACT

The quality of education delivered and achievement by school is dependent on the facilities provided for students to develop their full potentials. The purpose of the study was to assess the provision and maintenance of educational facilities by the Local Government Council and Community-Based Development Associations with a view to ensuring adequacy of education facilities in Ilawe-Ekiti. This study adopts the survey research method and used three different sets of questionnaire to collect research data from the authority of the Ekiti South-West Local Government Council officials, Community Development Unit of the Local Government Council and the 61 (CBDAs) officials available in the study area.Findings among others revealed that majority of the secondary schools were privately-owned, while the primary and nursery/primary schools were Community-owned. There were 8 secondary schools; 9 primary schools; and 25 nursery/primary schools in the study area. The maintenance carried out on school facilities was inadequate for majority of the facilities to provide high quality education. In view of the findings, there were need to improve the educational facilities through additional provision and maintenance of the existing schools; encourage people's participation in the conceptualization and implementation of new proposal to develop the town. Finally the paper calls on the three tiers of governments and other stakeholders to provide and inculcate good maintenance culture on our educational facilities for effective management with the intension of promoting high quality education in the study area.

Keywords: Community-Based Development Association, Educational facilities, Local Government Council, Maintenance, Provision

INTRODUCTION

Education facilities are material or resources that enhance teaching and learning. Educational facilities can be defined as the entire school plant which school administrators, teachers and students harness, allocate and utilize for the smooth and efficient management of any educational institution (Asiyai, 2013). Educational facilities serve as pillars of support for effective teaching; as well as the physical and spatial enablers of learning. According to Adedokun (2011) educational facilities are physical resources that facilitate effective learning. They include blocks of classrooms, blackboard, laboratories, workshops, libraries, equipment, consumables, electricity, water, visual and audio-visual aids, tables, desks, chairs, play ground, storage space and toilets. These promote and increase the production of results. Most governments in the third world countries like Nigeria face strong financial problems in providing educational facilities like school bus, laboratories, workshops, libraries, equipment, in the urban/rural setting. In Nigeria, provision of schools/education continued to increase without a corresponding increase in facilities which has to meet the needs of rapidly increasing users for effective teaching and learning. One of the main problems of education in Nigeria is underfunding, this has resulted in the depleting conditions of educational facilities in the country (Nigerian). These are of great concern to the government i.e. Local Government Council Authorities, Community-Based Development Associations, and other agencies in encouraging the provision and proper maintenance of schools and existing educational facilities.

The role of provision and maintenance of educational facilities in grassroots development and poverty reduction cannot be over-emphasize both in urban and rural environments. Provision

Okosun, S. E. & Olujimi, J.A.B. (2016). Assessment of Local Government Council and Community-Based Development Associations in the Provision and Maintenance of Educational Facilities in Ilawe-Ekiti, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1556-1562

in this paper means an item of goods provided/suppy and obtained for future use. The word maintenance, according to Eti *et al.* (2006) means preserving and keeping in good order as near as possible in their original state. By implication, maintenance means keeping in good order and shape all projects of development that are of benefit to the people. However, the attitude of people towards the maintenance of educational facilities is that the government property does not belong to anybody. To this extent educational facilities that were meant to benefit the masses are just rotting away, without being put to any good use as people are not interested in making such facilities sustainable. Governments have come to term with the LG for the need to be involved in grassroots development. However, the establishment of LGCs in Nigeria which aimed among others to facilitate rural and urban development through infrastructure development and delivery in which schools (i.e educational facilities) provision and maintenance is inclusive. The LGC is statutorily empowered to construct and maintain schools and other public facilities (FGN, 1999). The recognition and importance of this process is to tackle local socio-economic problems and to manage grassroots development. Despite these provisions, educational services in both urban and rural areas in Nigeria in inadequate. Sehinde (2008) maintained that in Nigeria, the overriding impression is that LGCs are weak in responding to the challenges posed by infrastructural development. This has led to self-help programmes through which private sector is now involved in educational facilities development. The CBDAs form one of the main actors of the Local Economic Development (LED) process. They have been responsible for the provision of communal facilities such as schools, markets, water supply, and town halls. Akinsolu (2004) asserted that educational curriculum cannot be sound and well operated with poor and badly managed school facilities.

The aim of Education for the 21st Century "is to enable every person to attain all-round development in the domains of ethics, intellect, physique, social skills and aesthetics according to his/her own attributes so that he/she is capable of life-long learning, critical and exploratory thinking, innovating and adapting to change; filled with self confidence and a team spirit; willing to put forward continuing effort for the prosperity, progress, freedom and democracy of their society, and contribute to the future well-being of the nation and the world at large. " *Hong Kong* Education Commission, 2000)", as stated by Edewor *et al.* (2003) the Nigeria people must be given good education to ensure improvement in their health condition so as to enhance their economic empowerment and help in decision making that will liberate them. In the education sector, it is common to see dilapidated school buildings with collapsed roofs without ceiling occupied by students, thus, making learning environment very unsuitable especially in hot seasons. All of these point to the fact that educational facilities as a social service are not adequately maintained. Norris (1997) defined LGC as the government of urban areas or rural areas subordinate having an independent legal existence. The functions of a LGC in Nigeria include provision and maintenance of primary, adult and vocational education. While CBDAs is regarded as an association that provides forum for people to articulate their views, aspirations and needs. The associations aim at helping people within a local community to identify their social need, and work towards achieving them.

Purpose of the Study

The purpose of this study is to assess the contributions of LG Council and Community-Based Development Associations in the provision and maintenance of educational facilities in Ilawe-Ekiti with a view to enhancing the performance of educational institutions in the study area.

The study objectives are to;

i. classify the existing educational facilities (i.e schools) according to ownership and conditions in the study area;

ii. highlight the involvements of the Local Government Council in the development of educational facilities in Ilawe-Ekiti ; and
iii. assess the performance of the Local Government Council and Community-Based Development Associations in the development of Educational Facilities

LITERATURE REVIEW

The importance of school in the education process has necessitated the need for the provision, management and maintenance of those facilities in the school system. According to Olutola, (1998) the operational input resources in education industry are referred to as school facilities, the provision, management and maintenance of these facilities have been found to be significantly related to school performance. In the study of Olutola's (1998) schools with good faculties recorded greater achievement in WASC examination than schools with poor educational facilities. Educational facilities provision and maintenance is a powerful instrument of development, especially among developing nations like Nigeria has led to the evolution of educational programmes such as the Universal Basic Education in Nigeria (Abdulkareen, 1999). Nigeria school system is witnessing expansion in school enrolment and school programmes. This has necessitate a great demand for more provision of schools, and the need to maintain the facilities, such like classrooms, libraries, laboratories, multipurpose rooms/halls, toilets and school fields for the teeming school population. Adedokun (2011) also stated that, in spilt of government hugh financial allocation to education in its annual budget, school facilities are still grossly inadequate in Nigeria. Consequently there is a called for the need to explore strategies in sustaining the school system. Over the years government and non-governmental agencies (i.e CBDAs) and individuals have been concerned about the management of education, the crucial aspect of this management is the provision and maintenance of educational facilities.

The provision and maintenance of educational facilities and services is essential for the promotion of efficient operations of any country, state, or town in enhancing the general standard of living. As stated by Okwakpam (2010), human needs are insatiable and the government alone cannot meet them. In recent times, various efforts have been made by government. One of the strategies employed to enhance development is through grassroots participation. Government has come to terms with the need to partner with the LGC and CBDAs as agents (or institutions of development) in addressing shortage in infrastructural facilities, including schools. Ilawe-Ekiti is faced with inadequate and poor state of the existing schools. Provision and maintenance in this paper is used to indicate the extent to which educational facilities such like school buildings/walls, classrooms, sports field and library in the Nigerian communities are affected so as to bring about better living conditions, (economic, social and cultural developments).

In this study the researchers observed that; most of the school compounds were bushy, majority of the signboards, gates and walls of the schools were defaced, coupled with dilapidated buildings and leaking roofs; (some of which have been blown off), rough floors and windows without louvers, poor illumination in some cases, broken chairs and desks. It appears adequate management and maintenance is not provided in the available schools/educational facilities. Educational facilities are supposed to be kept in good and proper condition near their original state by the school educational administrators. Based on our causal observation, it appears that owners of school are neglecting the role of educational facilities provision, management and maintenance. The question now is could this observation be the same for all nursery, primary and secondary schools in Ekiti State? It's against this background that this study was carried out.

RESEARCH METHODOLOGY

The survey research method was adopted for this study. The target populations were classified into four (4) groups; Ekiti South West LGC Caretaker Chairman, Community Development Unit in-charge of Community Development Projects in the Ekiti South West LGC office, Community/Quarters-Heads in Ilawe-Ekiti and CBDAs in Ilawe-Ekiti. A Non-probability sampling approach was employed for use in this study; it is carried out when particularly the researcher is not concerned about the representativeness of sample. A total census (i.e 100% coverage) survey was also conducted on all the 61 (CBDAs). Only the President/Chairman/Secretary of the CBDAs were interviewed. Only one questionaire was administered on the Ekiti-South West LGC Caretaker Chairman and also one questionaire was administered on the official in-charge of the Community Development Project Unit in the LGC office. Data were collected with the aid of structured-multiple choice questionnaire. It consists of sixty-one (61) questions which were set to elicit specific information from the respondents.

This study employed the use of four sets of questionnaire for data collection. In this study, the researchers in conjunction with the seven (7) Field Assistants administered the questionnaires. Students from the Department of Urban and Regional Planning, Crown Polytechnic Odo, Ado-Ekiti, were used. The data collected from the field were collated and proceed using the Statistical Package for Social Sciences (SPSS) version 19.

RESULT AND DISCUSSIONS

The discussions of the data were based on the research objectives generated for the study.

The Existing Ownership of Schools in Ilawe-Ekiti

Schools in Ilawe-Ekiti were mostly built by the government, Private individual and the community. Majority (i.e 56%) of the schools in the town were built by the community i.e the Faith Based Organizations (FBOs) this were owned by the church Missionary Society and (2.4%) were built by the Muslim Islamic Society. Through community participation efforts, the Faith Based Organizations (FBOs) built nursery, primary and secondary schools in the town. Some individual built schools (private schools), while few schools were built by the government in Ilawe-Ekiti. Findings reveals that (49.5%) of the secondary schools in Ilawe-Ekiti were Privately-owned, followed by Government-owned (38.0%) and Community-owned (12.5%). Majority (88.9%) of the primary schools in Ilawe-Ekiti were Community-owned while the remaining (11.1%) of the primary schools were Privately-owned. Furthermore (56.0%) of the nursery/primary schools in Ilawe-Ekiti were Community-owned, (40.0%) were Privately-owned, while (4.0%) were Government-owned nursery/primary schools.

The Existing Ownership of Secondary Schools in Ilawe-Ekiti, 2015

There are eight secondary schools in Ilawe-Ekiti; those include Oniwe Grammer School at Aaye, Glorify God Secondary School at Aaye, Victory College at Irorin, Oniwe Comprehensive High School at Irorin, Ejire Secondary School at Irorin, Solid Foundation at Okebedo, Corpus Christi College at Adin and United High School at Oke-Emo. Those secondary schools were mostly built by the private individual, private-owned secondary schools in Ilawe-Ekiti constituted (50.0%) of the total secondary schools, while (37.5%) were Government-owned secondary schools, Community-owned secondary schools represented (12.5%). However (75.0%) of the secondary schools in the town are in fair conditions, while (25%) are in good conditions. Secondary schools in Ilawe-Ekiti were built by government, Private individual and the community. Corpus Christi College is the first major secondary school in the town, built in 1967 at Adin by the community. Findings reveal that the involvement of private schools in the town has helps in improving the standard and quality of

education in Ilawe-Ekiti. (75.0%) of the secondary schools in the town are in fair conditions, while (25%) are in good conditions.

The Existing Ownership of Nursery/Primary in Ilawe-Ekiti

Table 1 shows the 25 names of nursery/primary schools in the wards in Ilawe-Ekiti. Majority (65.0%) of the nursery/primary schools in the town were owned by the community i.e the Faith Based Organizations, (29.0%) consist of individuals' private-owned nursery/primary. While the government owned nursery/primary schools in the town constituted (6.0%). Findings reveals that majority of the nursery/primary schools were established more than 22 years again and most of them are unkempt, the signboards and walls of the schools are defaced, as they are engulfed by weeds. Further findings revealed that the community-owned nursery/primary schools in the town were later handed over to the government. The criteria used in assessing the conditions of those schools in Ilawe-Ekiti, was carried out with the aid of rank size relationship. The ranking relationship shows the condition of nursery/primary schools in wards of Ilawe-Ekiti. Marks assigned to each ranking are as follow: Very good-5, Good-4; Fair-3; Poor-2; and bad-1. Having summed up the total percentage score of all the nursery/primary primary schools, the number of school facilities that scored certain marks was multiplied by 100 to calculate the percentage score. The result from the ranking relationship shows that condition of nursery/primary schools in wards of Ilawe-Ekiti is in fair state, which consists of 16 (47.0%). Number of good are 14 (41.0%), Poor are 4 (12.0%). The percentage of very good and bad nursery/primary schools cumulated to 0%. Like the foundation of a house, nursery/primary school education forms the bedrock of the educational system of any country.

Involvement of the Local Government Council in the Provision and Maintenance of Educational Facilities in Ilawe-Ekiti

The Community Development Unit of the LG Council is in-charge of Community development project undertaken by the LG Council. Provision and maintenance of educational facilities were embarked upon by the LG Council, Community-Based Development Associations and private individuals in the study area. Findings reveal that the participation of the people in educational development is satisfactory. However the problem of finance and human factor were of the hindrances in the provision and maintenance of educational facilities in the area. The community development unit of the LG Council only provides the available detail information's from year 2010 - 2015 on the cost of project, status of project and the nature of projects executed in Ilawe-Ekiti. However the educational facilities projects are discussed as follow:

E**ducational Facilities Provision and Maintenance Projects by the LG Council and CBDAs in Ilawe-Ekiti**

Educational facilities embarked upon by the LGC. Those include construction of 3 class rooms and office each in St Augustine's catholic nursery/primary school at Irorin, Ilawe Grammar School at Okebedo, and St. Stephen at Adin. The LG Council was responsible for the renovation of schools such as Ilupeju nursery/primary school at Aaye, Holy Trinity at Adin, and Irowelede primary school at Okebedo.

The educational facilities executed by the CBDAs include those embarked upon by the social clubs; the school clubs provided books and awarded scholarship to indigenes of the town, they provided boarding school facilities for the male and female hostel in Corpus Christi College at Adin, renovated classrooms, repairs toilets, roads and equipped the library at Adin, Faith Based Organization (FBOs) provided tables, chairs and books in Corpus Christi College at Adin. The CBDAs supports on educational facilities were on materials; this was very instrumental to the improvement of educational facilities in the town. The CBDAs are good

examples of grassroots development. Findings reveal that all the educational facilities projects of the LGC and CBDAs were completed; only the scholarship grants for students are currently on. The results showed that maintenance of the school facilities were inadequate. Renovation and construction was the most prevalent practice of the LGC and CBDAs in the town while students in the community and Government schools were responsible in maintenance of most of the school fields.

Table 1: The Existing Nursery/Primary Schools in Ilawe-Ekiti, 2015

S/N	Names	Wards/ Location	Ownership	Year of Establishment	Condition

RECOMMENDATIONS

Encouragement of maintenance culture among target population is inevitable. There is the need to promote maintenance culture in Ilawe-Ekiti. The school owners, administrators, teachers and students should develop and inculcate good educational facilities maintenance

culture that will prolong their durability and efficiency; People's participations and involvement in the formulation and implementation of policies on educational delivery is needed, because people's participation is one of the ingredients of good governance; More money should be disbursed to the LGC, in order to improve educational facilities through additional provision and maintenance of the existing schools; Finally, the three tiers of governments and other stakeholders should provide and inculcate good maintenance culture on our educational facilities for effective management and constantly organize seminars and conferences to sensitize people on maintenance culture from time to time with the intension of promoting high quality education in the study area. This will also help to improve and ensure sustainable provision and maintenance of educational facilities and develop capacity of LGC and communities in the area.

CONCLUSION

The LGC and CBDAs participation programmes have helped in developing Ilawe town /communities to some extent. The CBDAs have been responsible for the provisions and maintenance of educational facilities in the study area due to the government failure to do this. However the present monthly allocation from Federal Government to LGCs is grossly inadequate; and it is not enough to embark on provision and maintenance of educational facilities. The two tiers of government (local and state) particularly the LG that is close to the grass root should endeavor to identify these CBDAs, streamline their activities and provide adequate supervision, motivation, monitoring and evaluation of their projects through appropriate government personnel to support development in the study area.

AREAS FOR FURTHER RESEARCH

Impact of Local Government Council and Community involvement in the provision and maintenance of educational facilities on residents of Ilawe-Ekiti; Nigeria.

ABSTRACT

This paper analyses some characteristics of street begging in Akure city, Nigeria. The scope of the study focused on Akure city where an extensive field survey was conducted on the incidence of street begging. The study made use of both primary and secondary data. Using multistage sampling technique, a total of two hundred and forty (240) street beggars were sampled, constituting 12.5% of total 1,908 beggars in Akure. Data obtained from the questionnaires were processed and analyzed using Statistical Package for Social Sciences (SPSS) version 21. The research findings were presented in form of tables, percentages and charts as appropriate. Findings show that a large population of beggars in Akure took to street begging as a result of poverty and this accounts for almost half the total sampled population, that is, 49.6%. The next factor in order of magnitude is physical disability 32.9%, followed by those that attributed their activities to cultural beliefs 10.4%, and religious inclination 7.1%. The study recommends the building of rehabilitation centres in the study area, social welfare for poor beggars, and evacuation of beggars from the streets, sustainable landscaping, and poverty alleviation programmes among others.

Keywords: Beggars, Characteristics, Poverty, Rehabilitation, Social welfare

INTRODUCTION

Begging is simply defined as asking passers - by for money in public places (Kennedy and Fitzpatrick, 2001). The appearance of beggars who seem to spend most of their time on the streets and public spaces in many urban areas of Nigeria and in cities of some developing countries is in plain sight. This situation is a reflection of urban complexities worldwide and has become a very common and familiar experience for a long time. The population of beggars on Nigerian streets is growing rapidly. Today, their presence is a serious problem that requires remedy and rehabilitation (Gabriel, 2013).

However, not only have their numbers grown over the years, their lifestyles and the display of overtly aggressive behaviour make them the subjects of suspicion and hostility by the public at large and the law enforcement agencies in particular. The menace of street begging as a potential threat to the environmental, economic and social survival of humanity societal fabric is evident (Aliyu, 2006 and Ogunkan 2009). People who engage in begging even recognize the act to be a 'problem'. To them, it is harsh, humiliating, demeaning, degrading and frustrating (Lynch, 2005).

It is obvious that begging has become a global phenomenon which threatens the environment, economic and social survival of humanity. This is true of Nigeria where different categories of beggars are conspicuously found in motor parks, religious worship areas, markets, road intersections, venues of ceremonies among other public places, begging for alms (Jelili, 2006). Scholars have attributed the problem of begging to a number of factors such as poverty (Adedibu, 1989; Jelili, 2006), religion (Hanchao, 1999), physical disability (Adedibu, 1989; Jelili, 2006) and culture (Adedibu, 1989, Jelili, 2006).

The aim of this paper is to examine some attributes of street begging in Akure, Nigeria. Prominent indices of investigation include the factors of begging, categories of beggars, methods of begging, reasons for begging and body physique of beggars among others. It is imperative to state that the increasing incidence of beggars in Nigerian cities is not only due

Gabriel, E.; Fasakin, J.O.; Omole, F.K. & Ilesanmi, F.A. (2016). Analysis of Some Attributes of Street Begging in Akure, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1563-1570

to poverty and physical disability but also to the fact that majority of the beggars are satisfied with the "job" (Jelili, 2006). The presence of fake beggars and criminals has not helped the situation and may be dangerous to the society. Despite the evil posed by begging in Nigerian urban centres like Akure, it is curious that much research works have not been directed towards the investigation of the incidence of street begging and rehabilitation in Nigerian urban centres (Gabriel, 2013).

Statement of the Problem

Street begging is a serious issue, in the sense that its intensity and magnitude are increasing at an alarming rate in our society. The negative impacts of begging on social and physical environments are obvious in the tendency of beggars to delay and obstruct free flow of human and vehicular traffic and their high propensity to generate dirty materials either as waste or as parts of their belonging (Jelili, 2006).

A street beggar is known to be an individual such as children, elderly, disabled people, and families who normally beg in public spaces such as shopping areas, banks, public offices, churches, mosques, busy streets, among others (Adugna, 2006). Although, the problem of begging is a worldwide phenomenon, it is more pronounced in the third world countries (Adedibu, 1989; Ogunkan 2009). This is true of many urban areas of Nigeria where different categories of beggars are conspicuously found in streets, motor parks, religious worship centres, markets, road junctions, venue of ceremonies among other public places begging for alms.

Begging is recognized as a 'problem' by diverse stakeholders, including the media, politicians, retailers and traders, law enforcement officers and agencies, welfare and social service providers, the general public, and planners. Each of these stakeholders has a common interest in reducing the incidence of begging. The continued relevance of begging as both a political and a public policy problem is evidenced by extensive media coverage of the issue in recent years, together with governmental consideration of the regulation and governance of begging (Lynch, 2005; Petro and Kombe, 2010).

Although, the problem of begging is a worldwide phenomenon, it is more pronounced in the developing countries (Adedibu, 1989). Akure, a city in a developing country is presently faced with the menace, hence, the need for action. Moreover, in Nigeria, some government authorities have made various efforts to tackle the problem of street begging such as sending them back to their homes but without setting strategies on how to make street beggars attain their basic necessities of life. As a result, many urban authorities have been striving to control the influx of street beggars in the city without success. A quick examination of these efforts indicates that most of them are focused more on the symptoms rather than on prevention or eradication of the deeper structural causes of the problem (Petro and Kombe, 2010). Despite the problems of begging to the environment and socio-economic development of Nigerian urban centres, Akure as a case study, it is unfortunate that much research works have not been directed towards the rehabilitation of beggars. This signals the need for more to be done to contain the situation in a comprehensive and sustainable way.

The problems were investigated in this study based on the fact that, in Akure the Ondo State capital city, an increasing population of beggars is visible on the streets impacting environmental, social and economic discomfort in the city. There is no rehabilitation centre. There is no social welfare, vocational training programs for the beggars and poor landscaping among others. This study, therefore, is focused on investigating some attributes of street begging in Akure.

STUDY AREA

Akure is a traditional Nigerian city and like other traditional Yoruba towns in the country, it has been in existence long before the advent of British colonial rule in the country. The city is located within Ondo State in the south western part of Nigeria. Ondo State is one of the 36 states of Nigeria. It lies approximately on latitudes 7^0 5^1 and 8° 00^1 North of the Equator and longitude 5^0 45^1 East and longitude 6° 00^1 East of the Greenwich Meridian at an altitude of 370m above sea level. Akure is a medium-sized urban centre and became the provincial headquarter of Ondo State province in 1939. It also became the capital city of Ondo State and a Local Government Headquarters in 1979. These dual political roles of Akure have since acted as impetus to the influx of people into the city (Olujimi and Olamiju, 2011).

Akure is located approximately 700 kilometers South West of Abuja, the Federal Capital of Nigeria and about 350 kilometers to Lagos the former capital of Nigeria. It is located within the tropical rain forest region of Nigeria where rainfall is high throughout the year. The increased relative political influence of Akure as a state capital since 1976 has greatly promoted its rapid growth and increased socio-economic activities resulting in its spatial expansion from an area of about 16 square kilometers in 1980 to about 30 square kilometers in 2000 (Ministry of Works, Lands and Housing, 2000) the population of the city grew from 38,852 in 1952 to 71,106 in 1963. Its population was estimated to be 112,850 in 1980 (DHV, 1985); and 157,947 in 1990 (Ondo State of Nigeria, 1990). The 1991 national population census however, puts the population of Akure at 239,124 and its population in 2006 was 353,211 (NPC, 2006). In 2014, using a growth rate of 3.18 percent, the city is estimated to have 453,731 people using a formula for projection, $Pt = Po\ (1+r)^n$ (Gabriel, 2014).

METHODOLOGY

Primary data for the study were generated from the administration of structured questionnaires that focused on characteristics of street beggars. The questionnaires probed among other issues; the incidence of street begging, socio-economic and cultural characteristics of beggars. Secondary data were obtained from relevant institutions to this research work, such as, Ministry of Women Affairs and Social Development Akure Ondo State, Ministry of Lands and Survey Abuja, Ministry of Town Planning Akure, Ondo State, Ministry of Lands and Survey Akure, Ondo State among others. Since the street beggars keep moving, it was very difficult to prepare any sampling frame to select the desired sampling size. Therefore, purposive sampling technique was employed. Using multistage sampling technique, a total of two hundred and forty (240) street beggars were sampled, that is, 12.5% of the total, 1,908 beggars in the study area.

Further relevant information for the study were collected from in-situ observations, photographs, informal interviews and discussions with the beggars, especially the key informants who are the leaders among the beggars. Data obtained from the questionnaires were processed and analysed using Statistical Package for Social Sciences (SPSS) version 16. The research findings were presented in form of tables, percentages, maps and charts as appropriate.

RESULTS AND DISCUSSION

Analysis of Attributes of Street Begging

This section examines the analysis of some characteristics of the street begging in the selected land uses and streets within Akure city. The results are presented as shown in the following charts and tables.

Factors of begging

From figure 3 the findings showed that a large population of beggars in Akure took to street begging as a result of poverty and this accounted for almost half of the total sampled population 49.6%. The next factor in order of magnitude is physical disability 32.9%, those that attributed their factor to cultural beliefs 10.4%, and religious inclination 7.1%. The findings revealed that the menace of street begging in the study area is as a result of the compounded problems in the society. It ranges from abject poverty, homelessness, varying forms of destitution among others.

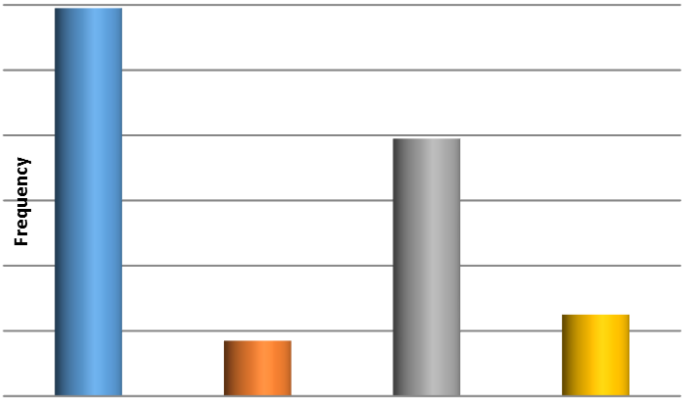

Figure 3: Shows factors of Begging.
Source: field survey, 2014.

Categories of street beggars

Table 1 showed the distribution of the types of street beggars within the study area. About 54.2% were destitute beggars, 13.8% were homeless or wanderers, that is, those without a place of abode in Akure, 05.4% were neglected female beggars, 11.7 % were children involved in begging and 15.0 % were aged beggars.

Table 1: Categories of Beggars

Category	No. of Respondents	Percentage (%)
Destitute / jobless beggar	130	54.2
Wanderer / professional beggar	33	13.8
Unskilled, uncaterred for female beggar	13	5.4
Old age beggar	36	15.0
Child beggar	28	11.7
Total	240	100.0

Source: field survey, 2014

Methods of begging

Figure 4 revealed the methods of begging among the beggars in Akure city. Out of 240 sampled beggars, 60% represents those that fall into the category of beggars whose method of begging is stationary, that is, those that beg at a spot. This finding revealed that most `stationary beggars` are found in such land uses as motor parks, religious worship centres and around banks in Akure. While the `wandering beggars` 40.0%, were roving beggars seen in such areas as markets, main junctions and filling station.

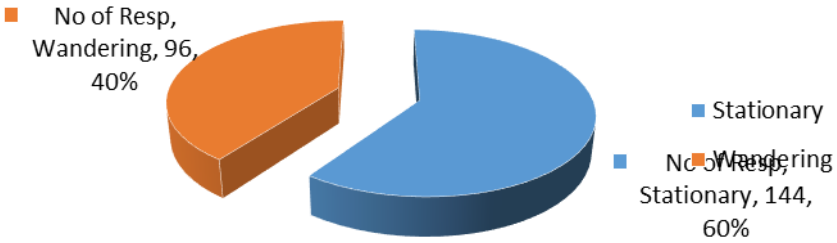

Figure 4: Shows factors of Begging
Source: field survey, 2014

Reasons for begging

Table 2 revealed the reasons for begging in Akure. From the sampled beggars, 45.4% were engaged in street begging because of the quest for money/materials, peer group or family influence 7.1%, physical disability 30.4%, lack of care/neglect 4.2% and unemployment/human capital deficit 12.9%. From the findings of this research it was revealed that, most of the beggars were engaged in street begging because of quest for money and material things which is in a way ascribed to prevailing poverty in the society.

Table 2: Beggars` Reasons for Begging

Reason	No. of Respondents	Percentage (%)
Quest for Money/Materials	109	45.4
Peer Group/Family Influence	17	7.1
Physical Disability	73	30.4
Lack of Care/Neglect	10	4.2
Unemployment/ Human Capital Deficit	31	12.9
Total	240	100.0

Source: field survey, 2014

Body physique of street beggars

Figure 5 showed the distribution of beggars in Akure by body physique. Findings indicated that majority of all sampled beggars were physically impaired (legs and hands/arms) which accounted for 31.3%, old aged beggars 15% normal, that is, beggars without any form of impairment 14.5%, leprous beggars 13.3%, visually impaired 12.5%, children involved in

street begging 11.7% and hearing 1.7%. These findings suggest that body physique of some of the beggars compels them to engage in street begging as they do lack alternatives or supports to sustain their livelihood as some of them find themselves in circumstances beyond their capacity and capability.

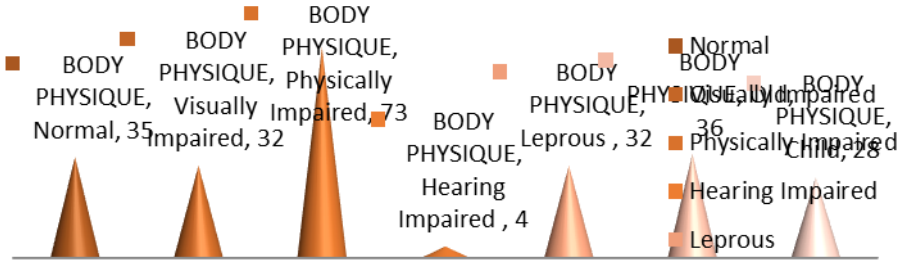

Figure 5: Shows factors of Begging
Source: field survey, 2014

CONCLUSION AND RECOMMENDATIONS

Analysis of characteristics of street begging is burdensome, because of the social, economic and cultural behavior of the street beggars. The study established that street begging is carried out by diversity of people regardless of factors and reasons for begging. The researcher is fully convinced that if rehabilitation centres are put in place and in good condition, social welfare fund for the poor beggars, vocational training; skill acquisition and entrepreneurial assistance to the inmates who are deprived beggars and other related measures are introduced in the study area and in some cities nationwide, street begging will be a thing of history. In line with the findings of this research work the following measures are recommended:

The Government should build rehabilitation centre(s) in the study area and some selected towns in the nation. For the mere fact that this promises to be good strategies of keeping beggars off the street, they should be provided with basic necessities of life such as water and electricity so that inmates will feel comfortable. The rehabilitation centres should also be offering skill acquisition and entrepreneurial assistance to the inmates who are deprived beggars. On the social welfare fund for the poor beggars; there is the need for Ondo State Government to develop a policy of giving Survival Monthly Allowance to the inmates and the needy. Evacuation of beggars from the street and deployment to their states of origin should be a continual and consistent process in the study area and by extension throughout the entire state. A census of beggars for planning and welfare purposes should be regular and consistent among others.

An Appraisal of Social Housing and Urban Poor in Nigeria: A Case Study of Ado Ekiti

Adeoti, S.[1]* & Olowookere, C. A.[2]

[1&2] Department of Urban and Regional Planning, The Federal Polytechnic, Ado Ekiti, Nigeria
** adeotisanmi@yahoo.com*

ABSTRACT

Housing as a complex and expensive commodity is equally considered to be one of the major components of social policy along with health, education, social security and personal social services. In order to meet the challenges of housing the deprived people, particularly the urban poor of developed Nations as well as the low income class of developing countries many policy documents have been designed over time . This paper therefore takes a look of the reality of National Housing Policy towards social housing of the urban poor in Ado Ekiti. Relevant data were collected through questionnaires from randomly sampled public housing estates in the city. The results were subjected to both descriptive and inferential statistical analysis The result of the findings revealed that provision of social housing are not only short in supply but equally not within the reach of the poor in term of income qualification and employment opportunities due to poor governance. The paper concludes among other things, suggestion for use the local building materials, private developer participation of housing delivery and adequate financial empowerment of the urban poor populates.

Keywords: Urbanisation Urban poor; Social housing, Private developer and Governance

INTRODUCTION

Housing has been universally accepted as one of the most essential needs for human survival simply because in all ramifications, housing is more than mere shelter as it includes access to much of social infrastructure that enhances livability indices such as education, health and open- spaces.(Ezenagu (2000), Wahab (2003) and Alser (2007),) It also includes access to physical infrastructure such as road, water, electricity and telecommunication. However, these indices do not only make housing to be expensive products but as a complex good that support social and urban externalities of which those with high income take the best, leaving the worst accommodation for the least well off in society.

As a matter of fact, the categories of the worst off in the society are mostly the urban poor. These groups are generally regarded as the low income earners who are equally engaged in the informal sectors of the urban economy. According to Ajakaiye (1999), the urban poor are self employed people of petty jobs such as hawking, barbing, repairing and local maintenance. They are also the unskilled labours who are employed to work in industries and construction site or those as result of unemployment take to casual work which includes the Taxi drivers and the popular Okada riders in our towns.

It is important to know that these groups of people formed the majority that are well pronounced in developing countries, particularly in Nigeria where the rapid rate of urbanization and the population growth do not correspond with the economic development. This no doubt, has contributed a lot to the manifestation of high level of inequality and poverty that make many urban poor to be homeless while many live in urban decay of slum and substandard housing environment.

The worrisome situation has made public intervention in housing delivery in term of social housing to be inevitable tools that provides accommodation for those who cannot compete in the housing market. This type of housing which was tenure for the very poor and housed low-waged working families was equally designed to provide for rent, part rent/ part buy at less than full market cost by a socially responsible agency.

Adeoti, S. & Olowookere, C. A. (2016). An Appraisal of Social Housing and Urban Poor in Nigeria: A Case Study of Ado Ekiti. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1571-1579

However, in developing countries particularly in Nigeria public housing intervention popularly known as Low income housing or affordable housing is very limited. At the same time, poor people invariably have no access even when a low cost housing scheme is put in place purposely for the poor because the well to do are the ones who eventually benefit.

In view of this fact, this paper appraises the poor and the public housing in Ado Ekiti, Nigeria.

THEORETICAL FRAMEWORK AND REVIEW

This paper is based on State intervention which is an offshoot of Marxist Theory of conflict where differential social class does not only form the dimension of social contradictions but equally leads to social inequality that relates with the problems created by injustice to collective consumption system of ensemble of social groups. In fact, the struggle results in state policies which serve the interest of the dominant class while the subordinate class sometimes win and wrest certain concessions.

Available records reveal that the world is not only experiencing rapid population growth, but equally witnessing high rate of urbanization that undergoing urban growth. According to UN (2012) in 2011 the global population reached the 7 billion mark and it is projected to climb over 9 billion by 2050. Hence, the population of the world that took thousands of years to reach 1 billion only took 200 years or so to make it sevenfold Likewise, the UN (2007) also pointed out that the proportion of the world population living in the urban was only 3 percent in 1800 and at 1900 almost 14 percent were urbanites with 12 cities of 1 million or more inhabitants while in 1950 about 30 percent of the world population resided in urban centers where numbers of cities of million people grown to 83. In fact, Fadare (2008) revealed that in 1950 about 733 million people or 29 percent of world population lived in urban areas and by 2005 the people reached about 3.172 billion or 49 percent of the world population and projected to hit 4.9 billion or 61 percent by 2030. Shehu (2003) also noted that within the last forty years, the numbers of urban areas in Nigeria increased from 329 to 1650 while the population of towns with 20,000 people and above increased from 3.2million to 32million.

The failure to prepare for this unprecedented and inevitable urban explosion carries serious implications on global security and poverty. For instance, environmental degradation makes the urban poor vulnerable to the spread of disease while one-third of the world's urban population live in slums of overcrowding without access to adequate shelter, clean water, and basic sanitation. According to Ravallion (2007), global poverty has become an urban phenomenon of which in the year 2002, 746 million people in urban areas were living on less than $2.00 a day. The absolute number of urban poor also increased within the last fifteen to twenty years at a rate faster than the rate in rural areas, particularly in Asia with the largest share of the world's slum dwellers, whereas, nowhere is the threat of urbanizing poverty is more grievous than in Africa with the fastest rate of urban growth and the highest incidence of slums in the world (Halfani 2007). As a matter of fact, the rapid rate of urbanization in Africa has been decoupled from economic development of which in the last fifteen years the number of slum dwellers has almost doubled in sub-Saharan Africa, where 72% of the urban population lives in slums (UN-HABITAT 2006). Likewise, in Nigeria about 18.4 million people who were living below poverty line in1980 aggravated to 125 million (78 %) in 2000 of which more than half of the people are living in urban centre (Ajakaiye 1999). This is simply because the more the increase in population of towns and cities, the more the urban poor.

History revealed that the antecedent of poverty in term of overcrowding, poor hygienic conditions, disease and other misery became more evident during the industrial revolution

and the aftermath of World War I; therefore making social housing to become a central tool for combating the menace by the enactment of acts. According to Claire (2008), Belgium with its 1889 Act, was the first in the world to start the social housing; Britain came second in 1890 with the passage of the Housing of the Working Class Act while France came third with the Loi Siegfried act of 1894. Similarly, the genesis of public housing in developing countries of Asia, Latin America and Africa has much to do with the colonial and post colonial style of governance (Wakely 2014). For instance, the unfortunate outbreak of bubonic plaque of 1928 in Lagos led to the establishment of the Lagos Executive Development Board (LEDB) to signify the ushering of Nigerian public housing programmes intervention, (Onibokun 1990 and Aribigbola 2000). According to Bustani, and Kabir (2010) the establishment of the Nigerian Building Society (NBS) after the Second World War provided housing for selected people in term of staff quarters for expatriate and Armed forces as well as construction of housing estates to serve the senior civil servant in the capital city of Lagos and regional headquarters like Kaduna, Ibadan and Enugu.

The social housing over the years has witnessed many changes globally of which Housing experts often ask whether social housing could be seen as the problem rather than the solution. According to Claire (2007) almost all those parameters which originally made housing as a social project, and which contributed to collective well-being and social cohesion have changed; particularly the population living in social housing and their social milieus as well as the standards, needs and conceptions of good housing. Malpass (2008) equally pointed out that social housing has changed from a broadly based tenure, accommodating a range of income groups, to an increasingly residual sector for the poor. This made the pattern of ownership and management of social housing in Britain to transform from local authorities to individual ownership through the sale of council houses under the right to buy in 1980, and the transfer of council housing to housing associations in 1988.

Nigeria over the years also witnessed a wind of change in the public housing provision. For instance, the first major changes occurred between 1970s and 1980s when NBS metamorphosed to Federal Mortgage Bank of Nigeria (FMBN) through federal government effort in providing affordable housing to Nigerians citizens on long term mortgage repayment arrangement and the national low income housing programme embarked by the government in all the States of the Federation, popularly known as Shagari low cost.

However, the failure of the programme led to National Housing Policy of 1991 with a slogan of Housing for All by the Year 2000A.D. Aribigbola (2008) explained that the policy has a vision of providing about 700000 housing units every year to meet the 8million housing deficit and provide sites and services scheme for all income groups, with special emphasis on low income groups in the major cities of the country through National Housing Fund of which both workers and government were to contribute 2.5% of their annual income and revenue respectively while insurance company, commercial and merchant banks were made to contribute between 10% and 40% of what they generated to the fund.

Unfortunately, the inability of the policy to achieve its target led to 2006 housing policy with the aim at removing the impediments to the realization of housing goal of the nation. The strategies adopted by the policy included among others the disengagement and encouragement of private developers into housing provision, the use of certified locally produced building materials as a means of reducing construction cost, making land for housing development easily accessible and affordable, ensure the use of relevant and fully registered Nigerian professionals to provide appropriate designs and management in housing delivery and promote a national housing market. According to Wakely (2014), in developing countries site and services schemes which was considered as a means to the housing

provision toward the end of the twentieth century became in relevant and abandoned by the end of 1990s and therefore seeking support for private participation in housing provision.

MATERIAL AND METHODS

The Study Area

The study area is in Ado Ekiti the capital of Ekiti State and focuses on the public housing schemes. The city which is located on latitude 7°4' north of the Equator and 5°15′ east of the Greenwich Meridian does not only witness progressive population growth but equally experience spatial expansion. As a matter of fact the population of the town that was less than 200,000 before the creation of state is now about 400,000 while the spatial expansion increased from 19.6 km^2 in 1996 to 36.7 km^2 in 2006

The city has also witnessed more physical developments, particularly in housing since inception as a state capital. For instance, the estimated total housing stocks of the city which were less than 2500 when the state was created were estimated through satellite imagery to be around 4000 units. Initially there were two housing estates in the city namely Ekiti State Housing Estate and the Federal Housing Estate which are located along Afao road. However, the town can now boast of eight housing schemes at different locations,

Methodology

The study is purely based on both descriptive and inferential statistics of which data were obtained from both primary and secondary source. The various Journals, text books and internet services remain the source of secondary data while structure interview and questionnaire serve as source of primary data A well structure oral interview was conducted with officials of both Ekiti State Housing corporation and the Federal Ministry of Housing and Urban development to get relevant information on their housing properties in term of total number of developed properties, types, location and the cost implications At the same time, administrative questionnaire was designed to collect information on housing characteristics as well as social economic of the prospective owners. These involved administration of about 196 questionnaires that were randomly distributed to sample 20 percent in various type of housing stocks located at each housing estate. The collected data were presented in tabular format and properly analysed by multiple regression method to determine the influence of socio economic factors of households on their housing tenure. The model of the regression which has the housing tenure as dependent variable and education status, income age and employment status as independent variables is specified as

$LnY = a + b1X1 + b2X2 + b3X3 + b4X4 + e$ where Y stands for the nature of housing stocks, X1 for education status, X2 for income, X3 for age X4 for employment status and e as error term.

RESULTS AND DISCUSSION

Descriptive Analysis

There are three categories of estates in the study area namely, the Federal government, the State government and the private developer. The Federal government has three estates with 396 housing units, the State government controls four estates of 380 housing units while private developer has one estate of 250 housing units, see table 1. The table clearly showed that the Federal government (Shagari) low cost housing estate contained one bedroom and three bedrooms flats while most of the recent housing estates have two bedrooms flat, three bedrooms flat, three bedroom flat special, four bedrooms flat and manson. Apart from Shagari low cost housing which had purchasing values of 10,000 and 18,000 Naira, others have purchasing values that ranged between 2million and 5million Naira.

Table1: The General Information about the Estates

Name of Estate	Developers	Year	Type	Unit	Cost in N
Federal Housing	Fed. Govt (PB)	1981	1 Bedroom	157	10000
			2 Bedrooms	10	18000

Plate 1:A view of Obasanjo Housing Estate

The table below indicates that majority of home ownership that represents 62.9 percent secured their properties with 10 percent fixed deposit and installment payment while those with outright purchase are 8.6 percent. At the same time, the 10-20 years period of payment has the highest percentage of 68.3. The table also noted that co-operative loan formed the major financial assistant with 45.7 percent

Table 4: The Housing Financial Information

Source Author Fieldwork (2014)

It is generally noted that majority of those who owned houses in these estates were between the bracket age of 25 and 50 years with 55.1 percent while none is below the age 25 years, see data below. The data also revealed that 87.2 percent of the house ownership is male while 89.8 percent are married with divorce of 1.5 percent as the least percentage.

Source author fieldwork (2014)

The economic background of the house owners in these estates are 68.4 percent publicly employed while the retirees came second with 22.4 percent, see table the below. From the table as well, those that earned above 1.5million constituted the majority of the house ownership with 49.5 percent while those that earned between 1.0 and 1.5 millions also came second with 25.5 percent. The table equally showed that those with tertiary education background formed the highest percentage of 72.5 percent.

Table 3: The Economic Background of Respondents

The Inferential Analysis: The result of the model summary which is presented in Table 4 with R as 0.712, clearly indicates a strong relationship among the variables while the (R^2) with value 0.50.7 implies that the regression has 50.7% of fitness

Table 4: Model Summary

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate
1	.712[a]	.507	.342	.83753

a. Predictors: (Constant), employment, income, age, education

The Anova table with Ho hypothesis that all the independent variables has no effect on the housing tenure is rejected when the p value <0.05. This implies that the variables have significant effect with 0.058greater than the p value of 0.05

Table 5: ANOVA[b]

Model		Sum of Squares	Df	Mean Square	F	Sig.
1	Regression	8.641	4	2.160	3.080	.058[a]
	Residual	8.417	12	.701		
	Total	17.059	16			

a. Predictors: (Constant), employment, income, age, education

b. Dependent Variable: location

The coefficient table also revealed that individual variable has significant influence the housing tenure with income taking the lion share while age has the least significant. The equation formed with the unstandardised coefficient b as indicated below is normally used to predict the trend of change in the variables

$$LnY = a + b1X1 + b2X2 + b3X3 + b4X4 + e = 3.018 + 0.130 + 0.015 - 0.084 - 0.055$$

Coefficients[a]

Model		Unstandardized Coefficients		Standardized Coefficients	T	Sig.
		B	Std. Error	Beta		
1	(Constant)	3.018	.296		10.201	.000

	Employment	-.055	.044	-2.390	-1.264	.230

a. Dependent Variable tenure:

Discussion

The Shagari government massive low cost housing programme made Ado Ekiti to receive 156 one bedroom flat and 10 three bedrooms flat. However, the fact that the government was able to delivered 47000 housing units out of the projected target of 120000 as pointed out by Waziri and Roosli (2013) is an evidence of shortage of housing expectation of the city. The involvement of private participation in housing delivery has contained in 2006 National Housing Policy actually contributed to the rapid growth rate of housing supply in the State. This is because the Federal and the State government that delivered only 225 housing stocks between 1980 and 2000 delivered 760 housing stocks between 2007 and 2010 when public/private participation (PPP) was introduced. This is actually more than thrice the quantity produced between two decades.

It is obvious that using the average household size of 4 persons with the average of 2 households per housing unit to divide the 308621 population census of Ado Ekiti in 2006 made the housing requirement to be 38578 as against the existing housing stocks of 3600 in 2009. Therefore, in spite of the tremendous improvement in public housing delivery, the city still has acute shortage of housing to accommodate the teeming population particularly the urban poor that are not less than 60 percent.

The situation where the low cost housing of Shagari regime in 1980 were placed at price between 10000 and 18000 Naira when the minimum monthly wage was 100 Naira while the two bedroom flat in public housing of 2007and above have the price value of 2.5million Naira when the least paid public worker receives the monthly salary of 18000 Naira coupled with low patronage of mortgage facilities and bank loan actually made public housing to be too expensive and practically impossible for the common poor to access with their low income. . It required more than a life-time for middle and low income earners to save such amount. So they simply ignored the buildings only for the high income earners and very senior civil servants to acquire and rent to them (those that could pay the rent), while most of them patronized slums

The location of those housing estates developed by the Federal and State government in the early 1980s and late 1990s as well as those recently developed through PPP were over two kilometer away from the fringe of the city. The situation made these poor people who cannot afford the means of transport to the city centre for essential facilities as well as their places of work not to bother to apply. Hence, Filani (1987) observation that in addition to the main problem of the houses not being affordable, the National Low Cost Housing (NLCH) programmes were located at the periphery of the city thereby creating higher cost of transportation to and from work for the occupants who are workers in the cities justified. He

further explained that in some cases infrastructural facilities like water, electricity and good roads were not provided thereby creating a lot hardship and misery to occupants. For these reasons the worker will prefer to squat with friends and relatives inside the city or live in slums

CONCLUSION AND RECOMMENDATIONS

Majority of the world population are poor and mostly live in urban area without access to proper housing the situation is the same in Ado Ekiti where there is a problem of huge housing deficit for the poor The little available public housing in the city are not only too expensive for the poor but equally located at a distant place for the poor accessibility. The paper also noted the effort of both the State and Federal governments in the housing provision to perceive that private sector is far more efficient provider of societal goods and services than the government.

As a way of recommendation, there is need to improve on the existing policies as follows:

The strategy of 'cooperative housing 'as a concept that has emerged as an increasingly important vehicle for the provision and maintenance of low- income housing in the National Housing Policy of Nigeria should be encouraged and supported with wide publicity and enlightenment. This will encourage the society, members to contribute, manage fund, and decide on housing programmes and implementation with joint effort

An innovative public – private partnership approach to housing is, therefore, required to make the kind of progress that is needed. This will synergize the technical and organizational expertise of the private sector with the regulatory functions of the public sector to improve the housing delivery

In order to make the cost of housing affordable to the poor citizen, government must not only make it a mere policy to use local building materials but must come out with workshop and training to enlighten and encourage housing developers of using the local materials.

There must be proper and intensified enlightenment campaign through media to explain the importance of mortgage and also ensure enough provision of facilities that can make mortgage housing fund accessible to all citizens.

Government must make it a policy to give tax rebate to housing developers and for those who are on housing loan through mortgage or any other bank loan.

ABSTRACT

Urban fringes are receiving more attention, given the transformational changes in both urban and rural areas plus the fact that both are becoming increasingly interwoven. The quantity and quality of public infrastructural facilities are guiding forces for the development of urban fringes in both developed and developing nations of the world. In developing nations, the focus of policy makers, planners and development professionals is on the welfare of urban centres at the expense of urban fringes. Consequently, this study examines the level and quality of public infrastructural facilities in Ibulesoro (an urban fringe of Akure) vis-à-vis its effects on sustainable physical and human development in the community. The study utilized the simple random sampling technique to select 20% of buildings (70) out of 350 in the community for homogenous characteristics. The eldest household head was interviewed in each building using the instrumentality of a structured questionnaire. Empirical analysis shows that: a higher proportion of respondents indicate high level of poverty with low level of productive capacity due to inadequate public infrastructural facilities both in quantity and quality; over 70% of respondents show that available infrastructural facilities are provided and maintained through individual and communal efforts; a higher percentage of respondents also revealed that educational, health and other social facilities and services are at their low ebb. Based on the findings, an integrated land use Master Plan for Akure with particular emphasis on infrastructure facility development for Ibulesoro and other fringe communities around Akure is canvassed.

Keywords: Developing Nations, Ibulesoro, Infrastructural Facilities. Poverty, Urban Fringe

INTRODUCTION

Urban fringe is synonymous with peri-urban, urban periphery, rural commuting zone, or the inner rural. It is an area around the urban settlement where urban and rural development processes meet, mix and interact at the edge of the city (Adell, 1999). It is therefore the edge of the city which combines both urban and rural characteristics. It is a borderline between the rural and the urban - a narrow zone with various widths outside the political boundaries of an urban area which is neither rural nor urban. It is often defined as a conflict zone at the interface between urban and rural landscape. The urban fringe as an area of very special characteristics, unusual dynamism and transition (Vries, Haccoû, Bruijn & Stortelder, 2012), requires research, policy and action in its own right; its planning and development is therefore crucial to sustainable development of the parent city.

It is pertinent to note that urban fringes which had been the medium for raw material production and agricultural practice have been neglected by the various levels of government in Nigeria (Chardwick, 1995). Amao and Ilesanmi (2013) note that, the urban fringe constitutes the habitat of a diversity of populations, including lower income groups who are particularly vulnerable to negative externalities of both rural and urban systems. These include; risks to health, life and physical hazards related to the occupation of unsuitable sites, lack of access to clean water and basic sanitation and poor housing conditions.

In developing nations, urban fringes are not usually given recognition by formal governments especially in the area of infrastructure provision and management. Infrastructure is synonymous with development, and the lack of infrastructure services signals barriers to growth and overall development (Olamiju and Fasakin, 2015). ADB (2012) notes that the

Olamiju, I. O.; Oyinloye, M. A. & Daramola, J. O. (2016). Public Infrastructural Facilities and Urban Fringe Development in Developing Nations: A Focus on Ibulesoro, Ondo State, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1580-1590

provision of infrastructure systems demand public sector involvement because of having some aspects of public good, which inhibit private firms from supplying them efficiently; entail a long project cycle and huge costs that private enterprises in developing countries often cannot afford; and the need for appropriate public sector policies and regulations. Hence, Olamiju and Fasakin (2015) conclude that without government involvement, provision of inclusive infrastructure is illusive.

Ibulesoro, the focus of this study is one of the numerous communities in Ondo state without access to good infrastructural facilities (ODSG, 2005). This paper therefore studies the effort of government in the provision of infrastructural facilities in Ibulesoro; the strategies adopted and the impact of this on the social and economic wellbeing of the people.

REVIEW OF EMPIRICAL LITERATURE

The first definition linked to urban fringe dated back to the World War II period. It was defined as "areas of transition between well recognized urban land uses and the area devoted to agriculture" (Wehrwein 1942). Many authors define the urban fringe from two points of views – the economic and distance from the urban centre. From the economic point of view, the urban fringe is defined as: "…the frontier in space where the returns to land from traditional and customary urban land uses are roughly equal to the returns from traditional and customary rural land uses. In theory, such a frontier should always exist, although its exact location on the ground may not be easily fixed (Hite,1998). From the urban-centric point of view, Chicoine (1981) defines urban fringe as areas that "generally include those areas bordering central cities, surrounding close-in suburbs and non contiguous nearby towns, and extending into the adjacent, open countryside." Based on this view, Webster (2002), considered the urban fringe as areas starting just beyond the contiguous built-up urban area and extends as far as 150 km from the core city center.

Several factors suggest the importance of the urban fringe as deserving greater attention on the part of policy makers. For instance, in most developed countries, increases in: household incomes; urban subdivision codes; infrastructure investment patterns; open space undervaluation; and commuting under-pricing, among other factors, translate into urban expansion on the urban fringe. In addition, the urban fringe is frequently the dumping ground for industrial enterprises forced out from the city centers either through laws and regulations or due to economic factors such as rising land prices (World Bank, 2007). In developing nations especially in Nigeria, the available public infrastructure in urban fringes are poor if not totally absent. Poor infrastructural facilities or complete absence of it in any community is an invitation to poverty. Around the world more than 1 billion people lack access to roads, 1.2 billion do not have safe drinking water, 2.3 billion have no reliable sources of energy, 2.4 billion lack sanitation facilities and 4 billion are without modern communication service (The Global Poverty Project, 2013).

Ayeni (1990) opines that one of the most pressing problems faced by towns and cities all over the world (especially in developing nations) is that of infrastructure ability. The issues of infrastructure and facilities involve not only the inabilities of cities to stimulate urban production by creating a constantly expanding market for agricultural production but also their inability to adequately provide the amenities and essential facilities both within the city and their fringes. Most fringe communities in developing countries experience spontaneous developmental pattern rather than planned growth as they fall outside the jurisdictional boundaries of the governing bodies of the urban area. The local governments and those of urban areas often act separately in terms of overall planning; this has made integrated fringe development the largest single hurdle to overcome (Masum, 2009).

Most urban fringes suffer deprivation due to absence or total lack of public infrastructural facilities and other social amenities. Urban fringe deprivation is well documented in literature (William, Steven and Eduardo, 1993; UN Habitat, 2003; Ogundipe, 2003; Eziyi, 2009; Fasakin, 2009; Olamiju, 2014; Dosumu, 2015). Inequalities in the spatial distribution of infrastructure and social amenities between the urban centres and the fringes can be responsible for deprivation in the latter. Olamiju (2014) notes that the provision of infrastructural facilities in Akure is concentrated at the city centre at the expense of peri-urban communities whose residents had to travel long distances to get access to these facilities. This trend shows that residents of urban fringes in Akure are deprived of basic amenities such as good roads, electricity and piped water supply among others.

Fox (1994) opines that infrastructure include those social services derived from a set of public works traditionally provided by the public sector, to enhance private sector production and household consumption; these include services like hospitals, water supply, electricity, roads, drainages, sewerage and etcetera. The adequacy of infrastructure helps to determine a country's success or failure in diversifying production, coping with population growth, reducing poverty, improving environmental conditions, etc. Also, it has been noted that infrastructural capacity grows step for step with economic output. For example, a one per cent increase in the stock of infrastructure is associated with one percent Gross Domestic Product (GDP) (World Bank, 2007)

Synoptically, infrastructural facilities are very essential in an environment for economic growth, and to enhance the quality of life. Ayodele (1996) suggests that there is both an economic and social dimension to infrastructure. The social dimension relates to social services which cover health, information and education among others; while the economic aspect relates to utilities such as energy, power, transportation, water and communication services. In conclusion, most of these services and facilities are concentrated in the urban centres at the expense of the urban fringes (Olamiju, 2014).

METHODOLOGY

Research Locale

Ibulesoro locates in Ifedore Local Government Area with its headquarters in Igbara-Oke, Ondo State Nigeria (Figures 1 and 2). A Yoruba speaking community in South West Nigeria, Ibulesoro falls on latitude $7^{0}15^{1}$ North and longitude 5^{0} 20^{1} East. The community is bounded in the North by Ijare; in the East and North by Akure Township; and in the West by Ipogun (see Figures 1 and 2 for the location of study area in its national, regional and local settings).

The topography is generally undulating but relatively plain. Historically, the paramount ruler of Akureland is a mentor to the Olubule (the paramount ruler of Ibulesoro) signifying the level of contiguity and socio-cultural relationship between the two communities. A prominent tourist centre in Ibulesoro is the Bobado River which is traditionally forbidden to albinos for historical and cultural reasons.

Ibulesoro enjoys warm, humid tropical climate with an average rainfall of about 1500mm per annum. The people of Ibulesoro engage in farming and petty trading. According to 1991 population census, the population of Ibulesoro is 3,003. Presently, the community has an average of 750 households (Olafiaji, 2010). With an average of 7 persons per household (Fasakin, 2000), the estimated population of the study area stands at 5,250 people. Observation reveals that, this community is not accessible to good water supply, electricity, health services, educational facilities and other basic amenities which make them to rely on Akure Township for survival.

Database Description

In a survey carried out in October, 2010; "the building population of Ibulesoro was 350 with about 752 households" (Olafiaji, 2010). Twenty Percent (20%) of buildings were sampled for homogenous characteristics; and the most senior household head was interviewed in each building using the instrumentality of a structured questionnaire. The questionnaire investigated 39 variables covering the socio-economic and public infrastructure components of the community. The variables were designed as questions with pre-coded alternatives specified. Trained research assistants, read and interpreted the questions to the respondents and administered the questionnaires on one-on-one basis for two weeks. They were instructed to read and interpret the questions in Yoruba (the local language in Ondo State) in case the respondents could not speak English language. Variables which bordered on socio-economic

characteristics of respondents and level of infrastructure development in the community were engaged in the analysis.

FINDINGS AND DISCUSSION OF RESULTS:

Finding on the socio-economic characteristics of respondents show that 40.3% were male while 59.7% were female. This trend shows that majority of deprived people in the study area is gender sensitive. The age composition of respondents shows that 40.3% are youths between the age of 18 and 30 years; 45.7% are middle-age adults between the age of 31 and 50 years; while40.0% are adults of 51years and above. This age composition shows that it is the vibrant, youthful and matured proportion of the population (especially females) that are mostly deprived of good infrastructure for development. This trend is against the Goals 5 and 9 of Agenda 2030 for sustainable development which is expected to achieve gender equality and empower all women and girls; and build resilient infrastructure respectively.

The marital status of respondents shows that 35.7% were single, 51.4% were married, 7.2% were widow/widower while 5.7% were divorcees. Since more than half of the population are married, the rate of procreation is likely to increase over the years more than the rate of infrastructure provision. The respondents are highly literate as about 46.8% of them had primary education, 37.1%, secondary education while, 6.5% had tertiary education and 9.7% had no formal education. Generally, the respondents engage in trading and farming as about 35.7% are traders and 34.3% are farmers with 5.7% as civil servants while 17.2% are artisans (who were self-employed). About 7.1% of respondents are unemployed. Consequently, most of the respondents are poor as over 51.0% of them earn below N10,000 per month. With this amount, an average respondent earns about N300 ($1.30) per day (see Table 1). This amount is very close to the international community average earning of $1.25 for extreme poverty; as nearly half of the population in the developing regions lived on less than $1.25 a day.(MDG, 2015). Olaseni and Alade (2012) confirmed that about 55 per cent of the Nigerian population lives on less than $1 per day, which is one of the highest poverty rates in sub-Saharan Africa.

Findings show that the main source of power supply in the community is the Electricity Distribution Board (EDB). As a result of poor/irregular supply, over 40% of households use generators as alternative source of power supply. When electricity is irregular, businesses suffer and the use of generators exposes residents to exhausts that are detrimental to their health. One important new innovation in power supply in Ibulesoro is the installation of a Biogas Digester by the West Africa Agricultural Productivity Programme (WAAPP) in partnership with the Federal College of Agriculture, Akure, Nigeria (FECA). The biogas digester converts animal dung into combustible biogas. This produces methane gas which can be piped into residences to supply energy for cooking, heating, and other tasks. The Nation (2015) note that this facility would not only reduce greenhouse gas emissions, it would create a potential business opportunities for entrepreneurs to supply biogas digesters to people who want to generate electricity at affordable cost. Respondents confirmed the training of local residents on the construction of the facility. This is a good development that must not be allowed to waste; if only the digester machine could be made readily available to the people at affordable cost. It is recommended that the local and state governments invest in the biogas facility project to ease the problem of irregular power supply in the community in particular and Nigeria as a whole. Plates 1 and 2 show the biogas facility and a beneficiary cooking with the Biogas Digester respectively

Table 1: Some Socio-economic Characteristics of Respondents

Occupational Status		
Occupation	**Freq.**	**%age**
Farming	24	34.3

Source: The Nation (2015)

It is pertinent to note that the people of Ibulesoro do not enjoy piped water supply in their homes. The only solar-powered borehole in the community is not networked, but rather a point source where residents queue for water. The chief source of water supply in the study area is the well as over 61.4% of respondents get water from this source while about 27.1 % uses the borehole. About 11.5% of respondents fetch water from streams and rivers (see Plates 3 and 4; Table 2). The predominance of well in Akure area generally may not be unconnected to the fact that it is cheaper and easier to construct than borehole and pipe borne water (Lawal and Basorun, 2015). Observation shows that most of the wells are earthed and not covered while residents use the rivers and streams as toilets. This trend shows the level of health hazard the people could be exposed to due to environmental pollution.

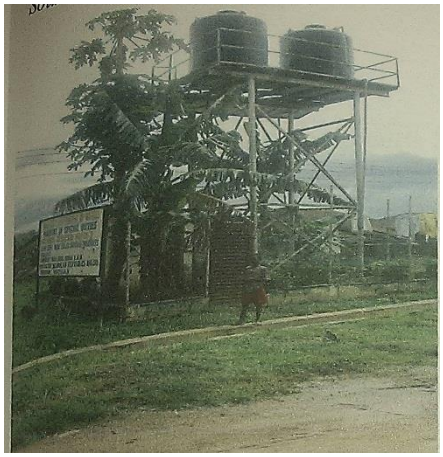

Plate 3: Public Solar-Powered Borehole with Overhead Water Tank in Ibulesoro

Table 2: Sources of Water Supply

Source	**Freq.**	**%age**
Piped Water	0	0.0
Borehole	19	27.1
Well	43	61.4
Stream/River	8	11.5
Total	**70**	**100**

Table 3: Nearness to Sources of Water Supply

Distance	**Freq.**	**%age**
Below 100m	14	20.0
100m-500m	9	12.9
501m-1Km	35	50.0
Above 1Km	12	17.1
Total	**70**	**100**

Nearness of respondents to sources of water supply was accessed (see Table 3). About 20.0% of respondents walk less than 100 meters distance from source of portable water supply to their homes; while about 12.2.0% walk between 100m-500m distance to sources of water supply. A cumulative 67.1% of respondents walk more than 500m distance from home to sources of water supply. This trend is above the minimum 500m approved walking distance to sources of portable water by WHO/UNICEF (Olajuyigbe, 2008). In addition, as a result of the long distance covered before getting to improved source of water, a lot of time that could have been used for other benefits is wasted.

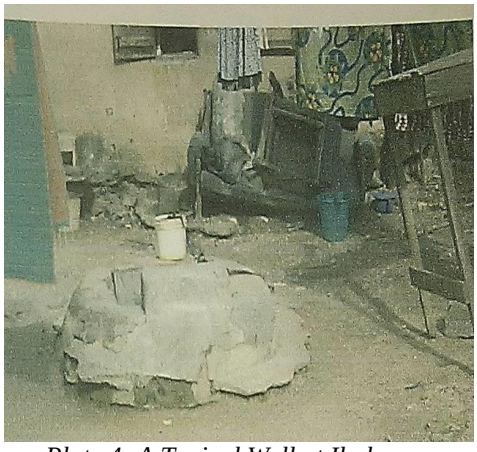

Plate 4: A Typical Well at Ibulesoro

For example Alaci and Alehegn (2009) observed that average households in urban fringe communities of Kogi State of Nigeria spends an average of 65 minutes per day, 455 minutes (8 hours) per week, 1820 minutes (30 hours and 33 minutes) per month and 21840 minutes (364 hours) yearly to fetch water. Olaseni and Alade (2012) conclude that water and sanitation infrastructure in the country is grossly inadequate and has implications for wealth creation and economic development. It is the responsibility of government of any nation to provide adequate quality of portable water for its citizenry (Ajibade et.al, 2012). It is therefore obvious that the failure of governments (be it local, state or federal) to provide adequate infrastructure facilities for her citizenry, degenerates their social and economic life.

Generally, 11.3% of respondents ranked the health facilities in the community as good while 88.7% ranked them as poor. This finding is a reflection of the state of health facility in Ibulesoro in particular and Nigeria as a whole. Observation and personal interview of individuals reveal that there is only one health centre in the community, which is without adequate facilities, hence residents seek medical care in Akure metropolis. This trend was reported by the National Bureau of Statistics (2008) in Olaseni and Alade (2012) that "…only three hospital beds were available for every 10,000 people while only 45.9% have access to medical facilities in the country in 2006". The inadequacy of health facilities in Nigeria especially at urban fringes is a reflection of non-commitment and mismanagement of resources on the part of governments at all levels considering the fact that Nigeria is blessed with abundant natural and human resources.

The educational facilities show similar characteristics as the health facilities. About 12.9% of respondents ranked public schools as good, 29.0% ranked them as fair while 58.1% opines they were poor. Under Section 18(1) and (3) of the 1999 Constitution of the Federal Republic of Nigeria, it is the responsibility of government to provide free and compulsory basic education with a view to ensuring that there are equal and adequate educational opportunities at all levels (Olamiju and Olujimi, 2011). Most educational facilities are concentrated at the urban centres at the expense of the fringe communities. Ibulesoro has only two primary schools. The school buildings are dilapidated and the classrooms are sub-standard in terms of availability of teaching and learning facilities (See Plate 1). On the provision and management of roads in Ibulesoro, 85.5% of respondents revealed that roads in the community were constructed/repaired through communal efforts and 14.5% agreed it was by individuals, while government involvement was nil. In addition, rural access roads leading to farms are neither tarred nor graded, this undoubtedly would have a backwash effect on the rural economy. This trend is a recurring decimal in the provision of road infrastructure in Nigeria: the rural areas had been neglected by the various governments at federal, state and local levels (Olamiju, 2014).

FGN (2009) noted that the current neglect of these roads implies a loss of network value of N80 billion per year and additional operating costs of N35 billion per year. This situation is economically unhealthy and cannot support the country's drive for economic transformation. About 82.0% of respondents indicated the absence of drainage facility in front of their houses while 18.0% confirmed its presence. These trends explain persistent flooding hazards experienced by residents after a little shower of rain.

Plate 1: A dilapidated secondary school building at Ibulesoro

CONCLUSION

The results have shown clearly that there are more females than males in the study area and the population is generally made up of vibrant youths and adults who reside at Ibulesoro and work/school in Akure. About 50% of the population are married; highly literate but not gainfully employed as they engage in petty trading and subsistence farming. They are therefore, generally poor as they live on less than 1 US dollar per day.

It is also clear from this study that provision of electricity in Ibulesoro is poor. However, the intervention of an NGO such as the WAAPP/FCA on the introduction of Biogas Digester to solve energy problem in the community is commendable. The major source of domestic water supply is the well which is usually uncovered and hence, unhygienic. The average distance of respondents to a portable source of water is about 1kilometrer. There is only one ill equipped health centre and two (2) dilapidated primary schools in the community.

Therefore, it is obvious that government involvement in the provision of infrastructure and social services in Ibulesoro and other fringe communities in Ondo State is limited if not absent. Infrastructural development policies, plans and programmes are carried out in time and space for the benefits of the people and improvement of their welfare; they have to be carried out in human settlements, hence proper plan and adequate provision for such settlements by government is imperative. Since Ibulesoro relies on the main city (Akure) for the extension of most infrastructure such as electricity and water among others, this paper recommends that the Ondo State government should embark on an integrated land use Master Plan with particular emphasis on infrastructure facility development for Akure (the main city), Ibulesoro and all other fringe communities such as Aye, Ipinsa, Igushin, Ikota and Irese among others, for sustainable urban-fringe development in Ondo State. To make this plan comprehensive and sustainable, the use of high resolution satellite data is canvassed; this will speed up the process of planning and management of infrastructure in the city and its fringe areas, especially in planning for water supply, electricity, and road network among others. This recommendation is in line with Patkar, (2003) opinion that satellite data is a veritable source of information for urban land-use and infrastructure planning.

ABSTRACT

Urban sprawl has been used to describe a wide variety of the undesirable aspects of urban growth; it is consciously referred to as, unplanned and uncontrolled development resulting in poor and much unplanned urban fringe. Across the world, there is growing concern and awareness about urban sprawl and its consequences, as urban system are evolving and emerging in surprising ways. Urban sprawl is a major problem in the course of development in developed and developing countries. This paper aimed at examining the challenges of sprawl development in selected neighbourhood of Suleja. The objectives are to examine the drivers of urban sprawl and challenges of urban sprawl development in the peri-urban of Suleja. Remote sensing along with Global Positioning System (GPS) and Geographical Information System (GIS) were helpful in this regards. This study reveals that the development of urban sprawl settlement in the suburbs of Suleja is as a result of rapid population increase and its proximity to Abuja, the Nigeria Federal Territory. The cost of land which is relatively cheap at the suburb has caused the shift in population to the peri-urban of the town forming a sprawled like characteristics of development, the town is growing without a proper planning, despites its advantageous location and proximity to the Federal Capital of Nigeria. Weakness of the physical planning agencies in enforcing planning standards, rules and regulation is the evidence of the current t pattern of growth of the town. However, the impact of urban sprawl development in Suleja is enormous; range from environmental to transportation and to economy. In order to reduce further impact, the peri-urban of Suleja should be planned and developed in the view and assumptions of Vence's theory of urban realm; creating a suburb that is independently sustainable and functional viable.

Keywords: Urbanization, Urban Sprawl, Urban Growth, Planning, Development

INTRODUCTION

The world's urban areas are now home to nearly half of humankind. Kofi Annan, the former General Secretary of the United Nation in 2001 emphasized that the world has entered into the realm of urban millennium, a period with a remarkable difference in innovations, for an irresistible urban growth (UN-Habitat, 2001; Idowu, 2015). The industrial revolution of the 18th century began the current phase of urban growth, which the world is facing in the recent time (UN-Habitat, 2001). The growth of the world population since the turn of the 19th century and particularly after the World War II has been unparalleled in the history of the world. With the increased population, the phases of urban settlements are changing rapidly, with the semi-urban areas and medium-sized towns turning into full urban town (Obateru, 2005; Idowu and Olaniyan, 2009; Idowu, 2015b).

UN-Habitat (2001), presented the global report on the collective implications of the growing population of the world during the two hundred years (19th and 20th centuries) of global economic expansions. It was published that the cities which grew at less than 30 million in that century, now recorded more than 3 billion at the beginning of the 21st century, with over 500 cities harbouring thousands of people. This implies that, the planet earth hosts a range of population of people across the world. Other studies also established that, the process of urban growth will, however, continue as this century advances. The prediction is that, there will be an increasing urban agglomeration in all regions of the world by 2050 (UN-Habitat, 2008; 2011; 2013; United Nations, Department of Economic and Social Affairs, Population Division - UNDESA, 2014; 2015).

Idowu, O.O.; Shaibu, S. I.; Adeleye, B. M.; Medayese, S.O. & Abd'razack, N.T.A. (2016). The Challenges of Urban Sprawl Development in Suleja, Niger State. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1591-1598

Consequently, growth is a natural phenomenon in life, therefore it is expected that cities and towns should grow (Popoola, 2014). Meanwhile, the growth of cities and towns increasingly subjected the urban environment into dramatic problems which ranges social to physical and environmental problems. The negative implications of urbanization and urban growth are widely linked to several problems such as urban sprawl development (Durieux, Lagabrille, and Nelson, 2008).

Urban sprawl has been used to describe a wide variety of the undesirable aspects of urban growth; it is consciously referred to as, unplanned and uncontrolled development resulting in poor and much unplanned urban fringe. There is growing concern and awareness about urban sprawl and its consequences across the world, as urban system are evolving and emerging in surprising ways (Downs, 1999; Torrens, 2006. Feng, 2009). It is agreed as one of the problems affecting the course of development, both in the developed and the developing countries.

The idea and early studies on urban sprawl is unanimously agreed to start from the United States of America (Hamidi and Ewing, 2014). As rightly observed by Franz et al. (2006) the discussions and researches on urban sprawl were anchored predominately in the context of the urban morphology and land use pattern in the US for a long time, but, it later spilled over to Europe and other regions of the world. Alabi (2009) and several other scholars, however, observed the variations in the degree of urban sprawl between the developed and developing countries, he accepted that there are differences in the challenges of urban sprawl all over the world. The components of urban sprawl, however, have been highly debated by several scholars in the field of urban studies; it means different things to different people. Concomitantly, it remains a hot topic attracting a considerable attention from geographers, planners and social scientists across the world (Downs, 1999; Paul and Tonts, 2005; Frenkel and Ashkenazi, 2008).

On the perspectives of urban sprawl Torrens (2008), Liu and Jiang (2011) and Idowu (2015a), however, maintained that, the term ‘urban sprawl’ is characterized to be popular, complex and as well surrounded by controversy. Several reports on sprawl begin with the admission that, sprawl has no definite definition, it is a value loaded term and a reference point in many planning literature (Frank, et al., 2000; Adaku, 2014).Other contentions areas in the study extend to the bottleneck associated with the characterization, measurement, causes and consequences (Torrens 2008; Hamidi and Ewing 2014). Several authors have made several attempts to describe how urban sprawl looks like, without a clear cut accepted features to describe it (Ewing, 1997; 2002; Burchell et al., 1998; Glaster et al., 2001). Franz et al. (2006) on the contrary, however, argued that these features describing urban sprawl are ambiguous; it’s jointly reflecting the causes and consequences in the same manner its presenting what characterized by urban sprawl, while, the existing methods for measuring urban sprawl have been contested worldwide. The entire areas still remain unresolved based on the divergent views of the scholars.

The causes of urban sprawl in the world are universal, but vary in character, impact and challenges (Oueslati et al., 2015).Urban sprawl has not only generated a series of studies and discussions in the developed countries, but also in the developing countries. For instance, in Nigeria, Mabogunje (1968), Olorunfemi (1979), Okewole (2002), Barredo, et al., (2004), Fabiyi (2006), Olujimi (2009) Alabi (2009), Aguda and Adegboyega (2013) among several others scholars have reported the sprawling nature of several urban centres in Nigeria. Barredo, et al., (2004), Olujimi (2009) and Aguda and Adegboyega, (2013), have attributed the rapid increasing urban agglomeration in Nigeria to the prevailing inadequate institutional framework, economic growth and population increase. The unprecedented demographic

changes have seriously laid huge challenges on the peri-urban space, mostly in the development of residential accommodations (Olujimi, 2009, Wapwera et al., 2015).

The location and proximity of Suleja to Federal Capital of Nigeria speaks volume on the development of sprawl settlements in the town. This study is aimed at examining and challenges of sprawl development in selected neighbourhood of Suleja. The objectives of this study include, examining the development pattern of the peri-urban settlements, to identify the physical characteristics of the selected per-urban neighbourhoods and the challenges of sprawl development on urban landscape.

STUDY AREA

Suleja, lies on latitude 7˚ 31′N and longitude 7˚58′E. The town was formerly referred to as Abuja prior to the time of the establishment of the Federal Capital Territory. The town is situated on the Iku River, a minor tributary of the River Niger at the Abuchi Hills and lies at the intersection of several roads. The Local Government reform of 1976 facilitated the creation of the Suleja Local Government Council from the defunct Abuja Native Authority. The Local Government Council shared boundary with Gurara and Tafa Local Government Councils in Niger State and Gwagalada in FCT. The Local Government land expanses for about 153.4 sqkm land coverage (Fig. 1). The Census report of 1991 put the population of Suleja Local Government at 151,300 persons, the population was estimated at 174,638 in 1996 and it rose to 216,578 people in the 2006 National population Census. This study is centred on four peri-urban neighbourhoods in Suleja. This consists of Maje in the Northern part of the Local Government, Chassa and Paulossa in the Southwest region of the town and Gwazunuin the Eastern part of the town (Fig. 2)

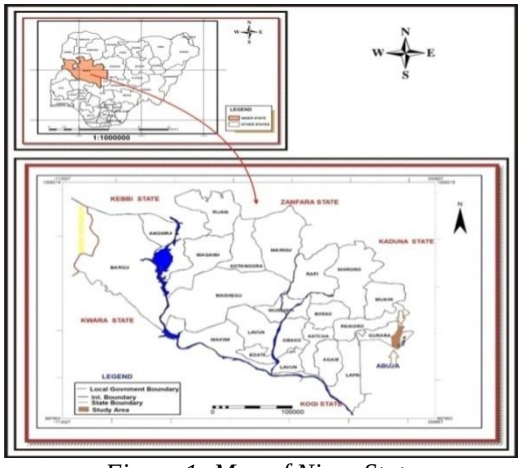

Figure 1: Map of Niger State

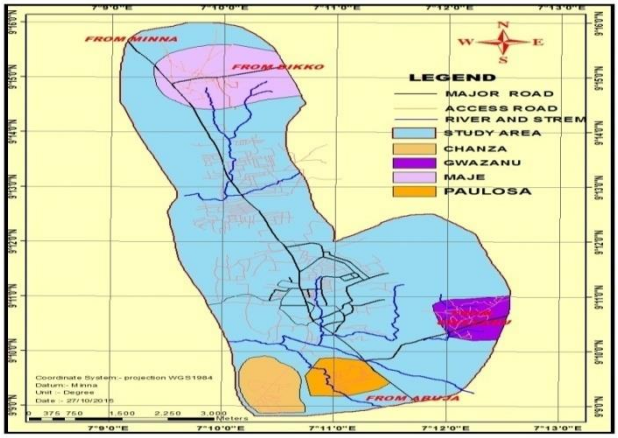

Figure 2: Selected Neighbourhoods for the study

METHODOLOGY

This study explored both secondary and primary sources of data required for this exercise. The secondary data employed in the study include the remote sensing imagery (Google earth data), Census data and published materials obtained from libraries and the internet. The primary data were sourced through the direct survey and investigation of the study area. Google earth image was retrieved from the internet and digitized using ArcGIS 10.2software in order to show the housing density and pattern of development in the selected peri-urban neighbourhoods.

RESULTS AND DISCUSSIONS

Patterns of Development in Suleja

The digitization and analysis of google earth image of the selected four neighbourhoods reveal the development pattern of the study area. For instance, in Maje, the neighbourhood covers approximately about 567,246.01sqmarea. Based on the pattern, this neighbourhood exhibited a continuous characteristic pattern, showing an intense development of unused land and forming unbroken fashion of development. Although the settlement is supported by major access linking Kaduna – Abuja road, haven bounded by the Minna – Suleja regional road (Figure 3). With the population of just 1,302, the outward march of low density is observed in ribbon low pattern development along major suburban highways is an evidence of sprawlin that axis of Suleja.

Paulossa neighbourhood covers about 548,017.88sqmarea with 1,866 people. Paulossa exhibited clustered pattern of development, haven linked the neighbourhood with several alleged environmental problems, in regards tothe natural feature (River and mountain) which bounded the area eastward, these featureshave bunched the growth and developmentof the neighbourhood tightly, minimizing the amount of land for development of residential or nonresidential units (Fig. 4).

Chaza neighbourhood covers about 49,361.87sqm area, with 900 people living in the area. This peri-uban neighbourhood is a low density area surrounded by open spaces (Fig. 5),it has the attributes fora high countinous pattern of leap frog development and the potential for the development to extend toward any direction in the neighbourhood. Gwazunu has the coverage of about 638,277.60 sqm area and the estimated population of 1,140 people. The settlement is characterized as clustered pattern settlement, bounded by roads and rivers

All these imply that, the peri-urban of Suleja commonly exhibits a clustered or continuity pattern of development, based on the advantages of landscape, terrain and the morphology of the town. In most cases, the relatively unstable land-form affects the pattern of development in the urban fringe.

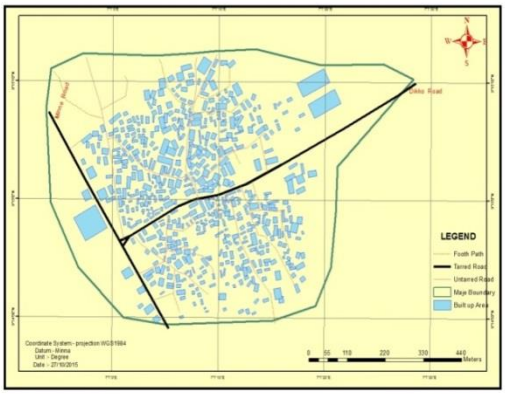

Figure 3: Development Pattern of Maje

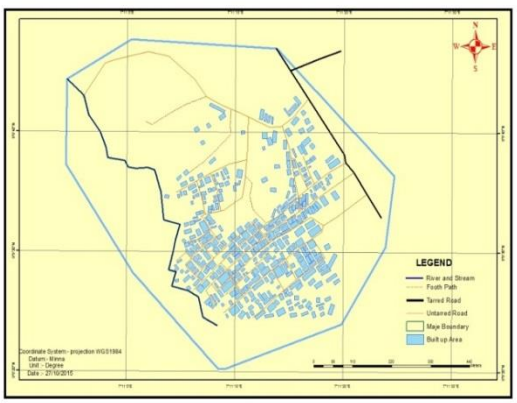

Fig. 4: Development Pattern of Paulossa

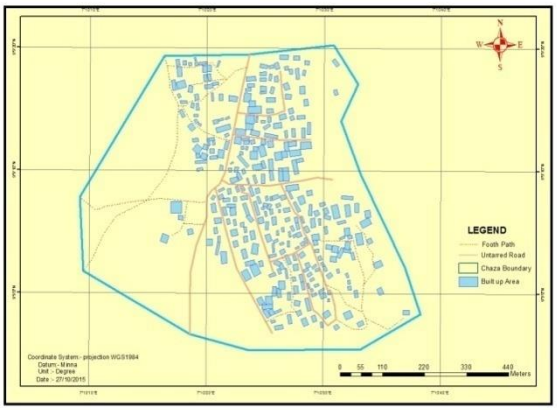

Figure 5: Development Pattern of Chassa

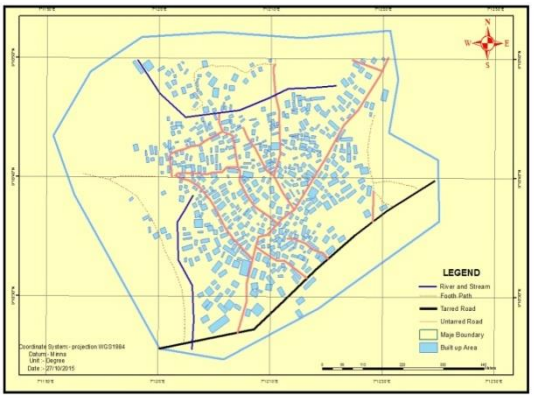

Figure 6: Development Pattern of Gwazunu

The physical Characteristics of the Selected Peri-urban Neighbourhoods

The data reveals the three major factors responsible or the spread of sprawl in Suleja and they are, social, economic and physical factors. Different attributes such as ethnicity and religion, safety and security, community or infrastructure facility, reduction in the rent and low price of land were among the major causative drivers of urban sprawl and the choice of neighbourhood in Suleja. Table 2 shows the physical, environmental characteristics of the selected peri-urban neighbourhoods.

Plate 1: Unplanned structure onPaulossa

Plate 2: Wastes deposit along Gwazunu

Challenges of Urban Sprawl Development in Suleja

The Challenges of urban sprawl development in the peri-urban of Suleja are basically categorized into three main headings:

i. **Transportation:** this category of challenge is enormous, as it is influenced by the use of automobiles. Studies by Gordan and Richardson (1997) Glaster et.al (2001) firmly asserted this with respect to the volume of traffic and distance travel by the residents of the neighbourhoods examined.

ii. **Economy:** the influence of market forces is more prominent in the spread of sprawl settlements. The influence of low rental value in these suburbs areas and the cheap cost of land are considered high in this study to promote the development of urban sprawl in Suleja. Also urban sprawl directly affects the provision of infrastructure facility into the hinterland

iii. **Environment:** this is seemingly numerous. This includes the development in the ecological unstable area, reduction of regional open space, indiscriminate disposal of wastes, increase pollution and higher energy consumption, increase runoff of storm water and risk of flooding, removal native vegetation and ecosystem fragmentation.

Table 2: Physical Characteristics of the selected Peri-urban Neighbourhoods

Environmental Attributes	Maje	Paulossa	Chassa	Gwazanu
Neighbourhood Layout	Unplanned residential landscape, presence of other complimentary land use like commercial area and industrial areas.	Unplanned residential area and presence of other complimentary land use.	Unplanned residential area and presence of other complimentary land use.	Unplanned residential area and presence of other complimentary land use.
Building Type	The buildings presence ranges from traditional houses to modern '. There are mixed use of buildings especially for the buildings along the major highways.	The buildings in this area are predominantly modern, and are mostly owners occupiers houses, with just few of them as tenement	The buildings in this area are predominantly traditional; it's mostly owners' occupiers' houses.	The buildings in this area are predominantly modern, and are mostly owners occupiers houses, with just few of them as tenement
Building Condition	The buildings in this area are of different categories, mostly, the houses are inadequate.	Buildings in this area are of different categories, reflecting the status of the residents of the area.	Buildings in this area are of different categories, reflecting the status of the residents of the area.	Buildings in this area are of different categories, reflecting the status of the residents of the area.
Condition of Access	Apart from the major access road, all other roads connecting houses were untarred and are in poor condition	The access roads are fair within the neighbourhood	The access roads are poor within the neighbourhood	The access roads are fair within the neighbourhood
Water Supply	Water supply to this neighbourhood is inadequate, as quite number of the population relies on water vendors and well	The neighbourhood was not connected to water mains.	The neighbourhood was not connected to water mains.	The neighbourhood was not connected to water mains.
Electricity Supply	Not regular	Not regular	Not regular	Not regular

RECOMMENDATIONS

In view of the patterns of development exhibited by the Neighbourhoods selected for this study Maje, Paulossa, Chassa and Gwazunnu) in Suleja Local Government area of Niger State, these Neighbourhoods were observed to exhibit a serious trend of clustered and continuous spread patterns. This pattern, however, is observed to have a serious negative impact on the sustainability of urban Agriculture in Suleja as these areas form the Peri-Urban Fringe of the city. There is, therefore, the need for a comprehensive Land use Planning and Development Control with a view to limiting the outward spread of the Neighbourhoods and Predisposing the Suleja and by extension Niger State to Food Insecurity and adverse effect of climate change.

The challenges of sprawl development in Suleja is exhibit three (3) dimensions that is; transport, economic and environmental dimension. There is therefore, the need for a comprehensive development plan which can be harnessed into the sustainable development agenda and the climate change framework in order to improve transport infrastructure, promote economic development through improved urban agriculture and proper land management and conservation to reduce the challenges of environmental degradation.

CONCLUSION

The suburbs of Suleja are increasingly spreading with the evidence of unplanned growing peri-urban neighbourhoods. The proximity of Suleja to the Federal Capital of Nigeria has attracted quite a number of people into the town, the low rental value and cheap land in the suburbs were few of the factors encouraging the movement of people into the suburbs. The patterns of development in the selected neighbourhoods have also established that the peri-urban of Suleja are intensely clustering and continuously spreading. The social, economic and physical factors, however, are responsible for the choice of neighbourhoods

ABSTRACT

This paper is a spin-off from the general concern expressed about gaps identified in the Nigerian urban environment. It is an expository research which, on the basis of secondary data, analyses slum development (upgrading) and urban renewal in developed and developing countries like Nigeria. This paper highlights the present state of the Nigerian urban environment and comes up with the following: overpopulation, over-stretching of infrastructure, corruption, gross inadequacy of housing, poverty, lack of political will around the issue, emergence of numerous slums and squatter settlements, insufficient legal and regulatory systems, based as major causes of increased pressure other urban environment. On the findings, the paper recommends measures to address the problems. The measures include improvement of urban cities, making legal and regulatory systems functional, Poverty reduction, and Government matching infrastructure with development, slum development, rural development etc. The paper concludes that without slum development and urban renewal in Nigeria, the country will continue to be behind global standards in environmental development.

Keywords: Development, Environment, Renewal, Slum, Urban

INTRODUCTION

Cities have become the front line for many of the world's most pressing challenges,from climate change, water scarcity and air quality, to economic disruption, public health and social instability. In the next 20(twenty) years, the world's urban population will increase more as majority of people will live in cities because we are in the midst of urban century.

Human wellbeing in cities relies on a complex Web of interconnected institutions, infrastructure and information. People are drawn to cities as centers of economic activity,opportunity and innovation. The scale of urban risk is increasing due to the number of people living in cities. While developed countries are busy trying to find out what's next in making their cities resilient, how to have healthy urban growth and how cities can be smart? The Nigerian urban environment is being subjected to crisis of unprecedented proportions.

The urban infrastructure in Nigeria is under great pressure from the teaming population migrating from the rural areas, including search of better means of livelihood. Hence the urban centers are experiencing growth that is not matched with development, resulting in emergence of numerous slums and squatter settlements and breakdown of infrastructural amenities due to over stretching. There is therefore gross inadequacy of housing and social services.

Slums are heavily populated urban settlement characterized by substandard housing and squalors. While slums differ in sizes and other characteristics from country to country, most lack reliable sanitation services, supply of clean water, reliable electricity, timely law enforcement and other basic services.

Background

Slums are home to the poorest of urban populations in Africa. The houses inhabited by slum dwellers are mostly decrepit, overcrowded, in neighborhoods that are prone to flooding &

Emma-Ochu, C. A. & Onwuka, E. (2016). Slum Development and Urban Renewal in Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1599-1607

beset with poor sanitation & shortage of portage water. (Bobadoye S. A. & Fakere A.A. (2013). Slum residences vary from shanty houses to built dwelling and because of poor design or poor construction have deteriorated into slums.

According to UN-HABITAT, around 33% of the urban population in developing world in 2012, or about 863million people lived in slums; with the highest population living in sub Saharan Africa (61.7%), South Asia (24.6%), South East Asia (31%), East Asia (28.3%), West Asia (24.6%), Oceania (24.1%), Latin America and Caribbean 23.5% and North Africa 13.3%.

Slums have posed a huge problem for developing because they are by definition areas in which the inhabitants lack fundamental resources and capabilities such as adequate sanitation, improved water supply, durable housing or adequate living space. Many governments have tried to find solutions to the problem, and one of the proposed solutions is slum upgrading. Slum upgrading is essentially a strategy in which the infrastructure of a slum is improved, such as giving adequate water supply and sewage to the community. Additionally, because of the tenuous legal status of slum inhabitants, often strategies include the legalization of the right to the land on which slums are built.

Slums such as Dharavi, in Mumbai, are the result of extensive urban growth. Slum upgrading goal is to transform these areas into decent housing areas

The concept of slum upgrading, a strategy for the improvement in a slum's infrastructure, is one that has evolved out of a period of unprecedented urban growth since the mid-20th century. In fact, nearly two thirds of the population growth that has occurred in that time period has been in urban areas. Not only have we seen the growth of urban populations a whole, but the world has also seen phenomenal growth with regards to individual cities, including megacities (cities in excess of 8 million inhabitants) and hypercities (in excess of 20 million inhabitants). The key factor in this has been that the cities that have grown most rapidly have been cities in the developing world. For example, the cities of Dhaka, Bangladesh, and Lagos, Nigeria, are forty times larger than they were in 1950. While much of this growth has come as a result of population explosion, mass migration from rural areas to the cities has accounted for a huge portion of this worldwide urbanization. The great increase in population has had tremendous implications in the urban ecology in the developing world. The major effect of this has been the rise of the slums.[Slum upgrading-Wikipedia, the free encyclopedia

Many countries have shifted policies towards slum upgrading policies (where the inhabitants are not inherently evicted from their dwellings) and away from what was once the policy and practice of governments – eviction and bulldozing. Some countries, such as China, still hold the policy of bulldozing squatter settlements (which form the basis of many slums), but other countries, such as Brazil, have shifted away from this strategy and worked on urban renewal projects via slum upgrading policies. Slum upgrading proved easier and cheaper and without the public relations nightmare that comes with pictures of housing developments getting bulldozed.

Yet until recently, most countries had very little in terms of formal policy measures to undertake slum upgrading, and so the problem of slums has generally gotten a lot worse over the years. The World Bank has undertaken many major slum upgrading projects since the 1980s, but fundamentally, it does not solve the problem of slums – it simply helps fix the problems with current slums. Worldwide, there are approximately one billion people living in slums. However, that number is expected to rise to two billion by the year 2030, and the policy of slum upgrading will not affect the mass migration of the rural poor to the cities..

According to the 2006/2007 UN-HABITAT State of the World's Cities Report, the countries of Egypt, South Africa, Mexico, Tunisia, and Thailand stand out in their efforts towards slum upgrading. Indeed, their slum growth rates had fallen markedly in the various countries (though the fact that the growth rate is still positive speaks to the fact that slums are not going away or even shrinking). The report went on to say that in order to stem (or at least slow) the growth of slums in the world's cities, countries are going to have to make some hard choices and make major financial commitments (with the help of the World Bank, a major player in the worldwide effort to promote slum upgrading) in order to accomplish the Millennium Development Goals towards lifting significant amounts of slum dwellers out of poverty.

Many slums lack basic local authority services such as provision of safe drinking water, sanitation, wastewater and solid waste management. Slum upgrading is used mainly for projects inspired by or engaged by the World Bank and similar agencies. It is considered by the proponents a necessary and important component of urban development in the developing countries. However, many people do not believe that slum upgrading is successful. They point to the difficulties in providing the necessary resources either in a way that is beneficial to the slum-dwellers or in a way that has long- term effectiveness.(Housing &Slum upgrading- UN-Habitat).According to Habitat for Humanity International some common barriers to slum upgrades are: Insufficient legal and regulatory systems, excessive land regulation, gender discrimination, corrupt inefficient, or inadequate land registration systems, disintegration of customary and traditional protections,Lack of political will around will around the issue.

In Nigeria, the inadequacy of affordable housing leaves the urban poor with a instinct to survive at all costs. The urban poor is compelled to provide some form of roof over his head. According to Uji, Z.A(2004), what he (the urban poor) does provide for himself may be well below what is generally regarded as acceptable by the so-called 'official standards' but it is probably as good as can be expected given the social and economic constraints under which he operates, the nature of the materials available and the type of technology utilized.

Purpose of Study

This research work is an attempt at critically highlighting the salient points in slum development and urban renewal in Nigeria.

Research Objectives

i. Identification of factors and causes of slum dwelling in Nigerian cities.
ii. Identification of issues and challenges in Nigerian urban cities.
iii. Appraisal of the state of the Nigerian urban environment.
iv. Identification of strategies to urban renewal.

Research Questions

i. What do you understand by slum and slum upgrading?
ii. Do you think that some factors are responsible for the degradation of the Nigerian urban environment?
iii. Do you agree that slum development (upgrading) and urban renewal will have a positive impact on the Nigerian urban environment?
iv. Do you agree that the Nigerian urban environmental growth is not matching infrastructural development?
v. Do you think that the following factors are challenges in urban development:
    a. Demographic factors
    b. Socio behavioral factors
    c. Economic Factors
    d. Environmental Factors

e. Financial Factors
f. Governance?

SLUM AND SLUM DEVELOPMENT

Slum is a dilapidated neighborhood where many people live in a state of poverty. The main objective of slum upgrading is to alleviate the poor living standards of slum dwellers. The concept of slum upgrading, a strategy for the improvement in a slum's infrastructure, is one that has evolved out of a period of unprecedented urban growth since the mid-20th century. In fact, nearly two thirds of the population growth that has occurred in that time period has been in urban areas. Not only have we seen the growth of urban populations a whole, but the world has also seen phenomenal growth with regards to individual cities, including megacities (cities in excess of 8 million inhabitants) and hypercities (in excess of 20 million inhabitants).

Urban Renewal

Urban renewal (also called urban regeneration in British English) is a function of urban planning. It has had a massive impact on the urban landscape of many cities and continues to do so in the present day. It has played an important role in cities worldwide such as London, USA, Melbourne, Victoria,Glasgow, Scotland etc.(Wikipedia, the free encyclopedia).

In the United Kingdom, it was a program of land redevelopment in areas of moderate to high density urban land use. Renewal has had both successes and failures. Urban renewal involves the relocation of businesses, the demolition of structures, the relocation of people, and the use of eminent domain(government purchase of property for public purpose) as a legal instrument to take private property for city-initiated development projects. This process is also carried out in rural areas, referred to as village renewal, though it may not be exactly the same in practice.

In some cases, renewal may result in urban sprawl and less congestion when areas of cities receive freeways and expressways. Urban renewal has been seen by proponents as an economic engine and a reform mechanism, and by critics as a mechanism for control. It may enhance existing communities, and in some cases result in the demolition of neighborhoods.

Many cities link the revitalization of the central business district and gentrification of residential neighborhoods to earlier urban renewal programs. Over time, urban renewal evolved into a policy based less on destruction and more on renovation and investment, and today is an integral part of many local governments, often combined with small and big businessincentives.

In USA(United States of America),large scale urban renewal projects in the US started in the interwar period. Prototype urban renewal projects include the design and construction of Central Park in New York and the 1909 Plan for Chicago by Daniel Burnham. Similarly, the efforts of Jacob Riis in advocating for the demolition of degraded areas of New York in the late 19th century was also formative. The redevelopment of large sections of New York City and New York State by Robert Moses between the 1930s and the 1970s was a notable and prominent example of urban redevelopment.

The Housing Act of 1949 kick-started the "urban renewal" program that would reshape American cities.

Urban Renewal, was a federal program started in 1949 with the goal of clearing large slum areas in and around the downtown areas of American towns and cities through the government’s coercive use of eminent domain and replacing the slums with new commercial development. The arbitrary premise behind Urban Renewal was that, if left alone, developers

in the free market would not rebuild or renovate slum properties, without the government helping them to do so by first condemning the properties. .

Additionally, urban renewal can have many positive effects. Replenished housing stock might be an improvement in quality; it may increase density and reduce sprawl; it might have economic benefits and improve the global economic competitiveness of a city's centre. It may, in some instances, improve cultural and social amenity, and it may also improve opportunities for safety and surveillance.

As many examples listed above show, urban renewal has been responsible for the rehabilitation of communities—as well as displacement. Replacement housing – particularly in the form of housing towers – might be difficult to police, leading to an increase in crime, and such structures might in themselves be dehumanising. Urban renewal is usually non-consultative. Urban renewal continues to evolve as successes and failures are examined and new models of development and redevelopment are tested and implemented.

An example of urban renewal gone wrong is in downtown Niagara Falls, New York. (Urban renewal-Wikipedia the free encyclopedia)

Urban renewal is controversial, although renewal projects did revitalize many cities; it was often at a high cost to existing communities. Examples like this abound in Nigeria, the case of the demolition of Maroko, a slum settlement on the outskirts of Lagos close to the highbrow Victoria Island neighborhood in 1990 and similar operations within the Federal Capital Territory of Abuja.

Strategies to Urban Renewal

Slum development or upgrading is essentially a strategy in which the infrastructure of a slum is improved, such as giving adequate water supply and sewage to the community. It can be extended to giving legal status to slum inhabitants, in the former of legalization of the right to the land on which slums are built.

Slum development or upgrading consists of physical, social, economic, organizational and environmental improvements to slums undertaken cooperatively and locally among citizens, community groups, businesses and local authorities.

Issues and Challenges in urban development

Sticky N. & Koch L. (2015), posits that there are issues and challenges in urban development which are summarized thus:

i. Demographic factors: Increasing demand for urban housing & infrastructure services due to more urban citizens in the future.
ii. Socio behavioral factors: Increase of social differentiation & increase of heterogeneous communities in urban areas: education,consumption & culture.
iii. Economic factors: Domestic macroeconomic growth needed to provide the basis of urban development.
iv. Environmental factors: Growing demand for infrastructure puts pressure on natural resources.
v. Financial factors: Current level of FDI & IDA & government financing are not meeting the demands for upgrading.
vi. Governance: Centralized & strict top- down approach to urban governance.

The State of the Nigerian Urban Environment

The Nigerian urban environment used to be attractive and descent with well planned clean streets, maintained landscape and buildings. Additionally, infrastructure like water, electricity, good drainage systems and proper refuse disposal amongst others were available and attracted people from the rural areas to the urban cities. Emma-Ochu, C.A.(2007).

The present Nigerian urban environment can be described as over populated, dirty,disorderly,in descent and unplanned amongst others. The amenities like clean water, clean streets,good roads,maintained landscape and buildings, proper refuse disposal mechanism which used to attract people from the rural areas to the urban cities are no longer there, but people still troop to the urban areas due to hardship and poverty level and where they cannot afford public or private residency, they settle for slums and squatter residence to survive.

So many factors have led to the present state of Nigerian urban cities and they are:

Overpopulation, Over stretching of Infrastructure, Corruption, Gross inadequacy of housing, Poverty, Lack of Political will around the issue, Emergence of numerous slums and squatter settlements, Insufficient legal and regulatory systems amongst others.

As earlier mentioned, developed countries are busy trying to find out what's next in making their cities resilient, how to have healthy urban growth and how cities can be smart? The Nigerian urban environment is being subjected to crisis of unprecedented proportions. This situation of inadequate environment leads to crowding and diseases, effect of climate change, increase in crime rate, amongst other bad effects.

An environment is capable of influencing growth, development, existence: mentally, physically and spiritually. To achieve these and more in our Nigerian urban environment, several strategies have to be adopted. Establishing a good degree of urban improvement through:

Redevelopment of Urban cities, Improving Urban landscape, Managing urban development problems. Supporting public participation in urban environmental improvement programs, Slum development, Giving attention to city appearances, Promoting planting of urban trees, Strict adherence to planning methods,building patterns and regulations etc.

Factors Resulting in the Formation of Slums in Nigeria

According to Bobadoye S.A. & Fakere A.A.(2013), the following factors in the formation of slums in Nigeria:

i. Scarcity of lands service and security of tenure
ii. Poverty and illiteracy
iii. Neglect to building and environment
iv. Use of substandard building materials
v. Poor maintenance culture
vi. Congestion
vii. Poor enforcement of sanitation etc.

METHODOLOGY

Data for the study was collected with the aid of a structured questionnaire which were administered to the various professionals in high institutions in Imo State, Nigeria; these were selected based on their knowledge and involvement with the topic in question. The questionnaire were administered to 50 randomly selected professionals but 30 were retrieved. The professionals includes Architects, urban planners, builders, estate surveyors and civil engineers. The data retrieved was analyzed using the relative Importance index and simple percentage respectively. This index was computed by the following equation [Lim et all 1995].

$$Importance\ Index\ = \frac{5n^5 + 4n^4 + 3n^3 + 2n^2 + n^1}{5[\mathrm{n1} + \mathrm{n2} + \mathrm{n3} + \mathrm{n4} + \mathrm{n5}]}\ x\ 100$$

Where
n1=No of respondents who answered a little degree
n2=No of respondents who answered some degree
n3=No of respondents who answered average degree
n4=No of respondents who answered large degree
n5=No of respondents who answered very large degree
The importance index was calculated. An ordinal measurement scale, which is ranking or rating data that normally use integers in ascending order was also used in this study. The respondents were asked to rank the factors that are responsible for increase pressure in the urban environment,Factors responsible for the degradation of the urban environment and factors that contribute to formation of slums in Nigeria according to degree of importance i.e.

i. 1-Affects with little degree
ii. 2-Affects with some degree
iii. 3-Affects with average degree
iv. 4-Affects with large degree
v. 5-Affects with very large degree

FINDINGS AND DISCUSSION

Table 1: Designation of Respondents

Respondents	Frequency	Percentage
1. Architects	**6**	**20**
2. Urban Planners	**7**	**23**
3. Builders	**7**	**23**
4. Estate Surveyors	**4**	**14**
5. Civil Engineers	**6**	**20**
Total	**30**	**100**

Table 1: Shows the percentage representation of the respondents, 20% for Architects, 22% for urban planners & builders, 14% for Estate surveyors and finally another 20% for civil engineers. This result expresses the opinion of the professionals in the study area.

Table 2: Years in practice

RESPONDENT	FREQUENCY	VALID PERCENTAGE
Above 5years	6	20.0
Above 10 years	8	26.7
Above 15 years	10	33.3
Above 20 years	6	20.0
Total	30	100

Table 2: Shows the respondents years of experience as professionals. With average working experience of 10 years, respondents are deemed experienced enough to supply reliable data for this research.

Table 3: Respondents opinion to this state of Nigerian urban infrastructure

Is the Nigerian Urban Infrastructure under pressure which invariably leads to the development of slums	Frequency	Percentage
	30	**100**

From Table 3: 100 percent of the respondents were of the view that Nigerian Urban Environment is under pressure which invariably leads to development of slums in the urban centers.
Factors responsible for increase pressure on the urban environment.

Table 4: Factors responsible for increase pressure in the urban environment

S/No	Factors responsible for increase pressure on environment	Importance index	Rank
1	Gross inadequacy of housing	64.8	1
2	Overpopulation	63.7	2
3	Lack of Political will around the issue	57.7	3
4	Inadequate Infrastructure maintenance	56.7	4
5	Poverty	52.6	5
6	Corruption	51.7	6

Table 4: Shows the factors and their relative important index with corresponding ranking. It can be observed that the most important factor is inadequacy of housing which has an important index of 64.8 and is ranked No 5, followed by Overpopulation, lack of political will around the issue, inadequate infrastructure maintenance, Poverty and finally corruption. This is justified by Bobadoye et.al (2013), stating that the inadequacy of the quality of most urban housing starts mainly from the poor physical state of the building.

Table 5: Factors responsible for the degradation of the urban environment

S/N	FACTORS RESPONSIBLE FOR THE DEGRADATION OF THE URBAN ENVIRONMENT	Importance Index	Rank
1	Insufficient legal and regulatory systems	58.7	1
2	Emergence of numerous slums and squatters	57.8	2
3	Poverty	48.8	3

Table 5: Shows the factors responsible for the degradation of the Nigerian Urban Environment. The number one factor responsible for degrading the urban environment is the insufficient legal and regulatory frame work. This is followed by Poverty and emergency of slum and squatter settlements. This is justified by Sticzay et.al (2015).

Table 6: Positive impact of slum development and urban renewal in Nigerian environment

Positive impact of slum development	Frequency	Percentage
1. Decent housing	**30**	**100**
2. Increased productivity (Poverty reduction)		
3. Low risk to health hazard		
4. Improvement in Urban physical and socioeconomic landscape are		

Table 6: Shows that 100% of the respondents were of the opinion that the factors in table 6 above are all positive impact of slum development (upgrading)

Table 7: Challenges to urban development

Factors	Frequency	Percentage
1. Demographic factors	30	100
2. Socio behavioral factors		
3. Economic factors		
4. Environmental factors		
5. Financial factors		
6. Governance factors		

Table 7: Shows that all the respondents were of the opinion that the following poses great challenges to Urban Development in Nigeria

Table 8: Factors that contribute to formation of slums in Nigeria

	Importance Index	Rank
Poor enforcement of sanitary laws.	65.0	1
Poverty and illiteracy	63.5	2
Neglect to building and environment	60.0	3
Poor maintenance culture	57.5	4
Congestion	50.5	5
Use of substandard building materials	50.5	5

Table 8: The number one factor that contributes to formation of slums in Nigeria is poor enforcement of sanitary laws and the others follow in order of ranking.

CONCLUSION

Slums are a clear manifestation of a poorly planned and managed urban sector and, in particular, a malfunctioning housing sector. Urban renewal (also called urban regeneration) is a function of urban planning. It has had a massive impact on the urban landscape of many cities and continues to do so in the present day. It has played an important role in cities worldwide.

We live in times of great and accelerating change: in human capability, population growth and societal upheaval. In response we can choose to use the following measures to address the problems of slum development in Nigeria.

i. Improvement of urban cities through private public partnership
ii. Enforcement of town planning laws and regulations by the appropriate authorities
iii. Alleviating Poverty through employment opportunities in environmental related areas like waste management, waste recycling, waste disposal etc.
iv. Education and enlightenment of the populace on maintenance culture with the aid of Building surveyors employed in those areas.
v. The total demolition of slum areas should be stopped by government since it does not solve the problem of urban development, rather there should be slum upgrading in areas that have not been planned by the government.
vi. When all these happens, the result will be positive impact like ensuring healthy lives and promoting wellbeing for all at all ages, ensuring availability and sustainability management of water and sanitation for all, making cities and human settlements inclusive, safe, resilient and sustainable as well as strengthening the means of implementation and revitalize the global partnership for sustainable development.

Gender Involvement in Sustainable Water Project Management in Ibadan, Nigeria: A Physical Planning Perspective

Olusa, A.[1*]; Olujimi, J.[2] & Okoko E.[3]

[1, 2&3] Department of Urban and Regional Planning, Federal University of Technology, Akure, Nigeria

ABSTRACT

Water is an environmental resource and it is essential to sustain life. Both male and female have different roles to play in the sustainable management of water as a resource hence this study aims at assessing the level of involvement of each gender at the management stage of Sustainable Ibadan Project (SIP) water projects. The nine identified water projects were studied and 729 respondents were selected within 500 - meter radius of the project site as recommended by the United Nations for the 9 project sites. It was revealed that projects that involved more women are better managed and involvement of more women in subsequent water projects is recommended. The study concluded that women are more interested in sustainability of community water projects because they are more hit by its scarcity.

Keywords: Gender, involvement, sustainable management, water and water projects

INTRODUCTION

Gender reflects a set of behavioural norms ascribed to men and women in a given social group or system. Gender thus reflects attitudes and beliefs that a particular cultural group considers appropriate for male or females on the basis of their biological sex. Allocation, distribution, utilization and control of resources reflect gender relations embedded in both ideology and practice (Peter, 2006). He stated further that in most parts of the world, there exist gender biases, which disadvantage women. This is in line with the submission of Metha and Srinivasan (2001) that gender is not a static condition; it differs across cultural, geographical and temporal context. It is contingent on factors such as age, class and tribe. Therefore, it is wrong to assume homogeneity amongst women.

Gender is also a term used to convey the process of social construction that mediates the relations between women and men. They are social as well as ideological and cultural relations suffused with power differentials that map the range of processes, behaviour, activities, forms of organization considered appropriate for women and for men given collectively over a period of time (Olurin, 2003). It was further stated that gender is a key concept in understanding the social differentiation of women and men. The activities involved cover not only interactions between individual women and men in the sphere of personal relationships but include all aspects of social activity, particularly the exercise of authority and power, divisions of labour, access to and control of resources of production, control of proceeds, remuneration of rewards for work, distribution of income, goods, consumption, participation in the political, cultural and religious activities.

Water is one of the most important natural resources and its effective management is essential, given its scarcity (Aladuwaka & Momsen, 2010). Issue of management of resources is the genesis of environmental conservation which makes it an essential ingredient for sustainable development by meeting the present needs without jeopardizing future requirements.

Due to different tasks involved in water supply (such as transportation and storage of water for cooking, cleaning and washing dishes and clothes, bathing children, household hygiene among others), women have different priorities, demands and knowledge on water management than men. However, women are not as widely consulted on issues relating to water supply and women's priorities and requirements are not given as much attention due to

Olusa, A.; Olujimi, J. & Okoko E. (2016). Gender Involvement in Sustainable Water Project Management in Ibadan, Nigeria: A Physical Planning Perspective. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1608-1613

different power relations between women and men (Intallance & Porter, 2010). This operates in most cities both in and outside Nigeria including Ibadan, our case study.

Ibadan was specifically selected for this study because the city exhibits both urban and rural settings and is well endowed with water resource in terms of existence of numerous natural springs that could be developed to provide potable water and even construction of deep well and borehole for the community use. Besides these features, residents of Ibadan have long records of insufficient supply of potable water that calls for deserved attention (Agboola, 1996).

Aim and Objectives

The aim of this study is to assess the implications of gender involvement in the management of water projects in Ibadan with a view to ensuring sustainability of the projects.
The specific objectives are to;

i. identify the water projects in Ibadan
ii. highlight the involvement of each gender at the initiation stage of the projects
iii. investigate the main contributions of the community to the water projects
iv. assess way(s) the projects are being managed
v. highlight the implication of gender in the management and sustainability of the water projects.

METHODOLOGY

Information were sourced from both primary and secondary sources. Secondary sources are books, journals and internet while primary data were sourced from questionnaire administration and focus group discussion. The sample population for the study were buildings that are within 500-meter radius from the project location. The project location was gotten by getting the coordinates of the location of the project site with the use of Global Positioning System (GPS) and the proximity analysis tool in the Geographic Information System (GIS) was used to identify the buildings that are within 500-meter radius. This gave a total of 14,412 residential buildings out of which 5% were randomly selected and this constituted 729 residential buildings on which the questionnaire was administered on a selected adult (that is, respondent) per building. The distribution of the 729 samples in each of the nine communities is as shown in Table 1.

The questionnaires were administered on adults of not less than 35 years of age who were believed to have good knowledge of the projects from inception as they were at least 18 years old (age of adulthood in Nigeria) at the inception of the project in 1996. Four research assistants were engaged in the administration of the questionnaires. The survey was conducted both on week-days and weekends to give opportunity to those that were not usually at home on week-days to participate.

Table 1: Sample Size for the Residents of Host Communities

S/No	Target (Community/Agency)	Number of Residential Buildings	Sample Size (5%)

	Total	**14,412**	**729**

FINDINGS

Main Contribution of the Communities to the SIP water projects

The communities made contributions to the development of the SIP water projects in their communities though at varying level. The findings during the FGD held in the communities revealed that all the communities donated the land used for the project free of charge and labours were also members of the host communities engaged at no charges, these are referred to as contribution in kind. Though some of the respondents (7.4%) do not appreciate this contribution which made them believed that their communities did not make any contribution towards the project. Some communities contributed to the project in cash (1.6%), some in both cash and kind (74.5%) and some in kind only (16.5 %). The cash contributions made by the communities were derived from levy. For instance, in communities like Bodija Market area, Agbadagbudu, Onipasan, Akeu and Odo-Ona/Gada, each building was levied one hundred naira (₦100) which was put together as the cash contribution by the communities towards the projects.

Table 2: Contribution of the Communities to the SIP water projects

S/No	Contribution of Communities To Projects	Frequency	Percent
1	No way	54	7.4
2	Cash	12	1.6
3	Kind	120	16.5
4	Cash and Kind	543	74.5
Total		**729**	**100.0**

Ways SIP Water Projects are Being Managed

There are statutory ways by which management of water projects should be done. As recommended by the Department of Health and Human Services of Centre for Disease Control and Prevention, USA (2012), proper management of water are measured through the following means;

i. Cost recovery strategy
ii. Replicating the project
iii. Upscaling / Expansion of the project.

The Federal Republic of Nigeria (2000), as highlighted in the water supply and sanitation interim strategy note stated the following as ways of measuring proper management of water projects. These are;

i. Fixture and replacement of faulty parts
ii. Monitoring on regular basis
iii. Determination and payments of water tariffs and rates.

From these two documentations, payment is common to them, that is, cost recovery strategy through the determination and payments of water tariffs and rates. Four of these SIP water projects - Agbadagbudu, Onipasan, Bodija Market area and Akeu complied with this as user-charge of ₦20 for any container of maximum of 25 liters is determined and paid.

The cleaning of the project site is done by the women through the wash of the site on regular basis. This is done with the assistance of the children. This fee is used to meet other management strategies like purchase of upscaling items among others. For example, Bodija market area community purchased power generating set; Onipasan community purchased two storex water tanks of 2,000 gallon capacity to complement the underground water tank. Also, attendants were employed in some of the project sites like the Bodija market area community

and Onipasan. These attendants are the ones that open the project site at 7.00 am and close it at 7.00 pm. They collect the user fee and oversee the orderliness at the project site.

Plates 1: The Upscaling Items at the Bodija Market Area Community Borehole Project Site

Plates 2: Upscaling Items at Onipasan Natural Spring Project at Onipasan Community

The project inspection being done by the Local Government Community Development Inspection Officers is a way of managing the project properly. The Community Development Inspection Officers usually visit the sites to inspect and SIP officials equally do monitor the projects. It can be inferred from these submissions that the SIP water projects are being properly managed but it is worthy of note that only the projects that charge user fee are buoyant to manage the projects well which include; Agbadagbudu, Onipasan, Bodija Market area and Akeu while the Moga natural spring project and Seeni borehole projects are no longer functional due to poor management.

The study probed into the area of involvement of women in environmental management. As revealed in Table 3, 57.1% of the respondents opined that women should be involved while 42.9% did not want women to be involved. The closeness in the percentage of those with the two opinions may not be unconnected with the fact that women are believed not to have good knowledge about such projects in the past but the current trend on the campaign against women maginalisation may be responsible for change in opinion of some of the residents.

Table 3: Involvement of Women in Environmental Projects

S/No	Women to be Involved in Environmental Projects	Frequency	Percent
1	Yes	416	57.1
2	No	313	42.9
Total		**729**	**100.0**

Test of Level of Involvement of Men and Women at the Initiation Stage of Development of SIP Water Projects

The level of involvement of both male and female at the initiation stage of the SIP water projects was tested in order to accept or reject the hypothesis that was postulated. The findings revealed that there was a significant difference between the level of involvement of male and female at the initiation stage. (Tables 4 and 5). This test corroborated responses of

the members of the FGD that the initiation stage is believed to be technical and it required a lot of negotiations hence, men were more involved than women.

As shown in Table 4, the Chi-Square value of level of involvement of men at the initiation stage is 14.250 with P-value of 0.000 and degree of freedom of 1.

Table 4: Percentage of Men Involved at the Initiation Stage of SIP Water Project as rated by each Sex

Sex	**Percentage of Men Involved at Initiation Stage (%)**									
	0 – 25		**26 – 50**		**51 – 75**		**76 – 100**		**Total**	
	F	**%**	**F**	**%**	**F**	**%**	**F**	**%**	**F**	**%**
Male	0	.0	0	.0	138	18.9	355	48.7	493	67.6
Female	0	.0	0	.0	36	4.9	200	27.4	236	32.4
Total	**0**	**.0**	**0**	**.0**	**174**	**23.9**	**555**	**76.1**	**729**	**100**
Chi-Square = 14.250				**P-Value = 0.000**				**Df = 1**		

Table 5 revealed that the Chi-Square value of level of involvement of women at the initiation stage is 44.640 with P-value of 0.000 and degree of freedom of 2.

Table 5: Percentage of Women Involved at the Initiation Stage of SIP Water Project as rated by each Sex

Sex	**Percentage of Women Involved at Initiation Stage (%)**									
	0 – 25		**26 – 50**		**51 – 75**		**76 – 100**		**Total**	
	F	**%**	**F**	**%**	**F**	**%**	**F**	**%**	**F**	**%**
Male	340	46.6	151	20.7	2	0.3	0	.0	493	67.6
Female	183	25.1	36	4.9	17	2.3	0	.0	236	32.4
Total	**523**	**71.7**	**187**	**25.7**	**19**	**2.6**	**0**	**.0**	**729**	**100**
Chi-Square = 44.640				**P-Value = 0.000**				**Df = 2**		

The P-value for both men and women is less than 0.05 which indicates that the values are significant hence, the null hypothesis (Ho) was rejected and the alternative hypothesis (H_1) was accepted. By accepting the alternative hypothesis, it means that there is significant difference in the level of involvement of male and female at the initiation stage of the SIP water projects

Test of Level of Involvement of Men and Women at the Management/Maintenance Stage of Development of SIP Water Projects

This study investigated the level of involvement of male and female at the management stage of the SIP water projects. As revealed in Tables 6 and 7, there is significant difference. At this stage, the activities involved are majorly cleaning of the project site and replacement of faulty parts.

The cleaning of the project sites are done more often while replacement of faulty parts is done as occasion demands. The cleaning is done by women and children while the replacement is usually handled by the PMC or CBA which have more male members than women. All these points are pointers to the significant difference between involvement of male and female despite that they are both involved.

The Chi-Square value of level of involvement of men at the management/maintenance stage is 91.900 with P-value of 0.000 and degree of freedom of 3.

Table 6: Percentage of Men Involved at the Management Stage of SIP Water Project as rated by each Sex

Sex	**Percentage of Men Involved at Management Stage (%)**									
	0 – 25		**26 – 50**		**51 – 75**		**76 – 100**		**Total**	
	F	**%**	**F**	**%**	**F**	**%**	**F**	**%**	**F**	**%**
Male	349	47.9	29	4.0	34	4.7	81	11.1	493	67.6
Female	103	14.1	43	5.9	0	.0	90	12.3	236	32.4
Total	**452**	**62.0**	**72**	**9.9**	**34**	**4.7**	**171**	**23.5**	**729**	**100**
Chi-Square = 91.900				**P-Value = 0.000**				**Df = 3**		

The Chi-Square value of level of involvement of women at the management/maintenance stage is 97.929 with P-value of 0.000 and degree of freedom of 3.

Table 7: Percentage of Women Involved at the Management Stage of SIP Water Project as rated by each Sex

Sex	Percentage of Women Involved at Management Stage (%)									
	0 – 25		26 – 50		51 – 75		76 – 100		Total	
	F	%	F	%	F	%	F	%	F	%
Male	98	13.4	34	4.7	12	1.6	349	47.9	493	67.6
Female	102	14.0	0	.0	31	4.3	103	14.1	236	32.4
Total	**200**	**27.4**	**34**	**4.7**	**43**	**5.9**	**452**	**62.0**	**729**	**100**
Chi-Square = 97.929				**P-Value = 0.000**				**Df = 3**		

The P-value for both men and women is less than 0.05 which indicate that the values are significant hence, the null hypothesis (Ho) was rejected and the alternative hypothesis (H_1) was accepted. By accepting the alternative hypothesis, it means that there is difference in the level of involvement of male and female at the management/maintenance stage of the SIP water projects.

It is worthy of note that the results of tests of level of involvement of men and women at the various stages of the development of the SIP water project shows that there are differences in the level of involvement of men and women at the various stages of the project development.

RECOMMENDATION AND CONCLUSION

The study revealed that the projects which involved more women are better managed than the ones with less number of women. The proper management of such project will definitely enhance sustainability and longevity of the projects. It was also observed that projects in which communities made financial contributions to will last longer as the community members regarded such projects as theirs. This will ensure continuous availability of good source of water for the use in the communities.

The study therefore recommends that in replicating the water projects in other communities, more women should be involved from the stage of project initiation through to the management/maintenance stage. Also, members of the host community should be made to contribute financially to the project in their communities as this will make them more committed to the project and take it as their project and ensure their sustainability.

ABSTRACT

The development and management of cities from antiquity to the 21st century have been central to urban discourses in all fields of environmental studies. This is with focus on the specifics of pressures on land, shelter facilities and other sectors to accommodate the geometrically growing urban population. Consequent upon resultant environmental challenges in cities and dwindling resources, these have been hinged on the sustainability debates. This paper examines the factors responsible for the formation, development and management crises of components of cities in developing nations with emphasis on Nigeria towards identifying sustainable practices and principles. It highlights the key urban environmental sectors and their principal stakeholders, discusses their roles and appraises their challenges, including their management strategies in some selected Nigerian cities. While the paper notes the existence of urban management initiatives and policies, it equally notes the challenges still confronting urban environmental governance. It concludes by asserting the need for all the three levels of government in Nigeria through its relevant agencies to mount a seamless enforcement operational system towards enhancing livable and sustainable Nigerian cities.

Keywords: cities, management, policies, professionals, resources, sectors, sustainability

INTRODUCTION

> *Befitting the nature of the urban, the complex multi-faceted make-up of the city, how cities have been studied is itself an entangled story. By their nature, the understanding of cities – how they grow and decline, are structured and function, give meaning to social life – intersects with each of the principal social science disciplines, sociology, economics, geography and political science in particular, as well as urban planning. To varying degrees, each social science discipline has developed distinctive epistemologies by which to understand the city, and the key issues of structure, process and change.* (Paddison, 2001:1)

The significance of understanding the complex urban phenomenon called city before examining its development and management strategies cannot be overemphasized and demands recalling its rigorous seminal definition in classical discourse as follow:

> *The city is not, however, merely a geographical and ecological unit; it is at the same time an economic unit. The economic organization of the city is based on the division of labour. The multiplication of occupations and professions within the limits of the urban population is one of the most striking and least understood aspects of modern city life..... The city is something more than a congeries of individual men and of social conveniences - streets, buildings, electric lights, tramways, and telephones, etc.; something more, also, than a mere constellation of institutions and administrative devices -courts, hospitals, schools, police, and civil functionaries of various sorts. The city is, rather, a state of mind, a body of customs and traditions, and of the organized attitudes and sentiments that inhere in these customs and are transmitted with this tradition. The city is not, in other words, merely a physical mechanism and an artificial*

Fadamiro, J. A. & Adedeji, J. A. (2016). Sustainable Urban Development and Management Strategies in Nigeria Perspective. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1614-1628

> *construction. It is involved in the vital processes of the people who compose it; it is a product of nature, and particularly of human nature.* (Park, 1925: 1-46).

This definition of the urban place encapsulates the natural, cultural, human, biological, religious, political, physical, social, economic and infrastructural components of city as a complex and organic environmental entity. According to Lawanson (2005) and Jiboye (2009), good mixes of these are necessary to securing functional and liveable city that will be sustainable. Jiboye and Omoniyi (2010) opined that a socially, economically or an environmentally sustainable system should achieve distributional equity; provide adequate social services including health, education, housing as well as functional and liveable environment among many others. UN-habitat (2012) equally highlighted four dimensions of equality in facilitating the development of a liveable and inclusive city as:

> *Social, providing all residents – regardless of race, ethnicity, gender or socio- economic status – with adequate housing and decent basic services, and facilitates equal access to social amenities, opportunities and other public goods that are essential to the general and environmental well-being of everyone; Political, upholding citizens' rights and liberties, and promotes social and political participation for the sake of better-informed and more democratic decision- making; Economical, fostering economic development by way of equal opportunities for business and access to employment, and promotes pro-poor economic policies;*
> *Cultural, promoting social integration and celebrating diversity.*

The development of urban enclaves in the developing world has been the subject of numerous authors at various spatial scales and dealing with different issues and challenges. These include shelter, infrastructure, real estate, environment and urban governance, sustainability, open spaces, environmental quality, among many others (Fadamiro and Adedeji, 2014; Cheru, 2002; Fadamiro and Atolagbe, 2005; Fadamiro and Odeyale, 2007; Igbuzor, 2009; Fadamiro and Adedeji, 2009; Fadamiro, 2010; Ogun, 2010; Yunusa, 2011). Considering the current and emerging environmental challenges in these contexts, the following questions are germane to guiding the discourse on the urban phenomenon globally and in Nigeria: What are the developmental forces on the urban enclaves? How have these forces been implicated on the quality of the cities? What are the policy frameworks towards achieving sustainable management of urban places and their success rates? This paper sets to attempt these questions focusing on the specifics of pressures on land, shelter facilities and other sectors in the urban discourse. It examines the factors responsible for the formation, development and management of the components of cities in developing nations with emphasis on Nigeria towards identifying sustainable practices and principles. It further discusses the concepts of urbanisation and its factors, the pace of urban developments in developing world and Nigeria in particular. It enumerates the urban development strategies, principal stakeholders and policy initiatives at international, continental and national levels.

Urbanization and City Development

Redmond (2007) opined that urbanization is essentially a shift of population from rural areas to cities, and the resulting growth of urban areas. Unfortunately, developing nations are grabbling with the outcomes of unplanned urbanization and the resulting cities are plagued with development of urban sprawls, slums, and squatter settlements. Urbanization also breeds inequality, social stratification and many other negative social outcomes. Indeed, "a growing extent of social disorganization and crime is a function of substantial inequalities in access to

land, housing and other services in the cities" (Connell & Lea, 1996:177). Specifically, UN-Habitat (2012) estimated that around 62% of African cities are composed of slums, much of them on informal land arrangements.

As a phenomenon, urbanisation may not be a problem. It only describes the process of change in the growth of population due to changing conditions in the society. It is equally a process of demographic, social, economic and physical change, which requires complex governmental action (Green 2011). As a social process, it hinges more on changes or alterations in the mode of interaction and behavioural patterns than on the availability of infrastructural facilities (Strein et al 2011). According to Anderson (2011) urbanisation is made possible mainly by mass communication, transportation and it implies spread of urban influences to other neighbouring areas as economic process. As an ecological process of aggregating for a variety of reasons, it involves social transformation along with shifts in the pattern of population, morphological pattern of settlement, and the locus of power and influence from the rural to the urban area (Anderson, 2011).

Fadamiro and Adedeji (2009) argue that statistical factor in term of population growth is a precursor to urbanization processes. According to Oluwasola (2007), the restriction of the definition of urbanization to terms of population concentration looks at first limited but it move us away from ambiguity and other forms of intellectual distress and helps us to eliminated other processes that may have opposing effects on urbanisation. In the same veins World Bank (2000) and United Nations (2000) largely perceives urbanization in purely demographic terms.

According to estimate by the United Nations, the world population has been put at 6.572 billion people, of which 3 billion (about 50%) now live within the urban areas, and by 2030, about 61 percent of the world population is projected to live in the cities; and this growth is expected to occur mainly in developing countries (UNFPA, 2007; Daramola & Ibem, 2011; United Nations, 2013). According to Population Reference Bureau (2008:5),

> *The world population has risen from 2.5 billion in 1950 to 6.7 billion in 2008. The proportion living in the developing countries of Africa, Asia and Latin America and the Caribbean has expanded from 68 percent to more than 80 percent. African's population, currently growing faster than any other major region, is projected to account for 21 percent of world population by 2050, up from just a percent in 1900. In 1950 less than 30 percent of the world population lived in urban areas, while a mile stone has been passed in 2008 with 50 percent of the world's 6.7 billion population living in urban areas. Despite this scale of urbanisation the vast majority of these urbanites reside in small towns and villages, not large modern cities. Just 37 percent of urban dwellers live in cities with 1 million residents, and just 8 percent are in mega cities of 10 million or more.*

Currently, this world population has been surpassed to well over 7 billion. The 2014 revision of the *World Urbanization Prospects* by UN DESA's Population Division notes that (United Nations, 2013):

> *the largest urban growth will take place in India, China and Nigeria. These three countries will account for 37 per cent of the projected growth of the world's urban population between 2014 and 2050. By 2050, India is projected to add 404 million urban dwellers, China 292 million and Nigeria 212 million.*

This is an improvement over the 2005 world population status. In 2005, out of the world population, 8 percent live in cities of 10million or more population, 7 percent in cities of 5 million to 9.9 million, 22 percent in cities of 1 million to 4.9 million 10% in cities of 500,000 to 0.9milion and 52 percent in cities of fewer than 500,000. Dawes (2004:2) speculated that the population of developing countries will double to nearly 4 billion over the next generation. He opined further that there will be the "burgeoning of new mega cities with populations in excess of 8 million, and even more spectacularly, hyper cities with more than 20 million in habitants" while the former aspect of this speculation is closely fulfilled (3.3billion against 4 billion speculated), the latter aspect with respect to hyper cites is yet to come. According to the United Nations (2006) by 2030, nearly two-thirds of the world's population will live in urban areas.

The possibilities in the developing countries are there as well. UNFPA (2007) estimated that by 2030, the 3.3 billion people currently living in urban areas will swell to almost 5 billion and "while the world's urban population grew very rapidly (from 220 million to 2.8 billion) over the 20th century, the next few decades will see on unprecedented scale of urban growth in developing world. This will be particularly notable in Africa and Asia where the urban population will double between 2000 and 2030: that is, the accumulated urban growth of these two regions during the whole span of history will be duplicated in a single generation! By 2030, the towns and cities of the developing world will make up 81 percent of urban humanity (UNFPA, 2007).

As the scale and pace of urbanization in Africa (Fadamiro and Adedeji, 2009) becomes more dramatic, Cairo and Lagos has emerged as the first African megacities. According to the UN-Habitat (2008) projections,

> *Before 2015, Kinshasa will be the third and is projected to surpass Lagos in size by 2025 when Kinshasa, Lagos and Cairo will have 16.7, 15.7 and 15.5 million inhabitants respectively. But this is not the full picture. Progressing urbanization introduces shifts in cities' spatial patterns and configurations. Traditional city based urbanization is moving towards regional urbanization patterns, including the emergence of city regions and their associated urban corridors, creating what is known as mega urban regions. Such regional urban systems comprise several multi-million urban cores. The regional urban systems of Suez-Cairo-Alexandria, Kenitra-Casablanca, Gauteng, and Ibadan-Lagos-Accra are key examples.*

In this emergence of urban corridors, centrifugal urbanization forces have replaced the earlier centripetal ones. Because of pressures on land use, highly escalating cost of real estates, urban poverty and a new dawn of urban renewal efforts consequent upon changing political landscapes and emerging landscapes of politics, the urban dwellers are forced to move to the peri-urban fringes where the pressures are perceived to be less. In the recent past, this pattern of urban development used to generate satellite towns like Egbeda in Ibadan, Nyanyan in Abuja and numerous peri-urban settlements along the boundaries of Lagos and Ogun States. These include Mowe and Shagamu. In the present pattern of urban development, these points of increasing population concentration are vastly having their boundaries disintegrating leading to the present urban corridors. If the current rate and pace of this pattern of urban development is sustained, the emergence of megalopolis is imminent in the near future.

Also in 2007, the 380 developed region cities in the top 600 cities by GDP accounted for 50 % of global GDP, with more than 20 % coming from 190 North American cities alone. The 220 largest cities in developing regions contributed another 10%. By 2025, 136 new cities from the developing world are expected to enter the top 600; 100 of them from China and 13 from India (Richard et al. 2011). According to UN-Habitat (2008),

> *Africa's three giant urban agglomerations, Cairo, Kinshasa and Lagos, continue to rise rapidly in their ranking among the world's largest metropolitan regions. In 2007, the urban agglomeration of Cairo had 11.9 million inhabitants; Lagos had 9.6 million and Kinshasa 7.8 million. In 2015, Cairo will have 13.4 million; Lagos 12.4 million; and Kinshasa 11.3 million inhabitants - 11th, 17th and 19th respectively among the world's largest metropolitan regions. Projections show that Kinshasa, with 16.7 million inhabitants, will be Africa's largest urban agglomeration in 2025, Lagos 15.8 million and Cairo 15.5 million, ranking 11th, 12th and 13th among the world's largest megacities.*

As far as Nigeria is concerned, 4.8% was urbanized in 1921. It was moved to 10.2% between 1952 and 1954. It further increased to 19.2% in 1963 and jumped to 42% in 2002. Estimation however suggests further increase to about 68% by 2020 (Ademiluyi and Solanke, 2008). In 2008, Nigeria was the seventh most populous country of the world out of the ten with population of 148.1 millions. The list has china as the highest of 1,324.7 million and Japan as the lowest (127.7 million). 2050 population estimate for Nigeria is 282.2 million moving to the sixth position out of the ten most populous countries with India in the first position (1,755.2 million) and Philippines (150.1 million) coming last (Population Reference Bureau, 2008). In 2014, Nigeria's population is estimated to be 177 million being in the 7th position with a projection of 396 million in 2050 to move to the 3rd position (Population Reference Bureau, 2014). This whooping population of Nigeria is largely urbanizing. The trend has continued from pre-colonial period through the sixty years of colonial rule to the present post colonial period. While the current rate of urbanization for the world is 2.5%, that of developed countries is 0.8%, developing nations generally is 3.4%, Africa's rate of urbanization is a "whooping" 4.4% and Nigeria has the highest of 5.5% (Oluwasola, 2007: 4). For instance, in 1950 Lagos, a giant city has a population of 300,000 which increased to 10 million in 2004. The two other giant cities of Nigeria are Kano and Ibadan, Ibadan being the third largest by population but the largest in geographical area. According to the 2006 census results, the population of Ibadan was 2,550,593 while that of Kano and Metropolitan Lagos were 3,848,885 and 7,937,932 respectively (National Bureau of Statistics, 2006).

Urban Development Forces

The developments of urban places have been attributed to two sets of push and pull factors (Bhatta, 2010). These are essentially centrifugal and centripetal forces that leads to increase in size of points of population concentrations and multiplication of points of population concentration. These can be due to migration from the countryside to urban areas and natural increase in population from excess of births over deaths. Migration is defined as "the long-term relocation of an individual, household or group to a new location outside the community of origin", push factors being "conditions in the place of origin which are perceived by migrants as detrimental to their wellbeing or economic security," and pull factors are "the circumstances in new places that attract individuals to move there "(Bhatta, 2010:9). Push factors are negative and include joblessness, poverty and lack of modern social, educational and economic opportunities, and general rural conditions. Pull factors include job opportunities and possibilities for a better lifestyle, including better opportunities for higher

salaries, better services, and better lifestyles, which attracts people to urban places (Thomas, 2005).

Urban development is also hinged on other city-generating factors in the urban design parlance, especially morphological patterns. In these patterns, natural features like geology, landforms and vegetation play key roles. Also, man-made features like transportation infrastructures, including roads, rail lines, water ways and air-transport facilities often determine the emerging urban forms in growing settlements. While there is a general consensus on the features of a sustainable development agenda amongst many working in the field of urban design, nevertheless there are differences in emphasis, (Carmona et al., 2003). Over a decade ago, Calthorpe (1993) outlined the principles for the Transit-Oriented-Development: an agenda that many could still accept as a general guide. In summary, the principles of Transit-Orientated Development according to Paddison (2001) are:

a. Organizing growth on a regional level so that it is compact and transit-supportive.
b. Locating commercial, housing, jobs, parks, and civic uses within walking distance of transit stops.
c. Designing pedestrian-friendly street networks which directly connect local destinations.
d. Housing should be a mix of densities, tenure and cost.
e. Sensitive habitat, riparian zones, and high-quality open space should be preserved.
f. Public spaces should be the focus of building orientation and neighbourhood activity and
g. Encouraging of infill and redevelopment along transit corridors within existing neighbourhoods.

Availability of transportation facility is therefore a high precursor to urban development and is the basic urban design agenda that is compatible with sustainable development ideas. They not only allow transit between the urban and countryside settings, they attract developments like housing, industries and enhance commercial enterprises. Also, resulting transportation nodes often supports commuters overnight stays and commercial activities and such nodes often emerges into transit-corridor cities like Ibadan and Lagos.

Furthermore, the perceived better conditions attract poor people from rural areas into urban areas mainly to seek economic opportunities. In contrast to the rural areas, cities are known to be places where money, services and wealth are centralized. Cities are places where fortunes are made and where social mobility is possible. Businesses that generate jobs and capitals are usually located in urban areas. While the source of such fortunes may be trade or tourism, it is also through the cities that foreign currency of possible higher values flows into a country. Also, cities are abodes of better basic services as well as other specialist services that are not found in rural areas while the job markets in cities are highly diversified compared to the few job categories of rural areas. Health is another major factor that is better enhanced in the cities because of the availability of higher levels of healthcare facilities. Other urban development factors include a greater variety of entertainment (restaurants, movie theatres, recreation parks and gardens, amusement centres, etc.) and a better quality of education.. All these lead to growth and development beyond the available capabilities of resources and the resulting challenges bedeviling the environment and its components.

Urban Environmental Challenges

The rapid growth rates of urban agglomerations and the lagging response by governments in developing nations of Africa and others have been associated with significantly increasing urban poverty, problematic urban environments and ever more complex urban management

issues. These include "uncontrolled growth of urban informal settlements, prevalence of substandard and overcrowded urban housing, inadequate basic urban services and infrastructure provision, declining urban livelihood options, frequent civil unrest, and infectious diseases and crime" (UN-Habitat, 2008:10). In most parts of Africa, cities and urban agglomerations have become centres of urban squalor, aggravated poverty and human misery. While they are rapidly becoming social hot-beds and breeding grounds for unrest and political risk, the rate of urban insecurity is unimaginable (Adedeji and Fadamiro, 2014). Consequent upon poverty, urban public spaces privatization, thriving of informal sector trading activities, coupled with anemic urban governance, the cities have been turned to hazardous places in environmental phenomena (Adedeji, Fadamiro and Adeoye, 2014). The cases have been worsened by global environmental hazards and crises in terms of climate change, ocean surges, tsunamis, volcanic eruptions, auto-accidents, professional quackery, volcanic eruption, earthquake, landslide, flood, cyclones, cold waves, drought, thunderstorm, heat waves and storms, fire outbreak, damaged pipelines, oil spillage, gas flaring, building collapse, chemical spill, road accident, food poisoning, epidemic industrial disaster, deforestation, war and plane crashes (Adedeji and Adeboyejo, 2011).

Unless carefully managed, the urban transition in West and Central Africa could have adverse implications for the regional economy, the environment and social stability. Most of the nations have unbalanced population concentrations and experience rapid urbanization without effective physical planning, development control and urban social policy. Lagos and Kinshasa are classic examples, combining haphazard, uncontrolled and unrestrained population and spatial growth with few additional housing, infrastructures, services and livelihood opportunities. "The region's urbanization is driven by demographic forces and perceived availability of urban livelihoods rather than by significant broad-based economic progress and urban livelihood creation." Despite the relative expansion of economic activity, the cities are becoming increasingly dysfunctional in terms of access to key resources and livelihoods for its urban dwellers. Social unrest and violence could be the outcome of these poorly functioning cities (UN-Habitat, 2008:11).

The fast expansion of urban populations has caused rapid increases in the demand for urban land. Urban plots cannot easily be reproduced or have the demand met by converting rural land at the urban periphery. As a result, land prices rise sharply and land becomes increasingly unaffordable to the urban poor. Because of the strategic importance of land, the prevailing land tenure systems and because land markets are not serving the needs of the urban poor, governmental interventions - both directly and indirectly – are critical to broadening access to land beyond those who can afford the open market prices. Land policy is an important tool in modifying land markets in the interest of national development, and particularly as an instrument for achieving greater equity and social justice. Local authorities, within their ideological and political confines, can moderate the land market to achieve specific planning and spatial aims or improved accessibility to urban land for a broad range of stakeholders, including low-income households and slum dwellers. In the absence of equitable land allocation in a market-driven environment, low-income households' limited financial capacities force them to solve their shelter and livelihood problems informally. Given their vast numbers, poor urban dwellers are now the dominant market sector. They transform the city to meet their needs in manners that are often in conflict with laws and urban development plans (UN-Habitat, 2008:12).

Urban infrastructure provision and development are the key components of proactive environmental approaches. Unsafe water, sanitation and hygiene account for about six percent of the disease burden in the region. In terms of services Lagos, Kano and Ibadan rank among the region's most deficient cities. Only three percent of the Ibadan residents has

access to piped water. Greater Lagos does not do much better, servicing only nine percent of its 10 million people. These are abysmally low rates, not only in absolute terms but also relatively if compared with Accra's 51.6 and Abidjan's 70.9 percent of the urban population served with piped water. Poverty is central to the human settlement sector as housing and services have become market commodities with access determined by the ability to pay market prices (UN Development Agenda, 2012). With piped water and improved sanitation, economic rather than social goods, they have gradually ceased to be the responsibility of urban managers. There is need for the region's governments and local authorities to start perceiving access to improved water and sanitation as a social good, a human right and an essential commodity for human health rather than marketable commodities. Successive governments in West African countries have shown much concern for transport planning and development. Increasing road networks notwithstanding, transport is in disarray. UNEP (2009) argued that sound management and concerted public outreach and preparedness efforts can prevent the devastating destruction that characterized urban disasters in the 20th century.

Sustainable Urban Development

At global, continental and country levels, there seems to be widespread agreement that solving urban environmental problems means the adoption of policies and programmes that lead to sustainable development. Sustainable development, however, has many different meanings (Pearce, 1989). The shades of meaning given to sustainable development closely mirror – or perhaps match – the writer's intellectual or emotional position along the spectrum of green philosophy. There is also a great danger that the concept will become meaningless, or simply be used as another wordy panacea instead of action for dealing with the environmental ills that befall the planet. The pursuit of a sustainable future for the human race in an environment of quality will require the design of effective policies and programmes which directly address the related problems of unsustainable activities and environmental degradation; they must also be politically acceptable in the jurisdiction where they are proposed. If these policies and programmes are grouped beneath the generic term 'sustainable development', then that term must have a generally accepted meaning which does not reduce it to an anodyne instrument for political obfuscation. A generally accepted definition of sustainable development, and a good point to begin an exploration of this concept, is taken from the Brundtland Report: "Sustainable development is development that meets the needs of the present generation without compromising the ability of future generations to meet their own needs" (World Commission on Environment and Development, 1987).

This definition contains three key ideas: development, needs, and future generations. According to Blowers (1993), development should not be confused with growth. Growth is a physical or quantitative expansion of the economic system, while development is a qualitative concept: it is concerned with cultural, social and economic progress. The term 'needs' introduces the ideas of distribution of resources: "meeting the basic needs of all and extending to all the opportunity to satisfy their aspirations for a better life" (World Commission on Environment and Development, 1987). Also, the term "sustainable development" has been viewed from different perspective. The World Food Programme, WFP (2010), defines it to mean allowing for "future generation requires that we preserve our remaining resources and that we had or rehabilitate resources that have been treated carelessly in the past". Blackwell, Goodwillie and Webb (1991) described sustainable development as a process of change in which the exploitation of resources, the direction of investment, the orientation of technological development, and institutional change are all in harmony and enhance both current and future potential to meet human needs and aspiration.

Huang, (2008) states that the best strategy for sustainable urban development and to limit urban decay is care for existing cities. This is especially a challenge in rapid urbanizing countries like Nigeria. This has been explored through urban renewal which has also been linked with the sustainable provision of basic amenities such as water, and electricity" (Vander and Graaf, 2010). Sustainability also "implies the careful husbandry of the natural and man-made environment. It implies a return to the mores of farming traditions, that is, leaving the land in a better condition than it was found" (Moughtin, Oc and Tiesdell, 1999:150). Urban environmental sustainability has also been described as "a process of change in which the exploitation of resources, investments, application of technology and institutional change are in harmony and enhances both current and future potential to meet human needs and aspirations" (Adeyinka, 2005). Urban sustainability debate is thus germane as "urban areas are central to the demographic, economic and environmental challenge of the 21st century (UN and UNCHS, 2010).

Sustainable Cities and Management Initiatives

The development of sustainable cities has constantly been hinged on sustainable urban governance and management initiatives at all levels. This is essentially the promotion of good governance as entrenched in the United Nations Global Sustainable City's Agenda and several others alike which target the poor and the vulnerable group for poverty reduction, job creation, provision of decent and affordable shelter; and ensuring a socially, culturally, economically as well as environmentally sound and serviced human settlements in other to improve the overall living conditions of the people in Nigeria (UN-Habitat, 2007; UNDPI, 2008). The premise of the nation's effort is as enumerated by the Earth Summit in 1992: "without improving environmental management, development will be undermined and without accelerated development the environment will continue to degrade". Accordingly, Wilmoth (2014) asserts that managing urban areas has become one of the most important development challenges of the 21st century. Our success or failure in building sustainable cities will be a major factor in the success of the post-2015 UN development agenda. These initiatives therefore naturally divide into two non-mutually exclusive groups: United Nations and Nigerian.

United Nations Urban Development and Management Initiatives

Between 1972 and 2012, the United Nations organised international conferences as global giant strides to achieve sustainable urban developments (Fadamiro and Adedeji, 2014). Specifically, the United Nations Conference on Sustainable Development (UNCSD) marked the 40th anniversary of the first major international political conference that specifically had the word "environment" in its title. The UNCSD was charged with securing renewed political commitment for sustainable development, assessing progress and implementation gaps in meeting previously-agreed commitments, and addressing new and emerging challenges. In addition, the UN General Assembly called for the conference to focus on the following themes: a green economy in the context of sustainable development and poverty eradication, and the institutional framework for sustainable development (IFSD).

Table 1 shows the milestone conferences and respective outcomes. The final outcome consists of the following summarized key resolutions on urban development and management strategies by the UN General Assembly on 11 September, 2012 (UN, 2012):

i. If cities are well planned and developed they can promote economically, socially and environmentally sustainable societies, recognizing the need for a holistic approach to urban development and human settlements;
ii. To promote an integrated approach to planning and building sustainable cities and urban settlements;

iii. Emphasize the importance of increasing the number of metropolitan regions, cities and towns that are implementing policies for sustainable urban planning;
iv. Recognize the important role of municipal governments in setting a vision for sustainable cities, from the initiation of city planning through to revitalization of older cities and neighbourhoods;
v. Developing sustainable, locally appropriate transport system;
vi. Recognize the importance of mixed-use planning and of encouraging non-motorized mobility including by promoting pedestrian and cycling infrastructures;
vii. Recognize that partnerships among cities and communities play an important role in promoting sustainable development.

Table 1: Timeline of Environment and Development Discussions

Date	Milestone	Outcomes or Issues
1972	United Nations Conference on the Human Environment (the "Stockholm Conference")	Stockholm Declaration; Stockholm Action Plan; and 5 resolutions calling for ban of nuclear weapons, a databank of environmental data, an environmental fund, actions on development and environment, and establishment of the U.N. Environment Programme (UNEP)
1987	Report of the World Commission on Environment and Development (the Brundtland Commission)	*Our Common Future:* Defines "sustainable development": meets the needs of the present without compromising the ability of future generations to meet their own needs"
1992	United Nations Conference on Environment and Development (UNCED) in Rio de Janeiro, Brazil	Rio Declaration; Agenda 21; United Nations Framework Convention on Climate Change; Biological Diversity; Statement of Forest Principles
1997	19th Special Session of the U.N. General Assembly	Programme for Further Implementation of Agenda 21
2002	World Summit on Sustainable Development (WSSD) in Johannesburg, South Africa	Johannesburg Plan of Implementation; Johannesburg Declaration on Sustainable Development; Marrakesh Process—recognized contribution of "partnerships"
2012	Informal-Informal Negotiations on the Zero-Order Draft Communique	Draft Communique of more than 200 pages; two subsequent sessions have reduced it to about 80 paragraphs.
June 13-15 2012	Third Prep Comm in Rio de Janeiro, Brazil	Agenda, Rules of Procedure, draft Communique, etc
June 16-19 2012	Sustainable Development Dialogues in Rio de Janeiro, Brazil and on the worldwide web	Recommendations expected from each of Dialogues on 10 topics, to be conveyed to the high level Rio+20 Partnership Forum
June 20-22 2012	High-Level Rio+20 Partnership Forum in Rio de Janeiro, Brazil	Communique *discussed below.*

Nigeria's Urban Development Agenda

Nigeria's urban development agenda emanates from that of United Nations being an active member. The Draft Objectives and Strategies for Nigeria's Agenda 21 (http://www.nesrea.org/images/NIGERIA%27S%20AGENDA%2021.pdf) remains the best white-paper from the United Nations initiatives which, according to Johnson (1993), has the following outlines:

i. Providing adequate shelter for all;

ii. Improving human settlement management;
iii. Promoting sustainable land use planning and management;
iv. Promoting the integrated provision of environmental infrastructure: water, sanitation, drainage, hazardous and solid waste management;
v. Promoting sustainable energy and transport systems in human settlements;
vi. Promoting human settlement planning and management in disaster-prone areas;
vii. Promoting sustainable construction industry activities and
viii. Promoting human resource development and capacity-building for human settlement development.

The mission of the agenda is to

> *"achieve a state of environmentally sound human settlements free from slum conditions and in which all have access to adequate and affordable shelter, efficient infrastructure and services which will foster sustainable economic growth, improved standard of living for the well-being of all Nigerians" (Adegoke et al, undated).*

This will involve providing an integrated infrastructural system of water, electricity, sanitation, drainage, liquid and solid waste management in cities to effectively implement and enforce all existing relevant sectoral laws, standards and regulations that make for sustainable human settlements.

Furthermore, there is need to encourage private sector and community participation in urban renewal activities, housing and infra-structural provision; replicate the Sustainable Cities Programmes (SCP) in major urban centres in Nigeria; develop and implement guidelines and put in place appropriate institutional arrangement for effective urban land administration (Sanni 2010). It also requires promoting green infrastructure and efficient transportation in cities.

Accordingly, the National Housing Policy was formulated and launched in 1991. The document outlines policies and strategies to provide decent housing for all by the year 2000 or in the shortest possible time. A fall-out of the policy is the establishment of the Housing Policy Council to monitor activities in the housing sector and evaluate policy impact on the sector. To achieve this, The National Housing Fund was established in 1992 to solve the problem of finance for housing development. The Federal Government, through the Federal Housing Authority (FHA) started the National Housing Programme in 1994 to produce 121,000 housing units for low, medium and high income earners. So far 600 housing units in various stages of completion are being constructed in Lagos, Kaduna, Port-Harcourt, Jos, Kano and Lafia (Adegoke et al, undated). Also, The Federal Government has provided through the National Sites and Services Programme over 15,000 plots at subsidized rate to the public. Over 250m has been committed to the programme in the last six years.

To address the goal of strengthening urban data systems, a National Index of Building Standards (NIBS) was established in 1994 to collect data on building starts and other housing indicators. The project is being undertaken by the Nigerian Institute for Social and Economic Research (NISER) in collaboration with the Federal Ministry of Works and Housing, Regional Workshops have been held on the use and implementation of NIBS (Obadan, 2003). Several policies have been adopted by government to improve Urban Management. These include:

i. The National Urban Development Policy formulated in 1992 to provide guidelines for urban development and management.

ii. Infrastructure Development Fund through a U.S. $180 million financial assistance from the World Bank, the Infrastructure Development Fund financed urban development projects in 15 States of the federation covering storm drainage, sanitation, urban roads rehabilitation, water and solid waste management, market development, water rehabilitation, motor parks development, river draining/channelization, street lighting.

iii. Sustainable City Programme, the country is participating in the sustainable cities programme under the UNCHS (Habitat) and World Bank/UNDP urban management programme (UMP). Under the programme, sustainable Ibadan. Project (SIP) is being implemented. Through the initiative, Local Governments, NGOs, CBOs, private individuals are encouraged to participate and contribute to urban improvement and management programme. The process of replicating the sustainable city programme has already begun. Two other cities, Kano and Enugu have commenced their projects. The sustainable Kano Project has already prepared the Kano Environment profile study forming the basis for consultative actions on the management of Metropolitan Kano.

iv. Capacity Building towards enhancing the management capacity of agencies responsible for urban development, technical assistance for human resource development has been received. Under the World Bank infrastructure Development Fund Programme, officers of State and Federal agencies were trained in various aspects of urban management and computer literacy. Supply and installation of computer hard ware and software were also sponsored. Other international agencies that have offered training assistance include the UNDP, UNEP, UNCHS and UNICEF. Furthermore, the following have been put in place to promote sustainable land use, planning and management: Land Use Act of 1978, Federal Land Registry and a similar one in Ondo State, Urban and Regional Planning Decree, Infrastructure Development Fund programme and Urban Basic Services programme (UBS) (Igbuzor, 2009).

RECOMMENDATION AND CONCLUSION

The need for collaborative efforts by all governmental Agencies at regional, national and local levels towards ensuring good governance and sustainable urban development cannot be overemphasized in view of the the poor outlooks of Nigerian urban

places. These include the New Partnership for Africa's Development (NEPAD) which is an initiative for speeding up sustainable development in Africa which Nigerian government should explore. Other counterpart initiatives like National Economic Empowerment and Development Strategy (NEEDS) and State Economic Empowerment and Development Strategies (SEEDS) (Ariyo, Odusola and Ayorinde, 2006; NEEDS, 2006; Ogoh, 2006),) which operate at the national and state levels in Nigeria should collaborate to ensure speedy actualization of the UN Global Agenda 21 and Goal 7 of the MDGs Agenda on the sustainability of cities. Also, the African Ministerial Conference on Housing and Urban Development (AMCHUD), a body of ministers responsible for housing and urban development in Africa (Okunola, 2010; Daramola & Ibem, 2010; Adegun, 2011) has a key role to play in facilitating these initiatives.

Furthermore, achieving sustainability in housing provision requires major societal changes, restructuring of institutions and management approaches. It also requires the appropriate political will based on the conviction of the responsibility of government to its citizens, and the need to create humane and decent environment for dignified living (Olotuah and Bobadoye, 2009). Since one of the most important challenges facing Nigeria is the provision

of affordable housing to the poor and low-income group in view of alarming rates of urbanisation, the resulting social, economic, environmental and political challenges need to be urgently addressed (Oduwaye, 2009). Despite a series of government policies towards housing delivery, one thing that is clear is that there exist a gap between housing supply and demand (Oduwaye, 2009), therefore, this should be urgently addressed. This can be through arrangements between government and private sector entities for the purpose of providing public infrastructure and housing in cities (Sanni, 2010).

The existing approaches of environmental planning and management in Nigeria is grossly deficient of citizen participation (Akinmoladun and Oduwaye, 2000) controlling the use of land and the character of buildings and communication routes so as to achieve economic security, convenience and incorporating local people in the decision making process should be re-visited. On the whole, there is an urgent need for the Federal Government of Nigeria through its relevant agencies to mount a seamless and premium enforcement operational system towards enhancing livable and sustainable Nigerian cities. This should be all-embracing to include spatial planning for safe and aesthetically sustainable cities, socially-inclusive urban enclaves and urban governance with enhanced all-round management strategies. All urban sustainability dimensions (Alberti, 1996) should be adequately planned for, including the following: Urban Patterns: community- population, economy, society; Structure – form, density, connectivity; functions- housing, industry, services, and transportation; Urban Flows: information and communication, natural resources- energy, water, materials; infrastructure and technologies; Urban Quality: environmental quality, human health, efficiency, equity, diversity and accessibility.

In view of the forthcoming Third United Nations Conference on Housing and Sustainable Urban Development, the New Urban Agenda tagged Habitat III in Quito, Ecuador, from 17 – 20 October 2016, focusing on "policies and strategies that can result in effectively harnessing the power and forces behind urbanization" (http://futureofplaces.com/2013/11/towards-habitat-iii-2016/) engaging all the stakeholders, it is expected that cutting-edge strategies would be formulated on sustainable urban development and management. The conference promises to open discussions on these important urban challenges and questions towards suggesting sustainable strategies for urban governance.

ABSTRACT

Slum is a consequential effect of unplanned urbanization in cities especially in developing countries. Insecure tenure, crime, overcrowding, uncollected waste and poor sanitation are problems that often characterized slum neighbourhood. The problems of Slum is not a peculiar problem as most slum areas tend to exhibit the same trait, these identified problems are evident in the slum area of Kpakungu, a Neighbourhood in Minna, Niger State. Since the inception of the present political dispensation (1999 till date), the state government has been enforcing all the planning tools to control its development but this has proved abortive. This study aims at appraising the characteristics of slum neighbourhood of Minna, Niger State with reference to Kpakungu between 1999 and 2014. This was achieved by examining the factors responsible for slum proliferation in kpakungu neighbourhood and the impact of town planning activities in kpakungu between 1999 and 2014. Quantitative approach was used in data collection and stratified random sampling was used to select respondents. The neighbourhood was divided into 8 units from which random sampling was used to select the respondents for the study. A total of 95 questionnaires were administered due to the size of the population and the respondents. Geospatial techniques were also used to substantiate data from both sources. The Rasi 700 gas meter was further used to determine the pollution level. The analysis of the spatial development of the neighbourhood indicated that there is a significant increase in the size of the slum between the periods of investigation. The pollution level of the neighbourhood shows higher level than the stipulated value of 10ppm for CO, 0.04-0.06ppm for NO2 and 0.01ppm for SO2 by NESREA. There is also increase in crime rate in the neighbourhood by 25%. The study recommends inclusive planning approach in the management and planning of neighbourhood and proper monitoring and implementation of development control measures should be enforced by the relevant agencies in the state.

Keywords: Development Control, Geospatial, Inclusive Planning, Pollution and Slum

Introduction

Over the years, scholars in urban studies are faced with the challenging phenomena of increasing rates of urban growth in the world, especially in developing countries, where less urban planning is being carried out to contain such growth in a viable manner (Egunjobi, Jelili, Adeyeye, 2007). Unplanned urbanization and rapid urban growth are linked to various environmental challenges in developing countries. Olthuis, Jiya, Eichwede and Zevenbergen (2005) opined that unplanned urban and rapid urbanization often result in chaotic development which in turn breed slum settlements in developing countries of the world with Nigeria inclusive. Also, Agbola and Agunbiade (2009) share the same opinion about development and slum formation. Slum settlements are defined as any neighbourhood or city with half or more of its residents lack access to improved potable water supply, sanitation, sufficient living area, durable housing and secure tenure (UN-Habitat, 2009).

Consequently, proliferation of slums areas are seen as major challenge to development in the developing countries. This is because slum areas are often characterized by appalling living and environmental conditions which frequently result to inadequate water supply, squalid conditions of environmental sanitation, breakdown or non-existence of waste disposal managements, overcrowded and dilapidated habitation, hazardous location, insecurity of tenure, and vulnerability to serious health risks (Arimah, 2010). More so, social vices such as drugs addiction, prostitution, smuggling, etc. are attributed to slum proliferation in

Adeleye, B.M.; Abd'razack, N.T.A.; Ndana, M.; Akande, O. S. & Popoola, A. A. (2016). Appraisal of Characteristics of Slum Neighbourhood of Minna, Niger State. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1629-1637

developing countries (Fourchard, 2003). All challenges that are associated with Slum areas are seen as an impediment undermining the actualization of goal number 7, target d of the Millennium Development Goals that seeks to improve the lives of at least 100 million dweller by the 2020 (IDB, 2013).

The rate of the proliferation of slum in the world at large is alarming and this calls for stern concern by stakeholders. According to the UN (2008) a total of one billion people worldwide were estimated to be living in slums currently and this figure translates to one-sixth of the world's population. Thus, with the rapid and unplanned urbanization experienced in most cities of the world, especially Africa, there is a likelihood of a significant increase in the number of slum dwellers and environmental problems that will accompany the influxes (IDB, 2013). Challenges posed by rapid urbanization are peculiar to all, but the developing countries are the ones finding it increasingly difficult to respond to these challenges (Siddharth, 2008).

Nigeria has also had its own fair share of slum proliferations which are evident in urban centres across the country. Olotuah (2006) opined that 75% of dwelling units in Nigeria urban centres are substandard and these dwelling units are cited in slums. In Minna, the Niger state capital Aliyu (2008) reported that 70% of the population of Minna reside in slums and squatter settlements. This analysis from Aliyu (2008) affirms Olotuah's (2006) assertion that 75% of urban dwellers in Nigeria reside in Slum neighbourhood. The "story" of slum proliferation is not different in the case of Kpakungu a neighbourhood in Minna, Niger state. The study area shows that it is an undulating neighbourhood which has valley towards the southern part. This allow for the indiscriminate sewage and solid waste disposal in and around the neighbourhood. The environment is filthy and shows high level of unplanned and uncontrolled growth. The people of Kpakungu neighbourhood are gregarious in nature and lives in a compact ties, they have similar social and economic characteristics. Due to negligence on the part of the authority and the poor socio-economic status of the people, Kpakungu neighbourhood has shown a near or total collapse of urban infrastructure which has resulted to high crime incident and growing environmental problem such as air pollution, uncollected waste, poor accessibility, poor sanitation, silted drains and erection of buildings without planning permit. These phenomenons have led to the growth of slum in Kpakungu.

Efforts to address these issues by the Niger State Urban Development Board right from the inception of the present political dispensation (1999 till date) have proven abortive. Against this background, the planning activities toward revitalizing Kpakungu were assessed in this study.

Aim and Objectives of the Study

The aim of this study is to appraise the characteristics of slum neighbourhood of Minna, Niger State with reference to Kpakungu between 1999 and 2014. To effectively carry out this appraisal, the factors that are responsible for slum proliferation in Kpakungu were examined, the trend of slum proliferation between 1999 and 2014 was analyzed, the implications of slum proliferation in Kpakungu is looked into and the impact of town planning activities between 1999 and 2014 are also examined.

STUDY AREA

Kpakungu, a suburb of Minna is located on Latitude 9°35’ North and Longitude 6°31’ East and occupies a land area of 801.402 Hectares and an estimated population of about 22,587 projected from NPC, 2006 population census. Kpakungu is one of the 24 neighbourhoods of Minna city and one of the largest populated neighbourhood in the city. Figure 1 shows the spatial extent of the neighbourhood and its location in relation to Minna. Kpakungu

neighbourhood is bounded by Fadipe, Soje, Barkin Sale and Gbaganu community to the North, East, South and West respectively.

MATERIAL AND METHOD

Sources of Data

Data for this study were collected through Primary and Secondary sources. A total of 95 questionnaires were administered using Stratified random sampling, and each unit has certain number of questionnaire based on the population of the unit. Kpakungu neighbourhood was divided into eight units for easy administration. At each unit a random sampling was employed to give each household an equal chance to be selected. At unit one, nine questionnaires were administered; at unit two, eleven questionnaires, were administered; at unit three, fifteen questionnaires were administered; at unit four, sixteen questionnaires were administered; at unit five, thirteen questionnaires were administered; at unit six, twelve questionnaires were administered; at unit seven, ten questionnaires were administered and at unit eight, nine questionnaires were also administered. The perception of the households on the issues of slum and town planning activities in Kpakungu neighbourhood was ascertained. Pollution levels in Kpakungu were recorded for seven days at three different intervals (morning, afternoon, and evening). This was done with the use of the Rasi 700 gas metre and the mean of the gases were computed. The coordinates of the location where these gases were taken was also recorded. Data on the development control in Kpakungu were sourced from Development Control Department of the Niger State Urban Development Board, Minna through an oral interview. Data on crime was obtained from the Nigeria Police Force Kpakungu Division, the crime report was later corroborated by the findings from the literatures on crime in Minna.

Post Processing

Spatial analysis of the growth of the neighbourhood over the planned period was obtained from three sets of images, which are the Enhance Thematic Mapper of 1999, 2006 and 2014 (Table 1). The area of interest (Kpakungu) was "clipped" out of the three images using Arcgis 10.2 software. Band combination of 4,3,2 were used to form the "False Colour" composite for the images via the use of the "New Map list" operation tool on ILWIS 3.3 Academic. On band 4,3,2 "False Color" composite, Vegetation appears in shades of red while Urban areas and Densely populated urban area come out in cyan blue and light blue respectively. Sample Set for urban areas and vegetation were created on all the images in question (1999, 2006 and 2014) after which the images were subjected to maximum likelihood classification on ILWIS 3.3 academic.

On each of the classified images of Kpakungu neighbourhood the urban area were digitized and then over laid. This task was performed in order to determine the direction and spatial extent of Slum in Kpakungu neighbourhood. Finished were composed into maps by adding graticules, scales, legend and cardinal point.

Data Processing Techniques

Data processing techniques used for this study include: Data evaluation, Image Sub-setting, Image Classification, Overlay Analysis and Map Composition.

Table 1: Image Properties

S/No	Image Year	Path and Row	Sensor	Captured Date
1	Kpakungu 1999	P189 R053	ETM^+	03 /04/1999
2	Kpakungu 2006	P189 R053	ETM^+	11/07/2006
3	Kpakungu 2014	P189 R053	ETM^+	04/04/2006

RESULT AND DISCUSSION

Factors Responsible for Slum Growth in Kpakungu, Minna

Several factors were advanced by the perception of respondents as reasons for its spatial growth. Factors responsible for slum proliferation in Kpakungu reveals that 3.2% of the

respondents were of the view that transportation nodes in Kpakungu must have influenced slum proliferation in Kpakungu, 15.8% of the respondents opined that economic activities in Kpakungu is responsible for Slum proliferation. Low land value was attributed for slum growth by 26.3% of the respondents in Kpakungu. Majority of the respondents (42.1%) are of the view that low rent must have influenced the growth of slum in Kpakungu while 12.6% of the respondent believed that the development of micro housing has swayed the growth of slum in Kpakungu (Table 2).

Table 2: Factors Responsible for Spatial Growth of Kpakungu

Factors	No of Respondents	Percentage
Transportation Node	3	3.2
Economic Activities	15	15.8
Low Land Value	25	26.3
Low Rent	40	42.1
Development of Micro Housing	12	12.6
Total	**95**	**100.0**

The result of the study indicated that all these factors contributed in different proportion to development of slum spatially in the neighbourhood. Though perception is subjective, it corroborated the findings of other researcher that low cost of illegal land, unplanned and unserviced land as well as low rental value is the factors that encourages slum development (UN-Habitat, 2003; Tibaijuka, 2005; UNDP, 2003; and World Bank and UNCHS, 2002).

Spatial development of Kpakungu, Minna between 1999 and 2014

Table 3: Land Area of Slum between 1999 and 2015

Year	Area (Hectares)	Percentage of Increase
1999	119.610	
2006	272.970	128
2014	482.940	77

Table 3 reveals a progressive growth spatially in the size of Kpakungu neighbourhood between 1999 and 2014. The spatial extent of Slum area in Kpakungu in 1999 (base year) was 199.610 Ha. In 2006, the Slum area rose to 272.970 Ha (128 percentage of increase). The relocation of Federal University of Technology, Minna and National Examination Council in 2005 to Gidan-kwano and Gidan Mangoro respectively, influenced the proliferation of slum in Kpakungu neighbourhood in 2006. These settlements (Gidan-Kwano and Gidan Mangoro) are all adjoining settlement to Kpakungu Neighbourhood. In 2005, construction of buildings were done to meet the housing need of staff of National Examination Council and Staff and students of Federal University of Technology with little or no regard for development control. Slum proliferation in Kpakungu increased by 77% in 2014 compared to 2006 size. As at the end of 2014, Kpakungu neighbourhood has spread territorially to about 482.940 Ha. The proliferation of Slum at this period can be attributed to increase in Commercial activities in Kpakungu. Figure 3 and Figure 4 shows the spatial extent of Kpakungu in 1999, 2006 and 2014 respectively.

The overlay of the spatial development of the Kpakungu slum over the study period is indicated in Figure 5. This was depicted by different colours, the red colour indicated the area extent of the neighbourhood in 1999, the green indicated the area extent in 2006 and blue colour implies the development in 2014. The overlay shows that between 1999 and 2014 (period of 16 years), the slum has expanded more than two folds.

The development of the slum is toward the western and southern part of Kpakungu neighbourhood. At the western axis Federal University of Technology and National

Examination council are seen as growth pole while Shiroro Hotel is seen as the growth pole at the southern axis of the neighbourhood.

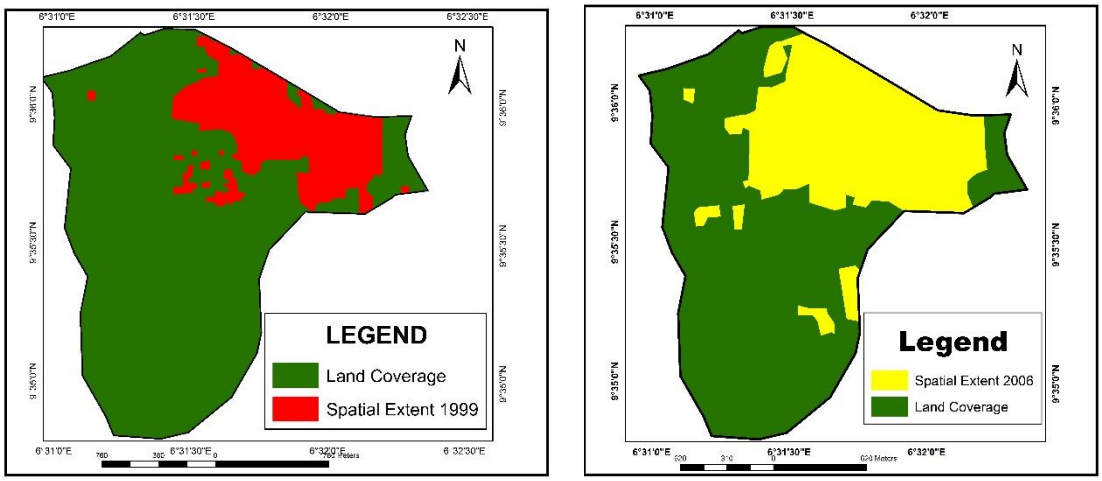

Figure 3: *Spatial Extent of Slum in 1999 and 2006*

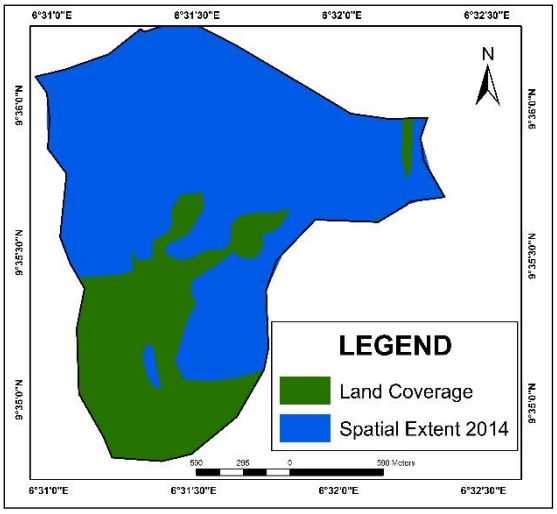

Figure 4: *Spatial Extent of Slum in 2014*

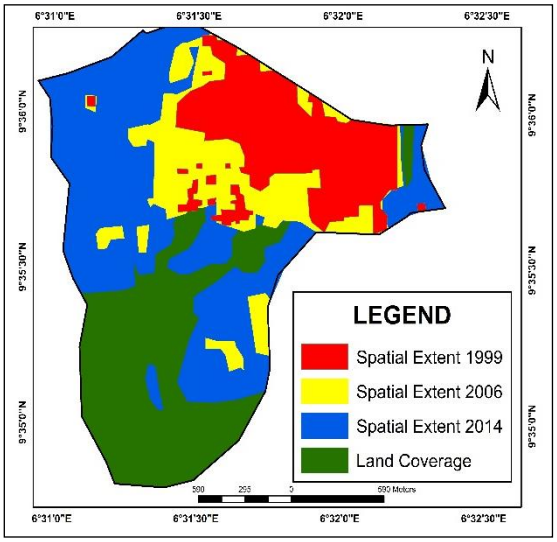

Figure 5: Overlay of Spatial Extent

Implications of Slum Proliferation

There are many implications of the slum development in Kpakungu, these ranges from all forms of social vices to local acts. The prominent types of insecurity faced by the inhabitant of Kpakungu neighbourhood are Armed Robbery, Burglary, Stealing and increase in Juvenile delinquency. A significant number (46.3%) of the respondents believed that stealing was more pronounced in Kpakunugu, 25.2 % of the respondents were of the view that burglary was rampant in Kpakungu, 25.3% of the respondents were of the opinion increased in juvenile delinquencies was raging Kpakungu while Armed Robbery which constitute 3.2% of the respondents was believed to be threatening.

According to the Nigerian Police force, Divisional Headquaters Kpakungu, a total of 86 cases of crime was reported between 1999 and 2014 in Kpakungu. The police force opined that out of the other neighbourhoods in Minna, the number of cases of crime in Kpakungu was more. As a result of this Kpakungu neighbourhood was termed as a hot spot area. Jinadu, Morenikeji, Sanusi, Dukiya and Owoyele (2013) in their study on "Digital Mapping of Crime Statistics in Minna" also termed Kpakungu neighbourhood as a hot spot zone when it comes to crime. Between 2000 and 2011, Kpakungu recorded the highest incidence of crime in Minna, Niger State and this was attributed to slum proliferation (Jinadu, et al., 2013). It was observed that the inhabitants of Kpakungu were faced with the problem of flooding, Land Degradation and Erosion at the western part of the neighbourhood these problems can as well be attributed to the slum expansion.

The problem of poor sanitation in Kpakungu was also seen in the manner of waste disposal as 33.7% (highest number of respondents) of the respondents disposed their waste in the drainage channels. The methods of burning and incineration were adopted by 6.3% of the respondents and 24.2% of the respondents respectively. The services of the Niger State Environmental protection agencies were employed by 23.2% of the respondents.

Problem of insecure tenure were also pronounced in the Kpakungu as 72.6% of the respondents do not have a secure tenure. Only 15.8% of the respondent could boast of a secure tenure. The low number of secure tenure in Kpakungu can be attributed to the organic nature of the neighbourhood.

Level of Pollution in Kpakungu Neighbourhood of Minna

One of the environmental consequences of slum development in Kpakungu is pollution as a result of poor sanitation and unclean environment. The national air quality standard according to National Environmental Standard and Regulation Enforcement Agency (NESREA) indicated that the amount of various components of the air ranges between 10ppm for CO; 0.04 -0.06ppm for NO_2 and 0.01ppm for SO_2.

Table 3: Level of Gas Emission in Kpakungu in 2011 and 2014

Coordinate		Standard	2011	2014
	Gases	Unit (PPM)	Unit (PPM)	Unit (PPM)
229272 1061852	CO	10	10.00	15
	H_2S	10	0.00237	5
	NO_2	0.04 -0.06	0.00312	14
	SO_2	0.01	0.00295	0.02

Table 3 reveals the level of gas emission in Kpakungu in 2011, after the average emission of the were recorded CO constitutes 10.00ppm, H2s constitutes ppm while No_2 and So_2 reads 0.00312ppm and 0.00295ppm respectively (ATPS, 2013). The level of gas emission increased in 2014, 15ppm was recorded for CO, 5ppm was recorded for H_2S, 0.02ppm was recorded for SO_2 and 14ppm was recorded for NO_2. The value recorded in 2014 were higher

than the stipulated value by the NESREA which state 10ppm for CO, 0.04 -0.06ppm for NO_2 and 0.01ppm for SO_2 (FEPA, 1999). The High pollution values can be attributed to slum proliferation and large concentration of Motor cycles in Kpakungu.

Impact of Town Planning Activities in Kpakungu between 1999 and 2014

Since the inception of the present political dispensation (1999) the Niger State Urban Development Board has been saddled with the responsibility of curbing the problems posed by slum proliferation in Kpakungu. Development control mechanisms were employed by the Agency on a smaller unit and building plans were properly scrutinized before approval. More so, site inspections were often carried out by the agency to checkmate the activities of contraveners in Kpakungu. The Niger State Urban Development Board opined that development control cannot be done on a larger scale in Kpakungu because the neighbourhood was just an organic settlement with no initial plan.

As a result of the ineffectiveness of the "smaller unit of development control" the Niger state urban Development Board proposed a Slum Upgrade for Kpakungu in 2008 before the entire Neighbourhood degenerate. The proposal of the Slum Upgrade for Kpakungu was defended that same year (2013) at the Federal Ministry of Lands, Housing and Urban Development.

The Slum upgrade proposal was accepted by the Federal Government and this was published in the memo of the National Council of Lands, Housing and Urban Development in 2013. Niger State Urban development Board believed that lack of political will by the government has hindered the implementation of the proposal. The Niger State Urban Development Board were of the opinion that the inability of the board to have her proposal approved has further made planning deteriorate in Kpakungu and this in turn has made development control ineffective in kpakungu.

RECOMMENDATION

Based on the major findings in the study, the following recommendations are made to ameliorate the problems of Slum proliferation in Kpakungu Neigbourhood.

There is need for slum upgrading in Kpakungu through rehabilitation, creation of accessibility as well as provision of urban basic services. This approach will go a long way to revitalize Kpakungu. More so inclusive planning approach should be adopted in the slum upgrade plan intended for Kpakungu, this will make the plan more viable.

The reconnaissance survey of the study area shows that there is no designated solid waste disposal area. The only waste collection point in the study area is far from the houses of the residents of the neighbourhood. The agency responsible for waste collection concentrated on only the designated dump site, and this has led to problem of indiscriminate waste disposal in drainage channels, open spaces uncompleted buildings. Niger State Environmental Protection Agency therefore need to address the problem of waste management in Kpakungu to forestall environmental and health hazard. Also public enlightenment campaign should be carried out on the dangers of insanitation by the Niger state Environmental Protection agency. This will help the inhabitant of Kpakungu keep a more hygienic environment.

All the Activities of the Niger State Urban Development Board should be well supported by the Niger State government through effective development control mechanism. In addition, Inhabitants of Kpakungu should be made to revalidate their tenure because this will assist in controlling slum development in Kpakungu and Minna at large.

CONCLUSION

From the analysis presented above, it can be seen that the relocation of the Federal University of Technology, Minna and NECO has contributed to the development of slum in Kpakungu neighbourhood of Minna. It was also observed that within the spate of 16 years, the Slum grows more than 2 folds (192.61 Ha in 1999 and 484.7 Ha in 2014). This implies that the slum is growing astronomically. The implication of this growth has been the increase in crime activities, poor sanitation and increase in air pollution beyond the national standard. The tools of town planning (development control) have not being able to stem the tide of unplanned development in the neighbourhood.

ABSTRACT

Peri-urban zones are areas capable of promoting urban and rural livelihoods and coping with the pressure and dynamics of population and land use changes. On the other hand, they constitute areas that lead to progressive degradation of the environment and collapse of institutions. This study examined the drivers of growth, characteristics and environmental challenges of the peri urban zones in Benin City, Nigeria using Ekiadolor as a case study. A sample size of 393 amounting to 30% of the total number of building stock in the area was chosen. For the survey, one household per building was selected. A random sampling approach was subsequently adopted to select any available head of household for interview. Some of the attributes investigated included occupation, family size, reasons for staying in the community, length of stay, buildings characteristics, infrastructures, road network and land related issues. The peculiar characteristics of a typical peri-urban community and its associated environmental problems were well amplified in Ekiadolor community. It was observed that the establishment of the College of Education and the accompanying employment opportunities was the major driver for the transformation of Ekiadolor to a peri-urban settlement. Other observed drivers include the relatively low housing rents and low cost of land in the community. The study concluded that the establishment of institutions such as universities, colleges of education and research institutes among others outside the immediate precinct of cities could trigger peri – urbanization and therefore recommends that adequate provision should be made in anticipation of the envisaged challenges that are associated with such development. The study further advocated for the creation of a specialized unit to plan and coordinate such settlements. It finally calls for a synergy between the peri-urban communities and the main cities through progressive integration.

Keywords: Benin City, Ekiadolor, haphazard growth, Peri-urbanization, urban growth

INTRODUCTION

Peri-urbanization refers to a process, often a highly dynamic one, in which rural areas that are located on the outskirt of established cities become more urban in character (Webster and Muller, 2004). This transformation occurs in physical, economic, and social terms, and often in piecemeal fashion. Peri-urban development usually involves rapid social change, as small agricultural communities are forced to adjust to an urban or industrial way of life in a very short time. High levels of in-migration are an important driver of such social change. Rapid environmental deterioration and infrastructure backlogs are usually another characteristic of the peri-urban landscape. Typically, peri-urbanization is stimulated by an infusion of new investment, generally from outside (Webster and Muller, 2004). Therefore, peri-urban area could be defined as the transition zone between fully urbanized land in cities and areas in predominantly agricultural use (Appiah, Bugri, Forkio and Boateng, 2014). Thus, it is characterized by mixed land uses and indeterminate inner and outer boundaries. In general, peri-urbanization often arises because effective land use guidance systems are virtually non-existent in many countries (Webster and Muller, 2004).

Key characteristics of the peri-urbanization process, particularly in developing countries include: changing economic structure, a shift from agriculturally based to manufacturing dominated economy; changing employment structure, rapid population growth and urbanization, changing spatial development patterns and rising land costs (Webster and Muller, 2004). The peri-urban (sometime also called the urban fringe) may be the dominant urban form and spatial planning challenge of the twenty-first century (Ravetz, Fertner and Nielsen, 2013). In older industrial or post-industrial countries, the peri-urban is a zone of

Olajuyigbe, A. E. & Ayodele, O. A. (2016). Assessment of Peri–Urban Zones in Benin City, Nigeria: A Focus on Ekiadolor Community. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1638-1648

social and economic change and spatial restructuring while in new industrializing countries, and most of the developing world, the peri-urban is often a zone of chaotic urbanization leading to sprawl (Ravetz, Fertner and Nielsen, 2013). Peri urban zone exhibits a relatively low population density by urban standards, scattered settlements, high dependence on transport for commuting, fragmented communities and lack of spatial governance (Ravetz, Fertner and Nielsen, 2013).

The term peri-urban is used frequently in the literature and in policy discussions, yet definitions are largely situational and case specific. They provide little basis for unified understanding of what constitutes peri-urban. Organization of Economic Co-operation and Development (OECD) (1979) therefore concludes that the term "peri-urban" cannot be easily defined or delimited through unambiguous criteria. It is a name given to the grey area which is neither entirely urban nor purely rural in the traditional sense; it is at most the partly urbanized rural area. Whatever definition may be given to it, it cannot eliminate some degree of arbitrariness.

The peri-urban areas have and continue to experience incessant push and pull tendencies from the cities and the rural areas due to their strategic locations, and multifunctional territorial nature (Ravetz, Fertner, and Nielsen, 2013).). According to Lawanson, Yadua, and Salako (2012) in their study of Lagos and Ibadan in Nigeria, the preference for the peri-urban areas for settlement and other commercial pursuits, is motivated by the fact that these fringes of cities have some of the relatively affordable rent in comparison to the main city and big towns.

Masanja (1999) identified two major driving forces for conversion and transformation of land use in the peri-urban peripheries. They include: demand for housing for the growing population and the deteriorating housing conditions and inadequate urban services. Webster (2002) however attribute the reason for conversion of land for urban development as being a result of higher economic gains from conversion and transformation to other land uses other than agriculture. With economic rationality of the land owners, they would opt for other activities with higher future earning returns on their land, against agriculture (Irwin and Geogeghan, 2001), in the end, subtly creating pressures on food security in the areas.

In general, peri –urban settlements are usually a reflection of the urban settlement. Urban population growth results to increased population densities within established urban areas as well as in the outward thrust of urban agglomeration, that is, peri-urban regions. It is therefore anticipated that the development of a peri-urban area is an inevitable consequence of urbanization and as cities in developing countries continue to grow, the peri-urban area moves outward in waves (DFID, 1998). This process is manifested primarily by an outward expansion of built-up areas and the conversion of prime agricultural lands for residential and industrial purposes (Brennan, 1999). As the cities expand, the main zone of direct impact is the peri-urban area.

Cities in Nigeria like other parts of the world are experiencing unprecedented rates of growth. According to the Nigeria National Economic Empowerment Development Strategy (NEEDS, 2004), *the rate of urban growth in Nigeria is one of the fastest in the world.* Since the emergence of ancient cities such as Benin, Kano and Zaria between the 14th and 17th century, there has been a steady evolution and multiplication of urban centres. The rate of multiplication however became greater from the 1960's with more urban centres emerging than before then. As at 1960 only four major administrative centres existed, these centres were Lagos, Ibadan, Enugu, and Kaduna. By 1967, the centres rose to 13, while it became 21 centres in 1987. The centres again rose to 30 administrative state headquarters in 1991.

Similarly administrative changes were undertaken at the local level resulting in the emergence of towns which are now headquarters of local government areas (Onokerhoraye and Omuta, 1994a).

In the 1996 state and local government creation, the number of state administrative centres increased to 36 while local; government headquarters increased to 774. These administrative centres have over the years attracted commercial and industrial activities which have in turn encouraged immigration from rural areas to them thereby leading to rapid urbanization. The 1950 estimated percentage of Nigeria's population living in the urban areas was 15%. This rose to 23.4% in 1975 and 35% in 1991. By the 2006 estimates, Nigeria has a population of 140 million. By this figure, approximately 60.7 million Nigerians are currently living in the urban areas. The rate of urbanization is 5.5% while the annual population growth is 3.0%. Using the 140 million estimates of 2006 and the rate of urbanization, it is believed that more than half of Nigerian population will be living in urban centres by the year 2020 (Oluwasola, 2007).

Rapid urbanizations have changed the urban landscape of most Nigerian cities. This rapid rate of urbanization according to Organization for Economic Cooperation and Development (1979) has significant impacts on urban growth and population increase. These impacts of economic growth and physical expansion of the urban area are not confined within urban boundaries; they reach into much wider areas surrounding urban centres, creating so-called urban fringe areas, or peri-urban areas. There have been concentration and congestion in inner cities and the opposite process of suburbanization and dispersal at the urban fringes, the peri-urban areas.

Onibokun, Olokesusi and Egunjobi (1987) and Onibokun and Kumuyi (1999) assert that various political and socio-economic factors have mainly been responsible for the rapid growth of urban population. The economic opportunities offered by cities are strong drivers for rural-urban migration. Many of these rural migrants find it difficult to fit themselves in the urban centres and therefore settle in the urban fringes (peri-urban areas). Pasquini and Maconachie (2005) also pointed out that the Nigerian structural adjustment policies of the 1980s forced many people to the peri-urban areas for agricultural purposes to supplement their meager income. Large numbers of urban residents, pushed out by high housing costs in the city, look for cheap accommodations in the peri-urban areas.

Peri-urban areas in developing countries pose many problems including unintensive use of land, low level of services and infrastructure, few job opportunities, uncoordinated development and high cost of providing services, lack of clear jurisdictions and weak planning control, etc. They manifest the deep seated problems that face third world cities and societies. Some of these causal factors are unsustainable urbanization and urban growth, poor economic policies and poor management of available resources, etc. Challenges of peri-urban areas in developing countries are similar in nature. Most of developing countries experience spontaneous development pattern rather than planned growth. Hence the challenge of peri-urban zones is development in informal way. Land development takes place without conforming to planning regulations. Due to high demand of land, marginal lands in low lying areas, hills and infrastructural setback are being filled up for development purpose, without considering any environmental impact. As corroborated by Onokerhoraye and Omuta (1994b), peri-urban area in Nigerian is characterized by incomplete range of penetration of urban utility services and uncoordinated zoning. The perception that the peri-urban area is no man's land accounts for environmental problems therein. Activities of land speculators who involve in indiscriminate subdivision of peri-urban land are also responsible for the environmental problems. Globally, peri-urban areas are often characterized by extremely

vibrant mix of land uses, not as a result of deliberate planning, but because unregulated development has taken place within the specific peri-urban area. Thus in a single street, commercial uses in form of stores, residential apartment, educational institutions, light or small scale industries and agricultural uses can all be found. All these land uses are also often associated with problems of safety, pollution (air and noise) and general poor quality of life.

These peri-urban areas, on the other hand offer many positive opportunities by absolving the overspill populations and jobs from the cities and therefore relieving them of serious problems of congestion, overcrowding and pollution. They also offer land for agriculture for food production for the urban dwellers and a means of living for many of the urban poor, cheap land for housing, industry among others.

Like many other settlements in Nigeria, settlements in Edo State are also fast urbanizing. The rapid growth in population and socio-economic activities of major towns in the area in recent years indicates this trend. In this regard, there has been an unprecedented transformation of many rural settlements into urban centres. This scenario is most amplified in Benin City which is now enclosed with notable peri-urban communities. This study intends to investigate the characteristics and the drivers of this peri-urban zone in the city using Ekiadolor Community as a case study.

MATERIALS AND METHODS

Research Site

The study area is Ekiadolor community in Benin City, Edo State, Nigeria. Benin City is a city in southern Nigeria, and capital of Edo State. It is located on the latitude 6^{o} 30N and 6^{o} 00E. The city lies in the Warm Humid Equatorial Region in the tropics with two dominant seasons, that is, the wet and dry season. The vegetation of the area falls within the rain forest belt. The predominant ethnic group is Bini which constitutes about 70% of the population. Other ethnic groups in this community include Igbo, Urhobo, Esan, Etsako, Ijaw, Isoko and Yoruba.

Ekiadolor community is about 18 km from Benin City. It is an ancient community. Prior to the establishment of the College of Education in the 1980s in the community, Ekiadolor could rather be described as a village. The establishment of the College of Education resulted into influx of people especially the staff of this College. Other ancillary workers especially traders and artisans also moved to this community. There was a general belief that the establishment of this College will herald rapid infrastructural development of the community. The high quality of life expected in this community led to the massive activities of land speculators and their indiscriminate land subdivision. At the inception of this College, house rent was rather too low in Ekiadolor. Thus, urban dwellers in Benin City who had been facing acute shortage of housing now found respite in Ekiadolor. This increase in the population of the community is further enhanced by its strategic location along the Benin – Ore Expressway. Thus, residents of Ekiadolor could easily commune between the city and the community with ease. This expressway also links Benin with other parts of Nigeria and also serves as connecting distributaries to major towns and roads that converge along its axis.

The Database

Ekiadolor is a community with a population of 5,593. It comprises of 32 streets with 1,350 buildings. Using the total number of buildings as sample frame and an assumption of one household per building, a sample size of 30% amounting to 393 buildings was used for this study. Based on this assumption, a total number of 393 questionnaires were distributed. Subsequently, random sampling approach was employed to select the 1^{st} building, and every 3^{rd} building was systematically selected in that order on each street from which any available

head of household was interviewed. This appears plausible since there are traits of homogeneity in habitability in this study area. For the purpose of data analysis, descriptive statistics including tables, charts, frequencies and means were utilized. Pictures were also used to depict the nature of the environment.

RESULTS AND DISCUSSION

Findings revealed that the working class group (31 – 50 years) constitutes the dominant (67.3%) age group in the study area. This group is the active force of any settlement and will have positive effect on the economy of the residents. Among these two groups are those that are still in the civil service and self-employed (Table 1). This observation reinforces the fact that the inhabitants of Ekiadolor community are possibly workers who were originally living in Benin City.

About 30% of the inhabitants in the area are illiterates. 23.4% have only primary school leaving certificate, while 20% attempted secondary school and 25.3% have tertiary education (Table 1). The implication of the low level of education of the people in the area undermined the importance of healthy environment as significant proportion of the inhabitants live below the minimum environmental standards stipulated in the planning code of the country.

A greater percentage, that is 46.4% of the respondents are within the income range of N151,000 – N300,000. This implies that they receive the stipulated minimum wage which is N18,000 per month. While only 15.4% receives above the minimum range and 38.2% receives below (Table 1). This shows a high prevalence of poverty in the area. This observation attests to the fact that the immigrants from Benin City to this community might be relatively low income group who are in search of low rents.

It was observed that 47.1% of the respondents are civil servants. Some are engaged in the College of Education in the community while a greater percentage are those who work in the city centre but have either built or rent an apartment in Ekiadolor in a bid to move away from the crowd in the city centre and its associated problems. This is closely followed by traders (31.2%). These traders are found within and outside the school premises with their various kiosks, shops used for various businesses like canteen, business centres, phone booths etc. Other occupations are farming (12.7%) and artisanship (8%) (Table1). The community still has pockets of fairly large vacant land that is yet to be developed.

The implication of the foregoing is that the establishment of the College of Education was a major driver for the transformation of the community to peri-urban settlement. In addition, one could infer that the relatively low rents and cost of land in the community must have informed other civil servants especially from Benin to build their own houses or rent apartments for living in this community. The data further revealed that the traditional occupation of this community is gradually waning as less than 12% are now into farming. The observed large pockets of vacant land in the community attests to weakness of physical planning instruments as buildings are arranged in haphazard manner.

Ekiadolor is essentially a Bini community. However, the study observed that the community is inhabited by different tribes. As informed by the Edionwere (the community head), apart from the Binis, others tribes in the community are Yorubas, Urhobos, Isokos, Ibos, Calabars, Kwales. Only 56% of the inhabitants are Binis. It could be inferred that a significant proportion of other tribes in this community might have been the College of Education workers and migrants from Benin City and other communities who have come to seek greener pasture and more comfortable accommodation.

Employment opportunities offered by the College of Education which also triggered trading opportunities among the inhabitants account largely (65.3%) for decision to reside in Ekiadolor (Table 1). Another significant reason (22.9%) is the prevailing low cost of land and rent in the community. Other identified reasons include safety (1.8%) and nativity (6.3%) (Table 1). Thus, it could be concluded that the most important drivers for the transformation of Ekiadolor into a peri-urban community are the establishment of the College of Education and the accompanying employment opportunities, low cost of land and low housing rent.

Table 1: Socio-Economic Characteristics

Variable		Frequency	Percent
Age Bracket			
	Below 20	2	0.5
	20 – 30	46	11.9

	Below N50,000	9	2.3
	N51,000- N150,000	138	35.9
	N151,000- N300,000	178	46.4
	N301,000-N500,000	42	11.0
	N500,000 +	17	4.4

A greater percentage of the buildings sampled are used for residential purpose. Most of the buildings (94.8%) sampled in the study area are bungalows (Table 2). While some are flats which are preferred by private owners who reside therein with their families, others are tenement buildings which are mostly preferred by developers who put the structures on rent because of their high rent yield. The pattern of building revealed in Ekiadolor is the informal type. It is obvious from these findings that Ekiadolor is essentially a residential corridor for the College of Education workers and the civil servants who commune daily between Benin City and the community.

The condition of housing in the study area is very poor due to the low quality of materials used for their construction, inadequate technology and poor planning standards of the building components. Most houses in the study area have relatively low habitability, as they were not properly maintained by their users who are mostly tenants. The area lacks any

evidence of physical planning and development control as about 80% of the landlords do not have any building permit for their buildings (Table 2). The buildings are scattered and do not conform to any building standard. They lack accesses. Setbacks and airspaces between buildings are rarely observed. These parameters are major determinants of the quality of an environment (Mabogunje, 1980). Thus, the quality of the environment in Ekiadolor community could be described as very low.

About 13% of the buildings are mud houses, 44.79% made with concrete, 26.83% plastered, and only 15.36% plastered and painted (Table 2). Roofing materials of the buildings in the community are 89.9% of zinc coated corrugated iron sheets types, only about 4.2% are made of PVC (Table 2). This depicts the different stages and years of development in the area.

In the assessment of general condition of the environment, about 50% of the respondents agreed that their environment is unkempt and overgrown with grasses. This was followed by the 28.5% who affirmed that the environment was dirty. Only 18.3% considered their environment as clean while 4.1% assessed theirs to be flooded (Table 2). Transect walks around the community further confirms this response.

Ekiadolor community has no approved layout. This implies that the community is unplanned while physical planning standards and regulations are compromised. This is a clear manifestation of lack of government presence in this community. Thus, buildings are indiscriminately built on drains, setback etc. In addition, there is no distinct road network pattern. Access to most buildings (51.7%) is by footpath while 48.3% has distinct access road. However, only 20.3% of the respondents access their buildings through tarred road (Table 2). This observation indicates that the Government failed to respond to the physical planning needs of this community irrespective of the envisaged increase in population following the development of the College of Education.

Most of the roads in the community are untarred (Table 2). However, due to constant use and lack of drainage the road is in a dilapidated state with potholes and flooded during the rainy seasons. There is no evidence of government intervention in the area of road construction and maintenance in the community.

Table 2: Building characteristics

Variables	Frequency	Percent
Building Type		
Bungalow	364	94.8
Storey Building	12	3.13

Tarred road	78	20.3
Untarred road	108	28.0

Most households (65.7%) in this community depend on pit latrine (Table 3 and Fig. 1). As confirmed by some respondents, age of buildings, ignorance, lack of proper education and awareness on health and hygienic issues are largely responsible for this option. Again, latrines are easier and cheaper to construct. Only 10.4% used modern day water closet, while 23.9% depend on open defecation (Table 3). This category of respondents makes use plastic bags which are subsequently thrown into the nearby bush, dunghills, backyards, stream and drainage channels. Thus, the community appears aesthetically unpleasing as it is polluted with plastic bags and human wastes making it vulnerable to diseases such as diarrhea, typhoid and cholera. This scenario indicates the high level of prevailing poverty in Ekiadolor.

Table 3: Household Facilities

Facility		Frequency	Percent
Toilet Facility			
	Pit latrine	198	65.7
	Water Closet	78	10.4
	None	108	23.9

	Others	38	9.5
Source of Energy			
	Electricity (PHCN)	355	92.5
	Generator	7	1.7
	None (Kerosene Lamp)	22	5.8
	Natural Gas	-	-

Figure 1: A typical latrine in the community

A large proportion of the buildings examined have bathrooms and kitchen, only that they are substandard, inadequate or inconveniently located. Many of the bathrooms are just small enclosures, some of which are made of materials like bamboo, rusted iron sheets, or planks and located at the backyard. The use of firewood and charcoal for cooking is common; hence many of the buildings have their kitchens located at the backyard, residents of such areas cook food in the open rendering food items and utensils vulnerable to disease causing pathogens. Only the few ones that used kerosene stoves cook at the passage or right inside their rooms.

Water supply is not a serious challenge in the community. Most respondents revealed that adequate provision is made for supply of water as it has about twenty six (26) boreholes constructed in different years and located at various streets within the community among

which twenty (20) are still functional. These bore holes were constructed by individuals, past governors and Federal government.

The state of waste disposal in the area is generally poor. There is no controlled method of waste disposal in the community (Table 3). Over 40% dispose their refuse in open spaces (Fig. 2); some through burning within residential environment (24.7%) thereby causing air pollution while others dispose theirs at road sides and drainages (22.5%).This hampers the free flow of run-off and constitutes comfortable breeding grounds for flies, mosquitoes other health-infected animals that could contribute to the spreading of diseases. In the rainy season flooding is also prominent in the area as a result of blocked drains.

Figure 2: Indiscriminate dumping of refuse

The main source of electricity supply to the area is through the Power Holding Company of Nigeria (PHCN), which accounts for 92.5% of the sampled households. About 1.7% used generating plant as supplements (Table 3). This is quite impressive as respondents were of the opinion that supply of electricity in the community is constant except for a situation where a fault is identified, then such area affected may be put in total darkness for weeks or sometimes months. To ensure adequate supply of electricity, the community is furnished with three (3) transformers which were facilitated by community members through the Ekiadolor Community Development Association. This association has also helped in other areas such as road maintenance, supplies of instruction materials to schools and security among others.

Other facilities investigated in this category include school, health and security facilities. Educational facilities available are limited in number. There are three (3) primary schools, three (3) secondary schools (one owned by the Government and two private owned) and a higher institution located in the community. The schools are poorly funded, managed, lack good structures, learning facilities and conducive environment (Figure 3). The students also do not have access to water and toilet facility. They make use of open field for defecation.

Figure 3: The existing schools is the community are in a state of disrepair

The community has three hospitals/ health centres. Two are owned by the government (Health Management Board and Primary Health care) while the third is owned by an

individual. The surroundings of the Government health centres are unkempt as they are engulfed by weeds. A large number of the respondents complained of having the facilities either farther away from their dwellings or completely absent within their neighbourhoods. A large proportion of the inhabitants confirmed paucity of health facilities in this community (Figure 4). No doubt, in terms of infrastructure, there is a palpable neglect of Ekiadolor community by the government.

Figure 4: The Primary Health Centre in the community appears unused as it is overgrown with weeds

CONCLUSION

This study has investigated the characteristics and the drivers of a typical peri-urban zone in Benin City, Nigeria using Ekiadolor Community as a case study. It was observed that the establishment of the College of Education and the accompanying employment opportunities was the major driver for the transformation of Ekiadolor to a peri-urban settlement. In addition, the relatively low housing rents and low cost of land in the community must have informed civil servants from Benin City to build their own houses or rent apartments for living in this community. Thus, Ekiadolor is essentially a residential corridor for the College of Education workers and the civil servants who commune daily between Benin City and the community.It was further observed that the traditional occupation of Ekialdolor community which is farming has waned over the years as most inhabitants are now civil servants.

There was a clear evidence of poverty in Ekiadolor as manifested in all the indexes of quality of life including educational facilities, health facilities, water and sanitation facilities among others. In general, evidence of government intervention in the development process of this community is scanty as manifested in the poor quality of technical and social infrastructure. This situation is further amplified by the weak applications of appropriate physical planning standards to regulate land use thereby resulting into haphazard development of this community.

It could be concluded from this study that the establishment of institutions such as universities, colleges of education and research institutes among others outside the immediate precinct of cities could trigger peri – urbanization. Such facilities have the potential of transforming their communities of abode to growth centres. Once this is envisaged, adequate provision should be made to meet the challenges that could be posed by such development.

In a bid to mitigate the anticipated effect of peri – urbanization especially with respect to checking the haphazard growth and expansion of the peri – urban community under focus and other communities in the developing countries and ensuring that developers adhere to planning standards for development, the creation of a specialized unit to plan and coordinate such settlements is advocated. This specialized unit should focus on the design and implementation of some planning strategies such as master planning, land use planning, development control that would curtail haphazard growth and ensure that developers adhere

to planning standards for development. The sub-unit handling development control should be strengthened in terms of finance and manpower to be able to efficiently discharge its duties. Other issues to be addressed by this unit include upgrading programme through rehabilitation/renovation approach as well as provision of urban basic services. Specifically, this unit should give adequate attention to the provision of necessary facilities that would enhance habitability such as the provision of adequate supply of water and sanitation.

The cooperation of government and community is essential to achieving the goals of this specialized unit. The government should be prepared to facilitate development in peri – urban communities while community members should be encouraged to be willing to contribute towards community development. Specifically, there should be a synergy between the peri – urban communities and the main cities through progressive integration. This is desirable since these peri urban communities are the agents that usually absorb the pressure and dynamics of population and land use changes in cities.

ABSTRACT

This study made use of mixed-method approach of Survey Research Design (SRD) to explore the socio-economic impact of urban sprawl on pattern of land use changes in Akure and its environs. The SRD methods involved structured questionnaire, observation and interview on selected households. The study area is organized into two areas – Akure Urban and Akure Peripheries. The average households in Akure Urban were estimated at 95,232 while those at the Peripheries (adjoining communities) were 14,794; totaling 110,026 households. Out of this, a sample of 1% was systematically selected for questionnaire interview in a succession of 10th buildings on one respondent per building. Findings revealed unguided expansion in the growth of the city and undue encroachment into green areas at the suburbs. There were incompatible conversions in land uses which were observed to be feedbacks from socio-economic status of residents. The study suggests effective zoning strategy to mitigate the unguided nature of the expansion. Adequate monitoring by the Development Control Department and other stakeholders in urban planning is also recommended to check the incompatible land use changes in the area. More importantly, the age-long master plan of Akure is noted for review while a more comprehensive regional plan is advocated to guide the development of the entire region.

Keywords: Urban Sprawl, Land-use Changes, SRD, Zoning, Akure

INTRODUCTION

The concept of urban sprawl has been described by different scholars in different ways. While some interpreted it to mean a fallout from increasing urban densities, land use and racial segregation as well as population growth, others conceptualized it as unplanned expansion of urban areas which is characterized by low density physical development and the non-existence of basic municipal infrastructure usually beyond urban fringes (Poahn, 2000; Glaeser and Kahn, 2004). Some early urban development researchers like Alonso (1964), Mills (1967) and Muth (1969) attributed the emergence of sprawl to *'mono-centric city model'*. This model suggests that spatial structure of urban areas results from the tradeoff between the rent of land and cost of commuting. The low cost-center coupled with relatively low rent at the peripheries of cities in many developing countries is facilitating the growth of peri-urban areas. Other factors such as the desire of urban dwellers to flee poor governance, housing congestion, lack of planning and inadequate social amenities occasioned by high pressure at the city center also contribute to city sprawling.

Land use change is a product of urbanization, which has been recognized as a global problem present in most countries of the world. Balogun et al (2011) affirmed that urban populations in developing countries grew by 40% between 1900 and 1975. This submission gives further alert that the trend will continue adding approximately 2 billion people to the urban population of the presently less-developed nations for the next 30 years. Arnfield (2003) argued that the world is becoming increasingly urbanized with 45% of the population already living in the urban areas as at the year 2000, with a projection that half of the world will live in urban areas by 2007. It was earlier estimated by the United Nation Population Fund (1999) that by the year 2025, 60% of the world's population will live in cities. According to UN-Habitat (2013), cited in Oduwaye (2015), it is expected from the advent of the urban

Owoeye, J. O. & Fasakin, J. O. (2016). Socio-Economic Implication Of Urban Sprawl on Changing Land Use Pattern in Akure, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1649-1657

millennium that 70% of world population will be living in urban areas by the year 2050. This trend shows the inevitability of cities urbanization.

Akure is not in any way going contrary to these submissions as the population has been more than tripled of what it used to be before it became the administrative headquarters of the state and local governments on February 3rd, 1976. For example, the population was just 71,106 in 1963. But with the influx of public servants into the town due to the change in its nomenclature, the population rose to 239,124 and 360,268 by the 1991 and 2006 national population censuses respectively with a projection of 476,159 to year 2014 (on 3.18 annual growth rate) when this study was carried out. The trust of this paper, therefore, is to:

i. investigate the socio-economic implication of urban sprawl on pattern of land use changes in Akure; and
ii. examine the impacts on adjoining communities with a view of proffering measures to mitigate the effects.

LITERATURE PERSPECTIVE

Land is vital to every development. It is an essential factor in production sector of a classical economy, next to labour and capital. In agricultural sector, for example, land is seen as the backbone as it offers substantial benefits that are crucial to the carrying out of its various activities. Observation from literatures shows that land use change is an essential issue necessary for economic development and social progress. Wu and Irwin (2008) believe land use change does not go without costs and consequences. As highlighted in his work, and Owoeye (2015), the costs essentially focus on reduction in the amount of land available for food and timber production as most of the agricultural lands are converted to urban uses. Urban development encroached upon rural areas often make such communities to lose their social identities through urban influence and interactions. Sometimes, it may bring serious segregation and disparity in income and economic activities among communities through excessive land use control emanating from city policies. This may hinder the efficiency of market forces in favour of rural dwellers. Land use regulations aimed at curbing land development often time raises housing prices, thereby making housing unaffordable to low- and middle-income earners. There are other challenges that land use change may pose to farmers on the urban fringes, such as destruction of farm products, especially if the lands are acquired before the maturation of the crops. This may generate conflict and setback for the concerned farmers. Wu and Irwin (2008) argued that competition for labour from nonagricultural sectors has the possibility of increasing farmers' overhead costs as labour become scarce and expensive to hire. Thus, urbanization causes lack of confidence in the stability and long-run profitability of farming to farmers (Lopez, Adelaja and Andrew, 1988). In view of this, the local agricultural economy may collapse when the total amount of farmland falls below a critical level as all supporting sectors begin to disappear.

As urban population continue to increase and more people desire privacy and green areas, so development continue to creep beyond city limit. Consequently, some other negative implications are experienced, such as increased community costs for maintaining roads, sewers, and other services needed when businesses and residences are spread out (Luther, 2005; Mashour and McDonell, 2005). Part of the effects also includes increased need for automobiles, traffic and noise pollutions. Researches have shown that providing public infrastructure and services for sprawling and low density subdivisions costs significantly more than providing for the same number of houses in urban areas (1000 Friends of Florida, 2005; Wu and Irwin 2008).

In spite all the negative implications, urbanization still presents important opportunities to farmers and rural dwellers. For example, the emergence of new customer based provides people in the rural areas great privilege of selling their farm products at higher prices and make huge profits. As observed in Lopez, et al (1988), vegetable producers tend to receive higher prices in urbanized areas. In like manner, Wu and Irwin (2008) acknowledged that the explosion of nurseries, vegetable farms, vineyards and other high-value crop industries in many sub-urban areas illustrates how quickly agricultural economies can evolve through urbanization. According to them, many farmers have shown remarkable adaptability in adjusting their enterprises to take advantage of new economic opportunities at the urban fringes. They farm more intensively in areas with high population density (Lockeretz, 1988; Wu, 2006). More than half the value of total farm production in United States is derived from counties facing urbanization pressure (Larson, Findeis, and Smith 2001).

Besides, it has been argued that suburbanization brings urban and rural people together. Most lands, watersheds and rock outcrops in rural places are utilized for urban uses, which in most cases, generate income for the rural owners and as well bring urban life closer to them. In view of this, Wu and Irwin (2008) opined that the urbanites and agencies have legitimate concerns about the use and condition of rural natural resources, just as rural populations have legitimate concerns about urban–based pressures on the natural world. This has important socio-economic implications on the natural environment, which may have profound impact on the society in future.

MATERIALS AND METHODS

The Research Locale

The study centers on Akure city and its immediate environments. Akure is a fast growing city in the South-western Nigeria; it became the capital of Ondo State on February 3rd, 1976. It is located between Latitudes 7^0 15^1 and 7^0 17^1 North of the Equator and between Longitudes 5^0 14^1 and 5^0 15^1 East of the Greenwich Meridian. It is about 204 km east of Ibadan, capital of Oyo state; 168 km west of Benin City, capital of Edo state; 311 km north-east of Lagos; and 323 km south-west of Abuja, the Federal Capital Territory of Nigeria. Akure town spreads over an area of about 15,500 km^2 in about 370m above the sea level. Its population figure by the National Population Census (NPC, 1963) was just 71,106.

The Database

Data collection for this study was essentially through mixed-method approach involving structured questionnaires, interview and personal observation. Other sources include

government ministries and establishments for historical milieu of the area as well as maps and population data used for the study. Internet facilities were equally explored for relevant information. The study area was disaggregated into three zones namely: the urban core, the transition zone and residential estates vis-à-vis the urban peripheries. The total population projected for the three zones is estimated at 476,159 in 2014 which was sub-divided into 95,232 households. The estimated household population for the eight adjoining settlements was 14,794. Altogether, 110,026 households were estimated in the two areas. From this, a 1% sample size was taken from each area for questionnaire survey. These were randomly administered in a succession of 10^{th} buildings to a household-head per building. Data collected were analyzed using descriptive statistics, chi square test, stepwise multiple regression and ANOVA statistical test.

RESEARCH FINDINGS AND DISCUSSION

A total number of 818 questionnaires were retrieved in usable form out of 952 that were distributed in Akure urban and 129 out of 143 disseminated in the adjoining settlements. Socio-economic variables investigated include length of stay, age, sex, marital status, educational level, occupation, employment status, and rent per room, rent per flat, income and household size of sampled respondents to unravel the socio-economic implication of sprawling incidence on pattern of land use in the study area.

Respondents' Length of Stay in the Study Area (LENSTAY)

As revealed in literature, respondents' length of stay was determined as a viable factor accounted for possible land use changes in a given area (Wu and Irwin 2008). A descriptive statistics was used in this research to explore this fact as shown in Table 1. From the table, over 50.0% of the respondents live in the core area of the city (i.e. zone 1) for more than 30 years. Majority of these people are indigenes who lived in family houses together with their extended family members. Personal interview conducted revealed that original owners of most of the houses at the city core are dead. They are only inhabited by children who, in most cases have altered the original uses, most of which were done indiscriminately without proper planning guide.

Table 1: Respondents' Length of Stay (LENSTAY) in the Study Area

	Zone 1		Zone 2		Zone 3		Total	
Length of Stay	**Freq.**	**%**	**Freq.**	**%**	**Freq.**	**%**	**Freq.**	**%**
Less than 1 year	22	7.1	23	7.6	22	10.5	67	8.19
1-10 years	57	18.5	132	43.9	109	52.2	298	36.43
11-20 years	39	12.7	70	23.3	58	27.8	167	20.42
21-30 years	31	10.1	39	13.0	11	5.3	81	9.9
31-40 years	102	33.1	23	7.6	6	2.9	131	16.01
Above 40 years	57	18.5	14	4.7	3	1.5	74	9.05
Total	**308**	**100.0**	**301**	**100.0**	**209**	**100.0**	**818**	**100.0**

Some of the residential buildings are sold and been converted to commercial, educational or mixed used of both residential and commercial purposes. This is common mostly along Adesida, Arakale and other major routes in the city core where most of the residential buildings are shared with various land uses, especially for commercial purposes. Some of these changes are seriously incompatible. For example, a residential building that was pull down and changed to petrol filling station within a residential neighbourhood is considered incompatible. In the other two zones; majority of sampled respondents (51.5% and 62.7%) resides in transition zone and residential estates/urban peripheries respectively in less than 10 years. This implies that most of the people are either new occupants or residents of newly built houses. In most of these buildings, the occupants do not have direct access to the right of changing the original purpose of the building nor have such intension since they are recent

buildings, except in few cases where some may have small shops or kiosks in the frontage of their rented apartments.

Implication of Socio-economic Variables on Land Use Changes in Akure

The result of Chi square (χ^2) test employed to examine the implication is shown in Table 2. In all, eleven socio-economic variables were investigated against the original purpose of land acquisition (PURAQ). The variables include age of respondents (AGE) and sex (SEX) distributions, marital status (MARSTAT), educational level (EDULEV), occupation of respondents (OCCUPAT), employment status (EMPSTAT), religion (RELIGION), rent per room (R_ROOM) and rent per flat (R_FLAT), annual income distribution (INCOME) and household size (HHDSIZE) of respondents.

Table 2: Chi square (χ^2) Result of Socio-economic Implication on Land Use Changes

Association	χ^2 Calculated	χ^2 Tabulated	Df	Asymp. Sig.	Decision
PURAQ vs. AGE	27.367	26.30	16	0.038	S
PURAQ vs. SEX	4.593	9.49	4	0.332	NS
PURAQ vs. MARSTAT	12.398	21.03	12	0.414	NS
PURAQ vs. EDULEV	37.201	26.30	16	0.002	S
PURAQ vs. OCCUPAT	43.762	36.42	24	0.008	S
PURAQ vs. EMPSTAT	48.945	26.30	16	0.000	S
PURAQ vs. RELGION	7.771	15.51	8	0.456	NS
PURAQ vs. R_ROOM	18.902	18.51	8	0.015	S
PURAQ vs. R_FLAT	16.973	12.59	6	0.009	S
PURAQ vs. INCOME	20.673	21.03	12	0.015	S
PURAQ vs. HHDSIZE	23.501	21.03	12	0.024	S

***S** = Significant **NS** = Not Significant at 0.05 alpha levels.*
***Grouping Variable**: PURAQ*

From the table, three of the variables examined (SEX, MARSTAT and RELGION) are found not significantly related with PURAQ at 0.05 levels. Therefore, they were excluded in further analysis carried out using stepwise multiple linear regression models. The summary of the regression models conducted to ascertain the level of the implication is shown in Table 3.

Table 3: Regression Summary on Influence of predictor variables on land use changes in Akure

Model	R	R^2	Adjusted R^2	Std. Error of the Estimate	Change Statistics				
					R^2 Change	F Change	df1	df2	Sig. F Change
1	.605[a]	.393	.356	.533	.393	3.511	8	316	.001

***Predictors:** (Constant), HHDSIZE, EMPSTAT, INCOME, R_ROOM, EDULEV, R_FLAT, AGE, OCCUPAT.*
***Dependent Variable:** Original Purpose of Land Acquisition (PURAQ)*

The multiple linear regression of R = 0.605 show a positive relationships between socio-economic variables examined and the original purpose of land acquisition (PURAQ) at 0.01 significant level. Thus, the general effect of these variables in predicting the changes in PURAQ variance is given by the coefficient of determination of R^2 = 0.393. This simply implies that 39.3% of possible changes in the original purpose of land acquisition (PURAQ) in the study area are caused by the accumulation effect of the eight socio-economic variables found significantly related with original purpose of land acquisition in the study area.

The result of two-tailed ANOVA test conducted to examine the overall significance of the regression parameters in validating the hypothesis of the study shows that the calculated F-change value of 3.511 is greater than the t-test value of 2.31 at 0.05 significant levels. Therefore, the null hypothesis that says 'Socio-economic variables have no significant implication on land use changes in Akure' is rejected. This opinion agrees with the view of Babawale (2013) and Olamiju (2014) who affirmed that 1.3 billion people who live in abject poverty around the globe are 'handicap' of making meaningful impact on land use changes.

This is because they are always at disadvantage and socio-economically incapacitated. They are always limited by the level of their income to actively engage in such activities related to land uses. It is therefore believed that as level of income and other socio-economic parameters improve, so is the possibility for residents gaining more potential to invest in land use activities in various dimensions.

Impact of Akure Urban Expansion on Adjoining Communities

At the urban fringes, the impact of the sprawl was examined on eight adjoining communities randomly selected at about 5-10km commuting radius round the city as shown in Figure 3. The impact was investigated using descriptive statistics as illustrated in Table 4, Figures 4 and 5. As shown in the table, over 95% of sampled respondents recognize urban impact on their communities while less than 2% could not perceive any impact. Various problems emanated from the expansion as observed by the respondents ranges from lack of labour for farm work (as identified by 62% of the sampled respondents) to conversion of rural lands to urban land uses (24.0%). It also includes congestion on few available facilities in the communities (7.0%) as well as incessant crimes in the adjoining communities (5.4%).

Table 4: Impact of Urban Expansion on LUC in Adjoining Settlements

Variables	Frequency	Percentage
Notice of Influence of Expansion		
- Yes	126	97.7
- No	3	2.3
Total	**129**	**100.0**
Problem Emanated from the Expansion		
- Incessant Crime	7	5.4
- Conversion of lands to urban land uses	31	24.0
- Lack of labour for farm work	80	62.0
- Congestion on few available facilities	9	7.0
- Others	2	1.6
Total	**129**	**100.0**
Accessibility to Urban Services		
- Roads	45	34.9
- Electricity	51	39.5
- Water supply	4	3.1
- Schools	18	14.0
- Clear Communication Network	11	8.5
Total	**129**	**100.0**

The major areas of influence as shown in Figure 4 centres on increase in level of civilization (37.2%), followed by high cost of living (25.6%), increased in housing demand (20.2%) as well as provision of urban facilities (16.3%).

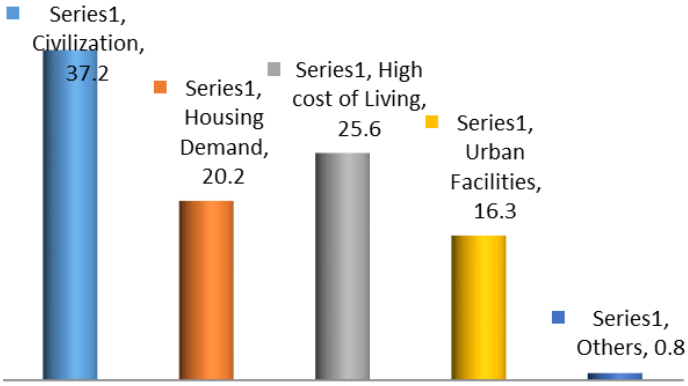

Figure 4: Area of Influence of Urban Expansion on the Adjoining Settlements

The level of accessibility to urban services in the adjoining settlements was equally examined to ascertain the availability of essential infrastructural services in them. As shown in Figure

5; electricity has the highest level of accessibility in all the eight selected settlements as indicated by 39% of the sampled respondents. This was closely followed by roads (35%), and then schools (14%) as well as clear communication network (9%). Only 3% has accessibility to water supply, essentially in places like Oba-ile and Ilara-mokin.

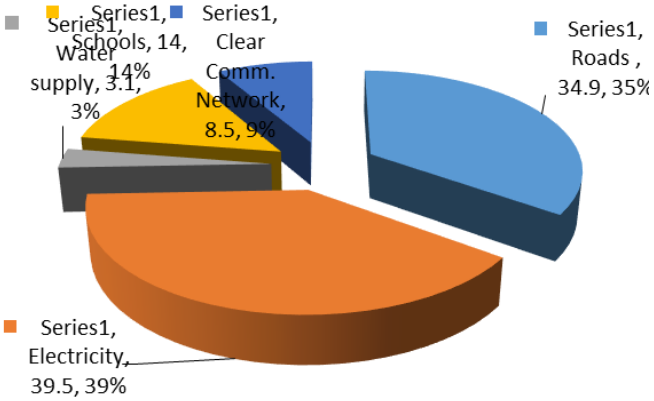

Figure 5: Accessibility to Urban Services in the Adjoining Settlements

In most of these settlements, house rent increased continously on regular basis as well as land prices due to urban expansion emenating from the city centre. This has served as advantage and opportunity for land owners and landlords to increase thier levels of income as well.

RECOMMENDATIONS AND POLICY IMPLICATION

The growth experienced in the city in the last three decades has been alarming and worrisome; and the trend seems to be continuing. However, the choice is not whether or not to allow growth to continue but the major issue is to have working plan to control the growth with a view of mitigating the consequences. With population growth and interface development increasing rapidly in Akure, the study suggests effective zoning method of lands allocation to various urban services and projects meant for city development. This should be supported with adequate monitoring scheme by the Development Control Department. Also, the age-long master plan of the city should be subjected to review and efficient implementation to guide the development of the city in a sustainable manner.

The existing land use in the study area is more of residential with other complimentary urban components punctuating the whole area. Findings show that most of the buildings are aged and dilapidated. In some parts of the city, especially in the core area; most of the old buildings are being removed and changed over to new ones. However, in the course of changing some of the buildings, the uses are always at variance with compatibility standard. They rather constitute nuisance than complementing the planning and environmental standards. In this regard, it is recommended that adequate monitoring be made by Development Control Department and other stakeholders in urban management to ensure compliance to planning standard. This should start from plan approval stage to erection and completion of structures.

To reduce the level of encroachment into natural vegetation in the course of expansion, it is also being suggested that vertical expansion be encouraged in the form of story buildings, high scrappers, and the likes. It is believed that this will reduce the rate of land consumption and improve the structural quality as well as aesthetic value of the environment. In this regard; the concepts of Smart Growth, Compact City and Urban Growth Boundary operated in most cities in United States and Europe can as well be adopted in the study area to provide effective policy framework to check undue expansion and incompatible land uses.

The existing Master plan of Akure was produced in 1980 and thus-far has become inactive, old and superseded. Hence, it needs to be reviewed while a more comprehensive Regional plan to guide the spatial growth and development of the entire region is requested. These

plans are to be administered by a constituted board which will be responsible for the maintenance of orderly and aesthetic environment as well as the preparation and implementation of planning schemes in the region in conformity with the state plans. This will go a long way to assist in regulating land uses for sustainable development of the study area.

ABSTRACT

Petrol Retail Outlets (PROs), popularly called Petrol Stations, provide motorists with Premium Motor Spirit (PMS) or petrol, similar petroleum by-products, other automobile consumables and related services. This study investigated the impact of the existence of PROs on adjoining land-use in six (6) Local Government Areas (LGAs) of Osun State, Nigeria. The objectives were to identify the locations of PROs in the study LGAs, assess the condition of the identified PROs and obtain residents' assessment of the impact of proximal PROs on their environment. With the aid of multi-stage sampling technique, forty-two (42) PROs and three hundred and ten (310) residents around the PROs were selected to elicit data using an interview guide and close-ended multiple-choice questionnaire respectively. Among other findings, it was discovered that about half of the respondents in the study area felt that the PROs were at least "good". Furthermore, part of the study area had history of fuel spillage into underground water source for residential use while problems such as noise pollution and traffic congestion are aggravated at the period PMS scarcity. Strict compliance with physical planning standards by both the approving authority and the developer, suspension of approval of PROs in some communities and sensitization of PRO operators on crowd management (at the period of petrol scarcity) are some of the recommendations made to mitigate the impact of PROs on neighbouring communities. It is hoped that risk to man and the environment will be minimized by the implementation of recommendations.

Keywords: Environmental Impact, Petrol Retail Outlets, Planning Implication, Pollution, Traffic Congestion

INTRODUCTION

According to Mohanka *et al* (2008), man, like other living creatures, lives in, depends on and influences the environment. His awareness of his environment has grown considerably over time. On global level, they further affirmed that increasing population pressure, urban development, industrialization and ever growing technologies are creating newer demands on every facet of the environment. With the global population having exceeded the seven billion mark and half of which now live in cities, the pressure on the environment has never been greater (Coleman, 2011; UN-DESA, 2014).

Barthwal (2002) cited the often referenced Munn (1979) which defines Environmental Impact Assessment (EIA) as an activity designed to identify and predict the impacts on the bio-geophysical environment and on man's health and well-being of legislative proposal, policies, programmes and operational procedures, and to interpret and communicate information about the impacts. In modern times, private developments have come to be included in those items that must undergo impact assessment.

Petrol Pumps are often referred to as Retail Outlets (ROs), which are the major facilities for dispensing petrol to consumers for fuelling internal combustion engines (Hindustan Petroleum Corporation, 2014). They equally provide other petroleum products, goods and services that are useful for proper functioning of automobiles. As desirable and necessary as the PRO is, it has become an albatross, not in itself but due to lack of appropriate policies to

Emmanuel, A. A. & Adisa, A. O. (2016). Environmental Impact of Petrol Retail Outlets in Selected Local Government Areas of Osun State, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1658-1666

guide its development or poor implementation of such policies. Economic consideration by PRO operators without recourse to environmental implications has "fueled" proliferation of PROs particularly in Nigerian cities, thereby aggravating the situation. This calls for concern.

Most researchers in this context have focused on locational analysis of the distribution of PROs. For example, Ibikunle (1997) in his work on the locational efficiency of petrol filling stations in Osogbo analyzed the locational pattern of the petrol filling stations in the city relative to areas they serve. This was informed by the need for firms to conduct studies of market-area development and evolution in order to develop their customer tracking capacities. Similarly, public sector authorities also needed such studies to be able to scientifically formulate viable goals, objectives and targets in their urban planning activities. Alabi (2004) worked on "Assessing the Locational Pattern of Filling Stations in Saki Town, Nigeria". He stated that most petroleum product marketers in Nigeria see the sale of petroleum products in a filling station purely as a lucrative business venture, resulting in the daily upsurge of filling stations and their haphazard location at sites considered marketable while neglecting compatibility and suitability based on regulations and standards.

However, not much investigation has been conducted on the environmental implications of PROs particularly in the southern part of Nigeria. This is the focus of this paper. The residents' perception and observation have been relied on in this research to ascertain the impact of existing PROs in the study area on the health of residents and the environment. It is assumed that residents, to a reasonable degree, could inform on possible threats or otherwise to their health and the environment by their perception and observation.

LITERATURE REVIEW

Conceptual Issues

The built environment is a man-made surrounding that provides a setting for human activities ranging in scale from personal shelter and buildings to neighbourhoods and supporting facilities and infrastructure. It is a material, spatial and cultural product of human labour that combines physical and social elements; an artificial surrounding so extensive and cohesive that it functions as an organism in the consumption of resources, promoting physical activities and active living in the urban environment (Emmanuel and Ayo-Odifiri, 2013; Wikipedia, 2015). It is also viewed as "the human-made space in which people live, work and recreate on a day-to-day basis" (Roof & Oleru, 2008). Many built environments have existed long before the advent of cautious planning, the introduction of which has tremendously witnessed a paradigm shift in the organic system of settlements. It is important to note that the built environment exists within the larger natural environment and makes use of the elements of the natural environment to develop.

Environmentalism is the advocacy for the preservation, restoration or improvement of the natural environment; especially the movement to control pollution (Merriam-Webster, 2015). It is equally defined as concern about and action aimed at protecting the environment (Oxford, 2015). An environmentalist is an advocate of environmentalism. A major objective of environmentalism is to reduce, if not eliminate, the negative impact that the development of the built environment could have on the natural environment. Natural-Habits (2009) highlights the relationship between environmentalism and sustainable development. Undoubtedly there is a connection between environmentalism and sustainability though sustainability touches more than just the environment.

Sustainability encompasses environmentalism to a certain degree as it is one of the critical factors to ensure sustainability of natural resources through environmental conservation and preservation. Environmentalism is aimed at controlling pollution and protecting biodiversity

by focusing on balancing various natural systems by becoming more earth friendly. But sustainability, in contrast, represents the idea that human society should operate by utilizing industrial and biological processes that can be sustained indefinitely. It requires that the processes be cyclical rather than being linearly oriented. As a basic concept, by embracing three core aspects namely environment, economy and social equity, sustainability focuses on creating a better world without compromising the ability of future generations to meet their needs. In all, sustainability focuses on protecting the environment, increasing the livelihoods of local communities and developing social equity. It is a way of doing business in harmony with the environment, improving livelihoods in a fair and ethical way and driving community development.

To achieve sustainability, physical planning has the target of achieving a conducive, safe and healthy environment in the process of development and redevelopment. In an all-embracing stakeholders involvement (in the principle of participatory planning), citizens and land use agencies can decide that a proposed development is environmentally unsuitable for a specific location, or they can require changes to make a proposal more suitable. This makes the representation of local residents very vital in the decision making process for locating communal facilities. Such facilities include but are not limited to PROs or service stations. Also, the involvement of Environmental Impact Assessment is critical at this point to inform the decision makers of the likely impact of the proposed PRO on the neighbouring community. The impact envisaged is largely in the form of pollution. Pollution on the whole is caused principally by human activities, though it can also be a natural process. It is classed according to the receiving agents of air as emission, water as effluent and land as dumps and disposal (Ukpong, 1994). Mba (1996) identified the major sources of water pollution in Nigeria to include industrial plants, decomposed domestic waste, solid mineral mining activities and petroleum mining operations.

Petrol or Premium Motor Spirit (PMS) or Gasoline is a by-product of fractional distillation of crude-oil or petroleum. Fatunmbi (2004) says that humans have used crude-oil in one form or another since at least the biblical times. Crude oil is an exceedingly complex substance, composed of literally thousands of different kinds of organic molecules and may vary greatly in composition across the world, depending on the age of the oil, which consists mainly of hydrocarbons. Petrol is used in generating power in internal combusting engines of automobiles and machines that provide electricity for domestic and other uses. Retail outlets are the major facilities for dispensing petroleum products to consumers. These retail outlets are very common in cities along major roads and streets, at jetties and public watersides. A retail outlet is also expected to have a mechanical workshop. Petrol is usually dispensed from Underground Storage Tanks (USTs) through pumps or dispensers. USTs and mechanical workshops are major sources of pollution, which need to be contained and controlled. Some other forms of pollution are indirectly created by the activities of PROs.

METHODOLOGY

Based on data obtained from Osun State Ministry of Lands, Physical Planning and Urban Development (OSMLPP&UD), which was updated by the researchers and a projection of the residents' population figures provided by the Osun State Field Office of the National Population Commission (NPC), Table 1 was generated for this study.

Multi-stage sampling was employed to carry out this research. In the first stage, the three (3) senatorial districts in Osun State were taken as strata. Each senatorial district comprises ten (10) LGAs. In the second stage, two (2) of the LGAs in each senatorial district (representing 20%) were selected in a purposive manner due to the peculiar urban character they exhibit. These are Osogbo and Olorunda LGAs in Osun Central; Ilesa West and Ilesa East LGAs in

Osun East; and Ede North and Ede South LGAs in the Osun West forming the sample frame for the study. Osogbo and Olorunda LGAs are located in Osogbo town, Ilesa West and Ilesa East LGAs are located in Ilesa town while Ede North and Ede South LGAs are in Ede town. For the actual data gathering, 42 PROs (representing 25%) of the 168 PROs in the six (6) purposively selected LGAs mentioned above were randomly selected for investigation while 304 residents (representing 0.02%) of the 1,515,875 population of same LGAs were selected for questionnaire administration to investigate the impact of the PROs on their environment. However, an adjusted total value of 310 respondents was employed (out of necessity) as sample size (See Table 2).

Table 1: *Projected Population Distribution of Residents and PROs in the Study Area*

Senatorial Districts	Selected LGAs	Population of Residents	Population of PROs
Central	Osogbo	578,632	59
	Olorunda	226,920	38
West	Ilesa Eest	310,000	13
	Ilesa Wast	260,400	20
East	Ede North	63,870	25
	Ede South	76,035	13
	Total	**1,515,857**	**168**

Sources: *OSMLPP&UD, 2015; NPC (Osun State Field Office), 2015*

Table 2: *Determination of Sample Size for Questionnaire Administration*

Osun State Senatorial Districts	LGAs	Total PROs	25% of PROs (A)	0.02% of Population (B)	Population per PRO (B/A)	Adjusted Pop. for Questionnaire Administration
Central	1. Oshogbo 2. Olorunda	97	24	165	6.9 approx. 7	7X24 = 168
West	1. Ilesa East 2. Ilesa West	33	8	72	9	9x8 = 72
East	1. Ede North 2. Ede South	38	10	67	6.7 approx. 7	7X10 = 70
Total		**168**	**42**	**304**	**-**	**310**

The Directorate of Petroleum Resources (DPR, 2010) as cited in Adisa (2011) stipulates a minimum distance of 100 metres from PROs to public and residential buildings as physical planning criterion. But such standard depends on the number of petrol pumps, amount of fuel drawn from them, traffic intensity, structure of the surroundings, and weather condition. However, Blamah *et al* (2012) in their study on "Locational Impact Assessment of Gasoline Service Stations in Karu, Abuja, Nigeria" found that residential, commercial and public/semi public buildings within a distance of 150 metres to the investigated service stations were at risk of hazards that emanated from them. On this premise, a copy of the questionnaire was administered in each of the targeted buildings within 150 metres radius around all selected PROs.

Interview guide and close-ended multiple-choice questionnaire were used to obtain primary data from the PROs and the neighbouring residents respectively. These instruments were complemented by direct observation and use of digital camera. Trained field assistants were engaged to elicit the required data between 8am and 6pm in a specific week from Monday to Saturday. Some of the offices which were visited to obtain secondary data include the Osun State Ministry of Lands, Physical Planning and Urban Development (OSMLPP&UD), Osun State Capital Territory Development Authority, Osun State Waste Management Agency, Federal Ministry of Lands, Housing and Urban Development, and the Department of Petroleum Resources (DPR) of Nigerian National Petroleum Corporation (NNPC). Data were analysed and presented using descriptive statistics with the aid of computer-based Microsoft Excel 2007.

FINDINGS AND DISCUSSIONS

Relevant Socio-economic Characteristics

The monthly income of most residents around investigated PROs is concentrated within ₦20,000 – ₦50,000. This is the range for a total of 64% of the respondents as could be observed from Table 3. Furthermore, a total of 61% of same respondents are civil servants and traders. This implies that the bulk of these residents are either salary earners (from government ministries and parastatals) or traders whose monthly earnings or profit cluster around an average of ₦35,000. This agrees with the fact that the study area consists of major cities dominated by government offices and complementary trading activities to meet the need of the population. As observed, only few higher income earners live within the busy sections of the town with concentration of PROs. The rest would prefer to live in a more serene environment. In the occupational distribution, farmers, students and retirees are fewer in these areas due to preference for outskirts with sufficient and needed farmland and a serene environment.

***Table 3**: Income and Occupation of Respondents*

Monthly Income (₦)	**Frequency**	**Percentage**
10,000 or less	27	9
10,001 – 20,000	37	12
20,001 – 30,000	68	22
30,001 – 40,000	64	20
40,001 – 50,000	69	22
50,001 – 60,000	22	7

Assessment of the Condition of PROs

In this context, the condition of a PRO mainly refers to the amount of space on which the PRO is located, the functionality of fuel dispensers and likelihood of UST leakage. These, to a large extent, determine the enormity of negative impact on the neighbouring community. A total of 58% of respondents in Osogbo (the state capital) rated the existing PROs as being *at least* good while the least percentage (11%) viewed them as "very good" (Figure 1). But in Ede, a total of 39% of respondents felt the PROs were *at least* good while 50% of respondents in Ilesa were of the opinion that the PROs were *at least* good. The disparity in the views and assessment observed across the cities (coupled with the highest percentage in favour of Osogbo) is not unconnected with the status of Osogbo as the state capital with the highest concentration of PROs in the state and which is expected to have the biggest and finest PROs (Table 1). In general, a total of 52% of respondents in the study area felt that the PROs were *at least* "good" (Table 4). This is still close to the middle mark. Therefore, it could be inferred that about half of the PROs are in good condition while the other half are not.

***Table 4:** Overall Assessment of Condition of PROs*

	Very Good		**Good**		**Fair**		**Poor**		**Total**	
	Freq.	%	Freq.	%	Freq.	%	Freq.	%	Freq.	%
Response Across the Study Area	44	14	117	38	97	31	52	17	310	100

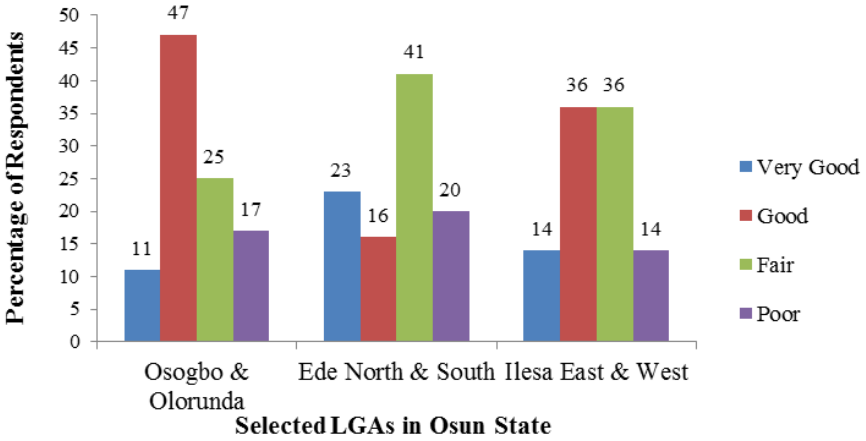

Figure 1: Assessment of Condition of PROs

Perceived Problems Caused by PROs

Various problems were identified by respondents. The least of such problems were notable health problems (such as nausea and respiratory problems), petty crime and automobile accidents. Traffic congestion and different kinds of pollution were identified as dominant problems (Table 5). It is difficult to conclude on which of the various types of pollution is most prominent across the study as they are interrelated in one way or the other. The indications for leakages are connected to problems of air and water pollution since they result in these forms of pollution. It was reported that such leakages occur when tankers come to supply petroleum products to the PROs coupled with leakages from USTs. This has resulted in noticeable pollution of wells which supply water for domestic consumption in the area.

It was equally reported that only 19% of the PROs carry out regular leakage and pressure tests on their station while the rest either never did or only seldom perform such tests. The indication for traffic congestion reveals a problem in itself but is equally related to noise pollution (in form of verbal altercations) caused by customers trying to purchase petrol (and sometimes kerosene). It is also a precursor to certain automobile accidents noticeable in the vicinity of some PROs in the study area. The mention of petty crime brings another dimension to security issues in connection with the presence of PROs; that which is different from the findings of Faro (op. cit) which indicated that lighting (in the night) and provision of security personnel by PROs provide a measure of security to neighbouring residential community. However, pick-pocketing, particularly during fuel scarcity cannot be ruled out. Some of the problems highlighted above were also discovered by Faro (op.cit).

Table 5: *Frequencies for Perceived Problems Caused by PROs*

LGAs	Traffic Congestion	Leakages	Air Pollution	Water Pollution	Noise Pollution	Petty Crime	Diseases	Auto Accident
Osogbo & Olorunda	34	37	22	17	32	13	4	10
Ilesa East & West	20	18	9	8	14	6	2	5
Ede North & South	18	12	6	2	16	3	0	2
Total	**72**	**67**	**37**	**27**	**62**	**22**	**6**	**17**

Perceived Problems during Fuel Scarcity

Dominant problems observed by respondents during petrol scarcity periods are traffic congestion, noise pollution and air pollution (Figure 2). This agrees with earlier indications. In the case of traffic congestion, major obstruction to traffic is caused by commuters who

park along the road for hours in anticipation of PMS supply to particular PROs and even during sales in such PROs. On single carriage roads, this problem is even more pronounced. Furthermore, as pointed out earlier, the noise pollution is related to the traffic generation and the presence of several customers at the PROs at this period while the odour from continuous dispense of petrol constitutes the observed air pollution. The slight indication for water pollution does not reduce its importance. However, the situation is not really worse than the normal times since any extra spill is mostly evaporated and if the condition of the USTs have not worsened.

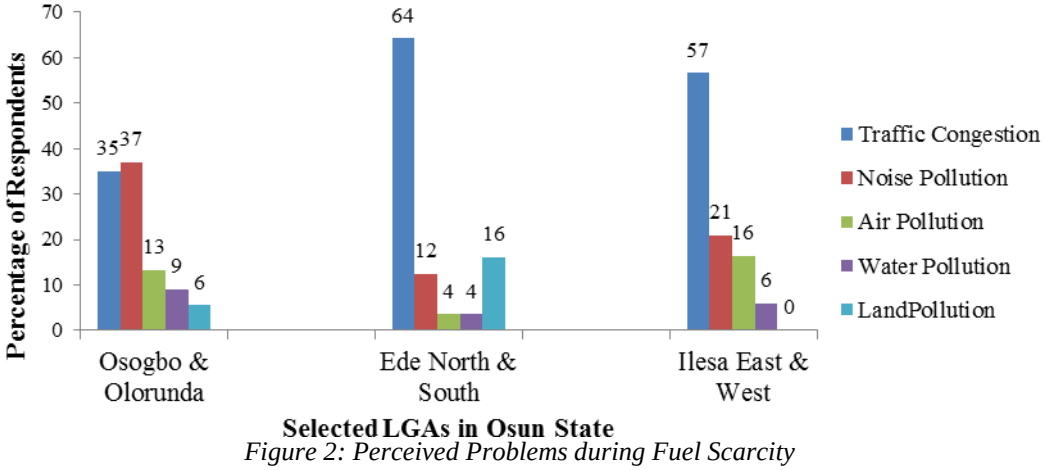

Figure 2: Perceived Problems during Fuel Scarcity

Observed Effects of Leakages into Water

Across the study area, the dominant noticeable effects of leakages into underground water from the PROs are bad odour and bad taste with indications for coloration in some cases (Figure 3). This was felt in homes or areas which relied mainly on wells (either directly or piped into apartments). Based on responses from the PROs, leakage tests carried out have revealed incidences of leakage from USTs of PROs in the study area. Though 57% of the PROs reported not to have had such experience after tests were conducted, the rest had recorded incidences of occasional or seldom leakages of the petroleum products sold by them. This equally implies that certain PROs have poor quality, damaged or worn out USTs. Some of the respondents did not observe any form of pollution in the domestic water supply. This "no change" scenario is significant across the selected LGAs or cities. This is due to the fact that some of these residences make use of public water supply from the State Water Corporation. The highest percentage (39%) of those in this category falls within Osogbo, the state capital while such indication is lower in Ede and Ilesa; still revealing the privilege associated with the state capital.

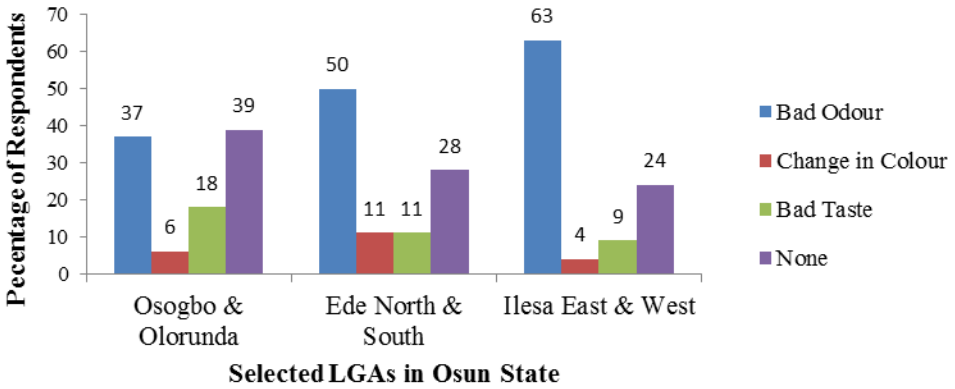

Figure 3: Observed Effects of Leakage on Water

RECOMMENDATIONS AND CONCLUSION

This study has provided information on the condition of PROs in major cities of Osun state, Nigeria. It has also revealed certain environmental problems associated with the existence of PROs coupled with the situation experienced during fuel scarcity and effect of leakages from USTs into underground water.

PROs are essential service stations for meeting needs of automobile users and generating power for domestic and business uses. Based on findings of this study, there is need to still reiterate the importance of adherence to standards in the building and maintenance of PROs. The negative impact of PROs on the environment which consequently affects the health of residents of surrounding communities has been ignored over the years. The proliferation of PROs based on economic motive without consideration for environmental safety is pronounced. The incessant approval of permit to build more PROs has not been justified on the basis of a higher demand or need. Therefore, the Town Planning Authority, which is the approving authority, must put a limit or temporary stop to approval of PROs in certain communities. The need to enforce repair or replacement of bad USTs of petroleum products in PROs that have failed leakage tests is very vital to save the environment and residents around such PROs. The Directorate of Petroleum Resources (DPR) must perform its responsibilities in this wise. The Ministry of Environment also needs to carry out routine checks and tests to ascertain pollution levels around PROs and to ensure compliance with standards and maintenance of quality and quantity of required facilities.

In Nigeria, the problems caused by petrol scarcity require a complex and holistic approach to addressing the cause(s) of the scarcity. Meanwhile, sensitization of PRO operators on crowd management during the period of petrol scarcity will go a long way in addressing the complaint of noise pollution. Organizations such as DPR could provide such training. The Federal Road Safety Commission (FRSC) will need to help manage traffic around certain PROs at times of scarcity to maintain smooth flow of traffic in affected areas. Environmental NGOs have in recent times carried out sensitization on achieving a safe environment with particular focus on the need to produce and use environment friendly products. The NGOs also need to create pressure groups that would insist that government carries out its responsibility in the control and monitoring of PROs.

Furthermore, the need for the academia to continue to provide necessary data and information on the existence of PROs, their conditions, types of impact and associated risks will ever remain germane to the maintenance of a safe human environment. Over time, this is expected to provide a time series data on how the existence of PROs has fared in the debate towards achieving sustainable development. It will provide information on whether the situation has improved or not.

It is believed that taking such steps as recommended above and engaging other strategies that are connected to minimising the impact of PROs on the environment will go a long way in improving the status quo in Nigeria as a whole.

The Trauma of Domestic Solid Waste Mismanagement in Akure Urban Region, Nigeria

Lawal, O. L. [1*] ***& Basorun, J. O.*** [2]

[1&2] *Department of Urban and Regional Planning, Federal University of Technology, Akure, Nigeria*
[*] *brigadierlawal@yahoo.com*

ABSTRACT

Solid waste is the most conspicuous of all waste generated in human communities. The mismanagement of this waste has a direct bearing on the quality of life and urban environment. This study assesses the situation in Akure urban region in Nigeria. Two thousand eight hundred and eighty one (2881) residential buildings in four residential neighbourhoods of Akure represent the research population. Using systematic random sampling technique, questionnaires were administered on the main producer of waste(woman) in each household at every 10th building interval. Thus,it gives a sample size of two hundred and eighty eight (288) respondents. Simple descriptive statistics such as frequency counts and percentages as well as Pearson's Product Moment Correlation test were used to analyze data. Analysis of data revealed that; open refuse dumpsite was the major means of waste disposal in Akure as majority of the residents did not have designated refuse collection points in their vicinity. This unwholesome practice brings offensive odour and breeding of various types of insects and infectious organisms that made malaria and typhoid fever prevalent in the study area. Rapid population growth and area extent of the city, indiscriminate dumping of waste, and shortage of fund as well as shortage of skilled and unskilled personnel have also incapacitated the effectiveness of waste management board. Some practicable recommendations were made based on findings.

Keywords: Akure, Solid Waste, Urban Region, Waste Management

INTRODUCTION

Waste has become a major problem in our societies today; it is a potential threat to public health, it scars the environment and it can be a block to the economic development of an area because of the negative images it presents (Gadget, 2011). Waste is generated universally and is a direct consequence of all human activities. As rubbish or materials not needed and economically unusable without further processing, "it originates from a wide range of human operations, such as industry, commerce, transport, agriculture, medicine and domestics activities" (Ajibade, 2007).Wastes are generally classified into solid, liquid and gaseous. The United States Environmental Protection Agency defines solid waste as any useless, unwanted or discarded material with insufficient liquid content to be free flowing (Chukwuemeka*et al*, 2012).Liquid wastes are commonly discharged into sewers or rivers, which in many countries is subject to legislation governing treatment before discharge.Gaseous waste is normally vented into the atmosphere either with or without treatment depending on composition and the specific regulations of the country involved. Waste is a factor of what is provided and consumed and the problem arising from it is of concern about protecting the quality of the natural environment.

Ita (2003) opines that waste is any material that lacks direct value to the producer and must be disposed. Similarly, waste is any material that is thrown away as unwanted (UNICEF 2006).Waste may be classified in many different ways, considering its origin (domestic, industrial, commercial, clinical, construction, nuclear, agricultural) or its properties (toxic, inert, inflammable). Without suitable treatment such waste becomes a source of contamination to the environment at large leading to air pollution (acid rain or traffic pollution), water pollution and oil pollution (Microsoft Encarta Premium Encyclopedia Suite, 2004). Increase in human population and income leads to an increase in demand and production of goods (Varian, 2010; Blanchard, 2009) and the resultant waste discharge to the environment. If waste is not properly managed it threatens environmental quality and public

Lawal, O. L. & Basorun, J. O. (2016). The Trauma of Domestic Solid Waste Mismanagement in Akure Urban Region, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1667-1676

health (Asase*et al*, 2009). The amount of waste produced by human activities is increasing in most part of the world, and is accompanied by problems of disposal.

Of all waste generated in the world today, solid waste is the most conspicuous which can be easily noticed by people (Eugene and Animasaun, 2011).The quantity and type of solid waste generated depends upon the function which a city performs, its economic status and the level of technological development (Imoh and Emmanuel, 2011). Cities and towns are increasing in number, area extents, population sizes, and functions. It is not unlikely that the large population coupled with the inability of the city governments to provide adequate infrastructure, and the living habits of the inhabitants is compounding the issues of wastes, (Aderogba, 2012).The problem of solid waste is a universal one as it exists in every society. Waste management problems only appear more serious in developing economies because of poor management framework.

Akure, the capital city of Ondo State in Nigeria has been experiencing expansion in terms of population density and explosion,thus, resulting to phenomenal increase in waste generation. Domestic waste constitutes the highest percentage of waste generated in Akure (Fakere*et al*, 2012). These domestic wastes are synonymously residential waste within the context of this study. It has a direct bearing on quality of life and urban environment.The objectives of the study, therefore, are to: (i) identify solid waste disposal methods in the study area; (ii) assess the role of government and the effectiveness of Waste Management Agency in handling solid waste in the area; (iii) investigate various health and other environmental hazards associated with solid waste disposal; and (iv) examine the current challenges plaguing solid waste disposal and management in the study area.

LITERATURE REVIEW

Waste, from the common knowledge is anything that lacks utility; an object or substance that the owner either voluntarily or involuntarily relinquishes ownership of. It is a potential hazard by virtue of its nature and composition and so its management is a hazardous activity. By implication, waste does not possess perfect-market goods quality (Ossai, 2006).Nigerian waste generation is on the increase at an estimated rate of about 0.5 – 0.7% per annum, with current figures ranging from 0.4 to 0.8 ton per capita per annum (Akinjare, 2011). Waste complexity is also increasing with biodegradable waste currently accounting for over 50% (Ossai, 2006). This amounts to over 50milion tons per annum average waste burden on the nation with less than 10% waste management capacity (Adedira*net al*, 2014). The 21st Century Nigeria is expected to witness technological growth, increased urbanization, private sector controlled economy and environmental awareness. These changes shall be accompanied by increased waste yield and complexity, more public demand for protection from environmental affront and consequently more integrated development policies with increased control of waste management. Waste management problem has increased at an alarming rate in Nigeria in direct response to rising population growth and industrialization (Ajibade*et al*, 2005).

Waste generation has been encouraged by rapid increase in population, changes or improvement in wages, massive expansion of the urban areas and the changing lifestyle or better standards of living as well as improvement in technology (UNICEF, 2001). Increase in population and income brings about increase in the production of goods and services and the resultant discharged of effluents into the environment. The alarming rates at which human beings generate waste constitute a great problem to the governments as well as individuals in large urban areas especially in developing countries like Nigeria. This is because residues of products used are not always destroyed but discarded and these contribute greatly to land pollution (Adedibu, 1983). As the population of Nigerian cities continues to soar, the problem

of waste management is at the fore of discussions in both public and private fora. Most of these discussions focus on how to effectively manage waste to curtail problems that may emanate, especially in respect of human health and provide for cleaner sources of energy from waste. Basically, solid waste can be classified into different types depending on their sources.

Source	Typical waste generators	Types of solid wastes
Residential	Single and multiple family dwellings	Food wastes, paper, cardboard, plastics, textiles, leather, yard wastes, wood, glass, metals, ashes, special wastes (e.g bulky items, consumer electronics, white goods, batteries, oil, and tires) and household hazardous wastes.
Industrial	Light and heavy manufacturing, fabrication, construction sites, power and chemical plants.	Housekeeping wastes, packaging, food wastes, construction and demolition materials, hazardous wastes, ashes and special wastes.
Commercial	Stores, hotels, restaurants, markets and office building	Paper, cardboard, plastics, wood, food wastes, glass, metals, special wastes and hazardous wastes.
Institutional	Schools, hospitals, prisons and government center	Paper, cardboard, plastics, wood, food wastes, glass, metals, special wastes and hazardous wastes.
Construction and Demolition	New construction sites, road repair, renovation sites, demolition of buildings	Wood, steel, concrete, dirt
Municipal Services	Street cleaning, beaches, landscaping, parks, recreational areas, water and waste water treatment plants	Street sweepings, landscape and tree trimmings, general wastes from parks, beaches and recreational areas; sludge
Process (manufacturing)	Heavy and light manufacturing, refineries, chemical plants, power plants, mineral extraction and processing	Industrial process wastes, scrap materials, off-specification products, slay, tailings
Agriculture	Crop, orchard, vineyard, dairies, feedlots, farms	Spoiled food wastes, agricultural wastes, hazardous wastes (e.g pesticides)

Source: Puja, 2015: Solid waste management: types, sources, effects and methods of solid waste management.

The above sources and types of solid waste require effective waste management. That is,waste management in terms of the collection, transportation, processing, recycling or disposal of waste materials (Ajadi and Tunde, 2010). It can also involve the systematic control of generation, storage, collection, transportation, separation, processing, recovery and disposal of solid waste (Rogdgers, 2011). Uchegbu (2002) agrees it is a planned system of effectively controlling the production, storage, collection, transportation, processing and disposal or utilization of waste in a sanitary, aesthetically acceptable and economic manner.Developed countries exercise the best management practices in waste handling and disposal while the less developed countries including Nigeria, generally lack adequate means to handle and dispose-off many wastes in an environmentally safe manner (William and John 1996). One of the major problems facing growing cities in the developing world is that of coping with the wastes generated. Cities are very much battling with the increasing challenges of solid wastes in particular and the battle is seemingly not being won. An estimated 20kg of solid waste for instance, is generated per capita per annum in Nigeria; which is equivalent to 2.2 million tons a year (Dunlap, 2002). This means that as population continues to grow and urban areas continue to expand, it is expected that more waste would be generated in the country over the years. Cities are centers where industrial productions are concentrated. They are also centers of high consumption and consequently waste generation.

One of the visible problems facing most cities in Nigeria is disposal of huge quantities of solid waste that accumulate in urban areas as a result of modernization (Malumfashi*et al*, 2011). In the foreseeable future, the government may not be able to solely undertake the

service of waste management because of the geometric increase in population accompanied by alarming rate of waste generation, dwindling financial resources and reduced allocations to waste management sector. This, therefore, makes private sector participation desirable. The sector can provide the needed capital for investment in municipal solid waste (MSW) management (i.e. collection and disposal of solid waste) and their involvement can help to increase efficiency. An integrated approach in MSW management as suggested by Ahmed and Ali, (2004) and Baud and Post, (2001), should involve all stakeholders (e.g. government, private sector and residents). This will help to reduce solid waste problems and promote sustainable waste management in developing countries (Animasaun andEzebilo, 2011).

MATERIALS AND METHOD

Research Locale

Akure is a traditional Nigeria city in Yoruba region of the country that existed long before the advent of British colonial rule (Afolabi, 2008). The city is located within Ondo State in the South Western part of Nigeria. Akure is a medium- sized urban centre which became the provincial headquarters of Ondo province in 1939; the capital city of Ondo State and Akure Local Government headquarters in 1976. These dual political roles of Akure have since acted as impetus to the influx of people into the city (Olujimi and Olamiju, 2011). Akure is located approximately 700 kilometers South West of Abuja, the Federal Capital of Nigeria and about 350 kilometers to Lagos the-former capital of Nigeria.

Akure lies on latitude 7^0 15^1 North of the Equator and on longitude 5^0 15^1East of the Greenwich meridian. It stands on the altitude of about 370 meters above the sea level (Ondo State Government Agro-climatological and Ecological Monitoring Unit, 2007). It shares geographical boundary withOwo Local Government Area in the east, Akure North and Ifedore Local Government areas in the north, Ile-Oluji/Okeigbo Local Government Area in the west and Idanre Local Government Area in the South.

Method

Survey design method was utilized for this study. In view of the extended geographical coverage of the city, this study was limited to four (two public and two private) residential neighbourhoods in Akure. It employed the use of a well-structured questionnaire to examine the methods and processes of solid waste disposal and managementin selected residential neighbourhoods in the city. With the aid of satellite imagery of Akure obtained via Google Earth coupled with reconnaissance survey, the numbers of buildings in the four selected residential neighbourhoods (Ijapo Estate, Shagari village, Apatapiti and Oke-Ogba) were determined to represent the research population.

Table 2:*Selection of respondents across the selected neighbourhoods in Akure*

S/N	NEIGHBOURHOOD	RESEARCH POPULATION	SAMPLE SIZE (10%)
PUBLIC RESIDENTIAL NEIGHBOURHOOD			
1.	Ijapo	688	69
2.	Shagari village	861	86
Sub-Total		1549	155
PRIVATE RESIDENTIAL NEIGHBOURHOOD			
3.	Oke-Ogba	579	58
4.	Apatapiti	753	75
Sub-Total		1332	133
GRAND TOTAL		2881	288

Source: Author's computation, 2014.

There are two thousand eight hundred and eighty one (2881) residential buildings in the study area. Using a systematic random sampling technique,10% (288) buildings were selected for resident's interview at every 10^{th} interval across the study area. In each selected building, questionnaire was administered on a respondent who is a woman in a household, preferably

married and above age 18. The domestic roles of women in cooking, cleaning and procurement of household items qualify them as a potential waste generator.The sample proportion is justifiable considering the homogeneity of population and similarity in the methods and processes adopted in waste disposal and managements.Data obtained from the research were collatedand analyzed using the computer Statistical Package for Social Science (SPSS) Version 16.

RESULTS AND DISCUSSION

This paper was specifically designed to examine the methods and processes adopted in domestic solid waste disposal and management by the inhabitants of Akure. In achieving this, methods, processes of solid waste disposal by the inhabitants of Akure were investigated; the role of Government in solid waste disposal and management was examined and resident's satisfactions with government's efforts were ascertained.

Method of solid waste disposal

Investigation carried out revealed that 21.8% of the respondents disposed their waste in dustbin, 26.7% in a centralized public container (receptacles), 44.7% in an open refuse dumpsite and 3.8% by incineration method.Apparently, most of the solid wastes are disposed on open dumps land not minding the fact that improper disposal of solid wastes is harmful to human health. As cautioned by Abul (2010), disposal of solid waste on land without careful planning and management is injurious to the environment and human health.

Refuse collection points

Across the study area, 48.7% of the respondents argued that there is no designated refuse collection point in their streets, 11.1% opined that there were between 1 and 2 points while20.1% claimed to have between 3 and 4 as well as 5 collection points and above respectively. The information above clearly shows that refuse collection points are not adequate and equitably spread across the study area.The extant refuse collection points cannot optimally cater for the volume of solid waste generated, hence, the prevailing huge uncollected solid waste with varying degree of harmful human and environmental problems. In the opinion of Ichimura (2003), poorly handled or undisposed solid waste in a particular area has a profound risk on the environment and human population.

Effectiveness of Ondo State Waste Management Authority (OSWMA) in waste management

From the field survey, 39.6% of the respondents were of the opinion that the Ondo State Waste Management Authority is not efficient in its service, but to 21.6%, the Board is fairly efficient;19.4% felt that the Board is effective and very effective respectively.One can deduce from the above that the level of effectiveness of the Board is not in line with best practices. The numbers of unhealthy open refuse dump sites discovered in the study area lay credence to this position. The common open dump sites are a reflection of lack of well-coordinated refuse collection sites. Traditionally, in most urban centres in Nigeria, wastes are disposed in uncoordinated open areas (Ogedengbe and Oyedele, 2006). Dumping of refuse in open areas causeshealth and pollution problems as wastes disposed in such area will encourage the growth of organisms that can transmit diseases to people living in such environment. Of the numerous open dumpsites discovered in the area, OSWMA has proscribed only one. The proscription became necessary because the site was unofficial and wastes disposed on the site are not aesthetically pleasing to the eye as it constitutes serious nuisance to the general well-being of the inhabitants.

Fig 1.*Refuse dump site proscribed by OSWMA at Shagari village Akure*.

Factors responsible for Domestic Solid WasteMismanagement

A number lot of factors, no doubt, must be responsible for domestic solid waste mismanagement in the area. From the perspective of the residents, 18.4% of the residents were of the view that rapid population growth and increase in the areal extent of the city was the major factor inhibiting seamless waste disposal management, 21.5% attributed it to shortage of fund, 25.4% to indiscriminate dumping of waste and 34.7% to failure of OSWMA to evacuate waste. Evidently, government intervention in waste disposal management was abysmally low.The phenomenal increase in the volume and range of solid waste generated as well as the expansion of population and areal extent of thecity may render the effort of theWaste Management Authority ineffective as the volume of solid waste generated in the city continues to increase at a faster rate than the ability ofthe authority to cope with its financial and technical resources constraints. This assertion conforms to the observation of Ogwueleka (2009), that solid waste management in Nigeria is characterized by inefficient collection methods, insufficient coverage of the collection system and improper disposal. Consequently, waste management in many cities fails to meet minimum acceptable standards with grave adverse effects on the urban environment, public health and quality of life (Ogedengbe and Oyedele, 2006).

Health and Environmental trauma associated with improper waste disposal

Solid waste if not properly managed can be hazardous to the environment and public health. About 46% of the respondents have been diagnosed and treated for malaria fever in the last one year, 28% for Diarrhea or Dysentery, 21% for Typhoid Fever and 5% Cholera. These may not be unconnected to defective waste management practices in the area. In a related study carried out by Fakere *et al.,* 2012, malaria fever was identified as the major disease associated with improper waste disposal. Tapas (2012) maintained that uncontrolled solid waste creates a lot of problems. These wastes frequently end in drains, causing blockage which upshoot in flooding and unhealthy state. The open burning of waste causes air pollution; the yield of burning includes dioxins that are hazardous to public health. Uncollected waste degrades the urban environment and acts as a breeding ground for vectors such as flies, cockroach and rodents that transmit or increase diseases such as typhoid, cholera, dysentery, plague, tuberculosis, encephalitis, typhus etc. Fire on disposal sites can cause major air pollution, causing illness and reducing visibility, making disposal sites dangerously unstable, causing explosion of smokes and possibly spreading to adjacent property. Burning rubbish or incineration releases hurtful gases some of which may contribute to global warming.

Means of improving environmental sanitation/ waste management

In a bid to bring about responsive environmental sanitation/waste disposal management, 9.0% of the residents suggested that public awareness and enlightenment programme on

waste management should be instituted, 37.5% opined that the number of refuse collection sites should be increased coupled with prompt evacuation of waste at the various sites, 26.4% called for the enforcement of sanitation laws while 27.1% advocated for public and private partnership in waste disposal management. The increment of refuse collection site as advanced by the residents cannot adequately solve the problem of solid waste as the city will continue to witness the influx of population that will ultimately lead to the increase in the areal extent of the city. As such, there is need for collaboration between government and private sectors in solid waste management as suggested by Akinola and Salami (2001) for more effective waste management. This measure will not only bring about effective solid waste management but it will also allow for a healthy environment for productive living.

Relationship between the factors responsible for Domestic Solid Waste Mismanagement (FRDSWM)and the means of improving Environmental Sanitation (MIES) in the Area

Using Pearson Product Movement Correlation Statistics, data obtained from various factors responsible for domestic solid waste mismanagement were correlated against that of the means of improving environmental sanitation in the area. This was done to reveal; the relationship that exist between these variables and the level of significance of such relationship (see table 3). Table 3 revealed that there is a strong relationship between factors responsible for domestic solid waste mismanagement and means of improving environmental sanitation. This is so because FRDSWM had 0.902 correlation coefficient with MIES at 0.01 level of significance.

Table 3: Correlation between factors responsible for Domestic Solid Waste Mismanagements and means of improving Environmental Sanitation

		Factors responsible for domestic solid waste mismanagement	**Means of improving environmental sanitation**
Factors responsible for domestic solid waste mismanagement	Pearson Correlation	1	.902**

The Ondo State Waste Management Authority Official Report

Records obtained from the Planning Department of Ondo State Waste Management Authority (OSWMA) showed that it was established in 1999 when the then State Government realized the need to address the problem of wastes in Ondo State. The scheme started in Akure metropolis (the State capital) and later extended to other towns and villages in the State. The main objectives of setting up the Authority are to:

i. rid the state of refuse pile up, environment blight and epidemic development;
ii. set guidelines and organize waste scavenging and recycling;
iii. ensure and cause the removal of waste in the environment in order to enhance healthy living; and
iv. promote waste to energy and waste to wealth activities.

The functions of the Authority are to:

i. complement or take part in the organization, monitoring and supervision of environmental sanitation campaigns so as to generate adequate awareness of the need for effective storage, collection and disposal of waste in Ondo State;

ii. rid the state of refuse through regular collection from individual houses, establishments, institutions and other designated areas for disposal to avoid refuse pile up, environmental blight and epidemic development;
iii. Collaborate with Local Government and other Agencies within and outside the state for actualization of its functions;
iv. ensure that every owner or occupier of a premises, household/commercial shops or stalls operate to the satisfaction of the Waste Management Authority; provide and maintain at least one portable covered refuse bin, the size and structure of which shall be approved by the Authority's officials for the collection and storage of refuse in their premises;
v. establish and maintain approved sanitary landfill sites within the state for the disposal of waste;
vi. keep record and collect user's charges or rates on the weight of waste disposed-off and collection of tipping fees at landfill sites;
vii. set guidelines for waste scavenging and recycling in order to generate revenue;
viii. ensure and cause the removal of sludge in individual, industrial and institutional premises or the environments and dispose of the same in a designated disposal site;
ix. inspect, ensure and enforce the provision of toilets at individual residences, commercial, institutions, industrial place etc; and
x. enter into contractual agreements with approved private agency where necessary for the actualization of the functions of the board, provided that such agreements is in line with the regulations of the board.

Disposal of Waste by the Authority

Solid waste collected from the study area is transported to a landfill site on acquired land along Igbatoro-Imafon road, Alagbaka, Akure for disposal. The landfill site is an organized dumpsite, fenced and secured with security guard and office complex. The engineering design of the site is standardized to ensure that the machines and equipment used for waste recycling is in place.

In spite of these impressive objectives and functions of the board, facilities available are grossly inadequate to cater for the teeming inhabitants of the city. Factors, such as phenomenal increase in population, volume of solid waste generated and areal extent of the city, inconsistency of government policies, shortage of skilled man power, poor funding, and management have incapacitated the effectiveness of the waste management authority.

CONCLUSION AND RECOMMENDATIONS

Cities are known to be engines of economic growth where solid wastes have become recurring features. To ensure sustainable management and improved quality of cities, there is an urgent need for environmental education and effective domestic solid waste management.Proper and timely management of waste leads to a sane environment while improper management adversely affects the environment and general well-being of the city dwellers. This paper has discovered that most of the residents of the study area disposed their waste in an open dump because of lack of designated refuse collection points in their vicinity. The phenomenal increases in population, defective waste management practices as well as inadequate data on per capital waste generation have made the services of waste management board grossly inadequate as most areas of the city are left unattended to with attendant health and environmental related trauma

Domestic solid waste can successfully be managed by the interplay of various factors as no single factor can bring about holistic management. All-inclusive management can be actualized through the establishment of refuse collection points at strategic locations in the

area. This represents a service system that will enable residents disposed their waste properly and promises prompt evacuation of waste at these collection points. Enforcement of environmental legislations by theWaste Management Board should be encouraged. Government services appear defective, hence, the need for a synergy between Ondo State Government and the private sectors. Public-Private Partnership (PPP) in solid waste management should be encouraged as a major driving force forservice delivery for a healthy living in the environment.

Government through theWaste Management Board and other Agencies should educate the public on the attendant problems associated with the indiscriminate dumping of waste in the open space. A Monitoring and EnforcementBoard (MEB) should be put in placeto regulate human activities in the environments. Through MEB, the public can be educated on modern waste management practices, give information on the volume and type of solid waste generated, and identify areas that have been denied government attention. Information obtained should be analyzed and to advise government regularly on the appropriate measures to be taken to allow efficient and effective waste management practices.

ABSTRACT

Most of Indian cities are in transition and are facing spatial development challenges. On one hand, the cities are developing new suburban areas with relatively better-built infrastructure and services; while on the other hand, the once primary and bustling central areas are succumbing to awful degeneration. To address the later scenarios, the government of India and state governments have lately laid emphasis on the urban renewal, redevelopment and regeneration through different schemes and missions to revitalize these areas and the cities as whole. However, the success of the schemes and most importantly, the revitalization of degenerated areas have produced mixed results. One of the prominent challenges of limited success of the interventions is the lack of fruitful participation and engagement of the stakeholders in the urban redevelopment and regeneration process. This exploratory research examines the challenges of stakeholders' participation, which leads to the partial success or total failure of such projects in Indian cities. The study develops a conceptual model based on systems concept. The model highlights a culture of fruitful stakeholders' participation and their responsible engagement for the success of the urban redevelopment and regeneration projects at local level. It is indicated that causal feedback relationships among various components of such projects and their inter-linkage with stakeholders would able to assist to diagnose and minimize the concerned areas of conflict and also augment the areas of fruitful engagements so that not only the redevelopment and regeneration processes will be successful, but also the cities can be reinvented by its people.

Keywords: Cities, Redevelopment, Regeneration, Stakeholders, Urbanism

INTRODUCTION

More often, what ails Indian cities is a question that always beckons. The moment answers to the question is offered, another common question that pops up is "what need to be done to improve the scenario". Is it that India is in the right direction in the development/ redevelopment of cities or something is lacking? According to many practitioners and academicians engaged in the urban development in India a basic issue emerges that we try to resolve our urban development problems without understanding the roots of the problems. We do not understand our cities, our urban problems and our people. Let us discuss an example of an important city in Eastern India as an illustration. The city is as old as of 1000 years and the urban culture is not very urbane as is understood in the Western world or in some of the larger and so called more modern cities of India. Unlike the individualistic and cosmopolitanism culture of the other modern cities, it is based on the age-old neighbourhood living system. It has certain physical and spatial constraints for future developments. However, as one of the most important cities of the region, it continues to grow and so do all its problems.

The irony in the development process of the city is that the most important question that comes to the mind of the most important person in the decision making process at certain period of the time of the city development- is that "how to beautify the city". Unfortunately one of the authors of this article was the person to whom the question was asked. And worse, the question was supported by two learned top leaders in the urban planning profession in the State. Now, let us understand how relevant the question is and from where it has come and who had the understanding of the issue. The question comes from a person who is not an

Das, D. K.; Sonar, S. G. & Emuze, F. (2016). Comprehending the Role of People in Urban Redevelopment in Indian Cities. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1677-1687

urban development professional, but holds the key position to take decisions that dictate the fate of the city. The question of beauty is not the real challenge that the city faces, although that is the focus of the decision makers. The city is contending with multiple challenges related to infrastructure, economic life and social disintegration.

If the issue is analyzed, we will find that the city needs to be functional before cosmetic / beauty related solutions come into play. If the city is functional and we do take care of our environment, then it would automatically become aesthetically appealing or as in the words of people beautiful. The next question is how we make the city functional, particularly if the city has degenerated significantly and languishing with a variety of problems. The answer although looks very intricate and complicated, yet very simple. Possibly the reinvention of our cities by its own people is one of the important solutions to be explored. What is reinvention of cities and how is it to be done by its people? To understand this, let us take the analogy of our individual houses. If we observe that when our houses is non functional or provides some kind of constraints because of certain spatial, environmental, demographic or cultural problems, we try to reinvent it by the process of reconfiguring the spatial layout, changing the functions of various elements of the house, redeveloping by additions or modifications or at times totally altering the whole function of the house itself to provide it a new meaning. Why do we do this alteration and how do we do this? The basic premise we consider in such a case is that we understand the house was performing its functions as envisaged without much concern at a certain point of time or when it was build. When it started creating constraints to whatever reasons it may have, we try to relook it from both physically, socially and emotional point of view and try to alter or improve its conditions to its best possible condition within the economic and emotional limits. This process leads to the improvement in the social, economic, environmental and emotional values of the house. When we talk about emotional value, it is to understand that everything has an emotional value and other values are mostly dependent on it. If we do not understand our house then possibly we will go wrong in its redevelopment or regeneration process. Thus, the important aspect that crops in this argument is that the person(s) who are emotionally attached to it, who take this decision of the redevelopment or regeneration process and whose emotions influence the redevelopment or regeneration process is critical. In the case of a house, it is the household or family, which is critical and therefore the family members are the most important persons to take decisions. Similarly, in a city redevelopment, renewal or regeneration, who is expected to lead to reinvention of the cities? It is the people who have the most stakes over its change process. They are the most important people to decide the development or redevelopment of their city. The neighbourhood, part of the city or the city as a whole and its environment need to be shaped according to their functional and emotional needs.

Do we give enough importance to this aspect while thinking of our city redevelopment or regeneration process? Theoretically it is partly yes and partly no. However, in practice, it is an absolute no. Let us examine this argument. The 74th amendment act of constitution (amendment of Constitution of India, 1992) empowers people to take decision and rather govern their own urban development. The constitution has paved the way for local governments for self governance at the local level. Municipal councils or Municipal corporation councils govern the affairs of the cities at the local level through a democratically election process. The local governments or councils are the representative of the people and they have the right to the governance of their cities and empowered to take appropriate decisions on behalf of people. Furthermore, people are consulted at the planning stage of any city development/ redevelopment process and feedbacks are taken before finalizing the plan. On this supposition, the system looks to work well. In contrast, let us examine if this system

really happen. The council or local governments although are set up constitutionally, it is highly visible that most of their decisions are taken based on the pull and push factors[i], which observed to happen in other parts of the world as evidenced from literature (Llinares, Page, Llinares, 2013; Matkin and Frederickson, 2009; Stone and Sanders, 1987). In some instances the individuals representing in the council sway the decisions although they have conflicts of interest. Conflict of interest in Indian conditions is not strictly defined. Political hegemony takes precedence over scientific logic and rationality (Beck, Thompson, Ney, Gyawali, and Jeffrey, 2011; Llinares, Page, Llinares, 2013; Matkin and Frederickson, 2009). The council is also at times is not well advised of about decisions by the professionals- may be due to various personal and professional reasons, such as individual affiliation to the decision makers, fears of loss of job, personal benefits, lack of actual knowledge or skills, rejection of professional advice, or the likes. Above all, the stakeholders or the people at large are essentially not parts of the decision making process. Although the system of feedback from the people or stakeholders do exist and sometimes practiced, it is done at a very late stage where their wishes or arguments do not hold much significance and are also not given enough priority. Besides, in some cases there are peoples' committees at various levels from neighbourhoods, area to city levels, and also at various professional levels within chambers of commerce, industry, culture, whose advices are sought. However, those committees do not have much authority and are basically advisory in nature without much significance in the decision making process. Moreover, those committees are also characterized by conflicts, fractions and self motives, thereby do not contribute much to the democratic decision making process of the development or redevelopment of the cities as envisaged by the constitution (Stone and Sanders, 1987).

It is thus construed that in the current scenario, stakeholders' participation is minimal in urban renewal process in India. Therefore, in this paper, the authors have made an effort to examine the current model of stakeholders participation in city development/redevelopment process and propose an improved model for participation within the constitutional frame work for the development of cities in general and regeneration in particular to reinvent the cities. For this purpose review of relevant literature and a qualitative survey research method were employed. The next section of the paper discusses about the approach followed for this investigation, the current system and argument for a new model and findings and discussions. The findings and discussion section include proposition of improved feedback model for stakeholders' participation, the model structure and framework, and selections, structure and functioning of the jury in the system. The paper concludes with an argument that there is a need for a new model with more inclusivity and fruitful engagement of the stakeholders in the decision making process. Also, the new model with feedback mechanism among the stakeholders despite certain limitations will better suit to a populous and democratic country like India to reinvent its cities.

APPROACH OF THE INVESTIGATION

The investigation was carried out through review of relevant published and literature and documents followed by qualitative survey and discussions with various stakeholders in city development process in India. For review of literature data bases like Scopus, ProQuest and Science direct were searched. Relevant published articles were selected after initial screening and critically reviewed. Besides, published and unpublished documents and archival records relating to urban development process and municipal administration were reviewed. The survey was conducted among the stakeholders by using qualitative survey method. For this purpose, two cities such as Cuttack (Municipal corporations) and Bhubaneswar (Municipal corporations) and one town Dhenkanal (Municipality) in Odisha state located in the Eastern

part of India were selected as case study areas. A set of stakeholders from the three urban areas that include local leaders, urban development professionals, members of chambers of commerce, contractors involved in urban development works, entrepreneurs, academicians, bureaucrats, municipal council members, political scientists were selected and approached for their willingness to participate in the survey. Discussions with the about 20 willing participants were made though semi structured interview process. Besides, discussions with more than 50 citizens either in groups and individually were made following random sampling and through unstructured interview process. The discussions were compiled in the snowballing process over a period of time during the between year 2011 and 2013. The data collected were compiled and qualitatively analysed.

THE CURRENT SYSTEM AND ARGUMENT FOR ANEW MODEL

The 73rd and 74th amendment of Indian constitution in 1992 strengthened the case for people's participation in development at local level. There is regular local urban governance system in place in urban areas of the country. The local governments more often are responsible for and oversee most of the urban developmental works within their jurisdictions despite the overlapping of organizations. An examination of the current structure (Figure 1) reveals that the structure and system is quite simple. The municipal government is placed at the third tier of the governance system of India. It is a democratically elected government entrusted with the decision making and execution of the local level developmental works with constitutional authority, policies and guidelines set up by the state governments and the central government. Thus, the local municipal government's is the lynch pin between the governments at higher levels and the people at the city level. The municipal council / government are assisted by a set of professionals for decision-making and execution. Municipal governments also depend on the financial support from the state government or central government through appropriate procedure in addition to own resources for the development of urban areas. However, the municipal councils are not solely responsible or entrusted with the development of the urban areas. Other urban development authorities with specific functions and responsibilities have been created in the urban areas. The urban development authorities, such as authorities, boards, commissions, regional development trusts, and corporations, are mandated to work in collaboration with the municipal authorities. They derive their authority from state governments and function directly under them. However, the collaboration does not exist in reality. The two entities tend to be at conflict with each other and in so doing complicate the development process.

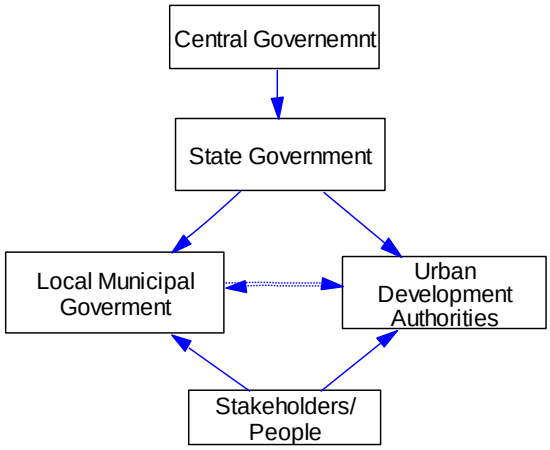

Figure 1. Current system of governance and stakeholders' participation for development or redevelopment of cities

When such conflicts manifest, constitutional authority provided to municipal authorities is undermined and also their work purview is constrained to certain extent and the inter-linkage is observed to be very weak contrary to the strong coordination and collaboration expected from both entities. Besides, these two separate entities without clear terms of reference and mandate are made responsible to the stakeholders and are expected to liaise with them for any developmental work. However, it is observed that the relationships of both these organizations with the people at the local level are only one way with top down approach Rarely the stakeholders concerns are listened to or feedbacks are appropriately considered in the decision making. Further, the large numbers of citizen groups, if they are available seem to prevent their coordination although some are able to influence local politics particularly through their contract (Beck, Thompson, Ney, Gyawali, and Jeffrey, 2011; Das and Sonar, 2015; Matkin and Frederickson, 2009; Vogel, 1999) both positively and adversely. Worse, the sway of individuals or persons in authority, and their whims complicate the matter. For example, India has a somewhat authoritarian civil service system (observation of authors supported by political experts and many common people surveyed although many may argue against and disagree), and because of the authority given to the incumbent civil servants at critical positions of decision-making, often they have the final say in decisions[ii]. Although, the civil servant's role is mostly advisory and concerned with facilitation, regular administrative and management of affairs, yet their critical positioning in the system allow them to sway the decisions[iii]. This is corroborated by a few experts in the city development and political scientists the authors discussed with and according to them

> "*… if the incumbent civil servant is authoritarian and has a sense of superiority, he restricts the role of professionals, and the less informed local leaders get swayed by such civil servants. The stakeholders and common people's accessibility to decision making is also restricted*".

Add to it, the intervention of judiciary in the name of grievance redress does not help the situation. In the current system, anybody who feels aggrieved by any kind of decision by the local governments or any other organization or individual relating to such developmental issues can knock the door of the judiciary and stops the development process partially or in total indefinitely The net implication is inappropriate development/ redevelopment of cities without the consent of the stakeholders or people, wastage of space, time and resources.

Thus when a urban redevelopment/ renewal/ regeneration scheme or process is initiated like Jawaharlal Nehru Urban Renewal Missions (JNNURM), Urban Infrastructure Development of Small & Medium Towns (UIDSSMT) and erstwhile schemes such as Integrated Development of Small & Medium Towns (IDSMT) at the local level be at its planning or implementation stage, they meet the same doomed fate of failure or partial success. A reality check and reflection of the schemes would suffice this argument as how many of the small and medium towns have been regenerated. Why the government has extended the term of the JNNURM mission without much reflection? Here the experts from urban development professionals and local leaders can be noted.

> "*….many of the development or redevelopment schemes in the small or medium towns have ether not taken off the ground or if started then they have been done in a piece meal manner and have little success. Most of them are languishing because of conflict, delay in planning and implementation issues"*.

Thus, although the constitution has provided the leverage to empower people to take their own decisions and be an integral part of the development in general or redevelopment/ regeneration process in particular, the obvious limitations of the current system restricts or

bars the fruitful participation and engagement of stakeholders/ people in such process. Therefore, it needs reflection and re-enactment of an appropriate model for fruitful stakeholders/people engagement, which would aid reinvention of Indian cities.

FINDINGS AND DISCUSSIONS

Improved feedback model for stakeholders' participation

According to Matkin and Frederickson (2009), politics and administration of urban areas often emphasize pluralist competition among political and business elites; Beck et al. (2011) argue that common people more or less are not heard in the decision making or any planning endeavours. However, Boaz, Chambers, and Stuttaford (2014) argue for a rights based approach that provides a framework for developing more meaningful approaches that move beyond public participation. Therefore, in a pluralist and democratic society like India, there is a need to move away from the political hegemony as well as move beyond the simple participation in terms of occasional consultation with local leaders or with a few people in the community. Besides, the argument in favour of a new or improved system is that the current top down approach of governance even within the urban local governance system; the non assimilation of perceptions of stakeholders; the manipulation of unscrupulous prospective beneficiaries with a sole aim of short term gains, are major barriers in contemporary redevelopment of cities in India (Das and Sonar, 2015). This situation calls for a new model with the devolution authority and responsibility and feedback mechanism. This also corroborates the arguments that the better expressed those choices are, the greater the input groups have in the local policy-making process. Also, public choice views emphasize the constraining (Jailly 2008, Tiebout, 1956), and limiting (Peterson, 1981) influence of market forces on local politics, as well as highlight the competitive mechanism for its impact on the offering of public goods. In this regard a governing coalition, which is stable having small size and homogeneity of interest (Stone, 1989), and its ability to learn is fundamental to the success of the local development or redevelopment at the aggregate city or lower level such as area or neighbourhood level (Beck et al., 2011; Das and Sonar, 2015). Further, the experts with the understanding of the local politics argue for a new model with decision making authority equitably lying directly with the stakeholders or people. According to them

> "*....the local governance system has failed to take people into confidence in decision making of their developmental works. The common men have become more informed, aware and responsive and can take the responsibility of their own well being more prudently and rationally than the people in authority under the current system".*

The model structure and framework

Based on the aforesaid premise, it is understood that the existing system is not effective enough to deliver expectations. Therefore, an improved model is proposed. Figure 2 presents the improved model for effective stakeholders' participation. The model is build on the basis of systems archetypes and causal feedback mechanism while considering the resources and limiting conditions, such as forces which cause delay and disturbances in both decision making and implementation.

At the apex of the system, remain the central government followed by the state government and municipal government in India. It is envisaged that there shall be two way communications between the central and state government, and between state government and municipal government as in the current system. However, in this system the municipal government shall remain as the pivotal agency for all the development issues at the urban area level. As the pivotal agency, the municipal government will have strong causal feedback

relationship with local people and urban development authorities involved in the development and redevelopment process. The municipal government will be directly responsible for the people at the local/city level. The urban area development authorities, if any, are interlinked to the municipal authorities and will remain responsible to it as a feedback relationship. The stakeholders are directly linked to the city development authorities, and city development authorities are responsible to the stakeholders as feedback relationship through municipal authorities. In this process, the municipal government and city development authorities will remain interlinked, responsible and accountable to each other as well as to the people. This process in fact will eliminate the present concern over the proper people's participation in decision-making and implementation and also duplication of work, shedding of the responsibilities by the authorities and conflict over the jurisdictions. As the city development authorities remain responsible and directly linked to the municipal councils, it will reinforce the local self governments as envisaged by the 74th amendment act of the constitution.

In this regard, there exist counter arguments and concerns. One of the major concern as noted by the chairman of a municipal council is that

> *"…when there is a governance system with democratically elected people's representatives in place, what is the need of such a feedback relationship with the stakeholders having accountability and responsibility".*

Also, a large number of participants in the decision making may create more conflict and confusion and cause delay, or may totally disturb the whole process as well[iv]. Add to it, the city development authorities are basically under the purview of the state governments, and how do they come under the municipal council without much structural change in authority and power system of the state governments. Besides, if that happens then there will be a major shift in the authority and accountability system having other governance and financial implications, which may add to the confusion.

Conversely, the argument against these concerns here is that stakeholders' participation in the decision making does not go against the policy of participation and spirit of the constitution. In fact, the constitution has envisaged the enlightening of the people and inclusive decision-making. Thus, when the elected political representatives at the local urban area level are unable to agree about stakeholders needs, and the administrative authorities are unable to uphold the spirit of the constitution, it is imperative that the stakeholders should step in to decide their well being. Besides, such a framework is in congruence with the principles (theories) of social organisation and governance where each group of stakeholders distils certain elements of experience and wisdom that are missed by the others and each provides a clear expression of the way in which a significant portion of the populace feels. Each group will have a fair say and possibility of being heard and responded to by the other groups; as a result a common solution may be arrived, although may not be by consensus rather through concessions. Consequently, each group will have significant presence in the decision making process without being overtly marginalising or eclipsing the other and most possibly in a just way (Beck et. al. 2011; Das and Sonar 2015; Thompson, 2008; Verweij, and Thompson, 2006).

However, there is a need for small, rational and informed group who should appropriately represent the stakeholders and be a significant part of the decision-making (Stone, 1989 Giffinger et al, 2007; Shapiro, 2008; Van Soom, 2009). Therefore, this model envisaged that there should be a small group of representatives selected from the stakeholders who will play significant roles in both decision-making and implementation. The group of selected stakeholders will be known as the jury. The jury would be pivotal in the systemic decision

making process for all the redevelopment/regeneration works and function with a strong feedback mechanism with the stakeholders, city development authorities and the stakeholders. The functioning, selection and structure of the jury is as follows:

Selections, structure and functioning of the jury in the system

The selection and structure of the jury is critical to its successful tenure. It should be selected from the people invited by the municipal government for the particular project. For example, the selection can be for a redevelopment scheme of an area of a city. The municipal government will prepare a list of stakeholders and people from the city based on their stakes on the project. An appropriate number of people (say 500 people or 1% of the total population, which ever less) will be invited based on a random selection process from the list of the stakeholders (which should include all the categories of stakeholders) already compiled by the municipal government based on census figures that shows the demographics of the urban area. The invitees shall be provided with all the information about the project concerned before hand to remain prepared for the meeting. Once the people/ stakeholders are available in the meeting on the scheduled day, a jury consisting of a small group (say 12 members) shall be selected by stratified random sampling process with an option of rejection of a nomination based on conflict of interest. That means if someone has certain conflict of interest with the project he or she will be withdrawn from the nomination and will be replaced by another person. The chairman/mayor of the municipal council shall act as the chairman of the meeting for the selection of the jury and a sitting judge from the District/sub-divisional courts as the case may be, shall be nominated by the District judge to oversee the jury selection process. The judge will also act as the arbitrator in case of conflict. The mandate and duration of functioning of the jury will remain until the particular decision is made on that particular occasion. However, once a person has acted as jury member he or she will not be repeated consecutively.

Once the jury is selected, it will be taken away immediately to a venue where they would hold their decision making process. The jury members will be kept away from every one until the decision is taken to avoid any kind of influence. They will be provided with all the necessary technical and professional information and support which shall aid in the decision making. One of the jury members will be selected by the members to act as the chairman of the jury. All the members will have equal voting rights. They will be allowed to deliberate on the issue elaborately before taking the decision. The final decision will be taken based on the unanimity or at least with two third majorities. The whole process will be done under the vigilant observation of a sitting judge nominated by the process as mentioned earlier. The decision taken by the jury will then be conveyed to the city development authorities that in turn convey to the municipal government for ratification. The municipal government will then inform about the decision to the people or stakeholders. In case any decision is not arrived at by the jury, then the process will be repeated from the beginning with a new set of stakeholders and a new jury. If such processes failed three times then the decision with simple majority will be accepted or if the jury is still divided then whole project shall be discarded. The same process can be followed for selection of implementation agencies such as contractors or consultants instead of the current process of selection by the development or municipal government. Further, the decision will remain binding to be followed and will be remained protected from any judiciary and/or administrative interventions unless otherwise there is any technical flaw in the conduct of the process, duly reported by the observers to the district judge, who in turn forward the report to the municipal government.

Thus, the stakeholders and the jury are linked to the decision-making process or implementation of redevelopment project of the city through the causal feedback loops. The stakeholders and municipal government, urban development authorities and implementation

agencies will remain responsible and accountable to each other and the stakeholders will have the right to query issues for the purpose of clarity and ownership of decisions.

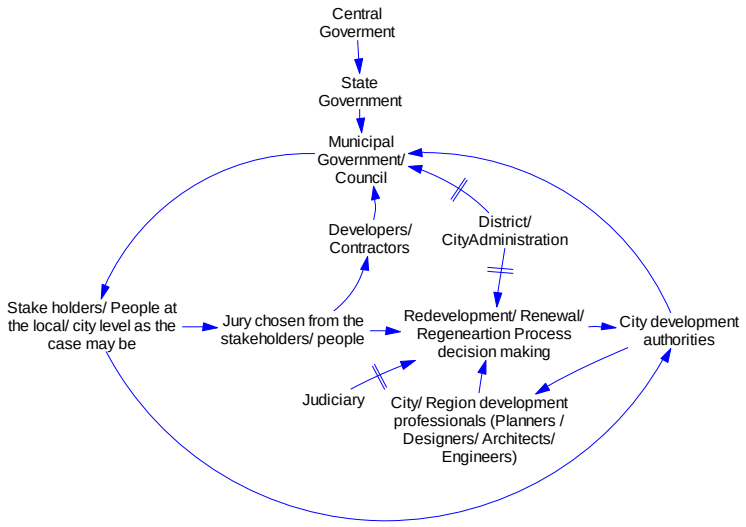

Figure 2. The improved model for stakeholders' participation in the city development

CONCLUDING REMARKS

The existing urban redevelopment/regeneration system and the proposed model have both positive and negative attributes. As such, the concept of a healthy community is closely related to the new urbanism and emphasizes that local government has a critical role to play in determining quality of life, environmental quality, and equitable benefits of social and economic development (Allister, 2004; Bobby, 2005; Hancock, 1993, 1995; Hancock & Duhl, 1986; Lombardi, 2011; Komminos, 2002; Giffinger et al, 2007; Hyeon-Suk Lyu, 2008; Shapiro, 2008; Van Soom, 2009). The present system is simple and also the constitution of India had given the local governments the authority to take decisions democratically without prejudice. However, experience has shown that the process has major flaws and the development or redevelopment work at the local urban level suffers. The decisions have been largely influenced by major lobbyist who exists in a shadow form in the political system; conflict of interest has not been properly controlled; the voices of common citizens observed to be feeble and remain unheard by the authorities. Moreover, there is no such feedback relationship with the municipal government other than the election, which comes at particular intervals. Therefore, if error of judgement happens or a mistake is done by the council or individuals intentionally or without intentions, though may be condoned, but the damage that would cause to the physical, spatial, environmental and socio-economic development of the urban areas or the damage that would cause to the stakeholders in particular or common people in general will remain for long. Thus, under the current system, despite the democratic set up of local self governance, constitutional empowering of the people has not been achieved in real terms and needs a new framework.

It should ne noted that the proposed model also has some limitations or complications. In particular, the authority of democratically elected local governments seems to be challenged. The development authorities may be under confusion with their hierarchical linkage to state governments and local governments. The whole decision making is dependent on a jury selected from a set of invited stakeholders. The stakeholders and jury may not have the technical and professional abilities to take important decisions and may not also be well informed. The selection of the jury may not work as it is envisaged. The judiciary and administrative interventions have been kept out. The majority of the stakeholders may not

agree with the decision of the jury. The jury may not come up with any concrete decisions. Besides, it may add to the cost and could be very time consuming.

However, in spite of the limitations the highlight of the improved or new model is that the stakeholders or common people irrespective of cast, creed, gender, race, and education have the right to take decisions for the development of their area and the planning and decision making shall become inclusive and multi actor based (Scot, 2007). As a chairman of chamber of commerce and industry of a town says

"*.....in this era of information and advanced technology every single stakeholder or citizen is well informed and is capable of taking rational decisions. Particularly the common men have more concern about the development or redevelopment works than the elected representatives or development authorities. There needs to be a better accountability and feedback mechanism which shall aid in proper decision making. Who could do it better than a common man like a shopkeeper, entrepreneur, teacher, doctor or even cobbler and rickshaw puller, who care more about his place of work and environment for the basic necessity of his livelihood?*"

Any stakeholder or person belonging to the area or city can be selected as a part of jury. This brings inclusivity and a sense of belonging to the people in the concerned urban area. The elected council members, the influence of lobbyist or authoritarian civil servants with attitude of superiority and high intellect will have minimal influence on the decision making. The prevention of judiciary and administrative intervention on the decisions taken by the people limit the delay in the development. Further, the whole process strengthened the spirit of the 74^{th} constructional amendment act and empowers the common man in reality. However, this may need some sort of change in power system and may require some amendments in the constitution, which is very critical and time consuming. It also needs the wisdom and acceptance of the already elected representatives and incumbent civil servants who would not want to see their authorities curtailed. The argument here is that we all understand that cities are our future and engines of growth. Indian cities appear to be in complete disarray spatially, physically, socially, economically and environmentally. Reinvention is of necessity and not a luxury today. Urban redevelopment/regeneration and renewal processes are integral to this reinvention. The delay or failure of the urban development or redevelopment schemes/programmes shall worsen the already disarrayed situation. Therefore, the fate of Indian cities cannot be left to the wishes of a few hands in the name of democratic set up. The system has worked for long enough to make us understand that there is a need for change.

As an end note it will be worthwhile to remark that one example of such success is Vancouver city in Canada. If a city like Vancouver could succeed in its social and economic construction through the complex linkages that tie agents to their environment, where the power arises from strong popular control and local democratic and participatory values, the group interactions produce and co-produce community development and provide an open yet stable, socially progressive yet fiscally conservative and pro-development city, why our cities can not follow such success (Jailly, 2008). Therefore, if we want to reinvent our cities with responsive citizens we must accept changes and if needed, the constitutional recourse be considered to empower people rightfully and allow them participate in the decision making and implementation process in real terms. The improved model proposed here may have its limitations, yet it will better suit to a populous and democratic country like India to reinvent its cities.

ABSTRACT

This study was conducted to provide local, up-to-date and reliable information concerning condition of selected slums in the suburbs of Abuja. This was with a view to minimizing over-reliance on non-indigenous information on slums which was inadequate for formulating or modifying local policies intervention programs. Usually, the difference in socio-economic status of citizens and the geographical variance influences patterns of slum settlements such that general or global information may not suffice in policy formulation. This study assesses housing conditions, water supply and sanitation, and security of tenure of dwellers in Aso- Pada ward. The study design methods includes literature review, reconnaissance and household surveys. This research is explanatory; hence, a non-probability purposive sampling technique was used. In order to select respondents for the questionnaire survey, the seven polling units of Aso Pada ward were considered. These are Kodupe Primary School, Tudun Wada Primary School, Kudu Luvu- OP, Koya- OP, Jen Kokoro- OP, Ebba- OP, Aso- OP; and also based on the 2006 population and housing census guidelines that says an Enumeration Area (EA) is made up of between 250- 500 people. The identified polling units were stratified and the respondents randomly selected from each stratum. Empirical data were obtained through questionnaires and interviews with 300 household randomly selected using a 5% sample population size and also through focus group discussions (FGD). Results showed that more than half of the respondents did not have proper land titles, houses were overcrowded and in dilapidated conditions. Other findings also indicate that 92% of the respondents were reluctant to develop occupied building due to lack of security of tenure of occupied plots, and a remaining 8% developed their buildings to standard as prescribed by local building codes within the study area. This was attributed to the fact that they possess secure tenure of their plots.

Keywords: Empirical data, Household survey, Housing conditions, Stratified randomly selected, Slums

INTRODUCTION

Providing local, up-to-date and reliable information concerning slum conditions would be of great benefit in prioritizing areas to improve and generate strategies that would address specific urban slum problems. Studies show that 3 billion people live in urban areas, almost 1 billion of them in slums; and worst hit is Sub-Saharan Africa where 72% of urban inhabitants live in slums (Catherine, 2011). The number of the urban poor living in slum will continue to increase, if appropriate measures are not taken. According to UN-Habitat as cited in Negera (2012), the number of slum dwellers worldwide continues to grow at a rate of 10 percent every year; as a result, future urban development will show further expansion, sprawling of slum and spread of urban problems if no remedial action is taken in the incoming years. With these enormous slum problems, the developing world mainly depends on global information on slums which is, in general terms, inadequate for formulating or modifying policies for designing different intervention programmes at local level because of aggregation and geographic variability (Lemma, 2005). This challenge of local level information on slums can be locally mitigated if slum studies are produced quickly and accurately, entire cities can also be assessed and slum areas prioritized for improvement or more detailed studies carried out (Parham, 2012). To proffer solutions to problems of local level information on slums, this study was conducted and slum conditions were investigated in Aso-Pada, Karu Local Government Area of Nasarawa State, Nigeria.

LITERATURE REVIEW ON SLUMS

The purpose of this section is to provide a conceptual background, mode of formation and characteristics of slum settlements. It will also highlight certain factors responsible for slums development in Nigeria and the global perspectives from various authors.

Definition

Slum has many connotations and meaning is seldom used by the more sensitive, politically correct, and academically rigorous fora (Lemma, 2005). Urban slums were defined as urban settlements, neighbourhoods, or city regions that cannot provide the basic living conditions necessary for their inhabitants to live in a safe and healthy environment (Jordan, 2015). It is often not recognized and addressed by the public authorities as an integral or equal part of the city. However, the UN-Habitat (2002) gave an operational definition of slum as a contiguous settlement where the inhabitants are characterized as having inadequate housing and basic services; and also defined a slum household as a group of individuals living under the same roof in an urban area who lack one or more of the following: Sufficient living space; Durable housing; Access to adequate sanitation; Easy access to improved water in sufficient quantity at affordable price; and other infrastructure and Security of tenure.

Slums Formation

According to (Negera, 2012) Slums develop in phases in relation to the prevailing circumstances, gives three basic stages of slum development which include Infancy Stage, Consolidation and Saturation Stage.

i. **Infancy Stage -** is the initial occupancy stage where patches of vacant land like on steep sided land, swamps, near river banks, hazardous areas, conserved areas, etc. become available to the slum dwellers. It could also occur on suitable lands and possibly emerge from decayed formal areas; because of job insecurity, slum dwellers prefer to live on hazardous areas than to live on suitable land of faraway places i.e. Aso Pada the study area
ii. **Consolidation Stage** – is the intermediate stage between infancy and saturation stages. At this stage, there is fast outward expansion and available land will be reduced by filling up additional building.
iii. **Saturation Stage** – is the stage at which the expansion stops as the vacant lands get filled up. At this stage overcrowding is highest and lowers the living standards of slum dwellers i.e. Aso Pada

Causes of Slums Formation

Slums are a product of many factors globally. (Davis, 2006) in his book "Planet of Slums" enumerated factors that resulted in mass production of slums in different parts of the world to include Mechanization of agriculture in Java and India; rapid urban growth in the context of currency devaluation and state retrenchment. However, (Negera, 2012) is of the view that the causes of slums formation are issue-related in nature and key among them are:

i. Urbanization which has population growth, rural to urban migration and globalization as major components;
ii. House and land related issues with main elements as high rental house, few affordable houses, high land value, inefficient land provision, dysfunctional land market, hazardous area or vacant land;
iii. Governance and policy related issues with ineffective housing policy, poor land management policy, institutional and legal failure, lack of political will and corruption;

iv. Social Related Issues which has its components as poverty, ignorance, low income, urban inequality and lack of opportunity.

Arima (2001) and Lemma (2005) believe that the current situation of slum proliferation in Africa can be partly attributed to the absence of studies that empirically link the prevalence of slums with possible driving forces at either the city or National level.

Causes of Slums Formation in Nigeria

Urban planners and other experts in the built environment attribute continuous formation of slum settlements in most Nigerian cities to a number of factors. Ineffective implementation of housing and urban development policies, push and pull factors urbanization and poverty, socio-cultural attitude, rural to urban migration, unemployment and bad governance are among other causes of slum formation in the country. In many Nigerian cities, buildings have been and are being constructed without approved layouts, springing up of illegal structures and disappearing of open spaces, apparent lack of good access roads in some parts the cities which are a product of poor implementation of existing development control and land use laws by states and local planning authorities (Aluko, 2011). Some authors believe that slum settlements develop as a result of push-and-pull factors. Yussuf, Bako, Omole, Nwokoro and Akinbogun (2014) found out that push factors such as high rents, loss of employment, forced eviction, political/communal/personal conflicts and pull factors like proximity to work place, transport facilities, low cost of living, cheaper rents/lands were responsible for slums formation in some parts of Lagos city. Sanusi (2011) discovered that development of informal (slum) settlements particularly in Minna Niger State, Nigeria had been occasioned by housing inadequacy, high urban population growth, inefficient city governance, poor urban development control, low human development, poverty results into self-housing development and illegal housing development especially residential development on ecologically unstable land, marginal land such as up-hills, flood prone areas. Another reason that slums develop in developing countries like Nigeria according to some authors is bad governance. Morakinyo, Ogunrayewa, Koleosho and Adenubi (2012) assert that governments often fail to recognize the rights of the urban poor and incorporate them into the planning, thereby contributing to the growth of slums because people are coming to the cities far faster than the planning process can incorporate them; in the interim, they build shack before government has a chance to learn of their existence. Some authors opine that urbanization has been contained in the developed world through development of critical infrastructures, but in the developing nations little has been done with respect to this. According to (Morakinyo, 2012), governments of developing countries don't have planning tools to deal with rapid urbanization, or the tools in place are not sufficient to address the reality on ground, instead they take a hostile approach towards urbanization believing that providing urban services to the poor will attract urbanization and cause the slums to grow, unknown to them however, the majority poor come to the cities looking for work, not water or services. The Centre on Housing Rights and Evictions (COHRE, 2014), decried that the Federal government of Nigeria at various occasions had pledged to provide adequate housing for growing populace, yet it had failed to fulfill its promises which had led to the proliferation of slum communities in and around most major Nigerian cities. But Zubairu (2014) blames the inability of state and local governments to minimize growth of slums in their respective domains, in Minna the Niger State Capital for example, there has been a steady increase in size and density of slum settlements across the city where the number of slum settlements keeps growing from 9 in 1993, 16 in 2003 and 21 by the year 2013. In Nigeria, some authors are of the view that rural-to-urban migration plays a role in slum formation. Akinwale et al (2013), found that majority of slum dwellers in Lagos Nigeria migrate to the city due to prevalence of poverty and unemployment in their various places of origin.

Background and Statement of Problem

Slum development in and around major towns, and cities of the world is becoming a growing urban phenomenon especially in developing countries. Perhaps, due to either failure of government, urban development policies, poor implementation of existing development control and land use laws, urbanization, urban poverty, rural-to-urban migration, or socio-cultural attitude of the natives of some communities towards governments physical development policies. Whether slum settlements develop in the core or on the peripheral parts of towns or cities, they are formed on either legally/illegally sub-divided lands, individually acquired lands, public vacant lands or lands belonging private corporate organizations.

The Research Problem

Ideal urban neighbourhoods can be situated in almost all parts of towns or cities either on public lands, privately acquired lands, or lands belonging to the native of a particular community. Regardless of the location, the development of such urban settlements especially those to be situated at the periphery of the towns or cities as part of the future expansion of those towns or cities are optimally guided by established urban physical development policies. The instruments employed to execute these urban development policies are usually the urban plan and the local plan. While the former deals with future physical form and the structure of towns and cities, the latter concerns with the detailed layout of the various local areas (zones) contained in the urban plan. It is a common complaint among residents of some settlements in Aso- Pada that slum conditions have been manifesting spatially. This study will investigate slum conditions and their causes in Aso- Pada, Karu Local Government Area, Nasarawa State, Nigeria.

The Justification

According to (Sanusi, 2011) informal (slum) settlements particularly in Minna, Niger State, Nigeria had been characterised by housing inadequacy, high urban population growth, inefficient city governance, poor urban development control, low human development, poverty which has resulted into illegal housing development on ecologically unstable land i.e. land such as up-hills, flood prone areas. Aluko (2011) blamed poor implementation of existing development control and land use laws by states and local planning authorities in many Nigerian cities for lack of good access roads in some parts the cities building construction without approved layouts, springing up of illegal structures and disappearing of open spaces. However, the problem of slums development is becoming worrisome and on the increase; and if causes of slum development in various urban settlements in Nigeria i.e. Aso Pada are not investigated, their peculiar physical and socio-economic characteristics cannot be effectively understood to mitigate further occurence.

According to Negera (2012) there is need to understand the slum development process considering the multiple faces of slums and their multidimensional nature specially between and within countries and cities. Parham (2012) also advocates conducting local slum studies that will address specific problems to provide reliable and up-to-date information on slums which are uncommonly available in other countries. Aso Pada was considered based on its peculiar slum characteristic features which ranked lowest as compared to other identified slums within the urban settlements of the greater Karu Urban Area.

Aim and Objectives of Research

Research Questions

i. What are the living, housing, water and sanitation conditions in Aso- Pada?
ii. Why do the inhabitants choose to reside in the slum areas?
iii. What are the challenges and problems that the slum dwellers face?

iv. How can the problems be mitigated for the improvement of lives of the people in slum areas in Aso- Pada?

Aim

The aim of this study is to assess the slum household living conditions in the study area with a view to providing local and up-to-date information on slum conditions that address specific urban slum problems.

Objectives

To achieve this, the objectives are to:

i. Identify locations of slum settlements in Aso- Pada ward, Mararaba, Karu Local Government Area of Nasarawa State.
ii. Observe the physical condition of the identified slum settlements, Aso- Pada.
iii. Examine the living conditions of slum dwellers in Aso- Pada.
iv. Provide recommendations for improvement of their living conditions.

Basic Assumptions

In other to achieve the objectives of this research work, the following assumptions were made:

i. The uncontrolled urban expansion and resultant spontaneous development as a result of population growth in Aso- Pada ward is enough evidence based on observation to categorise the area as a slum;
ii. The uncontrolled urban expansion and high population has led to unplanned and crowded housing conditions that over stretch reliance on sanitary facilities, building with low quality materials are typical characteristics of slum areas as can be relied on from literatures.

From the above statement, we can see a significant relationship between slum development and population growth in Aso- Pada of Mararaba district in Karu local government area.

STUDY AREA

The Karu Urban Area is an urban area in central Nigeria. The urban area is majorly located in the Nigerian state of Nasarawa, but with some parts stretching into the boundaries of the Federal Capital Territory (FCT). It has an area of 40,000 hectares (400 km²) and a population of some 2 million. It is one of the fastest growing urban areas in the world, with a growth rate of 40 percent recorded annually. The Abuja demolition of informal settlements in previous years has led to mass movements of people into the suburbs. As a result, settlements in Mararaba has experienced unprecedented urbanization, increase in demand for and rapid development of infrastructural facilities, social services and housing, changes in land tenure, increase in real property development and value, economic, social and political activities which are each contributing significantly to rapid sprawling of the area. From west to east, the urban area includes towns like Kurunduma, New Nyanya, Mararaba, New Karu, Ado, Masaka and newer, fast-growing towns such as One Man Village (which contains over 1 million people) and Gidan Zakara. Since the beginning of the 20th century, these districts have grown together into a large urban area and a major commercial centre of central Nigeria. (Source: www.en.wikipedia.org/wiki/karu_Urban_Area, retrieved 2015)

Sample Area

Greater Karu Urban Area (GKUA) has both urban and rural settlements. The major urban settlements within the greater Karu are Mararaba, New Karu, New Nyanya, Masaka and Uke.And in conducting this survey, we attempted to compare other settlement which have

been overtaken by new urban development and engulfed by the larger ones such as Zhenwu, Luvu, Kuchikau, Kodepe, Aso Pada, Ado, Koroduma and One Man Village. Aso Pada depicts a worst state of condition and exist in the periphery of Mararaba, Latitude 9^{o} $02^{'}$ $43.12^{''}$N, Longitude 7^{o} $36^{'}$ $18.40^{''}$E. It has developed over time due to the relocation of the Federal Capital Territory (FCT) from Lagos to Abuja and also the quest for accommodation by the growing population. The Abuja demolition of informal settlements in previous years has also led to mass movements of people into the suburbs, see fig. 2.

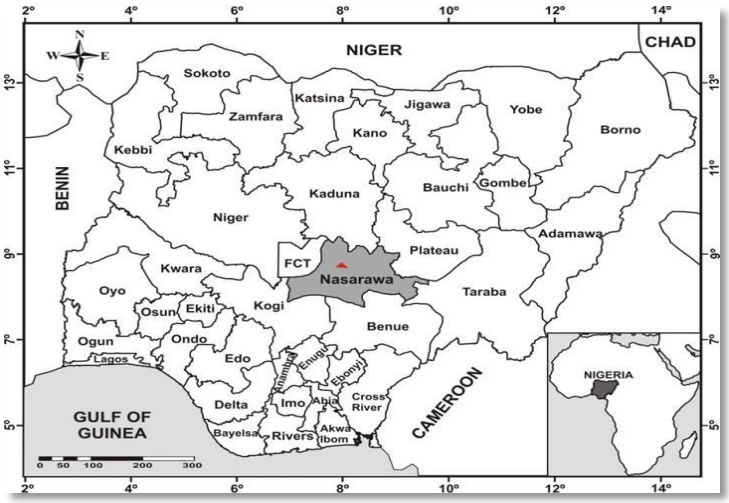

***Fig. 1**: Nigeria showing Nasarawa State **(Source**: NAGIS, 2015)*

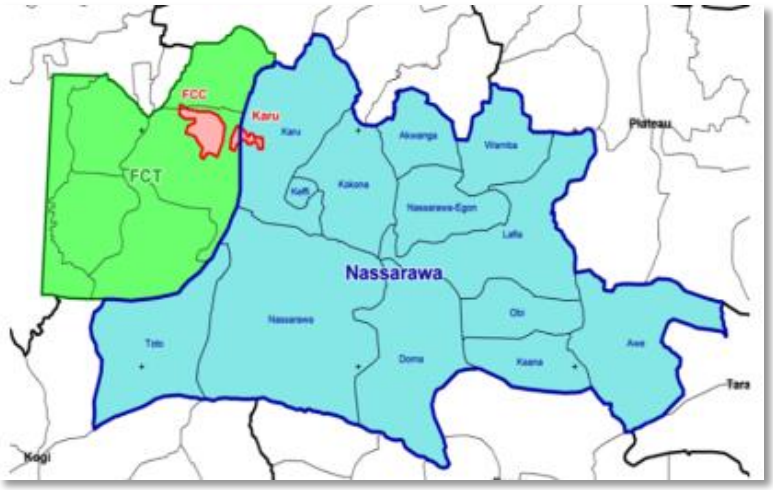

***Fig. 2**: Nasarawa State showing Karu L.G.A **(Source**: NAGIS, 2015)*

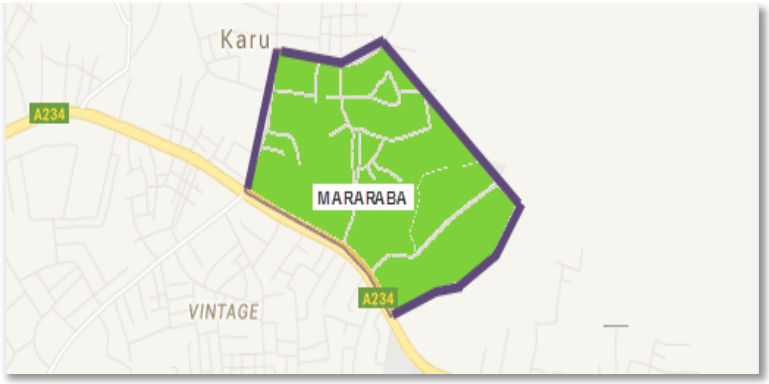

***Fig. 3:** Mararaba Boundary **(Source:** Google Earth)*

Sampling Frame

Currently the exact population of the area is not known as the National Population Census (NPC, 2006) undoubtedly grossly underestimated the population of the settlements. However, claims by Manok (2008); Karu LGA; Nasarawa State Urban Development Board (NUDB); land registration and demand for facilities, opined that the population of the planning area is about 4 million inhabitants. In order to select respondents for the questionnaire survey, the seven polling units of Aso Pada in Mararaba district were considered. These are Kodupe Primary School, Tudun Wada Primary School, Kudu Luvu- OP, Koya- OP, Jen Kokoro- OP, Ebba- OP, Aso- OP; and also based on the 2006 population and housing census guidelines which says an Enumeration Area is made up of between 250- 500 people. 300 questionnaires were administered representing a 5% sampled population of identified polling unit's. The units were then stratified and respondents randomly selected from each stratum.

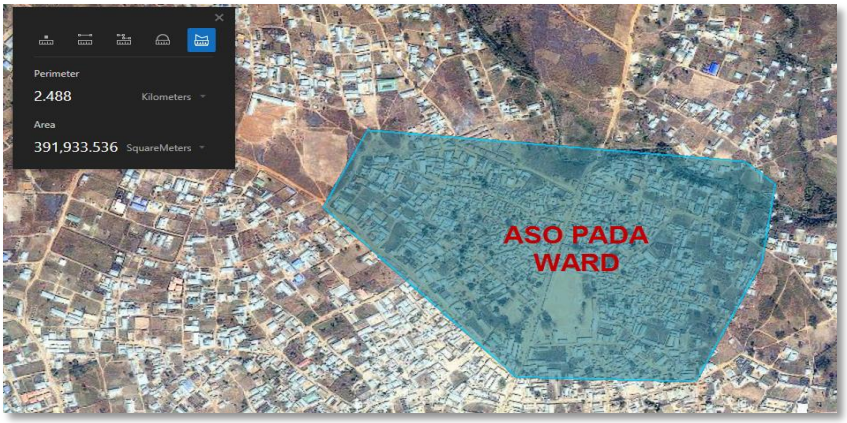

Fig. 4: *Satellite Imagery of the Study Area- Aso Pada* ***(Source:*** *Google Earth)*

METHOD OF STUDY AND ANALYSIS

The approach adopted in this study is a case study. A case study is "a methodology that is used to explore a single phenomenon in a natural setting using a variety of methods to obtain in-depth knowledge" is capable of accommodating different research techniques and is normally used when it is required to obtain in-depth knowledge with regard to a particular phenomenon Gayan, Bingunath and Dilanthi (2011). The data collected for this study was analyzed using descriptive and inferential statistics. A case study is preferred when research questions take the form of "how" and "why" Gayan (2011). A basic assumption was used in correlating the relationship between slum development and population growth in Aso Pada of Mararaba district in Karu local government area. Percentage was used to highlight the nature of the housing problems in the area. However, when a research is using case studies, it is difficult to make generalizations according to (Soy) in Romanus (2013). Therefore findings from the study will be supported with literature reviews to make it viable for generalizations. The investigation will involve field survey where data will be obtained from heads of households in the study areas.

Scope and Limitations

The scope of the study is limited to slum living conditions of dwellers in the proposed case study area (Aso- Pada of Mararaba district in Karu Local Government of Nasarawa State, Nigeria). The study on slum living conditions in the area is the first of its kind that will focus on physical and socio-cultural indicators. What peculiar trends will there be in terms of the physical conditions and socio-cultural status of the residents of the study area. These questions will be answered by this study.

DATA ANALYSIS

Housing Adequacy

Figure 5 shows that 48.3% of the respondents have 5-10 persons/ household, about 25% have 5 persons/ household, 11% have 4 persons/ household, 6.7% have 3 persons/ household, 5% have 2 persons/ household, 4% have 1 person/ household. The fact that 48.3% makes the highest is an evidence of high population index resulting in the quest for accommodation leading to slum formation in the area.

Access to Adequate Water

The findings from the field survey indicated the absence of pipe borne water supply leaving the inhabitants of the area with no option that to buy water for drinking and other domestic use from water vendors and from people who have sunk in boreholes for commercial purposes. Majority of the respondents said the water are usually not sufficient for their domestic use.

Access to Adequate Sanitation

The finding from this section reveals that the houses in the study area lack access to basic sanitation facility, very old in structure and condition. 49.3% of the respondents said they are made to share one toilet in a compound that accommodates more than six to ten household in the same compound, 41% have two toilets to share in a compound and relative 9.7% of the respondents do not even have a toilet leaving them with options of going to open spaces within the study area, bush and streams.

Structural Quality/Housing Conditions

This section reveals that the houses in the study area are old and in dilapidated conditions with old roofs and cracked walls. 56% of the respondents have their roofs to be leaking, 44% said their roofs were in good conditions and not leaking. A chunk population making 73.7% attest to the fact that their walls are cracked which pose a threat of collapse and habitats for reptiles i.e. lizard, 26.3% said their houses do not have cracked walls.

Occupancy Ratio

The following sections outline the household occupancy ratio profile of the respondents in this study. The population distribution of respondents as shown in the figure above explains the expected average household size to be 7, the population covered as analyzed from respondents is 2059, the total number of habitable rooms/ household is 462, the standard occupancy ratio is 2.5, the expected population as compared to the average household size and number of habitable rooms is suppose to be 1155, above all the spillover population in the survey area is 904. This indicates that the study area is over populated and there are insufficient rooms to carter for the spillover population causing an over stretch on the available social amenities and infrastructure. Most of the respondents attest to the fact that their income cannot afford them descent accommodation making it difficult to live elsewhere than this area. This conforms to the view that poverty, population increase and demand for cheap accommodation is a factor manifesting the development of slums as was observed in Aso- Pada, the study area.

CONCLUSION AND RECOMMENDATIONS

In conclusion, a common landholding pattern in the identified slum settlement, Aso- Pada ward is that the land is owned by one large landowner, often a family. According to local residents, a substantial portion of the land occupied today was purchased from these families and the buyer after buying from the land-owning families never carried out any form of regularization- a process through which planning and regulation authority formalyy institutional processes. Most of the ills of traditional tenure found in the study area can be

traced to or stem from tenure insecurity due to uncertainty. This research found that approximately majority of the respondents in Aso- Pada ward currently live in this slum as a result of tenure status. The overall environmental quality since the threat of forced eviction fosters a negative attitude among residents towards improving their environment. Most of the developable lands have been significantly developed illegally even the residual pockets of marsh and poorly drained plots are rapidly being filled too with all kinds of structures. This characterizes a poverty trap from which the poor find it extremely difficult to escape. The interplay of all these factors has tended to maintain these groups in a vicious circle of poverty and insecurity.

RECOMMENDATIONS

There is the need to generate data on slum development locally in developing countries like Nigeria. This is crucial to the well being of its citizenry, in other to achieve some level of consistency in generating such vital information, research at local level on slums should be encouraged so that suitable methodologies can be developed to that effect. However, a lot can be achieved in the area of identification, classification and slum upgrading in Nigeria. Other ways that can aid the generation of these data are:

i. Planning and public regulation agencies should be strengthening to enforce planning regulations across the various levels of government from bottom to top- local-state-national.
ii. Efforts should be made by the Government and Non Governmental Organization in the provision of water and basic sanitary facility in the study area;
iii. Planning and development control instruments should be enforced in ensuring that local building codes are adhered to;
iv. Land acquisition process should be made less stringent to allow the common man access to proper land title;
v. Affordable housing provision should be given the necessary attention to check overcrowding;
vi. There is the need to encourage behavioral change through campaigns and awareness in the study on the proper ways of managing solid waste and environmental degradation.

Architecture and National Development

Effects of Globalization of Information Technology Communication Facilities on Architectural Practice in Nigeria

Adegbehingbe, Victor Olufemi [1]* & Ogundiran, Ibikunoluwa Ajibola

[1 & 2] Department of Architecture, Federal University of Technology, Akure, Nigeria
** victoradegbehin22@gmail.com*

ABSTRACT

The world today is witnessing the breakdown of territories in all countries and all the countries are coming up into a conglomerate call the global village. This globalization was not brought about by accident; it was as a result of advancement in technology which has succeeded in bringing all the countries of the globe together. This nature of the world has influenced so many professionals practice including architecture. This study examines effects of globalization information technology communication facilities on the architectural practice in Nigeria. It employs the use of both primary and secondary data for the study. The primary data were obtained through the use of questionnaire. The study considers only firms headed by registered Architects in Lagos, Ibadan and Abuja as listed in the register of Architects registration council of Nigeria (2012). Secondary data sources were obtained from the publications of Architect Registration Council of Nigeria (2012), which listed 388 firms entitled to practice in Lagos, Ibadan and Abuja Nigeria. The study sreveals that computer ranked first on the list of available information technology facilities in the firms with mean score of 3.2. The list available shows that Internet facilities, with a score of 2.57 and very few firms had websites. It appears that most of the firms were not global, as the presence of the firms on the web is an indicator of globalization of the firms. The study revealed increased performance in the practice of architecture in Nigeria, brought about by the effective use of information and communication technology as opportunities of globalization. The study concludes that the advent of globalization has brought a lot of ease and effectiveness to the practice of architecture in Nigeria.

Keywords:

INTRODUCTION

Globalization has influenced so many businessesand professions among which includes the practice of Architecture which aims at taking responsibilities for the design, construction and supervision required for the accommodation of the members of the society in efficient and sanitary surroundings at home and at work(Martins,1995). Architectural practice which officially started in Nigeria in 1960 has responded to the call of globalization and has gone far beyond what it used to be in the 19th and 20th centuries (ogundiran, 2006). The practice of Architecture (in Nigeria) has gone to a class where architects are required to move at a pace of the world business practice evident in the adoption and use of information and communication technology, inter-boarders outsourcing etc ,for international services so as to address how best the architectscomplement competitive advantages that can be gained from the world wide operations (Knox and Taylor, 2005).

The advent of globalization in the practice of architecture in Nigeria is a consequence of the pressure of globalize architecture which sprang up from two sources: global culture of commerce and the global culture of design (Lewis, 2002). This study examined the availability of information technology facilities, application of internet facilities, existence of website and electronic mail addresses of architectural firms in Lagos, Ibadan & Abuja as case study and the effective use of these information and communication technology will provide opportunities for globalization of architectural practice.

Globalization and Architecture

Globalization culture has little or no provision for indigenous ideas. In fact, it aims at competing critically with whatever products or culture that is prevailing in the home

Adegbehingbe, V. O. & Ogundiran, I. A. (2016). Effects of Globalization of Information Technology Communication Facilities on Architectural Practice in Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1702-1709

countries. Globalisation is not meant to be friendly, rather it is an aggressive free world of the survival of the fittest. It has no human face. Exposing the nation's destiny to full global world would end up in neo-colonisation.The inability to carry out the use of other options of building materials is simply because of the extensive acceptance of cement as the only binding material for building components. Stabilised bricks have the capacity of reducing the cost of building by 40%. Yet, it is yet to be popular simply because the training of architects only refers to the use of cement and its products. Most curricula of building components and method hardly emphasise the use of stabilised bricks and yet this is the most relevant technology affordable to majority of Nigerian populace. Projecting from a research conducted by (Awotona, 1983), it was discovered that in Lagos, the Nigeria centre of excellence, only 42.3% of the residential buildings could be considered as good based on the minimum building standards. 17.4% are described as 'fair' while 40.3 are 'bad'. This is a clear indication of the true position of things today.

The Nigerian population growth rate of about 3.5%/annum is particularly very high. Most disturbing is the inequality in the growth of this population, as many of the major urban centres have doubled their population within the past three decades, while the rural population are continuously depleted. It is on record that the federal capital of Nigeria, Abuja is the fastest growing city in the world. This simply implies that the city is fast developing into an urban slum. There is no corresponding growth in infrastructures and physical developments thus creating more urban challenges.These are some of the peculiarity in Nigerian situation that requires specialarchitectural training. Nigerian cities and urban centres are growing phenomenally in area and population without planned direction due to the strain and stress of urbanisation and modernisation. This is reflected in the colossal deficiencies in housing, growth of urban slum, congestion of traffic, concentration of industries, social disorders and economic distress to mention but a few (Olateru-Olagbegi, 1982, Daramola, 2004).

The characteristics of Architectural firms and practices.

Architectural firms have been described as having a number of characteristics which in Emmitt (1999) opinions are ones which distinguish them from other types of business organizations. According to Winch and Schneider (1993), architectural firms provide a service, they are regulated by professional bodies, they are creative, and dependent on one particular industry, which is the building industry.

Architectural Firms as Service Firms

The majority of architects have been described as working in the building design, information and site inspection business (Sharp 1991). More specifically, architectural firms are concerned with providing service to a client which usually results in a product – the finished buildings (Emmitt 1999).

Architectural Firms as Professional Firms

The activities of the architects, architectural technologists and building surveyors are all regulated by their professional institutions and bound by respective code of conduct. Although the professional institutions were originally set up as a means of protecting their members' interests, some of their professional rules have limited the manner in which their member can trade, for example by restricting the manner in which they may advertise their services. The professional institutions are often perceived by their members as restricting the manner in which they can trade. Registered firms must comply with the relevant professional institution's code of conduct, otherwise the firm is free to act in any legal way it choose (Sharp 1991).

Architectural Firms as Creative Firms

Architectural firms are commissioned by clients to provide individual solutions to unique problems; they are primarily concerned with generating and maintaining creativity, an activity that many architects claim they would like to spend more time on in the modern office.Blau (1984) found that architects had a strong identification with work that was creative despite the fact that they worked in highly specialized or very technical areas. It has been observed that design is only a small part of an architect's job in-practice, much of their time are spent on issues relating to the construction of buildings, legal and financial considerations, the administration of individual jobs and personal management. When analyzed many of individual daily activities are concerned with issues generally referred to as management, yet it has been argued that management is a mystery to many design professionals, unsure whether it refers to business affairs or to bureaucratic control of the firm (Kaderlan 1991).

Architectural Firms as Building Industry Dependent

Architectural firms have a special relationship with one industry – building. This is not a homogeneous industry but is made up of many disparate strands. Buildings is essentially an industry of assembly (Emmitt 1999), regardless of the amount of prefabrication offsite, there are always factors unique to individual contract which makes it vary from one another within the same overall principles (Bennett 1981). Furthermore, buildings are fined to a particular location which means that materials and labor have to be taken to the site; thus building can never be a manufacturing process. Building is a complex problem because of the many different skills required during the different stages of the product's life cycle, requiring inputs from different areas at varying times.

Impacts of Globalization on Architectural practices

In his study of the impacts of globalization on the architectural practice in Kuwait, Mahgoub (2012) identified five aspects of globalization as economic, political, technological, social and cultural systems necessary for understanding the concept.

The global market place liberated professional services and labour, building materials and construction methods, trade and investment from the limitation of national boundaries. It allowed the free flow of materials and services across border and boundaries.

The impact of global politics on everyday life is apparent. Political events in one country affect other countries almost instantaneously. On the positive side, the rise of human rights awareness pointed on issues of the right to housing; housing of marginalized populations, and housing for the poor.

Telecommunication and information technology has produced a need for a new type of technological infrastructure, building types and design requirements. The electronic technology produced new breed of intelligent and smart buildings. The impact of the internet on architectural practice is evident in new trend of international firms to establish branches in different parts of the world utilizing the time difference to keep their business running 24 hours a day. For example, the easy transfer of drawings and documents aided in the globalization of architectural offices and projects is speeding the production and development of projects. Transportation technology affected urban and city planning theories and produced changes in understanding space and proximity. Building technology suggested new methods of construction and materials that require new methods of expression.

The traditional living/working habits that resulted in the separation between work and home during the 20th century, are giving way to new and revived forms of homework environment and mixed use planning that existed centuries ago.

Relationships between groups and individuals are influenced by ease of interaction and communication over the internet, permitting ‘’virtual’’ social interaction with people all over the globe. The internet offers information and knowledge about other societies that used to take long time to disseminate. The lifestyle of fast food chains, luxurious shopping centers, and other commodities is available all over the world today. The culture of the ‘global village’ disregarded cultural differences and increased similarities in lifestyle around the world throughthese icons of globalization.

The Opportunities of Globalization for Nigerian Architecture:

The use of computer in architectural practice in Nigeria has gained prominence. Globalization has impacted the practice of architecture in Nigeria with the use of electronic mail (e-mail) and other internet facilities. The use of Computer Aided Design (CAD) packages has facilitated faster and effective ways to present design concepts and co-ordinate with other professionals far away without being physically present. With wider and versatile use of the computer the architects in Nigeria are working as analysts, 3D presenters, furniture developers, hospital specialists, architectural historians, interior designers, landscape designers and urban designer. The latest version of Auto CAD series among others have proven to be essential tools that have contributed positively to the practice of architecture in Nigeria.

The Threats of Globalization for Nigeria Architecture:

Non-Sustainability or Urban Sprawl

Globalization has impacted so much on the practice of architecture in Nigeria and the results are evident in the physical aspect of the built environments. Simply put, most of the global-style developments in Nigeria are not sustainable. Most developments in Nigeria urban centers require large pieces of land, which are rare, resulting in the loss of a large amount of open space in the city, or new development spread outside the inner city, thus creating urban sprawl. The new sprawl of developments is often environmentally insensitive due to large amount of impervious surface previously or meant for green area, as in the case of Gwarimpa 3rd Avenue in Abuja, where the resulting commercial development are neither pedestrian friendly nor connected by pedestrian systems of the community.

Non-Cultural Designs and Construction

It was also discovered that the practice of architecture in Nigeria is gradually losing respect or appreciation for cultural or indigenous construction. The new development in Nigeria can no longer be identified by their construction or contextual characteristics.Most or all buildings in Nigeria are being built in international style. With fabulous photographs in slick magazines and professional journals, Nigerian architects scan and pane the globe sharing high-style concepts rendered in stylish materials. Glass, aluminium, stainless steel, copper, titanium which may not be easily accessed locally are now imported with ease having neglected our cheap local indigenous materials. Stabilized bricks have the capacity of reducing the cost of buildings by 40% (Daramola, et al.2012)

Architectural Anarchy

Architectural anarchy is another outcome of the manifestation of globalization in Nigeria. Anarchy, defined as lawlessness, social and political disorder caused by absence of government control. Architectural anarchy in the case of Nigerian practice of architecture arose from the negligence of the basic principles of architectural unity such as rhythm, balance, harmony, and contrasting the design and layout of buildings. The result of the research carried out by Bello et al (2007) in Ogbomosho revealed as the following manifestation of anarchy among others: Sitting of industrial buildings in the midst of

residential and public buildings, filling station in the midst of residential areas, and inappropriate location of religious houses within residential areas.

RESEARCH METHODOLOGY

The data for the research were obtained through primary and secondary sources. The primary data were obtained through the use of questionnaire. This study considered only firms headed by registered Architects in Lagos, Ibadan and Abuja as listed in the register of Architect registration council of Nigeria (2012).

Table1: No of Registered architectural firms in selected towns (Lagos, Ibadan & Abuja) in Nigeria

S/N	Town	No of Registered Firms
1	Lagos	206
2	Ibadan	54
3	Abuja	128
	Total	388

Source; Adapted from ARCON, (2012)

Samples of firms were selected from cities where the firms were mostlyconcentrated in Nigeria.

This study was limited to architectural firms and did not include all types of architectural practices. This study considered only firms headed by registered architects, (ARCON, 2012). This study was carried out at the level of firm rather than the individuals of the firms.The study adopted survey method. The firms studied included in the study population were those that are registered with the Architects Registration council of Nigeria, and are practicing in Lagos, Ibadan & Abuja. The primary data collection involved an extensive study of the architectural firms to obtain only the profile and technological data of the firms. Secondary data sources were secured from the publications of the Architects Registration Council of Nigeria (ARCON,2012) listed three hundred and eighty eight firms entitled to practice in Lagos, Ibadan and Abuja Nigeria as shown in Table 1.

The sampling method that was most adequate for the study was hybrid of two methods-purposive sampling and random sampling. This involved first purposively selecting the cities, where architectural firms were most concentrated in Nigeria, and then randomly sampling within the cities.

The study took its purpose samples from three cities, where architectural firms were most concentrated in Nigeria (Lagos, Ibadan, &Abuja). In order to obtain random samples within each of these cities, the sample frame that was used was based on the Register of Architectural Firms entitled to practice in Nigeria (ARCON,2012). Random sampling gave the individual firms in the cities equal probability of bearing selected.

Table 2 : The calculated appropriate sample sizes

City/Town	Sample Frame	Calculated Appropriate Sample Size
Lagos	206	110
Ibadan	54	32
Abuja	128	73
Total	388	215

Each sample was then selected randomly.

This study focused on principals/senior partners of firms, from whom information was sought about information technology usage of firm. This study took a cue from the studying by Symes et al, (1996) where the firm was used as the unit of analysis.

The instrument for collecting data was by questionnaire and was administered to principals or senior partners of firms. The questionnaire were combination of closed and open-ended questions.

The technological data included number of computers in firm, frequency of use of the internet to exchange information, and the application to which information technology is put.

The quantitative data were analyzed using descriptive statistics. Tables were used in presenting the results. Data was collected with the aid of six field assistants who were Practicing Architects in towns they administered the questionnairebetween June 2014 to August 2014, and various responses were analyzed by means of statistical package for social scientists (SPSS version13).

A total of 117 questionnaires were returned duly completed. The distribution of questionnaires relative to the duly completed forms is detailed out in table3.

Table3: Distribution of Questionnaires to Architectural Firms in Lagos, Ibadan &Abuja, Nigeria

Location	Sampleframe	No of Questionnaire	No of duly completed quest	% of duly completed questionnaire
Lagos	206	110	63	57%
Ibadan	54	32	16	50%
Abuja	12.8	73	38	52%
Total	388	215	117	54.42%

Table3 above shows the distribution of architectural firms in the three cities in Nigeria and also present the proportion of the responses to the questionnaires distributed. The responses were very low due to the fact that most of the firms using the addresses indicated in the Register of Architectural Firms in Nigeria(ARCON 2012) had moved from those locations. In addition, some firms were reluctant to fill the questionnaire claiming that they were very busy.

The study examined the availability of Information Technology facilities, application of interest facilities, existence of website and electronic mail addresses of firms.The firms were asked to indicate how available IT facilities such as the computers, the intranet, the internet were in their firms. The scoring for each firm for all the facilities were added, to arrive at the level of the availability of the IT facilities for each firm.

The total scores ranged from 2 to 18. Scores from 2 to 8 were coded as almost non-existent, 9 to 14 were coded as fair availability, while scores of between 15 to 18 were coded as high availability. Table4 shows that IT facilities were highly available in 40% of the firms, available 30.8% of the firms almost non-existence in 29% of the firms.

Table4: Ranking of availability of Information Technology Facilities

Facility	**Mean**	**Rank**
Computers	3.52	1
Intranet	2.71	2
The internet	2.57	3

Table4 shows that computers ranked first on the list of available information technology facilities in the firms with mean score of 3.52. Next in ranked was the intranet with a mean score of 2.71. The least available in the firm was the internet, which ranked last with a mean score of 2.57. This conform to the study carried by Amole(2006);Oluwatayo(2009).

FINDINGS AND DISCUSSION OF RESULT

The study found that information technology facilities were highly available in most of the firms. The most available of the facilities were computers, while the least available were internet facilities. The level of the use of the internet for basic tasks in most of the firms was moderate. The internet was mostly used for sourcing information, and correspondences with other professionals.The internet was least used for communications in the office.

The study found that most of the firms where decisions were highly centralized used the internet for designing and drafting. In addition, while most of the firms had electronic mail addresses, very few firms had websites. It appears that most of the firms were not global as the presence of the firms on the web is an indication of globalization of the firms.

The information technology driven firms are characterized by availability of the computer and the use of the internet to carryout basic tasks such as design, drafting and correspondences with staff in the office. The comprehensive local firms had the internet and the intranet on most staff desks in their offices, but they had no websites. The firm had a wide range of services and fairly used the internet for basic tasks in the offices.

Table 5.0 Ranking of the Application of Internet Facilities

Task	Mean	Ranking
Sourcing information for design	2.69	1
Correspondence with other professions	2.56	2
Graphic presentation	2.48	3
Correspondence with clients	2.37	4
Designing / drafting	2.21	5
Correspondence with staff in the office	2.19	6
Project management	1.93	7

The result shows that most of the architectural firms moderately used internet to carry out office tasks. The architectural firms mostly used the internet for sourcing out information, which can then be global in their operation. The firm least used the internet for project management.

Websites and Electronic mail addresses

The sampled architectural firms were asked if they had websites. The study shows that more than half (60.75%) of the firms did not have websites, only few (38.24%) of the firm had websites, while 1.01% of the firms were not sure they had websites. This is significantly different from the study carried out by Amole(2006) & Oluwatayo(2009).. This study now shows that there is an improvement in the use of Information Technology Communication facilities, which tend the firms to embrace globalization.

The study further shows that most of the sampled firms (89.37%) have electronic mail addresses, while few (10.63%) did not have any electronic mail address. This is a decline, when compared with the study carried byAmole (2006), & Oluwatayo (2009),while the study shows that more architectural firms had electronic mail addresses than those that had websites. It appears that the architectural firms adopted more of the mailing facilities than the internet provision. This result confirm the findings of the Amole(2006) & Oluwatayo(2009).

Tables 6: Possession of websites and electronic mail addresses

Possession of	% Ranking
Website	60.75
Non sure	1.01
Non possession of website	38.24
Possession of electronic mail address	89.37
Non-possession of electronic mail	10.63
	100

RECOMMENDATIONS AND CONCLUSION

It is recommended that while we embrace the opportunities brought by globalization, it should not be given blanket acceptance in the architectural practice in Nigeria. Globalization should not be the major emphasis in architectural practice, just like Daramola et al (2012) suggested for architectural education. 'Nigeria should not be seen as local but be encourage for further development through the emphasison the indigenous architectural grammar '(Uji 1991, Daramola et al 2012). They made it known that housing standards in any country is a product of the building technology as well as the available economic resources to execute it. Why then do we have to practice the architecture of copying from the magazines what we cannot sustain and when we have cultural heritage that we need to protect?

In conclusion, the practice of architecture in Nigeria while earnessing the opportunities brought about by the information and communication technology benefits of globalization to the fullest, strict caution must be exercised in the protection of our own tradition and cultural identities. Our architecture must be tailored toward the indigenous an climate functional needs of the Nigerians.

Contextual Harmony between Traditional Architecture and City Identity in Ebonyi State, Nigeria

Onanuga, O. A.[1*]; Folorunso, C. O.[2] & Ajewole, M.[3]

ABSTRACT

A city is a unique organism which has its' own identity formed and affected by the people, social, natural and anthropogenic factors among others. In order to create or sustain the identity, all building types have to be designed in contextual harmony, representing and respecting the character of the place in accordance with the lifestyle of its people, the materials for construction available, and technical possibilities open to them. The architecture of Igbo people emphasizes on the supremacy of spirituality, community and family lifestyle. This resilient indigenous architecture had been influenced severally by western culture via religion and colonization, yet they contain valued cultural heritage. This study investigates the Igbo architecture and suggests the need to revive it on public buildings. Public buildings houses the facilities that constitute an important part of the community's quality of life and most time reflect the state of technology and organizational resources of a place, therefore making it the best focus for the study. The public buildings in the cities of Ebonyi state were examined with regards to their conformity to the communal context of house design of the people. The paper also discusses the benefit of maintaining the identity to promote the city image thereby making it attractive for tourism purpose and also contribute to the economic development of the state. Findings show that the people of Ebonyi state are culturally inclined but the architecture of the public buildings does not conform to the cultural lifestyle of the people. Therefore, the paper suggests that architecture designs of these public buildings should take the culture, religion and festivals of the people into cognizance.

Keywords: City Identity, Ebonyi state, house design, public buildings, traditional architecture

INTRODUCTION

Igbo architecture generally revolves round the use of both natural and artificial resources. Their geographical location is believed to be responsible for this inward-looking philosophy. In the tradition of the Igbo people of Ebonyi state, the construction and architecture of houses incorporates a balance with nature and an emphasis on the supremacy of spirituality, community and family life through the fusion of family gathering and worship spaces, as well as sacred spaces allocated for deities in the household. This tradition that can broadly be categories under religion and communal lifestyles are always expressed and represented in their buildings architectural designs. Like in other parts of Africa or even the world over, their patterns of architecture reflects the cultural, environmental and defence needs of the people at any given period.

The philosophy and religious believes that have been established in their architecture, are embedded in the historical, culture and the real identity of the people. This identity has suffered influences of westerners since the 15th century (1472 to be specific) when western architecture was first introduced by the Portuguese who expanded the slave trade in the region, first as trading infrastructure, and then as colonial administrative facility (Elleh, 1996). The Colonial architectural policies that came to be in the early 20th century were a tool of mass displacement and a system of segregation. The European colonialist believed that Igbo architecture are inferior, and their culture as an anachronism that must be eradicated and replaced with better European ones (Chukwuemeka, 2009).

Onanuga, O. A.; Folorunso, C. O. & Ajewole, M. (2016). Contextual Harmony between Traditional Architecture and City Identity in Ebonyi State, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1710-1719

Although the Igbo indigenous architecture survived in many communities among certain categories of people, the valued cultural heritage of the people is fast fading away as the western architecture keeps penetrating every development in the study area. Chukwuemeka (2009) opines that the thought and effort that are put in the design and building of a house contain personal, social beliefs and practices as well as specificity of the owner's input, therefore, there is need to understand the architecture of the Igbo people as regards their cultural believe and religious meaning of construction type in other to sustain this architecture. This is needed to explicate the identity that is manifested in their traditional buildings and the history behind the architecture, thereby substantiates the need to revive the architecture through its use in public buildings design in the area. Public buildings are built to accommodate the needs of the community, and some play major roles in determining the location, intensity and timing of future development. These facilities also contribute to community's quality of life and are always strategically located depending on their function. Its major merit in reflecting the state of available technological and organizational resources of a place makes it the focus of this study. The subsequent discussion focuses on the design philosophy of the Igbo people of Ebonyi extraction explaining the trend of their architecture from tradition to post-colonial era.

DESIGN PHILOSOPHY OF THE EBONYI PEOPLE

The Study Area

Ebonyi State is in the South-Eastern region in Nigeria. It is inhabited and populated primarily by Igbo people. Its' capital and largest city, Abakaliki, is located 64 kilometres (40 miles) South-East of Enugu. The state lies between 73 degree North Longitudes and 5 degree 4 East Latitude, with land mass approximated at 5,932 square kilometres. The state was created in 1996 and shares boundaries in the North with Benue State, East with Cross River, South with Abia and West with Enugu. There are nine (9) primary dialects spoken in Ebonyi State, these are: Afikpo, Mgbo, Izzi, Ezaa, Ikwo, Kukele, Legbo, Mbembe and Oring. These languages are all subgroup of the Igbo language and are commonly spoken throughout south eastern Nigeria.

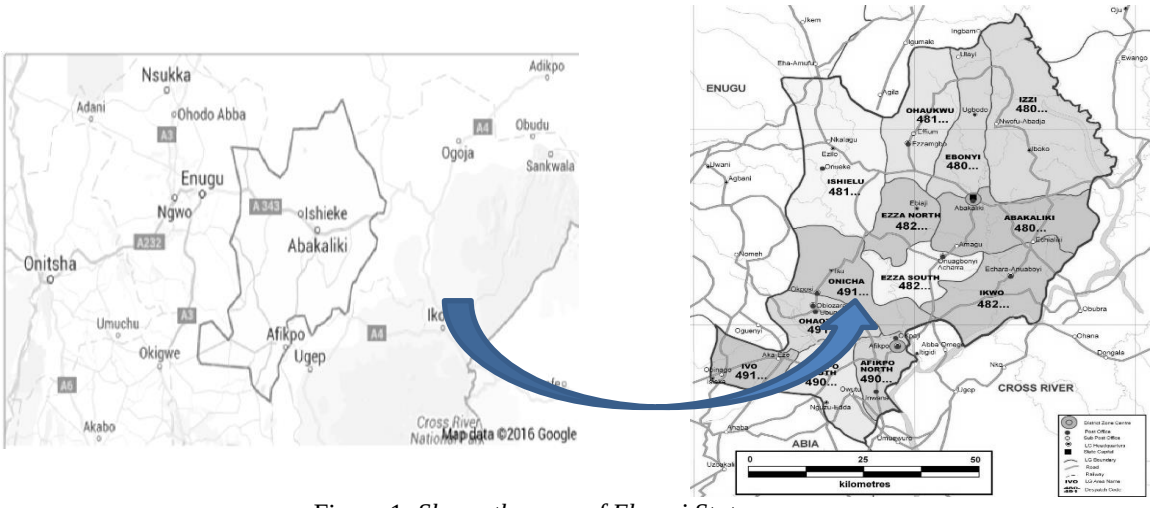

Figure 1: *Shows the map of Ebonyi State.*
Source: www.google.com/map data, 2016.

Based on 2005 census, Ebonyi State has an estimated population of 4,339,136 people and the inhabitants are spread across 5,935 square kilometres. The state is predominantly dominated by the Igbo's with other minority ethnic group from neighbouring state.

The Primitive Architecture of the Igbo Community

The traditional Igbo building architecture provided warmth, shelter and defence against animals and unwanted intruders. This is a direct reflection of what cave environment provides its inhabitants. The Igbo ancestors' first settlement were in the caves prior to the development of house building culture (Chukwu, 2015). Similarly, the house was fashioned to provide these basic necessities of life for the inhabitants and it was designed after the architectural structure of contemporary caves whose walls were usually virtually round in shape and covered with thatched roof. The settlement layouts, building structures and aesthetics represented the physical manifestation of a spiritual worldview, a balance with nature and respect for community membership and centrality. Forde and Jones described a typical Igbo settlement pattern to

> "*Consist of loose clusters of homesteads irregularly scattered along cleared paths radiating from a central meeting place of the village and/or village group, which contains the shrines and groves of the local earth deity or other chief spirit and also serves as the market*"

Therefore, in a typical Igbo society, two distinct areas were discernible – the public quarters (*ama*) and the kindred (*ezi*) (Chukwu, 2015).

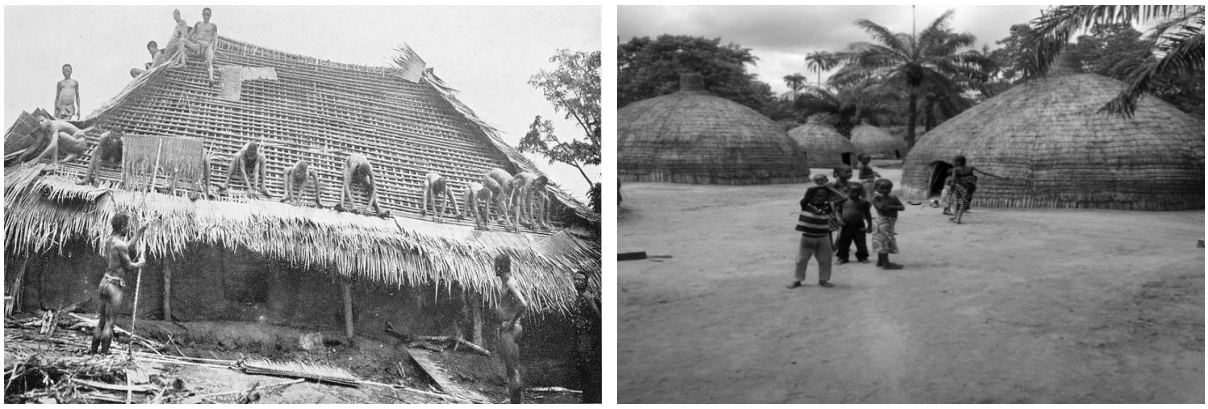

Figure 2: Showing the primitive architecture of the Ibo`s
Source: www.google.com/ibo culture

The kindred houses individual compounds built alongside other buildings of a family enclosed by a large wall. The main entrance was usually a gate. The number of houses in a given compound depended on the number of wives married by the man owning the compound. The major material used in building Igbo houses include mud, timbers, and raffia/palm stems (used for the support of the walls and roof). Homes were also places of creativity; women typically adorned the walls with painted designs, demonstrating an appreciation for artistic expression. The public quarters (*ama*) housed the assembly building and the shrines of the various deities of that community. These were always situated at the center of the community for public gatherings, discussions and meetings, as well as other community interactions. Today, such places are been referred to as "public spaces," and these areas were hugely important to the idea of bringing people from different parts of the area together.

The material for construction also generated from their culture and religious believe. They believe that the material made available for them was a gift from the mother earth god called "ALA", and this material is used easily with the help of a spiritual being (CHI) that gives rain in season and stops it at time of use. This believe and material association reflects in their architecture till today as local building traditions have been retained within modern urban

housing development in primarily Igbo-speaking areas of South-eastern Nigeria mostly for places such as social and cultural gathering in their residences.

Dike ancient war tower was one of the traditional architecture, made with indigenous materials that have stood the test of time (Fig 3). It is a 20feet tall multipurpose pyramid tower built by Dike Madueke, which aided the people to thwart the plans of their enemies. The interior of the tower has three deck, spy holes all around it and with the aid of ladder people climb from one deck to another. The ground floor of the tower is the most spacious and acts as a refuge for women and children, considered the most vulnerable in war time. The tower had recently been reduced in height to enable maintenance and preservation. It has survived years of weathering due to its special indigenous architectural skill that went into its construction. It takes a high degree of specialized language in order to communicate these architecture ideas; language that involves terminology of the concepts of geometry, measurement and logistics. The lack of active written records also means that people had no choice but to really know what it was they were doing and also know how to communicate that knowledge to others that they were working with, otherwise, they would not be able to produce these works. The existence of the skill for this type of construction is not likely to exist these days.

The Western Influence

The Igbo architecture and settlement design brought together an intersection between environmental architecture and design with spirituality and community centeredness. It also ensured a minimal environmental footprint. Admittedly, these were low-cost, simple technology methods, but households still effectively adapted their living structures to the tropical climate, especially the heat. Meanwhile, City consciousness and urbanity have become integral components of the Igbo society. All the cities in Igbo land have experience a fast growing development population. The receptivity and the amenability to change and access to western education, culture, Christianity and capitalism by the Igbo people resulted in the alteration of the Igbo architecture. The Portuguese in1472, began to expand the slave trade in the region through 15th, 16th, and 17th centuries and introduced Western architecture, first as trading infrastructure, and then as colonial administrative facility (Elleh, 1996).

The 20th and 21st centuries also witnessed an unprecedented influx of the people into the Western world perhaps in search of greener pastures. More so, as a result of cultural diffusion experienced both by the home front due to colonial incursion, neo-colonialism and by the Diaspora who presently are in serious romance with the western culture, much of the traditional practices have undergone serious modification. The alteration was gradual as the early western architecture utilized indigenous material for construction but their design features, such as opposite-window setting for cross-ventilation, extended roof to form awning, and inner demarcations, were of European or European hybrid conception (Ottenberg, 1959; oraegbunam, 2011)

Another imprint of western architecture is made manifest in physical structures such as roads, streets, hospitals, building architecture, house furniture and home facilities, and so on. Yet, in spite of the above foreign influence, certain traditional practices are quite resilient. In the neighbourhood, some traditional Igbo communities live in dispersed settlements. The Igbo village, which is a small face-to-face society, is still easily recognizable. The people embrace Christianity in large numbers, but their way of living and attitudes towards life is still conditioned by their traditional worldview.

The entrance of Western influence through the political, social and economic consolidation by the British not only strongly influenced architectural and urban design methods of places in Igbo land like Ebonyi, in particular, the emphasis on building settlements into urban centres, putting economic activity and industrialization at the center of urban life, served to dislocate traditional values of community centrality and an agricultural focus. Rather than an open community space at the center of town or a settlement, African cities have developed central business districts modelled after Western styles. Economic activity and money-generating opportunities have replaced people and social interaction as the center of community life. The massive conversion toward Christianity reduced the communal respect for the deities, and as a result, the emphasis on an allocation of physical space for religious purpose in the home environment using traditional material and methods of development.

PUBLIC BUILDING IMPACT FACTOR

Public and quasi-public facilities are built to accommodate the needs of the community, and some play a major role in determining the location, intensity and timing of future development. These facilities also constitute an important part of the community's quality of life and houses the social practice of the people. The City is host to a wide range of public buildings and facilities, including City Hall, fire stations, water wells, electric power substations, telephone and cable transmission lines, schools, and libraries.

The Public Buildings and Facilities Element provide background information on various structures and facilities operated by public and quasi-public agencies in the City and reflects the state of available technological and organizational resources. The element reviews these buildings and facilities in light of the issues of land use compatibility, aesthetic impacts, and functionality. It is also meant to provide sufficient information to assure coordinated, long-term planning that keeps pace with the growing community. In Ebonyi state, their social practice and traditional festival are taken place at the public building in the state. The design of these public building are not in conformity with the expected traditional design.

Figure 4: Showing the cultural festivals of the Ebonyi people
Source: www.google.com/ibo culture

The major social practices among the Igbo is the naming of the new born that involves some ritual activities, the *Okuku Onye Uwa* ceremony, and *Abam n'Obi* ceremony. For an Igbo child, the ceremony of being named is the starting point of being socialized into the membership of the community. Those who live well-spent lives die in socially approved ways, are given correct burial rites. The two major traditional festivals observed every year are the masquerade and the new yam festivals. The masquerade is a very important and colourful celebration and features the omata Ekpe and Ogbodu masquerade. Across various communities are festivals that can be repackaged to draw national and international attention. The Ojiji new yam festival in Izzi draws back more people to the town more than the Christmas and New Year festivities. In time past, the open space or town square were venues for these events and the venue were always designed culturally to fit the occasion (Fig. 4). Development has taken over the open spaces, they are now replaced with public halls and complexes. Taking the Akanu Ibiam conference hall in Abakaliki and the WDC conference hall (figure 5) as a case study, these buildings were oriented towards western architecture which disallows most of the things that add flavour to the traditional events. For instance, local wrestling cannot be performed on hard floor finishes, group dancing competition which is always done within circle of people is not compatible with fixed chair arrangement, shooting of local gun to the air as display of hunting prowess among others are evidently impossible in these type of event halls. The culture and style are altered and the flavour missed. However, the buildings lack the taste of the traditional culture and it is not in conformity with norms and religious belief of the people.

THE PROPOSED AFTERMATH

Social Sustainability

Social sustainability encompasses notions of equity, empowerment, accessibility, participation, sharing, cultural identity, and institutional stability. It seeks to preserve the environment through economic growth and the alleviation of poverty (Basiago, 1999). In the most basic sense, 'social sustainability' implies a system of social organization that alleviates poverty. In a more fundamental sense, however, social sustainability establishes the nexus between social conditions (such as poverty) and environmental decay (Ruttan, 1991). The theory of social sustainability calls for economic growth constrained by the requirements of social equity. It was posited that in order to link these, an enabling environment must be created that optimizes resource use, prioritizes resource allocation, and fosters equitable resource distribution (Basiago, 1999).

Indigenous materials are representations of the region's climate and culture. It is characterized by its' potential for comfort, functional, durability and energy efficient and it satisfies modern standard of living (Gardi, 1973). Indigenous materials promotes creativity and experimentation on the part of the builder while helping to reduce the demand on scarce natural resources. Using indigenous material can aid in the production of housing that is both monetarily affordable and environmental friendly, and most importantly, culturally oriented. Indigenous materials have the potential to save cost through reduced material cost, create job for under-employed and local contractor thus fostering social sustainability. Many indigenous materials are present in Ebonyi state, among which are: laterite brick made from clay, bamboo, straws, woods, palm fronds, stones and rubbles; but mostly not harnessed. The neglect of these materials had effect on its' improvement, although lots of researches had been done (Okpoko & Okpoko, 1999), implementation had been minimal in Nigerian present architecture. Figure six (6) shows a typical building constructed with laterite bricks and a recreation area constructed with bamboo. These show that the potential of these materials is almost inelastic. Creative use of these materials if properly harnessed can sustain the dwindling architectural style of the people.

Brand Identity for Ebonyi

The spread of a global culture and lifestyles is very fast, compared to previous times, and it emanates from an identifiable center (Taylan and Ümit, 2008; Ayna, 2011). Due to new communication technologies and media, culture has become a commodity, produced, offered and marketed, and so it has become an image. The world is becoming a single social space held together by the cultural transportation of semantic systems and symbolic forms (Hannerz, 1998; Ayna, 2011). Research findings from Anholt (GfK Roper Nations Brands Index and City Brands Index, 2005) shows that the way a country or place is perceived can make a critical difference to the success of its business, trade and tourism efforts, as well as

its diplomatic and cultural relations with other nations. Anholt (2005) posits that, "in today's globalized world, every city must compete with every other city for its share of the world's tourists, investors, talent, cultural exchange, business visitors, events and media profile. Arguing a case for the application of branding principles in the marketing of places, Peter van Ham suggested that "a state just like a company requires a strong brand.

To rise above the clustered political landscape, a state must be able to define and promote its vision while arguing the need for Canada to rebrand itself, Ferguson (2001) writes that, no state wants to be anonymous. The goal, rather, is to have a brand that makes winning friends and influences easy. Countries in the developed world have since realized the importance of strategic destination branding campaigns as a competitive advantage in the drive for investment and tourism dollars. This is not surprising for as Randall (2004) has once also posited that:

> "*The image we have of another country says a lot about how we view it as a tourist destination, a place to invest or a source of consumer goods.*"

This views supported Braymer's suggestion in the paper "*Branding a Country* (Braymer, 2003)" that Countries will compete daily with neighbours or block regions for tourism, inward investment and export sales, There's only so much business that can go around.

Having the indigenous architecture stains the entire cities in Ebonyi will create a concise brand on the city which could attract tourist, investors and export sales to the city (Chi and Qu, 2008). This in turn will improve the standard of living of the people in Ebonyi state which also equates to enhanced development in all of their communities. The land is filled with untapped treasure among which are fertile farmlands, rich salt deposits, vast deposits of solid minerals, and thriving quarry sites. The major cities that make up Ebonyi State include Afikpo, Uburu, Nkalagu, Ishiagu, Okposi, Amasiri, Onicha, Abakaliki, Eba Unwana and Onueke with a conservative population of well over two million people. This large population, with a sizeable number being agrarian, no doubt, is a factor to be reckoned with by any eagle-eyed investor especially in the Agriculture sector. Unwana beach, Ndibe beach, Oferekpe beach, Afikpo beach are some other side attraction for visitors to have fun. The Afikpo beach is usually a beehive of activities at weekends and public holidays as fun seekers gather there. This is a tourist potential that government should focus more on or encourage investors to upgrade it.

The major roads in the city which are very accessible and adorned with an array of beautiful flowers. Abakaliki Golf Course, located along Ezza Road, and the lawn tennis court are good leisure spots. The stadium hosts regular sports activities, especially football. The Ojiji new yam festival in Izzi can be made to look like the Offala festival of Onitsha, Eyo festival (Lagos), the Argungun fishing festival, the Durbar, the Ikeji festival (Imo state) or the Lebokun festival (Cross River State) where major companies notably the communication companies like MTN and Airtel sponsor and promote events.

Indigenous Material Treatment

The performance of indigenous building materials over long period of time, in all climates, and for all structural conditions is still not completely understood, nor worked out. Local building materials hold a promise of cultural environment, ready availability, low energy costs, aesthetics and simplicity of equipment requirement in the exploitation and utilization. They also have the potential to enhance a sustainable construction practice. Mud (Apiti), Grasses (ahiha), Bamboo (Achara) are some of the common building materials present in Ebonyi state. Generally, in Igbo land, it is widely used mostly in their private houses either at the recreation part of the design or the religious building. Bamboo is a sustainable and sturdy

building material that regenerates very quickly with the fastest growth rate reaching 100cm in a 24hr period. The use of bamboo includes building construction (as both exterior and interior design elements), and it is heartier than oak, much stronger than steel, flexible, light weight, and has water resistance properties. Other available construction materials in Ebonyi are Palm frond (Igu-Nkwu), Leave (Akwukwo), Wood (Osisi).

In the modern world today, wood is highly used for wall because of its workability, strength; durability of wood when sawed into converted timber. A skeletal form of building is set up and timber is arranged to fill the surface of the skeletal form. It can be arranged vertically or horizontally and if well-constructed, it can give a very strong and beautiful wall component. Wooden ceiling have advantage of reducing heat emission into the building because it is a poor conductor of heat, and it is also been laminated to improve its life span. Indigenous building materials have potential for being adopted as alternatives to conventional building materials even though it has been found to suffer persistent discrimination. There have been some research into their use, but implementation of the results of such researches has been limited by lack of patronage and social bias. Some of the reasons found to have contributed to this persistent discrimination include doubtful durability and life span, poor social acceptability, as well as the lack of well-established standards for these materials. It is therefore recommended that research findings on the characteristics of indigenous building materials, especially on the failings and innate characteristics be improved upon and architecture designs of these public buildings should take the culture, religion and festivals of the people into cognizance.

CONCLUSION

It has been proved from body of literature that Ebonyi people are culturally endowed. Therefore, their culture should be exhibited to the visitor via public buildings by making use of their available indigenous building materials and adoption of their method of construction. Daramola, Alagbe and Aduwo (2011), supporting Adeyemi, (2000) opines that emphasis should be laid on the crystallization of variations of concepts and ideas to reflect the past to research and re-identify the lost glory. Variations derived from traditional culture would be more authentic and long lasting than variations arising from official fiats or imposed conditions and concepts. The areas of potential benefit of incorporating indigenous building materials in building construction as it depicts cultural environment include: reducing costs of construction since materials found locally will be used thus eliminating costs associated with manufactured products and transportation, the development and propagation of indigenous technology and the provision of employment. These will invariably contribute to the economic growth of the nation, and provide source of research for both students and professionals of construction disciplines.

Celebrating the culture of the people and their way of life that include but not limited to branding to a state or community promote tourism, strengthen the national or regional identity, promote new work ethics, respect and self-respect, to mention a few. Initiatives should be taken by co-operatives, non-governmental organizations (NGOs) and government agencies, to promote the awareness on indigenous building materials in order to popularize their use. Also, by promoting the use of indigenous building materials, it will provide employment for the unskilled workers and income for the community where the indigenous materials are being harvested. It will create a forum to improve local technology by imbibing the western technology.

There are potential benefits associated with the use of indigenous building materials for building construction, but they are yet to be fully explored. Engineers, architects and builders

will require retraining to think in terms of these materials; standards and specifications need to be established; pricing and subsidy structures will have to be changed to give encouragement to the production of indigenous materials; most difficult of all, the general public, those who build or decide what is to be built, need to be re-educated to think in terms of building with indigenous materials rather than what has become conventional or fashionable to use.

Land Use Impact and Environmental Health Hazard of Abattoir Location in Ilesa, Osun State, Nigeria

ABSTRACT

Abattoirs are facilities available in most towns and cities for killing animals and supply meat for human consumption all over the world. Its waste has a complex composition and is harmful to the environment. This paper focuses on environmental health hazard and land use impact of abattoirs location in Nigeria, using Ilesa in Osun State as a Case Study. Data on the noxious effects were collected at four different abattoirs locations in Ilesa. 161 respondents were sampled in the direction of wind within 50 meters of the selected abattoirs. Stratified sampling was employed for selecting houses interviewed with the use of questionnaire. The paper observed the environmental quality of the abattoir and views of both operators and residents as well as the causes of environment pollution which includes air pollution and water pollution. The results of the investigations were later analyzed using Pearson's Product Moment Correlation to determine the level of correlation between the abattoir wastes generated and health of the residents. It was concluded that the waste have adverse effect on residential land use. This study recommended that the abattoir wastes should be be recycled to produce biogas, fertilizers, medicine, glue, photograph and plates for human use instead of causing environmental hazard on people.

Keywords: Land Use, Abattoir, Health Hazard, Environment, Pollution

INTRODUCTION

Abattoir has been known as one of the facilities in our neighborhood which must be managed in a proper way. Abattoir has been defined as premises approved and registered by controlling authority for hygienic slaughtering and inspection of animal processing and effective preservation and storage of meat for human consumption (Alonge, 1991).

Slaughter and processing activities of animal's sometime result in environmental pollution and disruption of ecosystem functionality contribute impurity in the form of wastes. In many part of the world, human activities impact negatively on the environment and biodiversity. Some of the consequence of man-made pollution includes transmission of diseases by water borne pathogens, eutrophication of natural water bodies, and accumulation of toxic chemical in the soil, destabilization of ecological balance and negative effect on human health.

Meat processing facilities produce solid, liquid and gaseous waste. Liquid and solid wastes tend to be worrisome due to the high content of putrescible organic matter, which can lead to the depletion of oxygen and disruption of water eco-functionality and a preponderance of diseases-causing organisms. The meat processing wastes come from stockyards, abattoirs and packing plants e.t.c; all these contain blood, fats, protein, gut content, heavy metals, antibodies hormones and other substances (Awulu and Itado, 1991).Abattoir wastes contain several pathogenic species of bacteria which affect animal and human health (Coker et al, 2001).

In many developing nations such as Nigeria, many abattoirs dispose off their waste directly into streams and rivers and also use water from the same source to wash slaughtered meat (Adelegan, 2002). The situation is not different in Ilesa, Osun State, where most liquid and gaseous wastes are released to the immediate environs of the abattoirs. In some instances, the solid wastes are deposited with other urban wastes, some distance from the abattoir. Efforts have been geared towards curbing the menace of pollution around the world, particularly by

Rotowa, O. & Enisan, G. (2016). Land Use Impact and Environmental Health Hazard of Abattoir Location in Ilesa, Osun State, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1720-1728

the United Nations Organization, such as United Nations Environmental Programme (UNEP). There are many international conferences and protocols to this effect; Rio de Janeiro Conference of 1992 in Brazil was one of the major efforts, collating previous environmental issues and bringing them to the fore.

Many researchers had considered various dimensions, in looking into the ways and the extents in which the location of abattoir affect our land uses and the quality of lives of individuals. In this paper, the need for the upgrading of the existing abattoirs in Ilesa at Omi-Eran, General Hospital area, Araromi and Irojo abattoirs is very crucial and important since those existing abattoirs are of poor standard with inadequate facilities. The need for the examination of the activities of the principal officers associated with abattoir operation such as health officers, veterinary officers and waste management officers should be examined. This paper aimed at examining critically the harmful effects of unhygienic environment and put forward recommendations for maintenance of those abattoirs. This was done by identifying the types of waste generated in the abattoirs, examination of the procedures for managing the waste, assessment of social-economic characteristics of the residents around the abattoirs and finally, investigate and determine the chemical composition of both solid and liquid waste from the abattoirs and their side effects on land use and human health.

STUDY AREA

Ilesa is located on latitude 7.39*N* of the equator and on longitude 4.38*E* of the Greenwich meridian and it is about 32 kilometers away from Osogbo, the capital of Osun State, Ilesa is 119 kilometers away from Ibadan, the capital of Oyo State and 85kilometers away from Akure the capital of Ondo State and about 97 kilometers to Ado-Ekiti the capital of Ekiti State. It serves as the Zonal headquarters for the Ijesa people who are found in Ilesa and the four other local governments of Obokun, Atakumosa West and East and Oriade Local Government Areas. Ilesa Township covers a landmass of about 144 square kilometers. It is strategic node and the main gateway from Osun state to Ondo and Ekiti State respectively. Many roads connect Ilesa and other parts of the state. This facts and the presence of telephone and postal facilities enhance easy communication with other towns within and outside the state. Ilesa was split into two local governments in 1997 namely Ilesa West and East local governments. Before 1967, Ilesa was the Divisional headquarters of Ijesa division

comprising Ijesa north, Ijesa south and Ilesa urban district council. This made the government to establish branch offices of the various ministries including that of work, transport and mines at the city centre which also has commercial and residential areas.

The people of Ilesa are mainly farmers, planting crop like plantain, yam, cocoyam, cassava, maize and varieties of vegetables. Cocoa which is one the cash crops of the country and the mainstay of the Nigeria economy before the discovery of petroleum cover a greater part of the arable land. Other cash crops include Kolanuts and Oil palm. However, a large number of people also engage in trade such as weaving, tailoring, blacksmithing, bricklaying, block making and butchering.

LITERATURE REVIEW

In Nigeria, nearly every town and neighborhood is provided with slaughter houses or slaughter slab. Edward (1979) recommended that abattoir should be built on firm gently sloping land and it should be away from other building, residential areas and factories. He further suggested that the site for abattoir should be well away from town boundaries. According to Alonge (1991), an abattoir is a premise approved and registered by the

controlling authority for hygienic slaughtering and inspection of animals, processing and effective preservation and storage of meat product for human consumption.

Abattoir Act of 1988 also defined abattoir as any premise used for or in connection with the slaughter of animals whose meat is intended for human consumption and include a slaughter house but does not include a place situated on a farm. These animals include Cattles, Sheep, Pigs, Goats, and other acquires animals. The killing of animals for community consumption is inevitable in most nations of the World. The public abattoir had been traced to Roman civilization and France in 15th and 16th centuries, public slaughter houses were among the public facilities. In Italy, a law of 1890 requires that public abattoir be provided in all communities of more than six thousand inhabitants.

Abattoir wastes and effluents vary from day to day depending on the numbers and the types of stocks being processed (Toye, 1985). Abattoir operations produce a characteristics highly organic waste with relatively high levels of suspended solid, liquid and fat. The solid waste includes condemned meat, undigested intestine, bones; liquid waste is usually composed of dissolved solids, blood, gut contents, urine and water. Animal food is always microbiologically contaminated by organisms living naturally or entering it from the surroundings, such as those resulting from processing operations.

Edward (1979) noted while writing on slaughter facilities for tropical condition that abattoir may be situated in urban, rural and nominated industrial sites and that each has advantages and disadvantages. The advantages of the rural site according to him out-weighted those of the other sites and recommended rural location be chosen where possible. He recommended that abattoir should be built on firm gentle sloping land away from other buildings in residential area and facilities. He further suggested that the site for abattoir should be chosen away from town boundaries. Edward (1979) further reports that the slaughtering of animals in abattoir of developing countries was carried out in unsuitable buildings by untrained slaughter man and butchers that were unaware of sanitary principles, hence waste generated by abattoirs are potential environmental quality problems.

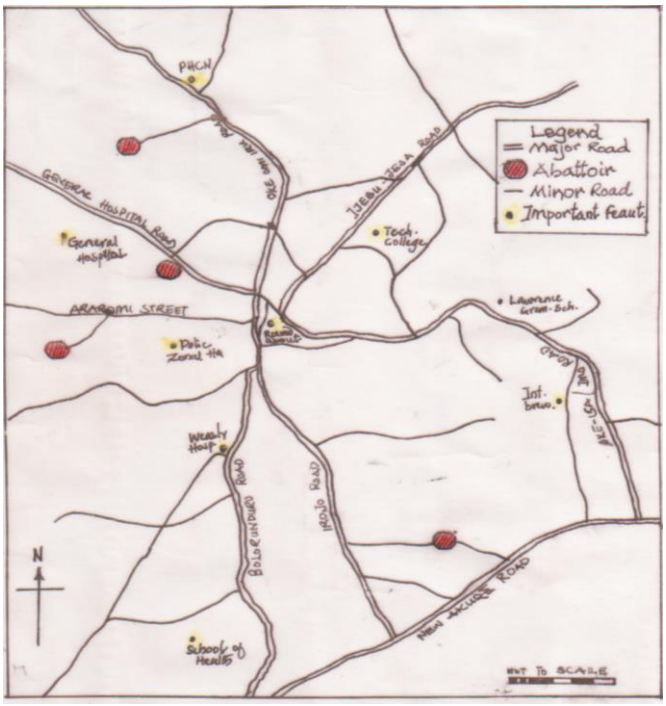

Fig. 3: Abattoirs Locations in Ilesha Town
Source: Ministry of Lands and Physical Planning, Osogbo, Osun State, May, 2015

Raymond (1997) submits that waste can affect water, land and air qualities if proper practices and management are not followed. Waste from animals that are washed into the streams, if not protected, reduced oxygen in water thereby endangering aquatic life and cause a serious problem of biodiversity. Observing that improper animal waste disposal can lead to animal diseases being transmitted to human through contact with animal faeces.

In many developing nation like Ghana abattoirs wastes are disposed into the streams or rivers and are not treated and the waters are also used from the same sources for washing slaughtered meat (Adelegan, 2002). The situation is not different in Nigeria where most liquid and gaseous wastes are released into the immediate environs of the abattoir. In some instances, the solid wastes are deposited with other urban wastes some distance from the abattoir. The pathogens from cattle waste could also be transmitted to human via water based recreation. The well in meat processing areas sometimes polluted.

Medical experts associated some disease with abattoir, for example wool sorter diseases, diarrhea, typhoid fever, asthma, pneumonia, chest diseases and respiratory diseases among others (Odeyemi, 2009). These diseases can spread from the abattoir to the neighbourhood via vectors or animals. However growing population with increase in demand for meat has resulted in increased abattoir related pollution and has attracted intervention in many developed countries like Canada France, Italy, Spain and Germany.

Impacts of Abattoir Location on Land Use Pattern

Location of abattoir is always near urban centers and very high amounts of wastes were produced in relatively small areas (Odeyemi, 1991). In most abattoirs in Nigeria the waste from the abattoir operations is a source of embarrassment as conventional methods for the disposal of animal wastes and manure, as well as slaughterhouse and other animal industrial wastes are inadequate in Nigeria. At zoo town in Port Harcourt, slaughter houses waste are channeled directly into a portion of one of the tributaries of the River Niger. Animal slaughtered in Omi-Eran abattoir alone can account for 65% of the total animal in Ijesa land. The wastes from the slaughtering ground in Omi-Eran General hospital area, Araromi and Irojo abattoir are washed into the streams that supply the environment / Community with water. The communities are blessed with a land that normally supplies them with good water when dug which is known as well water. During the dry season the well normally dry up and lead to highly irregular supply of water which makes these communities to always make use of the water from the streams.

High risk of pathogens is a strong indication of high pollution and hence, it is not safe to dispose the waste into the environment. The high count is due to the excreta from the animal intestines some of which is washed to the streams. The odour that emanate from the waste at Omi-Eran General hospital area, Araromi and Irojo abattoir are highly harmful. The solid waste that is dumped around the abattoirs is not far from the settlement / building. During the raining season the solid waste is washed and spread into the houses, causing maggots and flues infestations which lead to the subsequent outbreak of diarrhea. A new report from Food and Agricultural Organization (FAO) says livestock production is one of the major causes of the world's most pressing environmental problems, including global warming, land degradation, air and water pollution and loss of biodiversity. Using a methodology that considers the entire commodity chain, it was estimated that livestocks are responsible for 18 percent of greenhouse gas emissions, a bigger share than that of transport (FAO, 2003).

However, the report says that livestock sectors potential contribution to solving environmental problems is equally large, and major improvements could be achieved at reasonable cost. Based on the most recent data available, livestocks long shadow takes into account the livestock sectors direct impacts plus the environmental effects of related land use

changes and production of food crops animals consume. It finds that expending population and incomes worldwide, along with changing food preference are stimulating a rapid increase in demand for meat, milk and eggs while globalization is boosting trade in both inputs and outputs.

Abattoir Waste and Management

According to National waste Act, 1989 (Act 36b of 1989) which defines waste as any solid material or materials that is suspended, dissolved or transported in water (including sediment) and which spilled or deposited on land or into a water resources in such volume, consumption or manner as to cause, or to be reasonably likely to cause the water source to be polluted. Also Environment conservation Act (Act 73 of 1989) defines "Waste" as any matter, whether gaseous liquid or solid or any combination thereof which is from time to time designated by the minister as any undesirable product, emission, residue of any process or activities.

Abattoirs wastes worldwide are facing the tasks of treating and disposing of wastewater and residues. Abattoir waste water quality and quantity depend on water usage; the type of animal slaughtered and the amount of rendering or processing that is done on site. About 21% of an animal is wasted after processing (depend on animal type) and 80-90% of solid abattoir waste is recycled or reused mainly into feed industry (European Union, 2001). Much of the mass of abattoir waste ends up as a waste water stream from rendering plants. Fertilizer and gelatin industries are using hoof parts and bone meal. Land-application of blood is now less common. Large amounts of Nitrogen (N), Phosphorus (P) and Potassium (k) in waste blood make it a good source of plant nutrients. However, it can cause public nuisance due to odour and environmental concerns. Stomach contents have high levels of N, P and K and in well balanced proportions with N: P: K ratio of about 5:1:1. Wash waters contain lower levels of N, P and K. Thus, excess application of these wastes can cause potential waste pollution problems and may be harmful to plants (European Union, 2001).

Environmental Pollution and Its Control

Pollution is the introduction of contaminants into the environment to cause instability, disorder, harm or discomfort to the ecosystem i.e. physical system or living organisms. It can take the form of chemical substance of energy such as noise, heat or light. According to Wikipedia (2011) which indicated to general concern globally in the controlled emission of the greenhouse goes especially carbon dioxide, this therefore shows that ignorance about the effect of pollution worldwide is capable of destabilizing the human environment. Pollution makes flora and fauna sick, it even kills them. It contributes to climate change. Human beings are the cause and also have to be held resources possible for solution especially the youth because they are the future.

The management and control of all environmental waste into the water, land, air and entire ecosystem. The waste from Heating, Agriculture, Mining, Manufacturing, Transportation and other human activities whether they accumulate. The pollution can be curtailed through town planning measure. A principal method in this case is land use zoning method. In this method an area devoted for industrial will be developed accordingly through supervision by the development control unit. It can also be controlled through institution arrangement. This involves creating necessary body such as Federal Environment Protection Agency (FEPA) and State Environment Protection Agency (SEPA) which will be responsible for protection control policy formulation within the area of their jurisdiction. Also through Legislative measure, this is by controlling pollution through enactment of various laws that can prevent pollution as a result of human activities or natural changes. This may be in form of fines and jail terms. Other form of control is smoke and Waste reduction. This involves manufacturing firm to acquire more efficient and waste generating plants. It will also acquire considerable

amount of waste recycle and conversion to some other economic goods. Pollution control measures also involve efficient treatment. Industrial efficient will have to be treated before the waste is discharge into rivers and streams. The treatment should ensure that only cool water enter rivers and streams to control internal pollution. A collection pond where the treated water or water used in cooling machine should be provided. The water will then be discharged into the river or stream once normal temperature is achieved

MATERIALS AND METHOD

This research studies both large and small population by selecting and studying samples from population to discover the relative incidence, distribution and interrelationship between variables. It is especially appropriate for making descriptive studies of large population such as this study, thus is an appraisal research. The sample frame of this study is the total number of respondents from each household of the selected residential building in each of the areas and the butchers in those locations. Stratified sampling technique was employed which involves the division of the study area into residential and operational segments. Random sampling of the segments was done to obtain the number of respondents required from each segments with questionnaires targeted at the household heads of each houses and butchers. A dependable sample of 30% of the residential building selected in each location was taken to represent the target population. This amounted to 161 respondents for the survey research. Survey conducted for the butchers was total survey.

Table 3.1: Sampling Frame for the Household Survey and Abattoirs

S/N	Locality	Sample Radii Meter	Sample Frame	Sample Size of 30%	No of Abattoirs
1	Omi-Eran	300m	160 buildings	48 Respondents	84
2	General Hospital Area	250m	120 buildings	36 Respondents	32
3	Araromi	200m	140 buildings	42 Respondents	25
4	Irojo	300m	115 buildings	35 Respondents	18
	Total		**535 buildings**	**161 Respondents**	**159**

FINDINGS

During the research work, it was revealed that location of abattoir in residential environment have an adverse effects on the health of the residents and the ecosystem in the community. This means that abattoir have a negative impact on the land, air and water qualities which affect the aquatic habitat within abattoir environment.

The research analysis also revealed that Omi-Eran abattoir is a multipurpose and general abattoir where various animals were slaughtered on a large scale. The size of the abattoir facilities on ground and high level of patronage is a factor to this. The findings show that operators at Omi-Eran slaughters 66.04% of the cattle (cows) slaughtered in Ilesa while General Hospital Area slaughters 9.42%, Araromi slaughters 13.22% and Irojo slaughters 11.32% of the total cattle slaughtered in Ilesa. This shows that attention should be given to Omi-Eran abattoir wastes, pollutions, overstress of facilities e.t.c, because it generates more revenue for government than the other abattoirs based on the average number of animals slaughtered daily in each abattoir (Table 2).

Environmental condition of the study areas based on the research finding, 60% of the respondents (residents near the Abattoir) at Omi-Eran were of the opinion that the environmental condition of the Abattoir was fair. 21% agreed that the environmental condition of the Abattoir is good, while 19% agreed that the environmental condition was poor (Table 3). At General Hospital area, 42% of the respondent believed that the Abattoir was poor. While in that of Araromi, 48% of the respondent is of the opinion that the

environment condition was poor while at Irojo 47% of the respondents agreed that the environmental condition is also poor.

Table 2: Types and Average Numbers of Animals Slaughtered Daily in each Abattoir

S/N	Types Of Animal	Omi-Eran		General Hospital Area		Araromi		Irojo		Total	
		Freq	%	Freq	%	Freq	%	Freq	%	Freq	%
1	Fowls	145	54.90	40	15.10	39	14.90	40	15.10	264	100

An environmental health issue that is also important in the study area is disposal of waste water used in the abattoir into the stream without any treatment (Table 4). This unhygienic disposal of waste water in the study area also act as important factor hastening the breeding of mosquitoes and release of viruses and bacteria into the neighbourhood

CONCLUSION AND RECOMMENDATIONS

The study revealed that effluents from the abattoirs constitute potential hazard to the land use planning and development. There is a need for proper management and monitoring so as to improve the economic value, health of the residents and safe environment. It is suggested that the abattoirs should be relocated from residential environment to a place far away due to the environmental and health effect. It is also suggested that if the abattoirs cannot be relocated, they should be provided with necessary facilities and amenities, so as to improve the quality of meat and promotion of safe, healthy, conducive and convenient environment which is the focus of any government.

From the findings on the operation of Abattoir, the following steps could be adopted to improve and mitigate the rate of environmental degradation caused by the abattoir. For the living standard of the residents living in the Abattoir environment to be improved, the idea of relocation should be taking into consideration. Those abattoirs in Ilesa should be relocated to other places that is safe for the health of the people. Government should provide a new masterplan design of the new site that will take into cognizance the hygienic nature of meat sellers. Facilities and proper management measure should be provided in the new site in order to create new ideologies to the design and management of our urban environment. The rationale behind the relocation is due the damaging nature of the abattoir to environmental sustainability of their host communities. Due to the financial nature of the country and particularly Osun State, government could embark on renovation and refurbishment of the existing abattoirs in order to enhance and improve their physical state. Facilities need to be provided as it seems that majority of the abattoir lack basic facilities for proper functioning.

The Issue of Communication in the Construction Industry: A case of South Africa

Berenger, Yembi Renault[1*] & Justus, Ngala Agumba[2]

[1 & 2]Department of Construction Management and Quantity Surveying, Faculty of Engineering and the Built Environment, University of Johannesburg, South Africa

[*] renault08@yahoo.fr

ABSTRACT

Communication within construction presented exceptional problems. This is particularly evident within the construction sector, where interactions have the tendency to be characterised by unacquainted classes of people coming together for brief periods before dispersing to work on other ventures. Owing to its specific characteristics, the construction industry creates a complex communication environment. This paper sought to improve communication in construction. In order to define the problem in more detail and to achieve the purpose of the study, an exhaustive literature review on communication in construction was conducted, a total of ten experts on the practice of communication in construction in Gauteng (South Africa) were interviewed, through semi-structured, in-depth interviews. Findings revealed that the majority of issues regarding communication in construction were reported to be between demand and supply-side stakeholders. The robust interaction in construction projects between stakeholders seems to make construction projects very exposed to communication problems. Furthermore, a waste of time was revealed as a result of poor communication, a discrepancy in stakeholders 'power and about poor consensus particularly in the public sector, and a lack of stakeholders' ability to sympathise with the other parties involved.

Keywords: Communication, Construction Industry (CI), South Africa

INTRODUCTION

In today's world, people have a better understanding of the necessity to practice good communication in the society in order to effectively deliver meaningful communication. Construction is a fragmented and dynamic sector with a project-based nature (Perumal, 2011). More often, problems in construction are regarded as communication problems (DETR, 1998). Because of its unique characteristics, the CI forms a complex communication environment. For that reason, a lot of stakeholders work in regularly varying sets of relationships which are contractually driven. The culture presents a reality of conflicts and lack of reciprocal respect and trust [Dainty *et al.* 2006]. This study aims at improving communication in construction. To define the problem in more detail and to achieve the research aim, an extensive literature review on communication in construction was carried out, and interviews were conducted with experts in the field of construction in Gauteng (South Africa). This gave a first impression of the situation in the practice and literature of construction. The findings, as well as the empirical details from the interviewees, are reported in section 4 of the treatise. A more focused problem definition, the research aim and set-up to cross-examine the problem are also presented. The next section (Section 2) reports the literature study. The paper ends with some conclusions.

Purpose of Study

The purpose of this study is to improve communication in the construction industry, which would significantly lead to fewer delays and lower expenses.

LITERATURE REVIEW

Defining Communication

Many researchers have defined communication differently, however; the core meaning remains the same. Communication is the process in which information is encoded and imparted by a sender to a receiver via a channel/Medium (Perumal, 2001). The message is

Berenger, Y. R. & Justus, N. A. (2016). The Issue of Communication in the Construction Industry: A case of South Africa. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1729-1738

then decoded by the receiver and feedback given to the sender. According to Axley (1984), communication can be defined as a metaphorical 'pipeline' along which information is transferred from one person to another. It is the essential component of any system of human interaction as deprived of it, no significant or logical activity can take place (Thomason, 1988). Nevertheless, defining the term communication is difficult as it is such a multifaceted and vague concept. Communication can have a diversity of meanings, contexts, forms and impacts and so will mean diverse things to different people in various situations (Dainty et al., 2006). This is undoubtedly the case within the CI, where a plethora of dissimilar communication occurs concurrently. Communication requires that all parties must have an area of communication commonality (Perumal, 2011). According to the author, these communication commonalities include auditory means such as speaking, singing and at times tone voice as well as nonverbal and physical means such as body language, sign language, eye contact and even written communication. It is a process by which we assign and convey meaning in an attempt to create shared understanding. This process necessitates a wide repertoire of skills in intrapersonal and interpersonal processing, listening, observing, speaking, questioning, analysing and evaluating. Collaboration and cooperation occur through communication. They are three categories of communications in business (Perumal, 2011): written, verbal and non-verbal communication. Written communication comprises letters, emails, memos, reports and formal documents. Verbal communication comprises chat, presentation and voicemails. Non-verbal communication uses signals to communicate and study body language (Thompson, 2002).

Regardless of the complications inherent in defining what communication is, it is imperative that a working definition of the notion is developed to underpin the analysis of communications practice contained in this paper. To accomplish this, it is necessary to break down the concept in order to describe its composite components. These components can be summarised as follows (Dainty et al., 2006):

i. Communication generally includes the transfer of information, a general concept that comprises meanings namely process date, knowledge, skills as well as technology (Cheng *et al*., 2001). In construction, information is exceptionally varied given the important number of parties involved with construction activities.
ii. To communicate is to bridge a distance of some description, which can range from being short and simple, to long and complex (Skyttner, 1998). Once more, in construction, the disparate location of many of those involved with projects often require communication over longer distances than in, for instance, manufacturing environments.
iii. Successful communication (at an interpersonal level in any case) is a social skill involving the effective interaction between people (Hargie, 1986). In spite of development in off-site production techniques, construction remains a labour-intensive industry and therefore, social activity demanding communication between a wide variety of participants.
iv. Interpersonal communications between people generally require conveying facts, feelings, values and opinions (Kakabadase *et al*., 1988). Hence, interpersonal communications can be considered subjective and value laden. In many respects, construction is not an exact science and as such necessitates a degree of subjective understanding from those participating.
v. Communications do not only occur between individuals but can occur between groups or organisations (Baguley, 1994). Construction is inherently a team activity involving the concurrent involvement of many specialists so as to achieve efficaciously project objectives.

vi. Communication can be seen as a transactional process where something is exchanged between the parties involved (see Eisenberg and Goodall, 1993). Construction can be regarded as a series of transactions between the parties involved. Facilitating these transactions has been widely recognised as a key issue for the industry to address if it is to improve its performance in the future.

These various outlooks on communication all suggest that communication is basically about the transfer of information between people. Consequently, the point of communication in most cases is that one person (or team or organisation, etc.) desires another to receive information from another. Within an organisational context, this could be to convey an instruction to influence the actions of others, or may require an exchange of or request for information. To some extent, this interaction will be determined by the rules and norms of social behaviour, as it is people who translate the meanings and utilise the information (Gayeski, 1993).

Furthermore, this suggests that communication has to be a two-way process, as unless the transmitter of the information receives feedback that the message has been received, and then they will be unsure as to whether communication has taken place or if it has taken place successfully. Put simply, Therefore, communication involves the giving out of messages from one person and the receiving (and successful understanding) of messages by another in response (Torrington and Hall, 1998). The ways in which these messages can be conveyed are multifarious and may include speech, body language, writing, graphical or electronic media or any combination of these forms. As such, communication can be considered as a professional practice where proper rules and tools can be applied to improve the usefulness of the information communicated, as much as it can be a social process of interaction between people.

The Importance of Effective Communication

Nowadays, the importance of effective communication cannot be overemphasised. Almost every manuscript on how to manage people will cover important principles of how to communicate effectively with the personnel. At an individual and team level, people find it hard to operate in the industry if they do not develop a reciprocally agreed communication *modus operandi* to underpin their work activities (Dainty et al., 2006). Likewise, the management of organisational processes also calls for the establishment of a dynamic and effective communication channels that allow their numerous mechanisms to be conjoined appropriately. Armstrong (2001) briefly summarised the importance of communication to organisations as follows:

i. **Achieving coordinated results:** organisations operate using the collaborative actions of people, but independent actions lead to results discordant with organisational objectives. Coordinated outcomes, therefore, demand effective communications.
ii. **Managing change:** Almost all organisations are subject to constant change. This, sequentially, affects their personnel. Acceptance of and willingness to incorporate change is possible only if the reasons for this change are well communicated.
iii. **Motivating employees:** the extent to which an individual is driven to work efficiently for their organisation rest on the accountability they have and the scope for accomplishment afforded by their role. Feelings in this respect will depend upon the quality of communications from senior managers within their organisation.
iv. **Understanding the needs of the workforce:** In order to respond efficiently to the requirements of their personnel, it is important that they develop an effective channel of communication. This channel must enable feedback from the workforce on

organisational policy in a way that inspires an open and truthful exchange of ideas between employees and executives of the organisation.

Given the advantages of effective communication delineated above, the consequence of poor communications for an organisation is that employees will misjudge management decisions or respond to them in a way that was not deliberated. Equally, managers will misread the prerequisites of employees and will consequently suffer from lower performance and a higher turnover of staff.

Communication has become even more important as the business world has begun to move towards what is now defined by Dainty et al. (2006), as a 'knowledge-based economy'. A knowledge revolution has underpinned the shift towards a predominance of service sector organisations. Debatably, almost all large construction enterprises have now become service sector organisations, outsourcing the majority of their fruitful attitude and efficiently acting as managers of the process. Professional as well as managerial employees control their payroll, and it is these 'knowledge workers' whose intellectual capital becomes the ingredient that underpins organisational growth and development (Dainty, 2006). The challenge for such firms is how to generate knowledge sharing and enrich 'communities of practice' for improved performance. Communities of practice entail where groups of people who share a worry for the same questions, or set of problems come together and act together on a continuing basis (Wenger *et al*., 2002).

Additional prerequisite for effective communication in construction stems from the industry's tendency to experience change and transition. Dealing with change is more challenging in traditional industries like construction, which have revealed an unwillingness to embrace different ways of working, but is debatably more significant, taking into account the dissimilar pools of knowledge that must be incorporated in construction projects (Dainty et al., 2006). In the past, a 'silo' like mentality has triumphed which has been exposed to interfere with knowledge sharing within the industry (Dainty *et al*., 2004). Nevertheless, effective communication has the supremacy to break down such obstacles by bringing people together, thus promulgating improved cooperation and combined working within the sector. Therefore, effective communication can be regarded as the keystone of future industry improvement.

Communication in Construction

The literature on communication in construction has emerged in the early 1940s, mostly based on the situation in the United Kingdom [Emmitt and Gorse 2003]. Many problems regarding communication have been reported, with an emphasis on intra-supplier communication within the construction industry; demand-supply communication during the design phase; and communication between single demand and supply side parties, during the entire construction process. Here, the demand side comprises principals, users and investors and the supply side encompasses architects, contractors, subcontractors and advisors. The importance of improving communication in construction and the main factors influencing communication are discussed.

The efficiency of the construction process relies upon the quality of communication. According to Hoezen (2006), the following explain the reasons why improvements in communication are important:

i. An improvement in communication within the building team, in project teams and between the project manager and contractors could minimise failure (Thomas *et al.*, 1998; Franks, 1998; and Somogyi, 1999).

ii. More open communication at all levels could lead to innovations (Lenard and Eckersley, 1997) and better technical solutions (Atkin *et al.*, 2003).
iii. Improving communication in early stages of projects would positively influence the quality as viewed by all stakeholders involved (Emmit and Gorse, 2003; and Brown, 2001).
iv. Discussing the theme of communication during staff meeting would lead to better decision making, for example, less hastiness in moving to answers and better strategies of looking at the prerequisites first (Barrett, 1995; and Salisbury, 1998).

Various factors influence communication in construction; an overview can be derived from literature:

i. The first category of factors is connected to the organisation of the construction process (Hoezen, 2006). The Key aspects are the dissimilarity between formal and informal communication paths during the design stage (Mackinder and Marvin, 1982) as well as during the development stage (Pietroforte, 1992; and Higgin and Jessop, 1965); and the separation of design and production (Hill 1995).
ii. The second category involves the stakeholders themselves. Conflicting interests could result in hidden agenda, usually leading to limited communication (DETR, 1998; CIB, 1997; and Brown, 2001), and all stakeholders' frames of reference are considered of great influence on communication as well (Moore and Dainty, 2001; and O'Reilly, 1996).

Some studies have been concluded so that the CI could profit from improved communication. Even though the studies focus on numerous aspects of communication in construction, no literature overview has been discovered on the topic of demand-supply communication in construction.

Studies stressed on intra-supplier communication (e.g. head-and subcontractors) or intra-demander communication (e.g. principal and end user) or look at just one stage of the construction process. In the cases where communication between demand and supply side parties was studied, the focal point was on just a few stakeholders instead of considering many parties from each side.

METHODOLOGY

This study investigation began with a comprehensive literature review on the topic of communication in construction. In order to gain additional insight into communication issues, ten experts and professionals in the field of construction were interviewed. The selection criteria of the interviewees was based on their profession (constructor, consultant or professional principal); the type of projects they were currently working on or had worked on (Residential construction projects, building, institutional and commercial construction projects, industrial, specialised industrial construction, highway and heavy construction projects); and the sector they were working in or building for (private or public construction project).

The data were gathered through semi-structured, in-depth interviews. The format was that of a conversation with a structure and a purpose. Furthermore, to confirm the richness of the method employed, the participants in the study were first notified about the purpose of the study, what their participation involved, and how the results would be circulated. Subsequently, the interviewees were required to think of one or more particular projects that they were presently working on or had lately delivered. Open interview questions based on the purpose of the study allowed interviewees to talk about their experience. During the interviews, notes were made, which were transcribed directly after each interview. All types

of comments were grouped into three categories characteristics of the South African Industry; the importance of communication in construction; and the factors influencing communication. Due to the interview method selected, not all the interviewees' comments were analogous. For instance: some interviewees focused on the organisation of the construction industry as a whole, whereas others went into detail about contractual aspects. Regardless of these dissimilarities, there were lots of parallels and conflicting interpretations, drawing a clear picture of the communication environment as shaped by the construction industry. After the analysis, a synopsis of main topics was presented to the group of interviewees, sitting together. A discussion took place, during which nuances and adjustments were made. Interviewees clarified their observations to one another, providing further insight into the background of conflicting ideas. Based on this consultation, conclusions were reached.

DISCUSSION AND FINDINGS

Characteristics of the South African Construction Industry

The image of the South African CI, as perceived by the interviewees, is one of the industries made up of conservative, poor communication among stakeholders. Even more than in other sectors, human factors seem to ascertain most if construction projects develop in a good way or not: there needs to be some "chemistry" between the individuals involved to make the process go well (Hoezen, 2006). Because of the small margins, the hierarchy within the supply-side is rigid, and stakeholders behave in both strategic and calculating ways. This behaviour is a result of lack of mutual trust, reversely discouraging stakeholders to ameliorate their communication. The respondents stated that when something goes wrong, it results in pointing fingers on both sides, the claiming of extra efforts, attached to a declining level of trust. The interviewees further reported that trust is the main reason for principals' wishing to be involved in the whole process. Because of their tendency to control every detail, several consultants are implicated. In infrastructure projects top management just give the impression to get involved in the latter stages of the construction process only, while in public housing projects, for instance, their involvement is being asked more and more in earlier phases of the process. However, they still have little experience with it. Consequently, top management only thinks about the product to construct, rather than the problem it should tackle.

Discussions, as a result, tend to be about product specifications and project plans rather than about functional requirements, wishes and needs. Regardless of the fact that communication has been organised in much the same way for a long time, interviewees affirm that a dialogue is starting: constructors are reconsidering their professional relationships with clients, and government becomes conscious that procurement should be less detailed. In general, interviewees honour the industry for its devotion, hard work and expertise.

The Importance of Improving Communication: Interviewees' Perceptions

Overall, communication in construction was not identified as problematic by the interviewees; nevertheless, they acknowledged that communication processes are far from optimal. A waste of time was revealed as a result of poor communication. For instance, errors from early stages of the construction process have to be resolved later which, result in making adjustments in latter stages of the construction process and more often requires extra money. Interviewees believe that improved communication would undoubtedly lead to fewer delays and lower expenses. Furthermore, all stakeholders' contentment about the process as well as the standard of the product could escalate when they would communicate effectively.

Factors Influencing Communication: Interviewees' Perceptions

According to the interviewees, the main problem of communication in the South African CI lies in the lack of stakeholders' ability to sympathise with the other parties involved. This is

particularly the case between demand side and supply side parties. Knowing that designers and constructors do not experience how their choices affect the use and maintenance of the product, it is hard to communicate about these themes. This results in constructors who do not think along with the principal; principals who are not open-minded to the constructors' input; and designers who design objects that do not always match the wishes and needs of their principals. Moreover, the stakeholders' discernment of their functions in the process is not on all occasions viewed as professional. Respondents state that principals do not always think meticulously about their wishes and needs, and do not take responsibility so as to implement their will. Neither are constructors as responsible as respondents think is indispensable: they usually act in strategic and manipulative manners. The respondents approve that the preparatory measures of the project are necessary. Principals should get their requests clearer and consequently sufficient time should be spent on the brief. As regards the brief, some interviewees suggested that the brief should comprise mostly functional specifications; others stated that specifications should be unmistakable and detailed. Though, interviewees share a complete agreement that the principal's outlook of his or her own role is critical. For a clear communication, principals should consider themselves as chiefs and similarly act like this by being honest and straightforward regarding the prerequisites and making obvious the do's and don'ts.

Lastly, interviewees mentioned a discrepancy in stakeholders' power and about poor consensus, particularly in the public sector. Frankness about the budget available and reciprocal accountability could positively affect communication.

The Research Set-up and Problem of Communication in Construction

The interviews conducted in South Africa, support the findings in the literature. The factors influencing communication as declared by the interviewees have their place into either the organisation of the construction process or the interests of stakeholders involved. According to the results, interviewees seemed to concentrate on the communication between stakeholders on the demand side and stakeholders on the supply side. This is the area where the majority of issues were revealed, and therefore, demand-supply communication seems worth to be examined in more detail.

In the literature, communication in the CI is studied quite rigorously; nevertheless, the topic of demand-supply communication has not yet been surveyed exhaustively. Owing to this deficiency in literature and the relevance of the subject to the industry concerned, the objective of our study project is defined as acquiring insight into the organisation of demand-supply communication processes in construction and developing an approach to improve the efficacy of this organisation.

Communication was thus defined as a process in which the participants create and share information with each other so that to achieve reciprocal understanding (Rogers and Kincaid, 1981). In order to achieve the aim of the study, two research objectives were formulated:

i. To investigate how demand-supply communication is organised in construction; and
ii. To investigate the design processes of effective demand-supply communication for construction projects.

With reference to the above objectives, a research set-up was designed as follows:

Literature Study:

As already mentioned above the main goal of the study is to contribute to:

i. The field of communication by contributing to the knowledge on group communication, since stakeholders in construction, are part of different working groups);

ii. The field of management by defining how the organisation of demand-supply communication works in construction and;
iii. The field of construction by improving demand-supply communication.

The previous literature survey in the area of construction will be extended with an overview of relevant reviews on demand-supply communication in the sectors of designing and management. Some instruments are already accessible to an influence on demand-supply communication. Considering there is minor scientific base on the running of these instruments, additionally, an overview of demand-supply communication influencing instruments and procedures will be made (not necessarily in construction).

Theoretical Framework Development:
Dainty et al. (2006), proposed a model for group communication, combining several theories in the form of communicational (Shannon and Weaver, 1949), constructional (Walker, 2002); and organisational (Handy, 1999). The model contains both formal and informal communication routes, and members are regarded as individuals. Influencing factors in this model are members' roles (formal and informal); their degree of maturity and expertise; and all kinds of noise (language variances; changing frames of reference; physical noise (like plant and machinery), etc.).This model appears to be a good starting point for studying demand-supply communication. All factors influencing communication as identified from literature can fit within the model proposed by Dainty, Moore and Murray. Furthermore, the model could be developed and adapted to the aims of our study.

Empirical Research
In order to examine issues with demand-supply communication in the practice of construction, the structuring of demand-supply communication will be scrutinised in multiple construction projects, including tools used to enhance this communication.

Organisation of Demand-Supply Communication Processes
The empirical evidence will be analysed within the theoretical framework to acquire insight in the organisation of communication processes and factors that influence this. The consequences of methods and tools of this communication will be investigated.

Development of Approach
The insights gained will help to make recommendations for the use and development of methods and instruments to improve the efficiency of demand-supply communication in construction.

CONCLUSION

This research study started by defining a project to improve communication in construction. Based on the literature related to communication in construction and the interviews with experts in the South African CI, it was likely to address in more detail the issue of communication in construction. Literature concluded top management only thinks about the product to construct, rather than the problem it should tackle. The management of organisational processes also calls for the establishment of a dynamic and effective communication channels that allow their numerous mechanisms to be conjoined appropriately. A waste of time was revealed as a result of poor communication, a discrepancy in stakeholders 'power and about poor consensus particularly in the public sector, and a lack of stakeholders' ability to sympathise with the other parties involved. Further, it was reported that the majority of issues regarding communication were to be between demand and supply-side stakeholders. The robust interaction in construction projects between stakeholders (on demand and supply side) seems to make construction projects very exposed to communication problems. Interviewees also affirmed that dialogue is starting: constructors

are reconsidering their professional relationships with clients, and government becomes conscious that procurement should be less detailed. In general, interviewees honour the industry for its devotion, hard work and expertise. Interviewees believe that improved communication would undoubtedly lead to fewer delays and lower expenses. Furthermore, all stakeholders' contentment about the process as well as the standard of the product could escalate when they would communicate effectively. Because of the insufficiency of literature on demand-supply communication in construction, it can be stated that more research on the subject in question is needed.
