JOINT INTERNATIONAL CONFERENCE

Co-organised by

The Federal University of Technology, Akure (FUTA), Nigeria,
De-Montfort University (DMU), Leicester, United Kingdom
&
London South Bank University (LSBU), London, United Kingdom

PROCEEDINGS

of

THE JOINT INTERNATIONAL CONFERENCE JIC 2016

on

21st Century Habitat: Issues, Sustainability and Development

21st - 24th March 2016

held at

The Federal University of Technology, Akure (FUTA) Nigeria.

EDITORS:

Prof. Ebohon, Obas J.

PEER REVIEW PROCESS

The quality of the contents in this publication is guaranteed through thorough review process of abstracts submission and screening. All accepted papers were subjected to a blind peer review process. Papers in the various subthemes were reviewed by a minimum of two referees; from the abstracts submission through to the full paper submission and finally, the reviewers' reports were sent back to authors for modification and final submission.

FOREWORD

This Joint International Conference is about sustainability in its wider sense.

Sustainability suffuses all we do and is, arguably, the world's most talked about concept and, perhaps, least understood. This is partly due to the level of complexity associated with how the discourse around sustainability issues is framed; how the contexts associated with it are imagined; how the challenges associated with it are addressed and grappled with, and how the resources and solutions offered are meaningfully operationalized. The lens at which we use to view sustainability is seemingly the problem and the solution at the same time, and therein lies the conundrum.

Sustainability is an important area of discourse, as it pertains to how we work and how we lead our lives, now, while considering the lives, communities, and workplaces of future generations. At the same time, few would question the power that lies within a collective and a channelled effort, where there is sense-making, joined up thinking, and the sharing of lessons learned in addressing key sustainability issues in pursuant of key 21st century human habitat needs, expectations and desires.

It is pleasing to see some level of agreement in the recent UN Sustainable Development Summit (2015) held at the UN headquarters in New York, and around the 17 Sustainable Development Goals.

A host of stakeholders have a significant role to play in this regard, not the least of which are governments, practitioners, communities, academics, the third sectors, and users. The wider architecture, engineering and construction (AEC) sectors consume in excess of one-third of our energy use; over one quarter of all raw materials; and about half of our water use. In addition to this all other sectors are serviced or service the AEC sectors. The issue becomes one of interconnectedness and complexity, calling for interdisciplinary, joined-up, and holistic considerations. There is much to know and share.

This joint international conference particularly sets out to explore some of the developments, challenges, innovations, environmental friendly and adaptability offerings around sustainability. It also offers the scope to address, real estate, valuations and management concepts and practices. In addition issues around landscape design, tourism, remote sensing and industrial design are explored. There is also a growing interest around education and professional ethics, which are further explored and discussed. Similarly, both developing and emerging economies are grappling with issues around physical planning, urban renewal and urban poverty. These important issues are to receive due coverage during the conference. Same goes with issues around architecture and national development in both emerging and developed countries.

A number of developed and developing economies continue to experience major unrest and challenges leading to massive immigration across countries and continents, and security issues. At the same time, the low oil prices raise significant economic challenges to development. Housing provisions, in terms of sustainability and affordability, also continues to be an issue in a number of countries and continents. As built environment academics and researchers, these changes would have an impact on us in one way or the other. No doubt, it would form an interesting area of debate in our conference.

For this Joint International Conference, the call for papers elicited 320 abstracts. The International Scientific Review Committee has also worked tirelessly to uphold standard of quality and consistency of the papers. After the two stage blind review processes, we have 201 accepted papers. This means that if your paper have been accepted for the conference, and is in the proceedings, then you should feel very proud of your achievement. It is pleasing to note that a good proportion of the papers have come from both new researchers, including those engaged in their PhD studies, as well as established researchers and academics. The papers have also come from over 12 countries. Similarly, the topics are wide, covering different aspects of sustainability research and practice.

It is also worthy of note that the content of the papers reflect the use of different research methodologies and philosophies.

We hope that this conference affords us the opportunity to address some of the challenges that confront research, practice, policy making, education and the wider areas of sustainability, in this very interesting and challenging time.

We also look forward to the usual networking which is one of the hallmarks of such international conferences; to renewing old acquaintances and making new friends during the conference.

Prof. Ebohon, O. J.

Dr. Ayeni, D. A.

Prof. Egbu, C. O.

Prof. Omole, F. K.

ACKNOWLEDGEMENTS

A conference like this would be impossible to run without the help and assistance of a huge number of volunteers who have worked tirelessly to ensure its success. Our special thank you goes to the Local Organising Committee and Sub-committees, the International Organising Committee, and the International Scientific Review Committee who have worked tirelessly to meet all deadlines for paper review and for upholding the high standard of academic quality.

A special mention of Dr. Dorcas Ayeni, who also took on the majority of the organisational and administrative burden for the conference.

Thank you also goes to, Prof. F.K Omole, Arc. Olufemi Samson Adetunji, Mr Bayode .T, Dr Adelabu Samuel, Mr Ewuonwu Obiora and Mary Samson. Who were instrumental in the arrangement of papers for the conference proceedings and making sure that we were "ready to go" for the printers.

We are grateful for the support received from The Federal University of Technology Akure (FUTA), London South Bank University, UK and De-Montfort University, Leicester, UK.

A huge thank you goes to the Vice Chancellor and the Chief Executive Officer of the Federal University of Technology Akure (FUTA), Prof. A. G Daramola, for his vision in sowing the seed for this joint conference. We are also indebted to the Dean of School of Environmental Technology (FUTA), Professor J.A.B Olujimi, for his unwavering support in the organisation of this conference. We equally extend our gratitude to all Heads of Department in the School of Environmental Technology, senior academic members of staff of FUTA and all sub-committee members for their various supporting roles, and for the opening of the conference and the welcoming of national and international delegates.

A number of organisations, industrialists and academics have supported the conference in a number of ways. We are thankful for their kind generosity and support.

A special thank you to the Keynote Speakers; Professor Olunride Lafe and Professor Charles Egbu.

Finally, we are also indebted to members of the professional and non-academic staff of FUTA for their support in the organisation of the conference, and making sure that all who attended the conference had a worthwhile and enjoyable time during their stay in FUTA, Akure, and in Nigeria.

Prof. Charles Egbu

MAJOR SPONSORS

The Federal University of Technology Akure (FUTA) was established in 1981 to give prominence to training in technology and applied science and to assist in ensuring rapid technological and industrial development of Nigeria. The University which formally took off in 1982, has grown tremendously since its establishment to become the best University of Technology in Nigeria. Currently, it has 30 academic Departments spread within eight (8) schools. FUTA is located in Akure, the capital town of Ondo state, Nigeria. The vision of the university is to be one of the best Universities of Technology in the world, committed to carving out an enviable niche for itself as a centre of excellence, epitomized by high quality programmes, products and contributions to the society. The mission is to promote technological advancement of Nigeria through emphasis on programmes that will engender the development of such products and services in which the Nation possesses great comparative advantage. In doing this, the university is committed to providing a conducive teaching and research environment attractive enough to retain highly motivated leading academics capable of channelling research outputs to meeting peculiar national needs. Through its research output, train and produce highly technological –oriented and self-reliant high level manpower committed to self-employment as basis for national development.

London South Bank University (LSBU) has been transforming lives, communities and businesses for over 120 years. We take a practical approach; professionally accredited and connected to industry. We offer some of London's best courses in engineering for cities, surveying, construction, architecture and design. The breadth and quality of our research and enterprise activities is widely acknowledged. Our applied research tackles real-world issues. We are the top modern university in London, UK, for world-leading and internationally excellent research in General Engineering (which includes The Built Environment and Architecture research). LSBU provides a highly applied academic environment which supports students into professional careers by providing them with the knowledge and skills that are attractive to employers.

De-Montfort University (DMU) offers the perfect combination of outstanding teaching, first-class facilities and a fantastic student experience, placing research excellence and innovation at the heart of its mission. Our innovative and life-changing research has a direct and positive real-world impact, confirmed by the REF 2014, the most recent UK-wide initiative to access the quality of research in universities. We work with leading national and international employers to develop and deliver courses that equip our students with the knowledge, skills and abilities they need to succeed in a competitive job market. We also work with some of the most successful organisations in the world to offer 1,850 work placements a year. The Leicester School of Architecture is a prominent part of the university, established in 1887 the school is a leader in the field Architecture, offering innovative

architectural education at all higher education levels. The school has a track record of equipping students with a fearless approach to unforeseeable problems in the built environment.

CO-SPONSOR

LAFARGEHOLCIM was formed in 2015 as a result of the successful merger between two global cement giants – Lafarge (headquartered in France) and Holcim (headquartered in Switzerland). The merger, which was announced to be the second largest merger in 2014 has witnessed the emergence of the world's largest building materials ad construction solutions provider. With the world biggest material testing laboratory, LafargeHolcim with vision to be the leading and highest performing company in the building materials industry, is rated as the most advanced building materials company in the world offering an unprecedented range of products and services to answer the changing demands of the construction industry and the challenges of increasing urbanisation. LafargeHolcim is clearly the industry leader in terms of innovation, sales and manufacturing capacity. LafargeHolcim is located in 90 countries spread across all 5 continents with 115,000 employees. The company has 2,500 operations and is set to transform the global construction industry.

KEYNOTE SPEAKERS

Biography of **Professor Charles Egbu**

(PhD FRICS FCIOB FAPM FRSA FHEA)

Professor Charles Egbu is Dean of School of the Built Environment and Architecture at London South Bank University, England, UK, where he holds the Chair in Project Management and Strategic Management in Construction. His First Degree was in Quantity Surveying [First Class Honours] – Leeds Metropolitan University, UK, and he worked briefly as a site Quantity Surveyor for a large UK construction company. His Doctorate was obtained from the University of Salford, UK, in the area of Construction Management. He is a Fellow of the Royal Institution of Chartered Surveyors (FRICS); a Fellow of the Chartered Institute of Building (FCIOB), a Fellow of the Association for Project Management (FAPM), a Fellow of the Royal Society for the Encouragement of Arts, Manufacture and Commerce (FRSA), and a Fellow of the Higher Education Academy (FHEA). He is currently a Member of the Policy Board of the Chartered Institute of Building (CIOB). He was until 2014 a Director and member of the Board of Trustees for the Association for Project Management (APM), and Chairman of the Professional Standards and Knowledge (PS&K) committee of the Association for Project Management. He has lectured, nationally and internationally, at undergraduate and postgraduate levels in areas such as construction economics, contract procurement, project management, construction management, construction process improvements, sustainable development, and Innovation & knowledge management in complex environments. His research is in similar areas, where he has attracted in excess of £25m from many research funding bodies – nationally and internationally. He is an author of 12 books in Construction Management, Knowledge Management, Sustainable Development, Refurbishment Management, and Health & Safety in Construction. He is currently a Member of the Peer Review College of the UK Economic and Social Sciences Research Council (ESRC). He was a member of the Peer Review College of the UK Engineering and Physical Sciences Research Council (EPSRC- 2006 – 2009). He also sits on many editorial boards, and national and international scientific committees to do with research in construction management, project and programme management, innovation and knowledge management, and sustainable development. He was the Chair of the Association of Researchers in Construction Management (ARCOM: 2010 – 2012). He is a Visiting Professor to a number of Universities in Europe, Africa, and Asia. He has supervised over 25 PhD students and examined over 60 PhD candidates world-wide; and has acted as an External Examiner to many undergraduate and postgraduate programmes in many universities all over the world. He has contributed over 350 publications in various international journals and conferences and has hosted, chaired and spoken at many conferences in his areas of expertise. In addition, he has produced many practitioner-based reports, policy and guidance documents, and conducted many workshops and seminars internationally in his areas of discipline. He is also a member of the International Council for Research and Innovation in Building and Construction's Working Commission, where he is a co-ordinator of the CIB W102 on "Information and Knowledge Management", and the CIB W117 on "Performance Measurement in Construction".

Biography of **Professor Olurinde E. Lafe**

BSc (UNILAG), DHE (DELFT), MS (CORNELL), PhD (CORNELL)

Director – Centre for Renewable Energy Technology (CRET) & Professor – School of Engineering & Engineering Technology, Federal University of Technology, Akure (FUTA)
ACADEMIC HISTORY Prior to his joining FUTA as Engineering Professor and Director of CRET, Professor Lafe held senior academic positions at a number of universities including the University of Lagos, the University of Dar-es-Salaam, the University of Nairobi, Case Western Reserve University and African University of Science and Technology where he was a visiting distinguished professor of engineering.

SOLVING CHALLENGING PROBLEMS Professor Olurinde Lafe has spent the past 4 decades working on providing engineering solutions to development problems around the world. Professor Lafe has consulted with both governmental and non-governmental agencies including the United States Office of Naval Research - Strategic Defense Initiative Program on the "Star Wars" Project (where special multi-megawatt battery technologies were developed for space weapons), National Aeronautics and Space Administration (NASA), National Science Foundation (NSF), United States Department of Agriculture (USDA), United States Agency for International Development (USAID), United Nations Educational, Scientific and Cultural Organisation (UNESCO), World Vision International and Defense Advanced Research Programs Agency (DARPA).

PUBLICATIONS & PATENTS Professor Lafe has published numerous learned articles and written single and multi-author books. His latest book is "Abulecentrism – Rapid Development of Society Catalysed at the Local Community Level" (Springer, 2013). The development concept abulecentrism is what Nigeria needs in order to move forward. Abulecentrism seeks to achieve rapid and sustainable development of a given society by the strategic execution of projects and the provision of critical services at the local community level. Abulecentrism is built on the philosophy of using small, modular systems, such as a village, as building blocks for developing the greater society. Latest developments in renewable power systems are described extensively in the book.

INVENTIONS Professor Lafe's research and development efforts have resulted in 9 issued United States patents. His inventions have been implemented commercial and consumer products sold worldwide. Global telecom conglomerate, Nortel Networks, licensed his technology for their e-Mobility accelerator product. SONY Corporation used his invention for transmitting large digital files across the Internet.

CAPACITY DEVELOPMENT INITIATIVES Professor Lafe established the TechAlive Training Programme in Nigeria as a vehicle for capacity development in renewable energy systems. During the Year 2010, one hundred unemployed Nigerian graduates were given a 6-week intensive training in renewable energy (with emphasis on solar power) and clean-power related software engineering. Graduates of the TechAlive Programme are now involved in the design and installation of smart micro-grid community power systems for communities around Nigeria. In September 2012, another set of one hundred unemployed Nigerians were camped and given a 4-week TechAlive intensive training in renewable energy systems. These trainees constitute the pioneering set of workers for a nationwide PAWA774 initiative to generate, transmit and distribute 10MW of clean power in each of Nigeria's 774 local government areas (LGAs). PAWA774 is an acronym for Providing Alternative Watts for All 774 LGAs.

CHAIRMANSHIP OF POWER REVIEW COMMITTEES Professor Lafe has served as the Chairman of several committees setup to review renewable energy projects around the country. The plants range in capacity from 20MW to 1,200MW grid-tied solar power systems in strategic locatio45ns and different regions of Nigeria.

SOLVING NIGERIA'S POWER PROBLEM Professor Lafe has a clear, cost effective, and sustainable solution to Nigeria's power problem. His idea will provide an accelerated solution to the national electricity challenge, create millions of jobs in every nuke and cranny of the country and energize the economy in each of the 774 local government areas of the country. He has appeared on national television and published articles in national newspapers proffering his solution to the power problem.

JOINT INTERNATIONAL CONFERENCE PROGRAMME

Monday 21st – Thursday 24th March 2016

DAY 1: MONDAY 21ST MARCH 2016					**Venue**	**Time**
REGISTRATION					**2500-capacity auditorium**	**08:00 – 08:45**
OPENING CEREMONY (Moderator: Protocol Unit FUTA)					**2500-capacity auditorium**	**08:45 – 11:30**
Arrival of Special Guest of Honour, other Dignitaries and invitation to the High table					2500-capacity auditorium	**08:45** – 09:00
Anthems (National and FUTA)					2500-capacity auditorium	09:00 – 09:05
Welcome Address – Prof. J. A. B. Olujimi, Dean, School of Environmental Technology, Federal University of Technology Akure					2500-capacity auditorium	09:05 – 09:15
Introduction – Conference Chair- Prof Charles Egbu, LSBU, UK					2500-capacity auditorium	09:15 – 09:25
Opening Address by Vice-Chancellor, FUTA – Prof. Adebiyi Gregory Daramola					2500-capacity auditorium	09:25 – 09:35
Goodwill message by Ondo State Governor – His Excellency Dr Olusegun Mimiko CON					2500-capacity auditorium	09:35 – 09:50
KEYNOTE ADDRESS 1 – Prof. Olu Lafe					**2500-capacity auditorium**	**09:50 – 10:30**
Entertainment by Dance troupe					2500-capacity auditorium	10:30 – 10:45
Announcement and Acknowledgement of Sponsors and partners – Mr. Adegbenro Adebanjo (FUTA PRO)					2500-capacity auditorium	10:45 – 11:00
Speech by Major sponsors					2500-capacity auditorium	11:00 – 11:20
Vote of Thanks – Prof. Olatunde Arayela (Chairman, Local Organising Committee)					2500-capacity auditorium	11:20 – 11:25
Anthems (FUTA and National)					2500-capacity auditorium	11:25 – 11:30
Conference group photograph					Entrance porch of 2500-capacity auditorium	**11.30 – 12:00**
TEA BREAK / WELCOME COCKTAIL FOR SPECIAL GUESTS AND OTHER DIGNITARIES					**Corridors of 2500-capacity auditorium**	
PARALLEL SESSION 1					**PSR01 - PSR05**	**12:00 – 13:30**
Session 1A - Session Chairman – Prof. T. L. Akinbogun (DVCD) Rapporteur – Dr. I. B. Kashim (IDD)	**Venue**	**Session 2A - Session Chairman – Prof. J. A. Fadamiro (ARC) Rapporteur – Dr. (Mrs) M. A. Ajayi (ESM)**	**Venue**	**Session 3A - Session Chairman – Prof. O. O. Ogunsote (ARC) Rapporteur – Dr. O. O. Popoola (URP)**	**Venue**	**Time**

Session 4A - Session Chairman – Prof. A. O. Olotuah (ARC) Rapporteur – Dr. A. A. Emmanuel (URP)			**Venue**	**Session 5A - Session Chairman – Prof. D. O. Olanrewaju (URP) Rapporteur – Dr. M. B. Ogunleye (ESM)**	**Venue**	**Time**
THEME 1 Innovations, Environmental Friendliness and Adaptability				**THEME 5 Physical Planning, Urban Renewal and Urban Poverty**		
2016JIC-ST1-018 Mitigating Effect of Green Infrastructure on Environmental Degradation in Nigeria Urban Centres **Dipeolu Adedotun Ayodele & Fadamiro Joseph Akinlabi**			**PSR04**	**2016JIC-ST5-003** Analysis Of Factors Responsible For The Location Pattern Of Petrol Filling Stations In Akure, Nigeria **Olufayo, O. & Omole, F. K.**	**PSR05**	12:00 – 12:15
2016JIC-ST1-019 Assessment of Carbon Monoxide Levels in a Commercial District of Akure, Nigeria **Afolami, Adewale James; Ogunsote, Olu Ola; Elnokaly, Amira & Okogbue, Emmanuel Chilekwu**			**PSR04**	**2016JIC-ST5-005** Environmental Assessment Of Students Hostels In Federal University Of Technology, Akure, Nigeria **Rotowa, O.O.; Akinbode, T. & Gabriel, E.**	**PSR05**	12:15 – 12:30
2016JIC-ST1-026 Integrating Green Infrastructure to Enhance the Environmental Quality of High Density Residential Areas in Zaria **Musa Lawal Sagada**			**PSR04**	**2016JIC-ST5-014** An Appraisal Of The Geographical Influence Of The Cocoa Products Limited, Ile-Oluji As A Regional Agro-Pole In Ondo State, Nigeria **Akinbamijo, O. B. & Adegboyegun, K. A.**	**PSR05**	12:30 – 12:45
2016JIC-ST1-063 Integrating Life Cycle Assessment Into Architectural Practice In Nigeria **Oladokun, Oyindamola S. & Odekunle, Oluwole Olayide**			**PSR04**	**2016JIC-ST5-059** Environmental Impact of Petrol Retail Outlets in Selected Local Government Areas of Osun State, Nigeria **Emmanuel, A. A. & Adisa, A. O.**	**PSR05**	12:45 – 13:00
2016JIC-ST1-071 The Building Profession and the Challenges of Achieving Sustainable Buildings in Nigeria **Abiodun, Isaac**			**PSR04**	**2016JIC-ST5-029** A Survey On Social Studies Teachers' Opinion On Factors Inhibiting Successful Implementation Of Millennium Development Goals In Nigeria **Salihu, Jamilu Ja'afar & Adamu, Sule**	**PSR05**	13:00 – 13:15
2016JIC-ST1-072 Economic Impacts Of Energy Consumption And Supply In Office Buildings of Kaduna Metropolis, Nigeria **Salihu Murtala Muhammad & Ejeh Ekoja David**			**PSR04**	**THEME 6 Architecture and National Development** **2016JIC-ST6-003** Contextual Harmony Between Traditional Architecture And City Identity In Ebonyi State, Nigeria **Onanuga O. A.; Folorunso C. O. & Ajewole M.**	**PSR05**	13:15 – 13:30
Lunch					**Corridors of 2500-capacity auditorium**	**13:30 – 14:30**
Networking and Stakeholders meeting					**2500-capacity auditorium and the Vice Chancellor's Office**	**14:30 - 15:30**
PARALLEL SESSION 2					**PSR01 - PSR05**	**15:30 – 17:00**

Session 1B - Session Chairman – Prof. S. R. Ogunduyile (IDD) Rapporteur – Dr. Y. M. D. Adedeji (ARC)	Venue	Session 2B - Session Chairman – Prof. B. E. Ojo (IDD) Rapporteur – Dr. (Mrs) R. A. Oladapo	Venue	Session 3B - Session Chairman – Prof. D. R. Ogunsemi (QSV) Rapporteur – Dr. C. O. Folorunso	Venue	Time
THEME 1 **Innovations, Environmental Friendliness and Adaptability**		**THEME 2** **Real Estate, Valuation and Management**		**THEME 3** **Landscape Design, Tourism and Remote Sensing**		
2016JIC-ST1-037 Towards Achieving Low Cost Housing: Use of Traditional Building Materials (A case study of Fayose Estate, Ado-Ekiti, Nigeria). **Victor Olufemi Adegbehingbe**	**PSR01**	**2016JIC-ST2-036** Application of Construction Management, Procurement and Project Delivery Systems by Private housing developers in Nigeria for sustainable development **Raimi, Taofiq Idowu**	**PSR02**	**2016JIC-ST3-009** Assessing Nature-Based Tourism Potentialss For Socio-Economic Development In Ekiti State, Nigeria **Adeyemo, Akinola & Bada, Afolabi O.**	**PSR03**	15:30 – 15:45
2016JIC-ST1-058 Compressive Strength Characteristics of Laterized Palm Kernel Shell Concrete **Popoola, O.C.; Obaju, N.B. & Alake, O.**	**PSR01**	**2016JIC-ST2-041** Perceptions of Construction Practitioners on the Benefits of Construction Change Management Practices **Adedokun, Olufisayo Adewumi**	**PSR02**	**2016JIC-ST3-013** A Critique Of The Implementation Of Abuja Tourism Development Master Plan **Idris Isah Iliyasu**	**PSR03**	15:45 – 16:00
2016JIC-ST1-070 Evaluation of Different Plastering Materials for Mud Buildings **Alabadan B. A.; Ajayi E. S. & Y. P. Musa**	**PSR01**	**2016JIC-ST2-043** Assessment of Construction Cost Escalations in the Public Sector's Projects in Lagos State, Nigeria **Fatoye, E. O.; Enenmoh, R. C.; Opara, V. I. & Oyekanmi, O. O.**	**PSR02**	**2016JIC-ST3-016** Socio-Economic Impacts of Architecture on Sustainable Tourism Development in Nigeria: Case Study of Idanre Hills, Ondo State **Ola, Omobolanle Arike & Ayeni, Dorcas A.**	**PSR03**	16:00 – 16:15
2016JIC-ST1-073 Statistical Investigation Of Effects Of Different Brands Of Cement On The Strength Of Pavers **Yusuff, A. Q.; Adams,B. A.; Olatoke,T. I.; Emmanuel, I. B.; Adedeji, M. S. & Bankole, S. O.**	**PSR01**	**2016JIC-ST2-053** Assessment of Organisational Culture and Employee Commitment in Construction Companies in Lagos State Nigeria. **Abiola-Falemu, Joseph Ojo**	**PSR02**	**2016JIC-ST3-018** City Aesthetics And Sustainable Recreational Open Spaces In Planned Residential Estates: Focus On Lsdpc Estate, Lekki, Lagos, Nigeria **Ajenifujah-Abubakar, A. O.; Ayeni, Dorcas A. & Fadamiro, J. A.**	**PSR03**	16:15 – 16:30
2016JIC-ST1-074 Comparative And Statistical Analysis Of The Strength Of Pavers Made From *Milicia Excelsa* And *Gmelina Arborea* Sawdust **Yusuff, A. Q.; Adewole, A. T.; Shaib-Rahim, H. O.; Awotedu, O. L.; Alarape, A. B. & Adedeji, M. S.**	**PSR01**	**2016JIC-ST2-061** Factors Affecting Construction Project Handover and Feedback Mechanism **Oke, A. E.; Olatunji, S. O. & Ajulo, A. A.**	**PSR02**	**2016JIC-ST3-028** The Economic Impact Of Ikogosi Warm Spring On Its Immediate Environment **Olanrewaju, D. O. & Adedeji A. A.**	**PSR03**	16:30 – 16:45
2016JIC-ST1-076 Effect Of Blended Cement On The Hydration Properties, Compressive Strength And Environmental Compatibility Of Concrete **Folagbade Samuel Olufemi**	**PSR01**	**2016JIC-ST2-073** The Issue of Communication in the Construction Industry: A case of South Africa **Berenger, Yembi Renault & Justus, Ngala Agumba**	**PSR02**	**2016JIC-ST3-025** Graphic Communication For Sustainable Development: Eliciting Desired Response From Target Audience **Ebigbagha Zifegha Sylvester**	**PSR03**	16:45 – 17:00
Session 4B - Session Chairman – Prof. A. S. Asaju (ESM) **Rapporteur – Dr. T. O. Odeyale (ARC)**			**Venue**	**Session 5B - Session Chairman – Prof. O. M. Bello (ESM)** **Rapporteur – Dr. E. B. Oladunmoye (IDD)**	**Venue**	**Time**
THEME 4 **Education and Professional Ethics**				**THEME 5** **Physical Planning, Urban Renewal and Urban Poverty**		
2016JIC-ST4-008 Impact Of School Environments On Academic Performance: Feedback From Senior Secondary School Students **Okafor, C. A.; Maina, J. J.; Stephen, H. & Ohambele, C. C.**			**PSR04**	**2016JIC-ST5-013** Effect Of Infrastructure Provision On Residential Property Values In Ijaiye Housing Estate, Lagos, Nigeria **N.B. Ezeokoli & A. E. Nwosu**	**PSR05**	15:30 – 15:45
2016JIC-ST4-027 Promoting Environmental Sustainability For The Attainment Of Agenda 2063 In Nigeria: The Role Of Social Studies Education **Salihu, Jamilu Ja'afar & Muhammed, Aminu**			**PSR04**	**2016JIC-ST5-018** Residents' Participation in Infrastructure Provision and Maintenance in Residential Neighbourhoods in Akure, Nigeria **Fakere, A. A. & Ayoola, H. A.**	**PSR05**	15:45 – 16:00
2016JIC-ST4-030 Developing Independent Learning Among Lower And Middle Basic Pupils: The Impact Of Inquiry Teaching Strategy On Learners' Cognition Level			**PSR04**	**2016JIC-ST5-030** Assessment Of Local Government Council And Community-Based Development Associations In	**PSR05**	16:00 – 16:15

Salihu, Jamilu Ja'afar; Yahaya, Idris A'ishatu & Abdullahi, Munirat Binta		The Provision Of Infrastructure In Ilawe-Ekiti, Nigeria **Okosun, S. E. & Olujimi, J. A. B.**			
2016JIC-ST4-021 Mapping Of Secondary Educational Institutions Using Gps & Gis Technology In Shomolu Local Government Area Of Lagos, Nigeria **Oseni, Ayokunle Ebenezer & Ode Godwin Omenka**	**PSR04**	**2016JIC-ST5-043** Assessment Of Local Government Council And Community-Based Development Associations In The Provision And Maintenance Of Educational Facilities In Ilawe-Ekiti, Nigeria **Okosun, S. E. & Olujimi, J. A. B.**	**PSR05**	16:15 – 16:30	
2016JIC-ST4-028 Impact Of Field Trip Technique On Students' Cognition Level Of Environmental Health Hazards In Junior Secondary Schools, Kaduna State-Nigeria **Muhammed, Aminu & Salihu, Jamilu Ja'afar**	**PSR04**	**THEME 4** **Education and Professional Ethics** **2016JIC-ST4- 001** Facilities Maintenance-Towards Enhancing Learning and Teaching Environments: Case Studies of Higher Education Institutions (HEIs) in Nigeria **Mohammed Olowoake**	**PSR05**	16:30 – 16:45	
2016JIC-ST4-026 Community Participation In Education: The Role Of Parent Organizations (Pos) In Decision Making Process **ALFA, Muhammad Gimba**	**PSR04**	**2016JIC-ST4-018** Appraisal Of Stakeholder Management Practice In Tertiary Education Trust Fund (TETFund) Construction Projects **M. L. Ibrahim; Y. M. Ibrahim & K. J. Adogbo**	**PSR05**	16:45 – 17:00	

DAY 2: TUESDAY 22ND MARCH 2016					**Venue**	**Time**
REGISTRATION					**2500-capacity auditorium**	**08:00 – 08:30**
PARALLEL SESSION 3					**PSR01 - PSR05**	**08:30 – 10:00**
Session 1C - Session Chairman – Prof. J. O. Agbede (APH) **Rapporteur – Dr. O. Bamidele (ESM)**	**Venue**	**Session 2C - Session Chairman – Dr. M. A. Oyinloye (URP)** **Rapporteur – Dr. M. B. Ogunleye (ESM)**	**Venue**	**Session 3C - Session Chairman – Dr. A. E. Olajuyigbe (URP)** **Rapporteur – Dr. O. F. Kayode (IDD)**	**Venue**	**Time**
THEME 1 **Innovations, Environmental Friendliness and Adaptability**		**THEME 2** **Real Estate, Valuation and Management**		**THEME 3** **Landscape Design, Tourism and Remote Sensing**		
2016JIC-ST1-003 The levels of building stakeholders' motivation for adopting green buildings **Ayokunle Olubunmi Olanipekun**	**PSR01**	**2016JIC-ST2-017** Effect of Contractor's Selection Criteria on Cost Performance of Civil Engineering Projects **Akinmusire, A. O.; Adedokun, O. A. & Aje, I. O.**	**PSR02**	**2016JIC-ST3-034** Evaluation Of Pre-Consumer Textile Waste Treatment Practices And It's Potential For Economic Sustainablity In Akure, Ondo State **Adiji, Bolajoko Esther & Fagbenro, F. Moyo**	**PSR03**	08:30 – 08:45
2016JIC-ST1-009 An Assessment Of The Role Of Nigerian Architects Towards Climate Change And Global Warming In The Built Environment **Hassan Ozovehe Saliu & Lukman Achimugu**	**PSR01**	2016JIC-ST2-023 Effect of Unethical Practices on Procurement Performance of Public Building Projects in Edo State, Nigeria **Ebekozien A.; Uwadia, F. E. & Usman, D. A.**	**PSR02**	**2016JIC-ST3-040** Training for Industrial Design Product Development and Manufacturing in Nigeria: Implications for Sustainable Economic Development **Femi Kayode & Kanu, E. U.**	**PSR03**	08:45 – 09:00
2016JIC-ST1-011 Low Cost Approach to Energy Efficient Buildings in Nigeria: A Review of Passive Design Options **Ochedi, Ekele Thompson; Taki, Ahmad & Painter, Birgit**	**PSR01**	**2016JIC-ST2-040** Readiness of the Nigerian Building Consulting Firms to Adopt Lean Construction Principles **Olamilokun, O..; Ibrahim, A. D. & Ahmadu, H. A.**	**PSR02**	**2016JIC-ST3-035** Merging, Art, Design And Technology: A Virtual Tour Design Of The Department Of Industrial Design, Federal Univerity Of Technology, Akure, Nigeria **Ibiwoye, T. I.; Ogunlade, B. & Ugah, H. O.**	**PSR03**	09:00 – 09:15
2016JIC-ST1-013 Climate Change And Challenges Of Environmental	**PSR01**	**2016JIC-ST2-044** Assessment Of Construction Productivity Of	**PSR02**	**2016JIC-ST3-042** Adoption of sustainable risk management: A	**PSR03**	09:15 – 09:30

Sustanability In Lagos State, Nigeria **Dipeolu, A. A.;** **Jolaoso, B. A. & Elemide, O. O.**		Indigenous Construction Firms In Southwestern, Nigeria **Olawale T. Akinmoladun & Ibironke E. Ariyo**		study of chemical exposure in textile industry in Nigeria **Akintayo, Wole Lateef**		
2016JIC-ST1-014 Evidence Of Climate Change And Adaptation Strategies Among Grain Farmers In Sokoto State, Nigeria **Ikpe, E.' Sawa, B. A.; Ejeh, U. L.; Meshubi O. A. & Oladimeji J. S.**	**PSR01**	**2016JIC-ST2-046** Assessment of Lean Construction Practice in the Nigerian Construction Industry **Adegbembo, T. F.; Bamisaye, O. P. & Aghimien, D. O.**	**PSR02**	**2016JIC-ST3-030** Preference of Visual Aesthetic Architectural Features amongst Practicing Architects **Omale R. P.**	**PSR03**	09:30 – 09:45
2016JIC-ST1-015 Analysis Of Public Perception Of Climate Change And Its Impact On Health And Environment In Zaria City And Its Environs **Ikpe, E.' Sawa, B. A.; Ejeh, U. L.; Meshubi O. A. & Oladimeji J. S.**	**PSR01**	**2016JIC-ST2-052** Sustainability of Compressed Stabilized Interlocking Earth Blocks (CSIEB) for Building Construction in Nigeria **Aghimien, Douglas Omoregie & Awodele, Oluwaseyi Alabi**	**PSR02**		**PSR03**	09:45 – 10:00
Session 4C - Session Chairman – Dr. A. A. Taiwo (ARC) **Rapporteur – Dr. A. M. Adebayo (ESM)**			**Venue**	**Session 5C - Session Chairman – Dr. (Mrs) V. A. Bello (ESM)** **Rapporteur – Dr. G. E. Ajayi (SVG)**	**Venue**	**Time**
THEME 4 **Education and Professional Ethics**				**THEME 5** **Physical Planning, Urban Renewal and Urban Poverty**		
2016JIC-ST4-012 User Perception Of Comfort In Offices: A Case Study Of Architecture And Quantity Surveying Departments, Ahmadu Bello University **Stephen, H.; Maina, J. J.; Okafor, C. A. & Ohambele, C. C.**			**PSR04**	**2016JIC-ST5-039** Characterising Peri-Urban Sprawl Of A City In A Developing Country: Case Study Of Ibadan, Nigeria **Fasakin, J. O. ; Dosumu, N. A. & Omole, F. K**	**PSR05**	08:30 – 08:45
2016JIC-ST4-013 Assessment Of The Relatedness Of Quantity Surveyor's Skill Requirements For Diversification Of Practice Firms In Nigeria **Akinola, Joseph Aderemi; Ogunsemi, Deji Rufus & Awodele, Oluwaseyi Alabi**			**PSR04**	**2016JIC-ST5-046** Public Infrastructural Facilities and Urban Fringe Development in Developing Nations: A Focus on Ibulesoro, Ondo State, Nigeria **Olamiju, I. O.; Oyinloye, M. A. & Daramola, J. O.**	**PSR05**	08:45 – 09:00
2016JIC-ST4-015 Assessing The Cad Proficiency Level Of Architecture Graduates In Selected Architectural Firms In Akure, Nigeria **Olasunkanmi Samson Fagbemi; Adesola Moyosoluwa Ojo & Ayeni, Dorcas A.**			**PSR04**	**2016JIC-ST5-047** The Challenges Of Urban Sprawl Development In Suleja, Niger State **Idowu, O.O.; Shaibu, S. I.; Adeleye, B. M.; Medayese, S. O. & Abd'razack, N. T. A.**	**PSR05**	09:00 – 09:15
2016JIC-ST4-023 Effective Training for Construction Craftsmen and Optimisation of Productivity in the Nigerian Construction Industry **Dantong, Jack Sam Dalyop; Prucnal-Ogunsote, Bogda & Awulu, Samson**			**PSR04**	**2016JIC-ST5-052** Ajoda New Town Development, Oyo State, Nigeria: Lessons For Building Future New Towns In A Sustainable Manner **Ayangbile, Oluwabukola Adetola**	**PSR05**	09:15 – 09:30
2016JIC-ST4-024 Unethical Professional Practices and Poor Craftsmanship of Construction Projects Performance in Nigeria: Consequences and the Way Forward **Dantong, Jack Sam Dalyop; Prucnal-Ogunsote, Bogda; Okwoli, Peter & Dassah, Elizebeth**			**PSR04**	**2016JIC-ST5-057** Assessment of Peri–Urban Zones in Benin City, Nigeria: A Focus on Ekiadolor Community **Ayo E. Olajuyigbe & Olufolake A. Ayodele**	**PSR05**	09:30 – 09:45
THEME 6 **Architecture and National Development**			**PSR04**	**2016JIC-ST5-025** Building Tradition, Slum and Housing the Urban Poor: An Exploratory Study **T. Oluwaseyi Odeyale & Kayode Fagbemi**	**PSR05**	09:45 – 10:00
2016JIC-ST6-002 Effects Of Globalization Of Information Technology Communication Facilitieson Architectural Practice In Nigeria **Adegbehingbe,Victor Olufemi & Ogundiran, Ibikunoluwa Ajibola**						

TEA BREAK					**Corridors of 2500-capacity auditorium**	**10:00 – 10:30**
KEYNOTE ADDRESS 3 – Prof. Charles Egbu **Topic: Quality and Robustness in Ph.D Research**					**2500-capacity auditorium**	**10:30 – 12:00**
INDUSTRY DEBATE - Challenges and Solutions of achieving sustainability in Nigeria					**2500-capacity auditorium**	**12:00 – 13:30**
Chair/Moderator – Dr. Ayo Olajuyigbe 4 Panelists – Chairmen of Built Industry professional associations in Ondo State					2500-capacity auditorium	12:00 – 13:00
Questions and Answers					2500-capacity auditorium	13:00 – 13:30
Lunch					**Corridors of 2500-capacity auditorium**	**13:30 – 14:30**
PARALLEL SESSION 4					**PSR01 - PSR05**	**14:30 – 16:00**
Session 1D - Session Chairman – Dr. O. I. Aje (QSV) **Rapporteur – Dr. H. A. Ayoola (ARC)**	**Venue**	**Session 2D - Session Chairman – Prof. M. A. K. Smith (CSP)** **Rapporteur – Dr. N. Saka (QSV)**	**Venue**	**Session 3D - Session Chairman – Dr. J. O. Basorun (URP)** **Rapporteur – Dr. A. E. Oke (QSV)**	**Venue**	**Time**
THEME 1 **Innovations, Environmental Friendliness and Adaptability**		**THEME 2** **Real Estate, Valuation and Management**		**THEME 3** **Landscape Design, Tourism and Remote Sensing**		
2016JIC-ST1-005 ICT Integration In The Transport System **Nwankwo, Benjamin N.**	**PSR01**	**2016JIC-ST2-057** Impact of Macroeconomic Factors on Production Costs of Building Project in South-South Region of Nigeria **Emmanuel T. Adu & Anjiba D. Lamptey-Puddicombe**	**PSR02**	**2016JIC-ST3-005** Mapping and Analysis of Urban Land Use and Land Cover in Akure, Nigeria **Simeon Ogunlade & Gbenga Enisan**	**PSR03**	14:30 – 14:45
2016JIC-ST1-012 Socio-economic consideration of Housing Transformers and Non-transformers in Selected Government Estates in South-Western, Nigeria **Victor Olufemi Adegbehingbe**	**PSR01**	**2016JIC-ST2-069** Project risk factors effects on civil construction cost in the Niger Delta Region Contractors' and Consultants' Perspectives **Anjiba D. L. & Emmanuel, T. A.**	**PSR02**	**2016-JIC-ST3-011** Geospatial Analysis of the Distribution of Health Facilities in Peri-urban area of Ifedore, Nigeria **Olusola Popoola; Yusuph Adekoya & Tayo Obasanmi**	**PSR03**	14:45 – 15:00
2016JIC-ST1-020 Sustainable Site Planning; A Soil Conservation Strategy for Residential Developments in Lagos, Nigeria **Akagwu Mamajaunkwun**	**PSR01**	**2016JIC-ST2-071** Budgetary Reliability of Design Stage Elemental Cost Plan in Building Procurement **Adafin, J.; Wilkinson, S.; Rotimi, J. O. B. & Odeyinka, H.**	**PSR02**	**2016JIC-ST3-022** A Gis Approach In Spatial Distribution Of Water Pipeline Through Primary And Secondary Network In Lagos State **Ariyo T.O.; Tata H. & Omogunloye O. G.**	**PSR03**	15:00 – 15:15
2016JIC-ST1-031 Impact Of Cities Physical Development On The Aged Lifestyle In Akure, Nigeria **Onanuga Omotayo Adebayo**	**PSR01**	**2016JIC-ST2-072** Methodological Approaches to Risk Assessments during Cost Plan Production **Adafin, J.; Wilkinson, S.; Rotimi, J. O. B. & Odeyinka, H.**	**PSR02**	**2016JIC-ST3-023** Mapping And Spatial Distribution Of Petroleum Products By Marketers In Nigeria **Tata. H.; Ariyo T.O. & Omogunloye O. G.**	**PSR03**	15:15 – 15:30
2016JIC-ST1-055 Perception Of Residents On Impact Of Proximity Of Religious Camps On Residential Properties In Nigeria **Adeniran, Y. Olusegun & Bamidele M. Ogunleye**	**PSR01**	**2016JIC-ST2-097** Impact of Risks on Tendering and Procurement of Building Projects in Lagos State **Dosumu, Oluwaseun Sunday**	**PSR02**	**THEME 5** **Physical Planning, Urban Renewal and Urban Poverty** **2016JIC-ST5-050** Sustainable Urban Development and Management Strategies in Nigeria **Joseph Akinlabi Fadamiro & Joseph Adeniran Adedeji**	**PSR03**	15:30 – 15:45
2016JIC-ST1-066 Assessing Compliance With Noise Control Guidelines In The National Building Code For Residential Estates In Ondo And Ekiti States, Nigeria **Ganiyu, Sikiru Abiodun**	**PSR01**	**2016JIC-ST2-056** Risks Associated With Stakeholders At The Pre-Contract Stage Of Construction Projects In Ondo State, Nigeria **Dorcas Moyanga & Michael Ayodele**	**PSR02**	**THEME 2** **Real Estate, Valuation and Management** **2016JIC-ST2-016** A Study of Developers Speculative Activities in Lagos Urban Fringe **Esther O. Thontteh**	**PSR03**	15:45 – 16:00

Session 4D - Session Chairman – Dr. K. T. Gbadamosi (TMT) Rapporteur – Dr. O. S. Adelabu (IDD)	Venue	Session 5D - Session Chairman – Prof. (Mrs) O. F. Osundahunsi (FST) Rapporteur – Dr. O. O. Ojuri (CVE)	Venue	Time
THEME 4 **Education and Professional Ethics**		**THEME 5** **Physical Planning, Urban Renewal and Urban Poverty**		
2016JIC-ST4-004 Pedagogic experience of spreadsheet applications to contemporary valuation of property investments: Perspective of the Federal Polytechnic, Idah **Ataguba, Joseph Obaje & Ogungbenro, Matthew Taiwo**	**PSR04**	**2016JIC-ST5-048** Slum Development and Urban Renewal in Nigeria **Chidinma Emma-Ochu & Onwuka, Ethelbert**	**PSR05**	14:30 – 14:45
2016JIC-ST4-007 Drawing Pre-Knowledge And Design: A Case Study Of Year Two Undergraduate Architecture Students Of Ahmadu Bello University **Ohambele, C. C.; Maina, J. J.; Stephen, H. & Okafor, C. A.**	**PSR04**	**2016JIC-ST5-055** Appraisal of Characteristics of Slum Neighbourhood of Minna, Niger State **Adeleye, B.M.; Abd'razack, N.T.A.; Ndana, M.; Akande, O. S. & Popoola, A. A.**	**PSR05**	14:45 – 15:00
2016JIC-ST4-016 Sustainable Architectural Education: Perceptions From University Of Jos Post Graduate Students **Allu, Evelyn L. A.**	**PSR04**	**2016JIC-ST5-066** Comprehending the Role of People in Urban Redevelopment in Indian Cities **Dillip Kumar Das; Sanjaykumar G. Sonar & Fidelis Emuze**	**PSR05**	15:00 – 15:15
2016JIC-ST4-019 Factors Affecting Academic Performance of Architecture Students in Nigerian Private Universities **Opoko Akunnaya Pearl; Oluwatayo Adedapo Adewunmi & Ezema Isidore C.**	**PSR04**	**2016JIC-ST7-006** Investigating Slum Household Living Conditions In Aso Pada- Ward, Mararaba, Karu L.G.A. Of Nasarawa State, Nigeria **Kigun, P. A.; Surajo, L. A.; Buba, Y. A.; Majidadi, T. S. & Makwin, G.**	**PSR05**	15:15 – 15:30
2016JICST4-025 Architectural Transformations in an Educational Facility and its Impact on Teaching and Learning: a Study of the Department of Architecture Ahmadu Bello University Zaria **Halima Sani-Katsina & Aisha Umar Shuaib**	**PSR04**	**2016JIC-ST5-049** Gender Involvement In Sustainable Water Project Management In Ibadan, Nigeria: A Physical Planning Perspective **Olusa Adekemi; Olujimi Julius & Okoko Eno**	**PSR05**	15:30 – 15:45

Building Adaptation and the Impact of Maintenance Budget: Case Studies of Selected Higher Education Institutions in Nigeria

Olowoake Mohammed

Department of Building Technology, Moshood Abiola Polytechnic, Abeokuta, Nigeria
olowoake.mohamed.mapoly.edu.ng@gmail.com

ABSTRACT

The purpose of this study is to proffer solutions to shortages of staff offices and lecture rooms in Higher Education Institutions where old existing buildings are abandoned. However, such buildings could be adapted and backed up with adequate budgets. A cursory look at some of the HEIs buildings studied suggests that they are abandoned. The objectives are: To evaluate Works and Services Departments constraints in relation to building adaptation and budgets by conducting semi-structured interviews (qualitative), and survey (quantitative) for the staff and students of the selected HEIs in Nigeria; to develop a strategic framework to support building adaptation and effective budgeting techniques, and evaluate the framework by conducting interviews for experts. The study reveals some interesting results: Shortage of staff offices and lecture rooms could be resolved by adapting existing abandoned buildings after renovations. Data for budgeting for adaptation could be collected via reconnaissance surveys and letters of complaint for defects from the users. On the basis of the findings, these recommendations have been proposed: The Works and Services Departments could carry out reconnaissance surveys of their built environments with a view to identifying the affected buildings. The use of appropriate data collection techniques for the budget preparation is very essential. In addition, letters of complaint for defects from the assets users are also essential.

Keywords: Abandoned, Adaptation, Budget, Environment, Performance

INTRODUCTION

Wilkinson et al., (2011) define adaptation as a means of reducing building related urban energy consumption and greenhouse gas emissions. They add that, the need to adapt buildings and to reduce environmental footprints increase as the world concentrations of carbon increase, as built environment contributes half of all greenhouse gas emissions, and government is called upon to look for ways to lessen the part cities play in global warming, and adaptation is a sensible means of reducing building related greenhouse gas emissions-in order to mitigate the impacts of climate change and enhance the city for another generation of citizens and users. Fianchini (2007) explains that, adaptation is any work to a building over and above maintenance in order to change the building capacity, function or performance that is any intervention to adjust, reuse, or upgrade a building to suit new condition or requirements. In addition, there is the need for maintenance budget.

Adaptation factors include economic, social, environment, technological, legal and physical categories (Wilkinson et al., 2009, Remoy and Vander, 2007). Others include local economy, age of asset; physical conditions, heritage value, size and user demand (Fianchini, 2007). Building adaptation is an "essential component of sustainable development" as large numbers of obsolete buildings might blight the built environments, and after adaptation, they increase the value of the assets (Wilkinson et al., 2011).

In addition, the provision of an annual maintenance budget is germane to effective and efficient building adaptation, and such budget to be prepared from the reconnaissance surveys of the built environments. However, submission of an annual adaptation budget derived from reconnaissance survey of the built environment could accompany the use of maintenance toolkit. (Olanrewaju et al., 2011) assert that, "budgetary allocation for tertiary institutions buildings adaptation on annual basis is only one percentage of the total allocation for the

Olowoake, M. (2016). Building adaptation and the impact of maintenance budget: Case studies of selected higher education institutions in Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. *Procs. of the Joint International Conference (JIC) on* 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 2-7

education sector, and this is inadequate to cater for the maintenance backlogs".(RICS, 2009) asserts that, "any maintenance operation should be run to budget, and should be set up by taking information from the data collected".

Objectives of the Research

i. To review literature on building adaptation and budgeting techniques
ii. To evaluate Works and Services Departments constraints in relation to building adaptation and budgets by conducting semi-structured interviews (qualitative), and survey (quantitative)
iii. To determine if there are adequate staff offices and lecture rooms for the staff and students of the selected HEIs in Nigeria.
iv. To develop a strategic framework to support building adaptation and effective budgeting techniques
v. To evaluate the framework (by conducting interviews for experts)

Research Methods

For the purpose of the study, the researcher used mixed methods, that is, semi-structure interviews (qualitative) and questionnaire survey (quantitative) to collect data. For the first phase of data collection, the researcher conducted semi-structured interviews for the twelve directors of works and services of the selected HEIs in Nigeria. The use of the qualitative approach enabled the researchers to gain insight into the phenomena being studied, have deep understanding of the study area, improve the accuracy of judgments, and ensure that the variance reflects that of the trait being studied and not that of the method. According to Creswell (2003) and Rubin and Rubin (2005) that interviews would facilitate the collection of data with sufficient depth thus allowing the researchers to draw both meanings and ideas from the research participants. In addition, the researcher used questionnaire survey for the second phase of data collection from the technical officers (to validate) of the selected HEIs works and services in Nigeria.

Results and Discussions-Qualitative

Use of appropriate Procurement Strategies: From semi-structured interviews conducted, the following emerged

i. Outsourcing: Contractors and Consultants
ii. In sourcing: Director of Works and Services or Interviewee, project or construction team, Maintenance Officers or in-house technical staff or Labour.
iii. Professionals: Combination of outsourcing and in-sourcing technical staff.
iv. Tendering Procedures (TP)
v. Fluctuations and Variations (FV)

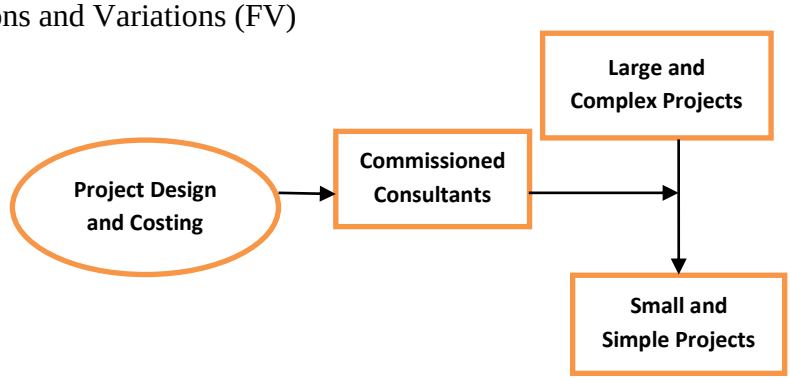

Figure 1: Use of Commissioned Consultants for project design and costing to achieve quality. Large and complex projects to be executed via outsourcing, and the in-house technical staffs to execute simple and small projects

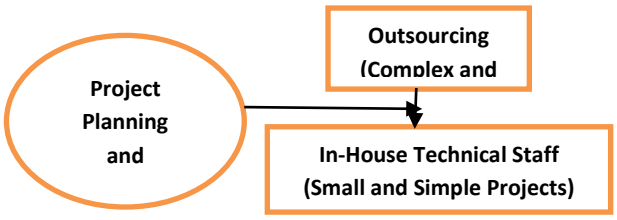

Figure 2 Project Execution-Large and complex projects to be outsourced, and small and simple projects to be executed by in-house technical staff

Figure 3 Procurement Strategies: Use of Outsourcing

Outsourcing involves contracting out of projects to qualified and competent contractors to execute. However, it is necessary to determine the type and nature of projects to be outsourced. From the interviews, large and complex projects could be outsourced, because of the complexities and the largeness of the projects. In addition, the departments could also outsource the project designs to qualified, experienced, and competent consulting firms to achieve quality. As it is the practice, the consulting firms, especially well-seasoned professionals among the personnel could be part of the project monitoring, control, supervision, and evaluation team (establishment of a control unit within the Works and Services Department).Other members of the team could be drawn from among the seasoned professionals in the Works and Services Department. The main duties of the unit are quality of project components, materials, and labour, with adequate considerations for cost and project agreed time. The unit monitors and controls project execution to avoid project over-run.

i. **Use of In-house Technical Staff:** The use of in-house technical staff to handle simple and small maintenance projects is desirable. Such projects can be more expensive if executed via outsourcing. These types of jobs are minor repair or replacement in nature, and they can be completed by the in-house technical staff within three- to-four days, and attracted little costs. In addition, the designs of such jobs could be handled by Consultants or by in-house technical staff (HEI-Planning and design unit).

Below shows the framework for "Planned Preventive Maintenance Method-Control Toolkits":

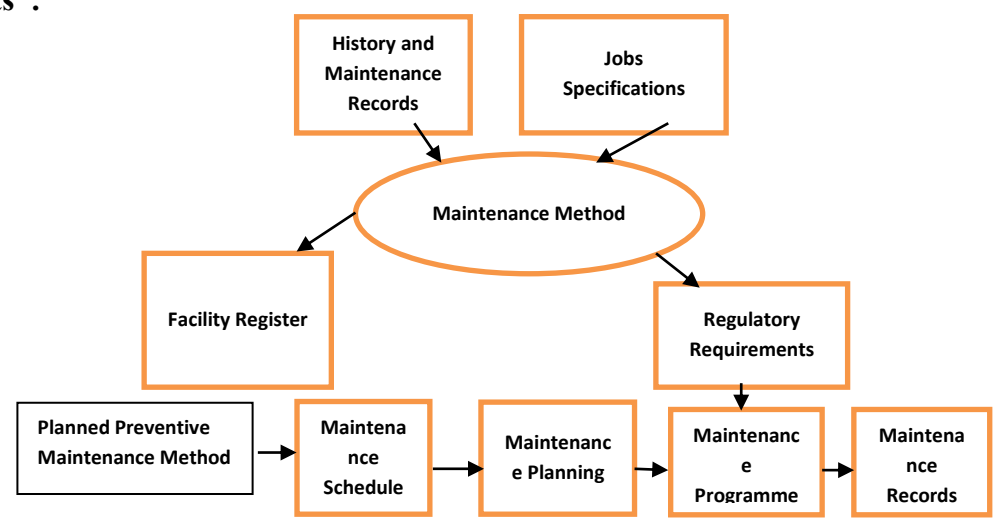

Figure 4: Maintenance methods involve the processes that could be adopted and used to cure, predict, or prevent failures occurring in buildings (Olanrewaju et al., 2011).

It is the organisation policy by the management that dictates the type of methods to be used by considering factors such as, culture, core business, technology, and other factors both internal and external to the organisation (RICS, 2009). Olanrewaju et al., 2011 assert that, most organisations prefer the use of curative method (restoration back to normal position), some combine conditions survey with curative method (that is, predictive with corrective methods).However, the best approach as confirmed from the interviews responses is **"Planned Preventive Maintenance**" method. To add more, this method prevents failures from occurring by using some maintenance control toolkit, such as, maintenance schedule, maintenance programme, jobs specifications, and facility register. Similarly, works and services departments of HEIs in Nigeria could attach the maintenance control toolkit with the annual maintenance budget (derived from the reconnaissance surveys of the built environments, and surveys conducted on users satisfaction of the built environments).

vi. Annual Adaptation Budget

From the semi-structured interviews conducted, there are various ways of calculating for HEIs Works and Services built environments budgets:

- **Budget Forecasting (BF)**
- **Previous Year Budget plus a Percentage Increase (PYBPI)**
- **Previous Year Budget with consideration for market prices of Components and Materials (PYBCM)**
- **Reconnaissance Surveys (RS)**

vii. **Below shows the framework for Maintenance Budget**

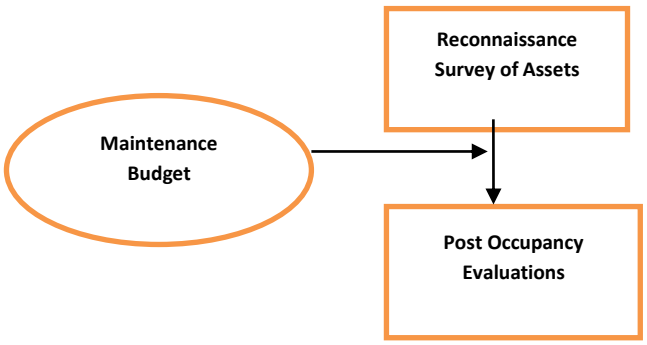

Figure 5 Maintenance Budget

From the results of the interviews, some of the HEIs do not run maintenance budget, they prefer the use of central budgeting system. Maintenance projects are carried out whenever there is the need to rescue situations that are going out of control (curative method).Those HEIs that are running maintenance budgets, majority of them prefer to add certain percentages to the previous year maintenance budgets for the coming year. Some HEIs use the prevailing market prices of labour, materials and components to add a lump sum to the previous year budget to make up for the year running, while some of them use Forecasting. However, none of the above mentioned techniques are suitable enough for the preparation of maintenance budgets for the HEIs built environments.

Results and Discussions-Quantitative

Out of a total of 156 respondents, 120 of them filled and returned the questionnaires. This is 76.92% of all the participants, and this makes the results obtained from the survey credible.

Majority of the HEIs Lecture rooms and Staff offices in Nigeria are provided with adequate facilities. However, there is room for improvement in the provision of adequate supply of furniture, ventilation, electricity, portable and drinkable water. Emphasis should also be placed on regular waste collection and treatment.

i. In the majority of the HEIs in Nigeria, complaints about noticed defects in staff offices and lecture rooms are lodged with the head (Director) of works and services departments.
ii. Majority of the HEIs works and services departments do not use maintenance budgets. Those that prepare and use maintenance budgets, use faulty techniques in the preparation of HEIs built environments annual maintenance budgets.
iii. Maintenance budgets of the HEIs built environments are prepared based on previous year budget plans.
iv. In most HEIs, response rate to Users' Complaints about defects are delayed due to delays being suffered by the works and services departments from the HEIs management in approving and releasing maintenance cash.
v. In addition, previous year maintenance projects in which maintenance cash was approved and released still re-appear in the following year (cultural influence) budget for implementation.
vi. Many of the HEIs Works and Services Departments base their maintenance budgets preparation on forecast.
vii. Most of the HEIs built environments noticed defects are major ones, due to delays in approving and releasing of maintenance cash by the HEIs management.
viii. Majority of HEIs works and services departments adopt and use faulty maintenance method and in-appropriate procurement strategy.
ix. Most HEIs do not carry out regular maintenance work on their built environments. This is due to the following: adoption and use of in-effective and in-efficient maintenance method, delays in approving and releasing maintenance cash, and adoption and use of in-appropriate procurements strategy.
x. Majority of HEIs works and services departments adopt and use curative and condition survey maintenance methods.
xi. Most HEIs works and services departments are under-funded due to the use of faulty maintenance budget, in-effective maintenance method, in-appropriate procurement strategy, and lack of sustainable programme.
xii. Majority of HEIs works and services departments do not have full complements of technical staff, hence, both small and simple projects and large and complex projects are outsourced. This makes the projects deliveries very expensive.
xiii. Majority of the HEIs works and services departments' staff members are not professionals. Most of the maintenance projects, budget preparation, and sustainable programmes are outsourced.
xiv. Most of the HEIs Works and Services Departments Technical staff lacks necessary technical skills and knowledge to perform their official duties satisfactorily.
xv. Majority of the HEIs prefer to keep backlogs of repairs and replacements of defects. They prefer building new staff offices and lecture rooms to maintaining the existing ones on time (curative method).
xvi. Most HEIs Chief Executives are not maintenance or technically inclined. They view regular maintenance of existing built environments as waste of revenue. They always favour erecting of new staff offices and lecture rooms for personal gains (attitudes).
xvii. Most HEIs do prefer existing buildings to be in dilapidated conditions or collapse before carrying out maintenance works on them (curative method).
xviii. Majority of the HEIs works and services departments do not prepare and use maintenance control toolkit. And, the absence of its use prevents the timely approval of maintenance budget, and adequate release of maintenance cash.
xix. Majority of the HEIs do not have full complements of technical staff, and those with full complements of technical staff, the staff do not have needed technical skills and

knowledge to perform their official duties satisfactorily. Most of them are not professionals, so, they out-source most of the maintenance projects.

Validated Framework

In order to validate the developed framework, semi-structured interviews were also conducted for Senior Technical Officers in four of the sampled HEIs in Nigeria. The question items bothered on the simplicity; sequences; adaptability, and cost effectiveness of the developed Framework. In summary, they all agreed that the framework is simple to understand, adaptable, and that, the stages involved are well arranged in sequential order. They argued further that, its use can help achieve effective project quality control, save cost, and ensures delivery to agreed time.

Conclusions

In Nigeria, some HEIs do not prepare and use maintenance budget. Those who prepare and use maintenance budgets derived from in-appropriate data collection techniques. For effectiveness, such data could be collected via carrying out reconnaissance survey of the built environment and from the letters of complaints from the assets users. The researcher used semi-structured interviews conducted for the 12 Directors of works and services departments of the selected HEIs to do the evaluations of the selected HEIs works and services departments in Nigeria. The strategies used for the development of the framework were derived from the literature review, and the results of the semi-structured interviews.

Recommendations

i. It is a good practice for each HEI to prepare and operate with maintenance budget, and such budget could be prepared from data derived from the reconnaissance survey, and users' satisfaction survey of the HEI built environment at the same time. This type of budget could be adequate and reliable.
ii. It is also a good practice for the HEI Works and Services Departments to carry out surveys of users' satisfaction of the built environment twice in a term time (at the beginning and at the end). This could enable the departments to know the needs and the feelings of the assets users.
iii. It is important for HEIs works and services departments in Nigeria to outsource large and complex projects, and use in-house technical staff for simple and small projects.
iv. HEIs works and services departments to establish quality control units within the departments.
v. HEIs works and services departments to adopt and adapt Planned Preventive Maintenance Method to preventive facilities failure and prolong their service years.
vi. HEIs works and services departments to prepare and use sustainable programme for their built environments.

The Levels of Building Stakeholders' Motivation for Adopting Green Buildings

Ayokunle Olubunmi Olanipekun

Civil Engineering and Built Environment School,
Queensland University of Technology, Australia
ayokunleolubunmi.olanipekun@hdr.qut.edu.au

ABSTRACT

As a result of the challenges that encircled green building in the building sector, building stakeholders' motivation for adopting green buildings has generated a considerable research interest in the literature. Given that building stakeholders' motivation for adopting green buildings is a psychology process, insights from the psychology theories of motivation such as Goal setting theory, Herzberg's two-factor theory etc. Revealed that the previous studies have only goal or intention at their core – meaning that they were only concerned with factors that promote (or not) the adopting of green buildings by building stakeholders. However, in addition to the core of goal or intention, there are different levels of motivation that leads to the achievement of the goal, and this is founded in another psychology theory, the self-determination theory (SDT) of motivation. Yet, this has not been explicitly (if at all) applied to explain the motivations for adopting green buildings by building stakeholders. The objective of this paper is to introduce the levels of motivation as proposed by SDT of motivation in terms of how they apply and predict building stakeholders' motivation for adopting green buildings. The methodology used was a Literature survey of 30 publications, the literature on the SDT of motivation, from the field of psychology, is used to inform the levels of building stakeholders' motivation for adopting green buildings, from the green building literature. The findings revealed that the levels of building stakeholders' motivation for adopting green buildings are external regulation, introjected regulation, identified regulation, integrated regulation and extrinsic motivation, and the difference in one level to another is the self-determination involved in a motivated action. As a recommendation, the design of policy interventions aimed at motivating the adoption of green buildings in the building sector should be structured based on the levels of building stakeholders' motivation**.** This paper concludes that the levels of motivation proposed by SDT of motivation can explain and predict building stakeholders' motivation for adopting green buildings.

Keywords: Developers, green building, motivation, psychology, self-determination theory, stakeholders.

INTRODUCTION

Green building is encircled with many challenges such as complex delivery process, high capital and transaction costs of development etc. (Qian, Chan and Ghani Khalid, 2015; Zhang et al., 2012), and as a result, motivation is a salient requirement for building stakeholders' adoption of green buildings (Cole, 2011). Consequently, many studies (Abidin and Powmya, 2014; Marker et al., 2014; Zhang et al., 2011) have delved into the subject of motivation, mainly as it applies to the building stakeholders' adoption of green buildings. The major contribution is the elicitation of the factors that promote building stakeholders' adoption of green buildings, and are categorised into government/polity factors, moral factors, economic/market factors, information and education factors, and lastly, corporate factors.

Clearly, this is a valuable contribution to the knowledge and practice of motivating the adoption of green buildings in the building sector. From the point of view of psychology theories of motivation, the previous studies have only the content of goal or intention at their core (Deci et al., 1991) - meaning that the previous studies were only concerned with factors that promote (or not) the adoption of green buildings by building stakeholders. Some of the psychological theories in question are Maslow's hierarchy of needs; Herzberg's two-factor theory etc. (see Kelly, 2004; Curtis, 2010). It should be emphasized that the concept of motivation is founded in psychology – which explains human behaviour or actions (Popa et al., 2013), and as observed by Nurul Diyana and Zainul Abidin (2013), the action of building

Olanipekun, A. O. (2016). The levels of building stakeholders' motivation for adopting green buildings. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F.? Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 8-19

stakeholders to adopt green buildings is a psychologically motivated process – for instance, from intention to forethought and to action.

However, in addition to the core of goal or intention (which is to build green), there are different levels of motivation that lead to the achievement of the goal (Green building). This can be found in another psychology theory, the self-determination theory of motivation (Ryan and Deci, 2000a). The SDT of motivation proposed that the motivation for the performance of an action has different levels – and the difference in one level to another is the self-determination involved in the performance of an action by a person or a group of people (Amabile, 1993, Rigby et al., 1992). In an increasing order of self-determination, these levels of motivation range from external regulation, introjected regulation, identified regulation, integrated regulation and intrinsic motivation (see Pelletier, Tuson and Haddad, 1997; Pelletier et al., 1995).

However, the levels of motivation, as proposed by SDT of motivation has not been explicitly (if at all) applied to explain the motivations for adopting green buildings by building stakeholders, and according to Healy (2015), this could result to missed opportunities in the effort to increase the adoption of green buildings in the building sector. As a result, this paper introduces the levels of motivation, and how they apply to building stakeholders' motivation for adopting green buildings. In this study, building stakeholders are the professional roles (e.g. architect, skilled trades, cost consultants etc.) and the non-professional roles (project owners, tenants etc.) that can affect, or are affected by the sustainable construction (Feige, Wallbaum and Krank, 2011). It could be argued that different building stakeholders have different motives and/or interests per time (Hakkinen and Belloni, 2011); however, sustainability is a focal issue that is globally important to all stakeholders on an equal basis (Feige et al., 2011).

By way of structure, the introduction which provides a background and context is presented. This is followed by a review of literature, where the issues surrounding the motivation for adopting green buildings, and the link between the SDT of motivation (SDT) and motivation for adopting green buildings are presented. The next are the research method adopted, the findings and its policy implications. Lastly, the conclusions and areas of further research are suggested.

LITERATURE REVIEW

Issues in Motivating the Adoption of Green Buildings

The adoption of green buildings by building stakeholders is affected by myriad of challenges such as difficult and complex project delivery process (Zhang et al., 2012), high capital and transaction cost of green building (Qian et al., 2015), inadequate professional knowledge and expertise to fabricate and install green building features (Li et al., 2014) and the change-averse nature in the building sector – which is imbibed by many building stakeholders (Ahn et al., 2013). In order to overcome these challenges, and at the same time promote the adoption of green buildings, there is need to focus ultimately on motivating building stakeholders (Cole, 2011).

Many studies have consequently investigated building stakeholders' motivation for adopting green buildings in the building sector, and these are categorised into differently. The first is the government/polity factors, which refer to the intervention of the government towards promoting the adoption of green building through the force of the law (mandates and legislations) (Abidin and Powmya, 2014), and various voluntary programs such as incentive policies (Zhang et al., 2011). The second is the moral factors, which relate to the persuasion and/or inspiration of building sector stakeholders by the worsening environmental conditions

– thereby prompting actions such as green building (Abidin and Powmya, 2014). The third is the economic/market factors, which refers to the economic gains and high business potential of green buildings that potently attracts building stakeholders (Marker et al., 2014). The fourth is the information/education factors, which insinuate increased level of green awareness, especially through the rating certifications, that translate to the adoption of green building by building stakeholders (Potbhare, Syal and Korkmaz, 2009), while the last is the corporate factors, which represents the motivations for adopting green building or green practices by the building organisations. These include the organisational resources and readiness, reputation etc. (Abidin and Powmya, 2014; Love et al., 2012).

Despite the valuable contributions evidenced from the previous studies, the motivation for adopting green buildings by building stakeholders has only the content of goal or intention at its core - that is, the major emphasis are the motivations (factors) that lead to the achievement of a goal or the performance of an action (used in this paper). By extension, the emphasis is on the direction of actions in terms of which type of motivation direct actions towards achieving desired outcomes - and this aligns with many psychology theories of motivation such as Maslow's hierarchy of needs, Herzberg's two-factor theory, Goal-setting theory, Expectancy theory etc., where the major emphasis is the goal or outcome and the motivations leading to desired outcomes (See Curtis, 2010; Kelly, 2004). However, the motivation for adopting green buildings by building stakeholders has a goal or intention at its core (which is to build green), with an additional consideration that there are different levels (or amount) of motivation that lead to the achievement of the goal (Green building). This is founded in another psychology theory, the SDT of motivation (Ryan and Deci, 2000a), but yet unexplored towards promoting the adoption of green buildings among building stakeholders in the building sector.

Link between Self-Determination Theory (SDT) and Motivation for Adopting Green Buildings

The self-determination theory (SDT), a psychology theory, proposes that the motivation to perform an action varies in amount or level – and the difference in one level to another is the self-determination involved in the performance of an action by a person or a group of people (Ryan and Deci, 2000a). For instance, the level of motivation of a project owner that develops some green building projects, or inculcates certain green features in building projects because it will improve the flagship or the brand of the project owner in the open market is different from the level of motivation of the project owner that performed the same action because of government mandates or regulations. The level of motivation in the former reflects a case of personal endorsement and a feeling of choice on the part of the project owner, while the latter reflects a case of compliance with an external control. Hence the level of motivation in the former is more self-determined, or more self-regulated, while latter is controlled or externally regulated.

Despite the difference in their levels of motivation, the actions performed by the project owner in both examples are instrumental to achieving separable outcomes of flagship and brand in the open marketplace or avoiding sanctions for not following government mandates or regulations. When an action is performed by a person or a group of people as a result of its instrumental value, it is regarded as extrinsic motivation (Gagne and Deci, 2005), and can vary in the degree to which it is autonomous (Ryan and Deci, 2000a). This is in contrast to intrinsic motivation – which refers to the performance of an action by a person or a group of people because they derive spontaneous satisfaction out of the performance of such action (Vallerand, 2004). The adoption of green building or green practices in some quarters because it gives the feeling of solving what can be regarded as seemingly difficult task conforms to intrinsic motivation (e.g. See Woodruff, Hasbrouck and Augustin, 2008). The prospect of a

reward or sanction does not stimulate an intrinsic action. According to Amabile (1993), intrinsic motivation does not manifest because of some separable outcomes such as rewards, external prods or pressures, hence it is regarded as the least controlled motivation or the most self-regulated (Babiak and Trendafilova, 2011).

It could be seen that intrinsic and extrinsic motivated actions differ in their regulation process, yet both are instances of intentional (i.e., motivated) actions (Deci and Ryan, 2000a). This means there is a purpose for either of intrinsic and extrinsic motivated actions. This contrasts amotivation - which is an action performed by a person or a group of people without clear understanding or sense of purpose (Pelletier et al., 1997). Green building or green practice represents a significant change notion from the conventional building practice, particularly in the building sector. Hence the adoption of green building, or green practices by a person or a group of people may not be an action that lacks intentionality – therefore amotivation is expunged from this study. According to Gagne and Deci (2005), the levels of motivation as proposed by SDT of motivation posit a self-determination continuum (Figure 1). This ranges from amotivation (expunged), to external regulation, introjected regulation, identified regulation, and integrated regulation – all being the different levels of extrinsic motivation, and lastly to intrinsic motivation (Gagne and Deci, 2005; Vallerand, 2004). Clearly, the levels of motivation as proposed by SDT, apply, and explain the manner of adopting green buildings by building stakeholders.

RESEARCH METHOD: LITERATURE SYNTHESIS

This paper employs literature synthesis – which can be defined as combining a number of different pieces of information to build a conclusion (Howsawi, 2014). Specifically, the literature on the SDT of motivation, from the field of psychology, is used to inform the levels of building stakeholders' motivation for adopting green buildings, from the green building literature. There is no universal form or structure of literature synthesis; rather it is based on the key research question being investigated (see Henning, 1999). Consequently, the levels of motivation as proposed by SDT of motivation are described, and the corresponding explanations and predictions in the context of "motivating the adoption of green buildings" are prescribed. The Table 1 reveals the synthesized literature of 30 publications covering both fields of psychology (A) and green building (B).

FINDINGS

Levels of Building Stakeholders' Motivation for Adopting Green Buildings

This section describes the levels of building stakeholders' motivation for adopting green buildings in the building sector. The levels of motivation as proposed by the SDT of

motivation are initially described, in terms of meaning and context, and then followed by how they apply to building stakeholders' motivation for adopting green buildings. They include, and summarized in Table 2:

External regulation

Externally regulated level of motivation corresponds to the actions performed by a person or a group of people in order to attain some separable outcomes that are external to the actions performed such as the offer of a reward or threat of a punishment (Guay, Ryan and Deci, 2000). This means that the attached or the prospective separable outcomes are the motivations behind the performance of an action or actions (Vallerand and Blanchard, 2000). As revealed in many studies (e.g. Nurul Diyana and Zainul Abidin, 2013; Zhang et al., 2011; Chan et al., 2009), building stakeholders' motivation for adopting green buildings is mainly an externally regulated motivation. For instance, the study of Qi et al. (2010) revealed that it is the contractors' main motivation for adopting green building in China, while the incentive programs and policies has been strongly instrumental to motivating the adoption of green buildings by building sector stakeholders in many countries (Cidell and Cope, 2014; Liu and Xu, 2015; Lee and Koski, 2012).

ER- External regulation; INTR-Introjected regulation; IDR-Identified regulation; INR-Integrated regulation; IM-Intrinsic motivation; A-Psychology literature; B-Green building literature

Introjected regulation

The introjected regulated actions are the actions performed through internal pressures that are contingent on self-esteem, such as the feeling of pressure in order to avoid guilt or anxiety to attain ego-enhancements or pride (Ryan and Deci, 2000a). The study of Babiak and

Trendafilova (2011) revealed that 43% of executives, though in sport organisations, felt that being viewed as a 'good citizen' was one of the most influential motivations for addressing environmental issues. In addition, building stakeholders are pushed to adopt green buildings, particularly the eco-labelled ones, because they add flagship and brand to owners or owners' engagement (Aliagha et al., 2013). According to Pelletier et al. (1997), this level of motivation is no longer externally regulated, and the presence of external motivations is no longer required to perform an action. In fact, an executive partner of a global firm once reiterated that separable outcomes such as energy cost savings is not the main motivation for adopting green building, but the ego-desire to become global leader in sustainability and corporate social responsibility is the main motivation (Boyle and McGuirk, 2012). As an introjection regulated action, it is experienced as partially part of the self of the person or the group of people performing the action(s) (Vallerand and Losier, 1999).

Identified regulation

According to Vallerand (2004), this level of motivation means that a person or a group of people are motivated to perform an action because they have identified with the importance of such action and thus accepts its regulation as their own. When this happens, the adoption of green building by building stakeholders becomes an action performed with a sense of choice or volition (willingly) because they are aware and have identified with the importance and value of the action performed (Samari et al., 2013; Deci et al., 1991). This manner of adopting green building by building stakeholders is said to be motivated through identified regulation – which is more self-determined than introjected regulated actions (Deci et al., 1991). Samari et al. (2013)'s study revealed that building sector professionals that have identified with the importance of green building, particularly through environmental education, are able to adopt green building practices more easily. Similarly, green building users with green experience are able to identify with green building value and benefits, thereby willing to pay more for green development (Chau, Tse and Chung, 2010).

Integrated regulation

This is the level of motivation that a person or group of people performs an action because it is congruent with their values and needs (Barkoukis et al., 2008). In contrast to identified regulation, an action is performed not only because of its significance but because it is consistent with self-schemas the actors possesses (Pelletier et al., 1997). For instance in the UK building sector, many building stakeholders exhibit as personal value, a high level of environmental consciousness, and this has been their major motivation for adopting green practices (Wang et al., 2014). In organisations, ingrained green or sustainability values inform the implementation of necessary actions including building production (Richardson and Lynes, 2007; Jain and Kaur, 2004) – an example is a client organisation in Australia was able to develop a high rated green building because it conforms to the value of the company to achieve at least the minimum Green Star rating in its building development (Love et al., 2012). According to Pelletier et al. (1995), the actions motivated through integrated regulation closely aligns with the personal or organisational value of the actor, hence it is considered performance with a very high self-determined level of motivation. Nevertheless, an action is still being performed for its instrumental value with respect to some outcome that is separate from the action under this level of motivation (Barkoukis et al., 2008).

Intrinsic motivation

The actions that are performed by a person or a group of people purely motivated by the pleasure, positive experiences, and satisfaction associated with such are said to be intrinsically motivated (Ryan and Deci, 2000a). In sustainability science, many authors

(Aliagha et al., 2013; Moganadas et al., 2013; Chen and Chai, 2010; Woodruff et al., 2008) agree that intrinsic actions are relative to the attitude of environmental concern and/or counterculture bio-centric activism – which is the perception of a person or a group of people that they are integral part of the natural environment. Tan (2004)'s study found that the exemplification of the attitude of environmental concern, especially in the adoption of green building or green practices by building stakeholders, creates a feeling of satisfaction or pleasurable experience. Reiteratively, intrinsically motivated actions are not performed in order to achieve some valued outcomes such as rewards (Pelletier et al., 1997), but for the positive experiences associated with exercising and extending ones capacities (Hasegwa, 2008).

Policy Implications

The insights from the SDT of motivation can guide the design of strategies and policy interventions to improve building stakeholders' adoption of green buildings in the building sector. This can be solutions that introduce form or structure to the design process of policies for motivating the adoption of green buildings. Because of the in the levels of motivation as proposed by SDT, and also to ensure more effectiveness, policy interventions should be designed to focus on each of the levels of building stakeholders' motivation separately (See Potbhare et al., 2009; Rigby et al., 1992). Moreso that the level of success of policies or programs aimed at motivating the adoption of green buildings by building stakeholders is considerably determined by how policies are designed (Pearce, Dubose, Bosch, 2007).

Notable, many existing policy interventions aimed at motivating building stakeholders' adoption of green buildings are designed segmentally – such as instituting and focusing policy interventions local, state-wide or nationally (Lee and Koski, 2012). Policy interventions are also instituted to motivate different professional or non-professional roles in the building sector – whereby policies can be targeted at contractors (Dobson et al., 2013), differently from professional builders (Tinker et al., 2006). It is also not uncommon for policy interventions to be targeted distinctly at the constituent segments of a green building – including integrated design, energy performance, water conservation etc. (Pearce et al., 2007). Clearly the design of policy interventions to focus each level of motivation is in line with previous and existing practices.

In light of the above, particularly during the process of policy design, there is need for policy makers to identify the levels of motivation of building stakeholders who are the target of policy interventions aimed at motivating the adoption of green buildings per time, through interviews and/or surveys, and longitudinal observations and experiments (Seeliger and Turok, 2015, Zhao et al., 2015) so as to reveal the dominant level of motivation of building stakeholders as emphasized in Liu et al. (2012). The identification of the levels of motivation of building stakeholders, particularly the least self-determined levels of motivation, can ensure specificity in policy design – whereby for each level of motivation, identified green building practices are matched with outcomes that regulate or motivate building stakeholders, and perhaps in the right quantity or measure. In this manner, public accountability is justified in terms of prudent administration of policies for motivating the adopting of green buildings (Pearce et al., 2007).

According to May and Koski (2007), the separable outcomes that regulate the least determined levels of motivation such as legal procedures, grants, administrative assistances etc. are costly to implement and time consuming, and this usually generates extensive debates and indecision among policy makers (Circo, 2008). Policy interventions should therefore encourage the shifting from the less self-determined to the more self-determined levels of building stakeholders' motivation for adopting green building (i.e. identified regulation,

integrated regulation and intrinsic motivation) (Deuble and John de Dear, 2012) – which are more inherent in the values and attitudes of building stakeholders. Policies such as supporting and endorsing the activities of the (willing) building stakeholders (or early adopters), can help build up their green ideals and values to the level that they will become self-determining in their adoption of green buildings (Pearce et al., 2007).

Table 2: Summary of the levels of building stakeholders' motivation for adopting green buildings and their modes of regulation

Levels of motivation	Modes of regulation	Selected reference sources
External regulation	This level of building stakeholders' motivation for adopting green buildings is regulated by separable outcomes that are external to the actions performed such as rewards, threat of punishments etc.	Liu and Xu, 2015; Cidell and Cope, 2014; Nurul Diyana and Abidin, 2013; Lee and Koski, 2012; Zhang et al., 2011; Qi et al., 2010; Chan et al., 2009
Introjected regulation	This level of building stakeholders' motivation for adopting green buildings is regulated by internal pressures that are contingent on self-esteem such as the feeling of pressure in order to avoid guilt or anxiety to attain ego-enhancements or pride	Boyle and McGuirk, 2012; Babiak and Trendafilova, 2011
Identified regulation	This level of building stakeholders' motivation for adopting green buildings is regulated through identifying with the value and importance of green building practices	Samari et al., 2013; Chau et al., 2010
Integrated regulation	This level of building stakeholders' motivation for adopting green buildings is regulated by the "green" self-schemas, values or beliefs of the building stakeholders	Wang et al., 2014; Love et al., 2012; Richardson and Lynes, 2007, Jain and Kaur, 2004
Intrinsic motivation	This level of building stakeholders' motivation for adopting green buildings is not regulated. Instead green buildings are adopted by building stakeholders for pleasurable experiences and satisfaction. In addition, the feeling of autonomy, relatedness and competence catalyses intrinsically motivated green building	Aliagha et al., 2013; Moganadas et al., 2013; Chen and Chai, 2010; Hasegwa, 2008; Woodruff et al., 2008; Tan, 2004

Additionally, policies interventions should be design to instill "green or sustainability" culture in the daily professional practices of building stakeholders. This can be achieved through the type of education that target building stakeholders at the point of engaging in building practices (Huang et al., 2014) – for instance, developers can be required to undergo compulsory training on best practices that promotes sustainable construction as a condition for bidding for building contracts, while professionals in the building sector can be required as a matter of compulsion to undergo similar training before being licensed to practice. Policies such as this should be legislated – which is a longer term and more permanent means of instituting policies (Dubose et al., 2007). According to Schelly et al. (2012), acculturated green building practices within and outside the building sector conforms to the more self-determined levels of motivation e.g. integrated regulation.

Policies that promote community participation can also encourage the more self-determined levels of motivation – whereby a community of building stakeholders is organized under a uniform agenda, and as agents of change. Studies have shown that community participation encourages self-determined level of building stakeholders' (and actors outside the building sector) motivation for adopting green buildings (Moganadas et al., 2013; Schelly et al., 2012; Sadeghi-Tabrizi, 2010; Hasengwa, 2008). As participants of such community, building stakeholders consider it a moral and value adaptation to engage in green practices, rather than

for extrinsic benefits (Sadeghi-Tabrizi, 2010). Within such community cluster, role models or mentors – who are the more active participants, usually provide necessary guides and mentoring to other less active participants to the extent that it becomes moral to adopt green practices (Moganadas et al., 2013). Analogously, the building stakeholders' level of motivation for adopting green building can become more self-determined through the development of demonstration projects – which serves as niche that provokes value perception of green buildings among an establishment of community of building stakeholders (Berry et al., 2013).

Building stakeholders' level of motivation for adopting green buildings can become more self-determined through participatory environmental governance by policy makers. Known as voluntary environmental governance (VEGA) in some quarters, it is the involvement of both policy makers and building stakeholders (or private sector stakeholders) in a more collaborative environmental rule making and implementation (van der Heijden, 2013). According to Schelly et al. (2012), this approach encourages stakeholders to implement green practices out of the sense of responsibility, rather than for extrinsic reasons.

CONCLUSION AND FUTURE RESEARCH

In this paper, the adoption of green buildings has been highlighted as a motivation issue, particularly for the building stakeholders who are faced with many challenges in the process, and revealed the use of the psychology theory of self-determination to explain and predict the levels of building stakeholders' motivation for adopting green buildings. From the psychological point of view, building stakeholders' motivation for adopting green buildings is not only goal or intention orientated as depicted in the myriad of previous studies – whereby the main emphasis was the factors that promote (or not) the adoption of green buildings by building stakeholders. Rather, in addition to the pervasive goal or intention orientation, insights from the SDT of motivation reveal that building stakeholders' motivation for adopting green buildings varies in level – with each level differing from one another based on the self-determination involved in the adoption of green building.

External regulation, introjected regulation, identified regulation and integrated regulation are the different levels of extrinsic motivation. The last of the levels of motivation considered in this study is intrinsic motivation – which describes the pleasurable experiences or satisfaction that building stakeholders' derive from adopting green buildings. Often, intrinsic motivation goes with environmental activism, in which its exemplification by building stakeholders leads to the feeling of satisfaction. However the levels of building stakeholders' motivation are often overlooked by researchers in providing the background knowledge for motivating the adoption of green buildings in the building sector. More significantly, policy makers are also not giving cognizance to the levels of building stakeholders' motivation in the design of policies and programs for motivating the adoption of green buildings. To avoid missed opportunities in the theory of motivating the adoption of green buildings in the building sector, it is important to take the levels of building stakeholders' motivation into account in the various researches that seeks to create new means of improving the adoption of green buildings in the building sector. In practice, taking the levels of building stakeholders' motivation into account introduces more structure and accountability into the design of policies aimed at motivating the adoption of green buildings, particularly in terms of matching of identified green building practices with outcomes that regulate or motivate building stakeholders for each level of motivation. In addition, there is more explicitness about the more self-determined levels of motivation, and how building stakeholders' levels of motivation can become more self-determined through policy interventions.

The SDT of motivation is well grounded with about three decades of research to its credit, many of which have provided valuable insights into the concept of motivation in different spheres like educational learning, sports, employment etc. In the building sector, further insights can be generated by validating the levels of motivations proposed by SDT of motivation empirically from the views of building stakeholders of different classes. This will provide quantifiable information on the levels of motivation of respective building stakeholders that are targets of policy interventions aimed at motivating the adoption of green buildings per time e.g. developers.

ABSTRACT

Building of healthcare facilities is considered a complex task owing to the inherent uncertainties. From feasibility study through design and construction, so many intricate factors should be considered by project managers to make healthcare projects successful. Lots of building components, diverse stakeholders' needs, progressive healthcare technology, specialized functions, different financing methods, and particular building codes and regulation make managing construction of healthcare facilities a challenging task for project managers. Therefore, understanding the criteria for successful delivery of these types of projects is critical for project managers. Although, evaluating success factors of general construction projects has attracted attentions in recent years, little research has been engaged that address specific nature of healthcare construction projects. This paper aims to identify success factors of healthcare facility projects by interviewing practitioners who have substantial experience in construction of healthcare facilities in Iran. The qualitative nature of the study creates an opportunity for experts to reveal their insights about projects success factors through open-ended interviews. The result can be used by project managers as a guideline to handle healthcare construction projects successfully.

Keywords: Healthcare Facilities, Healthcare Construction Projects, Iran, Success factors

INTRODUCTION

Construction industry has an important impact on Safety, health, environment and society (Cheong Yong and Emma Mustaffa, 2012). Success of construction projects have direct effect on mentioned parameters. One of the problems, in project management, is unawareness of success factors which lead to its failure. All projects have been developed for specific purposes so they could be called successful if they are completed in scheduled time, cost and quality. So, there is a need to clearly define success factors in construction projects. After defining these factors, the success rate of projects can be measured. No research was conducted in Iran regarding project's success factors. While initially success in projects are measured based on pre-determined factors. These factors could be different during the size and function of projects. Therefore knowing factors is the first step to measure project's success. The purpose of this research is to distinguish success factors of healthcare construction projects in Iran. This article tries to find main reasons of success through interviews with managers and civil engineers with at least 15 years of experience in contracting, consulting and employing companies and assess them.

LITERATURE REVIEW

Several researches have been carried out about success of construction projects in different countries specifically in Europe and Easters Asia. Study on the success factors of construction projects was first done by Rockart in 1982. On the things which really make the difference between success and failure. Defining success factors of a project is in reaching its goals which should be provided for the participants. (Sanvido et al.1992, Tiong and Cooke-Davies 2002). In projects success can be announced when it is completed according to the schedule, preplanned budget and needs of stockholders. Project's proper function, profitability for contractors and no claims are factors of project's success. (Akintoye and Takim 2002). Factors of project's success can be divided into two groups: hard, tangible and measurable objectives and soft mental and spiritual and less measurable ones. Time, cost and quality criteria are widely known as the triangle of project management while safety, environmental health and technical factors are also improving. Clients' satisfaction, proper communication

Reza Z. D. & Ehsan, A. (2016). Identifying Success Factors in the Construction of Healthcare Facilities in Iran. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F.? Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 20-25

among the elements of project and absence of dispute are factors that can guarantee a project's success. (Erling and Svein Arne, 2000 Chan, 2004; Erling et al., 2006). In academic literature clients' satisfaction is a variable in project's success during last decades in and by the time of completing the project evaluating client's satisfaction and project's success are very close to each other (Jugdev and Muller, 2006).

METHODOLOGY

At the beginning, the existing literature on success factors in projects was studied. Focusing had particularly been on the resources that identify success factors in different countries and health projects. Review of literature helped this research to recognize factors of project's success in other countries. Qualitative method has been used because the target of this research is to recognize success factors in healthcare projects. This method helps the researcher to focus deeply on the subject and identify its hidden angles. In order to focus on experiences of experts, interviewing has been chosen as the main data collection method. To identify success factors in Iran, 20 interviews have been conducted with experts involved in the construction industry of Iran with at least 15 years of experience. All of the interviewees have the experience in constructing healthcare projects and they have been chosen by Snow ball sampling method. The demographics of the interviewees are shown in Table 1. Interviews have been conducted in open ended manner so the interviewees feel at ease explaining their points of views. Then the interviews were transcribed. Gathered information regarding the subject is based on valuable experts' experiences. Qualitative analysis was done by coding method. In this method the researcher recognizes the theme by reading the interviews transcription. Gathered information is categorized in this fashion and each group has been integrated which would be discussed in data analysis part.

Qualitative Data Analysis

According to the gathered information, success factors in healthcare projects are divided into eight groups which are explained below. It worth mentioning, this information is context dependent and cannot be generalized to wider setting.

Table 1: The Demographics of the Interviewees

ROW	CODE	ROLE	Education	Field	Experience (year)	Organization Type
1	C1	Project Administrator	Bachelor	Civil Engineer	15	Client
2	C2	Physics	Specialist	Oncology	30	Client
3	C3	Project Manager	Bachelor	Civil Engineer	20	Client

Scope

Scope includes the processes required to ensure that the project includes all the work required, and only the work required, to complete the project successfully. Plan Scope is the process of creating a scope management plan that documents how the project scope will be defined, validated, and controlled. The key benefit of this process is that it provides guidance and direction on how scope will be managed throughout the project (Project Management Institute (PMI), 2013).

All project managers use project scope management throughout the project life cycle to identify and control all aspects involved in a project without a planned scope so practical deliverables are not possible. Importance of Scope in Project Management. Based on gathered information scope management project in healthcare construction projects could be evaluated under two category of pre-construction studies and feasibility studies. According to O1 one of the biggest owners' problems is not knowing the scopes of projects. Weak pre-construction studies of consulting companies are due to not knowing the details of projects and it has happened many times that there has been no concordance between the culture, climate and the assigned land. C1, C2 and C3 are all expert managers who are aware of early studies importance and they believe that it is one of the reasons of project failure. They all believe that project X (for privacy reason the real names of the projects are changed) is an obvious example.

Time

Time includes the processes required to manage the timely completion of the project is one of the most important factors in healthcare projects (PMI, 2013). Planning, scheduling, political reasons and lengthening of correspondences are four groups of factors that challenges time. N2 believes that project completion are only doable when it is done according to the schedule but N3, N5 and O5 consider precise planning more important than scheduling which is less important. N1 implicitly confirms the above mentioned but accurate determination of priorities and implementation of enforcement activities in more detailed and fragmentary in order to specify prerequisite for any activity are important factors to reach an accurate schedule. But all of the interviewees believe completion of projects in recent years has always been increasing and usually projects face delays. O3, a manager with more than 35 years, emphasizes political reasons increase the time of healthcare project completion and sometimes even suspend them. O6 and C7 mentioned decrease in profitability of projects as the impact of delay in project completion. C6 and C5 mentioned converting old office system

to automation to decrease time of correspondences. Although it doesn't seem helping to the reasons of projects success, in fact any requests by construction agents are under impact of corresponding time.

Cost

Cost includes the processes involved in planning, estimating, budgeting, financing, funding, managing, and controlling costs so that the project can be completed within the approved budget (PMI, 2013). Based on gathered information, plus the above mentioned factors, value engineering is also a parameter in success of project success. Most of interviewees believe that cost is the most important reason in project success (O4, O8, N3, C7, C2 and C4). O3 with high management and administrative experience in healthcare projects believes injecting credit to projects is one of the most effecting factors in project success. O2 believes the opposite and emphasizes credit injection without control over the cost, not only leads to project success but also is one of the factors that challenge the project success. C5 and C6 approve O2's idea and believe that low but controlled fund has better impact on project success than high and uncontrolled one. C4 mentioned project Y which was completed by value engineering which is an efficient parameter to reach success in projects. O7 confirmed C4's comments plus mentioning that using value engineering is not possible in all projects and a deeper look should be taken to the funding but he did not mention a method to replace value engineering.

Quality

Quality includes the processes and activities of the performing organization that determine quality policies, objectives, and responsibilities so that the project will satisfy the needs for which it was undertaken. Quality uses policies and procedures to implement, within the project's context, the organization's quality management system and, as appropriate, it supports continuous process improvement activities as undertaken on behalf of the performing organization (PMI, 2013). Quality works to ensure that the project requirements, including product requirements, are met and validated. Based on gathered information quality parameter could be studied under seven groups: 1.Standards compliance 2.cost estimation 3.proper building methods 4.role of sub-contractors 5.machinery 6.technology 7.quality material.

O4 and C7 believe standards compliance satisfies the required quality of projects but C3, O6 and O7 reject this and believe standards compliance just leads to completing the project and does not have any roles in necessary quality. For reaching proper quality in healthcare projects, proper administrative and materials should be used. O8 with 40 years of experience in this field believes choosing proper minor contractors and up to date technology usage are important factors in project implementation. C4 and O1 mentioned the important role of proper cost estimating in reaching high quality and added improper cost estimating would lead to challenges regarding machines usage and the quality of the project is greatly threatens by wrong choices. O6 while confirming this topic declared by developments in knowledge, technology and variety in software had increased the mistakes in costs estimation in recent years. C2 is a well-known specialist who emphasizes on the quality of the project which has a direct effect on hospital working efficiency and people's health and decrease in quality sometimes leads to doubling the patients' illness. He pointed that in project Z lack of required quality in patients'' rooms worsened 5 patients' conditions.

Human Resource

Human Resource includes the processes that organize, manage, and lead the project team. Project team members may have varied skill sets, may be assigned full or part-time, and may be added or participation of team members during planning adds their expertise to the process and strengthens their commitment to the project. Moral factors, team work and knowledge are tree reviewable groups of human resources. The role of human resources is undeniable in success of a project (C3). Human resources could be parameter of success when they go along order, accuracy, honesty and working consciousness. Doing the work just for the sake of getting done would not help the project (O7). C5 and N2 while confirming O7's ideas added lack of motivation in human resources of a project is one of the concerns of contracting

companies. While confirming previous ideas mentioned project X in which lack of motivation by human resources led to delay. O1 referred to teamwork and its effect on working efficiency, believes wrong and sudden decisions and personal interest of some top executives are strongly inhibiting factors for reaching success. C6 rejected this theory and defended high executives and believes administrative health work dominates healthcare projects. C4 and O5 consider using experts as the easiest ways for reaching success and believe using inexperienced and irresponsible human resources is a parameter that is faced in healthcare projects. O8 agrees with this idea and expresses education is a fundamental and undeniable parameter and believes that using young, educated and well aware of new technologies human resources along experienced ones is a fast way to reach success.

Risk

Risk includes the processes of conducting risk management planning, identification analysis, response planning, and controlling risk on a project. The objectives of project risk are to increase the likelihood and impact of positive events, and decrease the likelihood and impact of negative events in the project. Proper risk management could be one of the factors in success of projects. The importance of project risk management has been needed more and more but activist in construction industry are still facing the problem of risk being unknown and unidentified. Identifying the risks of a project and finding proper solutions could improve the success of the project (N4). C7 agrees with N4 and believes uncertainty of project could be decreased by ensuring of identification of risk.

Environmental

Since the emergence, human has dealt with nature and had always tried to control its destruction (N2). Humans have altered the nature along their needs and this alteration went on until the point that humans are the main reason of destruction of the environment and environmental protection while completing a project has an important role in its success but unfortunately it has been ignored (O2). O5 by approval of this view believes that the effects of administrating the projects should be considered in primary studies of project and proper solutions must be offered for these undesirable effects. C1 refers to project X in which improper design of wastewater treatment system of the project cause problems for the region's ecosystem. O7 believes before constructing healthcare projects their adverse effects on the environment should be studied to choose a location with the least harm to the environment.

External Matter

External matter could be studied under tree groups: politics, economy and rules and regulations. O8 has specific emphasis on rules and regulations and their effect on success of projects and gives several examples during his 40 years of experience in healthcare projects of how violating the rules and regulations led to project's failure. He believes funding problems have always been challenging for the projects in Iran and led to their higher uncertainty. C4 confirms O8 and adds the rules are unilateral in favor of employer is one of the factors of failure. C6 rejects C4 and O8 ideas and speaks of the complete rules and refers to less important role of politics in success of projects. C5 agrees with C6 regards the complete rules but believes political and economic factors are inseparable from the success of projects.

Conclusion

The results of the researches in Saudi Arabia, Jordan and Emirates are very close to the the results of the researches done in Iran. It seems that Middle Eastern countries suffer from similar problems. To minimize the occurrence of delays, proper knowledge about it should be given to the project team. Plus the fact that in case of delay occurrence, collaboration and cooperation between the functors of the project can reduce its negative impacts. Improper increase in funding of development projects with the support of oil revenues is not only not the solution but will also increase the problems and costs, in which case the need to make proper choices would fade and unnecessary costs would be imposed to the projects. Ignoring and incompetence of feasibility study, construction management methods, comprehensive design principles and value engineering just be leading to more time, higher costs and

reduction in quality. In Iran mismanagement problems have turned into a crisis which demands proper choices, reforms in management structure and in all aspects of the project from phase zero to operation. To reform management systems, selecting a simple worker or a manager must be based on their expertise and their commitment to work and success of the project would be the forefront of all things. Study phase, primary and detailed planning, recognizing employer and other stakeholders' demands should all be in a way that reduce the need for change in the operating phase as much as possible. As in delay each factor leads to the other one, even by minimizing one factor, delay could be avoided more and more.

ICT Integration in the Transport System

Nwankwo, Benjamin N.

Department of Computer Science & Information Technology,
Paul University, Awka, Anambra State
ben.nwankwo@yahoo.com

ABSTRACT

Transportation is a fundamental aspect of every nation's economy; allowing people to travel to and fro places within a period, also ensures efficient, effective delivery of goods and services. But recently, transport infrastructures of many nations are coming under significant and multiple pressures due to increased urbanization, rising global population, terrorism and conflicts, as well as climate change effects. ICT plays fundamental and transformative roles in the industry today. With the integration of modern ICT technologies, from modern control systems to sensor technologies, better transport management can be achieved. Also, by using embedded technology systems to create vehicle networks, a better system of transport can be put in place for timely and efficient human, goods and service delivery. The methodology used was secondary data collection where relevant publications and books were perused and utilized. It is recommended that both the public and private sectors of the economy should embrace this modern technology so as to eliminate the numerous problems associated with the conventional transport system. By so doing, economic growth and development can be sustained.

Keywords: Urbanization, ICT technologies, Control systems, Censor technologies, Embedded systems

INTRODUCTION

The Integration of Computer Systems in Transportation is the orderly application of computer and other communications technologies into the management of transportation especially land transport which is the form of transportation with highest passenger rate among other forms. The application of these ICT tools will provide efficient traveler information in order to increase safety and effective road transport systems. This integration involves vehicles, drivers, passengers, vehicle attendants (conductors), road transport workers and managers that synergize as well as the environment and linking with the complex transport infrastructure so as to improve the safety and efficiency of road transport system.

A recent report by the World Health Organization (W.H.O) in 2013 has it that approximately 1.24 million people die yearly on the world's roads and another 20 to 50 million sustain non-fatal injuries as a result of road traffic crashes. In the report entitled "Road Safety in the W.H.O African Region: The Facts 2013" on road traffic deaths in selected African countries says Nigeria accounts for the highest fatalities with 33.7 percent per 100,000 populations every year between 2000 and 2010. This places Nigeria as having the second worst traffic fatalities in the world. South Africa closely trailed Nigeria. She came second in Africa with 31.9 percent per 100,000 populations, followed by DR Congo, Ethiopia, Kenya, Tanzania and Uganda. In the same report, Africa was listed as the "least motorized out of the six continents in the world, but suffers the highest rates of road fatalities" of the 37 countries that the survey covered with death rates well above the average of 18 deaths per 100, 000 populations. The fatality figures for U.S.A and Britain are 15 and 7 percent respectively.

Altogether, the W.H.O (2013) report confirms the grim reality of the carnage on our roads. By all accounts, the survey calls to question the safety of roads in the country. It also highlights the recklessness of many of our drivers, the poor maintenance of our vehicles and our numerous dilapidated roads with attendant bad spots that have become deathtraps and dens for Robbers. Road accidents happen often in Nigeria commonly attributable to bad roads

Nwankwo, B. N. (2016). ICT integration in the transport system. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 26-32

and non-compliance with road safety regulations such as driving under the influence of drugs and alcohol, using cell phones while driving , refusal to use seat belts, non-usage of pedestrian bridges, disobedience of road signs, etc.

The Federal Road Safety Commission (F.R.S.C) was created in 1988 to ensure highway safety for motorists and other road users. This agency determines and enforces speed limits for all categories of roads and vehicles, controls the use of speed limiting devices, co-operate with other related agencies in prevention of accidents on the highways and also enforcing laws on road users; safeguarding them from untimely or incurred deaths. A lot of challenges have hindered their performances in this regard over the years. Starting from inadequate manpower and logistics, lack of adequate and modern communication devices, insufficient personnel and rescue equipment, their inefficiencies have not abated the high fatality rates on our roads.

From their (F.R.S.C) records, between 2006 and 2013, the F.R.S.C recorded 41,118 deaths from road accidents in Nigeria. The 2014 F.R.S.C report highlights that about 7, 924 injury cases were recorded in the first quarter, 7,663 in the second quarter and 7, 093 in the third quarter. Of all these fatal injuries recorded in that report, about 1,848 persons lost their lives in the first quarter, 1,406 in the second quarter and 1,176 death cases in the third quarter. The outcome of the W.H.O survey corroborates the F.R.S.C's report that the rate of traffic deaths in the country is alarming. According to the agency, in 2009, deaths resulting from road accidents were 7,000 with 969 of them children. In 2010, according to W.H.O, Nigeria recorded 5,279 deaths from road crashes. Between January and June in 2011, 2,218 precious lives were lost in a total of 2,234 accidents while 3,000 persons died in road accidents between January and October 2012. Road accidents, no doubt, have particularly been on the upward swing in the cities than in the rural areas. The major hazardous roads are the Lagos/Benin highway and the Zariaga end of the Abuja- Okene highway in Kogi State where heartrending deaths have been recorded in recent times. There is no gainsaying the fact that many of the highways across the country have become deathtraps due to a combination of so many factors, amongst them: poor state of the highways and the recklessness of the drivers.

It has become glaring from both the W.H.O report and F.R.S.C statistics that road traffic deaths have become one of the worrisome problems that require urgent attention in the country. As the world population and economy grow, it is estimated that the volume of traffic in the world will increase from 8 million at present to 40 million by the year 2020. Without significant changes to the management of road transport systems, these scarring figures are likely to soar significantly. The traditional driver training, infrastructure and safety improvements may contribute to a certain degree to reduce the number of accidents but not good enough to curtail this menace. This research work "Integration of Computer into Transport" seeks to offer the best solution to the problems so far encountered in the current traditional transport system.

The Transport System and Electronic Information

Safety is one of the core driving forces behind the evolution, trend and implementation of the proposed system. The system will aim at improving and enhancing transport safety, mobility and infrastructure. Information technologies are represented in all fields of the society and science, including the traffic and transport. They are the base of intelligent systems.

It should be apparent that in order for the transport system to become sustainable, all that is necessary is for society to decrease the amount of transport they consume. This is much easier to state than it is to accomplish. Regulatory policies could be formulated to accomplish this end or nations could encourage voluntary actions to accomplish the same end. It goes

without saying that the former is very unpopular and the latter is unsuccessful. Because of this, ICT innovation in the transport system is seen as possible ways of accomplishing the same outcome. To this end, a simple model of the transport system that applies to a better transport system which involves the layer, actors involved and the target of the system is introduced(Table 1)

Table 1: A simplified layer model of the transport system

Layers	Actors involved	Target of ICT innovation
Layer 4. Persons and freight Persons (drivers), parcels, containers, bulk, etc.	Private car users Public transport users Freight transport users	Drivers' behavior: route selection, driving speed, reaction in driving, reduction of driving tasks. Passenger behavior in public transport: mode choice and route selection. Quick first aid after accident. Freight: routing and load matching.
Layer 3. Vehicles moving through the system Trains, cars, busses, vans, bikes, vessels, etc.	Owners of private vehicles Logistics providers Chain organizers Vehicle manufacturers ICT manufacturers Public transport companies	Size of flow, speed of flow, identification of obstacles, in-between vehicle distance in flow (longitudinal, lateral), collision avoiding.
Layer 2. Services on the infrastructure Public transport services, services for maintenance and transport management	Public transport companies Operators of links and nodes ICT system manufacturers Public authorities	Providing/preventing access of public transport services to persons Matching different services.
Layer 1. Physical infrastructure (links and nodes) Rail, road, airline, pipelines, waterways, etc.	Infrastructure providers Infrastructure owners Public authorities	Providing/preventing access of infrastructure links and nodes to vehicles

Impacts of interest for analysis are mainly generated in the layer of vehicle flow (3) and the layer including persons (drivers) and freight (4). The main differences between ICT applications in some of them are fixed (or semi-fixed) in layer 1 as they form part of the physical infrastructure, e.g automated guide ways (physical), on-road signing including variable messaging, surveillance systems, and on-road access and charging systems, while others are mobile in the sense that they are in-vehicle systems or personal (portable) systems. Another main difference between ICT applications resides in the type and number of layers required to implement the application. Thus, some applications make use of one layer, while others make use of two or three of them. If more layers are involved, particularly including layer 1, the technical complexity is greater, because of the additional infrastructure requirements. A situation of more layers also implies the involvement of a larger number of different actors, potentially leading to delay in the adoption of the innovations concerned.

ICT innovations in the transport system can also be categorized according to the roles of the information concerned from the following:

a. Information to support choices of car drivers and passengers, e.g. on-road information on upcoming congestion, routing advice from a navigation system, or the real arrival time of trains.
b. Information to reduce options or limit drivers' behavior, e.g. avoiding parts of networks, or limits to driving speed.
c. Information that alerts drivers or passengers without constraining behavior, e.g. various modes of advanced driver assistance, like collision avoidance and lane keeping systems.

d. Information that serves to take over drivers' decisions, fully or partly, like in electronic bonding of cars and in intelligent speed adaptation.

The above roles that information plays show different degrees of constraints upon drivers' free choices. For this to be fully effective, legal issues concerning responsibility and liability enter the scene and these still need to be settled, like responsibility and legal liability of drivers, ICT system manufacturers and the operators of network systems. This situation acts like a barrier and tends to delay the adoption of the innovations concerned.

ICT APPLICATIONS, AIMS AND EFFECTIVENESS

Certain technologies that aid effective transportation are developed such as Excessive Driving Reduction System, Congestion Relief System, Variable Message Signs, Advanced Traveler Information Systems, Intelligent Speed Adaptation (ISA), Dedicated Short Range Communication, Fatality Reduction Accident Sensors, In-vehicle Accident Sensors and Advanced Drivers Assistance.

Excessive Driving Reduction System

Excessive driving contributes to fuel utilization, as well as the generation of air toxics detrimental to urban and global environments. The technologies intend to decrease the need for travel or to increase the efficiency of travel. For it to be effective, signalization and navigation systems would be embedded.

Signalization

ICT can decrease fuel use by increasing the efficiency of the movement that does take place. This outcome can be accomplished through improved signalization. Such signalization can be phased in some areas and demand responsive in other areas, but the objective is to decrease the amount of vehicle standing time while the motor is running. Under the former the traffic signals are set so that signals in a series will change at a set frequency so that the vehicle does not have to stop. In the latter case the signals will change in response to a vehicle approaching a sensor in the roadway. Signalization–both phased and demand responsive – are widely applied. In a more advanced mode, signalization forms part of Vehicle Guiding Systems aimed at the creation of continuous flow at certain sections of roads without stops.

Navigation Systems

Geographic positioning systems (GPS) in conjunction with geographic information systems (GIS) offer the possibility of decreasing the amount of time spent on search behaviour by motorists. Assuming one is willing to input one's origin and destination to the system, the shortest route will be proposed. In an alternative mode, an increasing number of motor vehicles will undertake the way finding for you and minimize unnecessary travel. The use of mobile communication in route advising seems underestimated for private car use and deserves more attention. It is obvious that for privacy reasons, this kind of system is not yet popular among private car drivers. The situation is different for freight transport, where systems of tracking and tracing are being introduced in finding most efficient network connections, e.g. in the routing and bundling of freight.

Congestion Relief System

Congestion is a function of the interaction vehicles have with each other due to speed flow relationships when volumes approach capacity. It is not just vehicles going slow, or

vehicles traveling at high speeds, that lead to congestion, although these contribute to the problem but so much need to travel instead of using ICT facilities. The video surveillance response system helps in this regard.

Video Surveillance and Response

Several cities maintain a continuous monitoring of key network locations to determine if traffic is moving or encountering congestion. Such monitoring can be done with strategically located sensors or television cameras. If flow interruptions are apparent they are usually caused by a disabled vehicle. Once these events are perceived, a repair/assistance vehicle is dispatched to the location. Upon arrival at the problem site, the objective is to remove the obstacle to flow and offer assistance (tyre replacement, and so forth) or transport to the motorist.

Variable Message Signs (Informational Signing)

Electronic changeable message signs along the highway have proven to be of some assistance in communicating with drivers regarding major congestion points on the road ahead. Often these signs (sometimes called Amber Alert signs in the United States), give directions as to ways to avoid upcoming congestion points related to accidents, congestion, and the like. It is important that such signs not be used on a continuous basis since drivers tend to ignore them if they always have some type of message on them. A simulation study for different European city-regions on effectiveness of VMS (Variable Message Signs) on road network efficiency suggests quite modest results. Reductions in overall network travel times are 1-2% for the use of VMS in regular congested circumstances, provided that there is spare capacity in the network. Estimates for impacts on pollutant emissions and fuel consumption are similar to changes in overall travel time. Whereas the above changes are quite small, driver perceptions of the benefits turned out to be much higher. This points to a potentially important role for this application in the development of integrated transport strategies, because the provision of information may encourage the acceptance of demand management measures.

Advanced Traveler Information Systems

Personal information systems may take different forms and may be in-vehicle for car drivers and portable for passengers using public transport. Based on real-time information, the best route and connections (in public transport) are given. In advanced modes, opening times of facilities (shops, services, etc.) and the length of stays are used as an input, enabling an overall space-time optimization of activity chains. This system helps travelers to plan their activity and traffic chains.

Intelligent Speed Adaptation (ISA)

These systems also use in-vehicle electronic devices enabling one to automatically regulate vehicle speed. Like the previous technology, experiments indicate a higher effectiveness in less congested conditions (UK) (Liu and Tate, 2004). High speeds can be effectively suppressed; leading to a reduction of speed variation, but more slow moving traffic cannot be induced. In addition, it was found that ISA with full penetration could lead to a reduction of fuel consumption by 8%.

Dedicated Short Range Communications

These systems are based on information exchange between cars and may pertain to accidents, weather conditions, road construction and similar events. In more comprehensive options, technical performance of the car can be communicated with the serving garage. Also, by integrating navigation systems, information about empty

parking places and similar information can be transmitted to the driver. These systems partly rely on mobile communication between vehicles on the same route (oncoming and following traffic) and are still in the stage of development. "Early versions" are currently used in public transport (busses, taxies) and in freight transport.

Fatality Reduction Sensors

It is estimated that some 90% of all traffic accidents can be attributed to human failure, such as a lack of alertness or fatigue (Marchau et al., 2005). Vehicle radar technology is already available that warns drivers of obstacles in their path. The same technology could be tied into an on-board computer system and used to make it nearly impossible for the vehicle to crash into other vehicles or objects. It would do this by accelerating, decelerating, or stopping the vehicle. Today, advanced in-vehicles technology is available as options in up-market car models, such as Mercedes, Lexus and Citroën (NRC-Handelsbad, August 5, 2005). Network safety seems to be heading primarily in the direction of automated guide ways that would control the movement and speed of cars. Note that the technologies earlier discussed also serve to reduce fatalities.

In-Vehicle Accident Sensors

It is generally recognized that many seriously injured individuals can survive such incidents if they can be transported to a medical facility quickly. The use of ICT in this case is intended to ensure this. A number of motor vehicle models being manufactured today come with sensors attached to the air bag system. Once the air bags are deployed, a communication of this event is sent to a dispatcher. The dispatcher in turn can communicate with the driver or other occupants of the vehicle and determines if any type of assistance (repair vehicles, ambulance and so forth) is necessary. At this time several high-end models offer this service, however all models of General Motors in the US offer this. It should enable faster response to accident scenes than has been typical as before.

Advanced Drivers Assistance

In the context of improving safety the in-vehicle Automated Cruise Control (ACC) and Intelligent Speed Adaptation (ISA) are interwoven. Automated Cruise Control that primarily serves vehicle safety performs both the longitudinal and lateral control task. Citroën today installs a system that warns the driver as soon as he/she moves to another lane without using the signal, by drawing attention through moving his/her seat. The lateral control task works by infrared sensors that measure variation in reflection of the standard markers on the road surface. In the EU, much research is currently devoted to in-vehicle collision avoidance based on sensor systems replacing infrastructure measures. An ultimate configuration is a 360º car surround system as a "safety belt". The systems that are currently studied vary in terms of technology, e.g. different radar sensors, infrared and visible spectrum imaging, laser technology, and in terms of distances and speeds involved (Lu et al., 2005). Research into such systems is in progress today, but the systems are still in an experimental stage waiting for solutions that are more robust, i.e., not vulnerable to influence of weather/atmospheric conditions and interference with other electronic systems, and more acceptable in cost or price. For example, Lexus plans to introduce lighting systems that monitor speed, braking performance and weather conditions, and automatically adjust the amount and type of lighting as a warning (active lighting).

Quite some attention has been paid to the impacts of Intelligent Speed Assistance (ISA). We mention estimated safety effects of full automatic speed control devices up to a 40% reduction of injury accidents and 60% reduction of fatal accidents (e.g. Marchau et al., 2005). For

the Netherlands, estimates reveal a fatality and heavy injury reduction of up to 30 and 38% on roads with speed limits up to 90km/h. In addition, estimates of the impact of automatic positioning and collision avoidance systems indicate similar maximum reduction levels for particular systems on particular types of roads.

CONCLUSION AND RECOMMENDATIONS

Information and communications technology, no doubt, has come a long way towards enhancing the movement of man, goods and services which is the basis of transport. Modern transportation has gone beyond physical movements. ICT innovations in transport are intended to enhance the safety and efficient transport system which the conventional transport system does not offer. Even though the cost of providing these technologies may be high, the benefits are invaluable. A better environment, more safety, ease in necessary transport of goods and services and growth and development of economies will be achieved if the technology is integrated. Those countries that have long been using it have benefitted a lot from it. Those that are still foot-dragging should take a cue from them and enjoy the unquantifiable benefits that this system will bring.

Low-Energy Building Strategies for a Sustainable Built Environment in Nigeria

Adegbie Morisade

Department of Architecture, Federal University of Technology, Akure, Nigeria
moadegbie@futa.edu.ng

ABSTRACT

Incorporation of low-energy strategies into buildings is essential to achieving sustainable built environment in Nigeria. Low-energy strategies enhance reduction in energy demand and the use of cleaner energy for various purposes in buildings. The current energy crises witnessed in Nigeria has led to massive use of alternative back-up power sources in buildings for the purpose of space cooling, lighting and powering of appliances. This condition leads to increase in the burning of fossil-fuel which affects the environment negatively by increasing the release of greenhouse gases and also incurring high energy costs for the purchase of the fuel on the long run. Designing low-energy buildings to achieve high energy efficiency is a lead way to sustainable buildings which is important to achieving a sustainable built environment in Nigeria; it therefore becomes imperative that these strategies be incorporated in all building types in Nigeria. This paper reviews low-energy building strategies that can be incorporated in buildings within Nigeria in order to reduce operational energy demand. It also highlights potential benefits to sustainable built environment in Nigeria.

Keywords: Buildings, Built Environment, Low-energy, Nigeria, Sustainable

INTRODUCTION

The concept of sustainable development and building practices has gained more attention in most countries of the world in the last few decades because of the negative impacts buildings have on the environment. These negative impacts were result of increase in energy use to meet the various needs of cooling and heating in buildings, powering of appliances and equipment, construction and manufacture of building materials. The International Energy Agency, IEA (2013) stated that cooling and space heating accounts for over one-third of all energy consumed in building globally. This shows that comforts energy is high compared to other forms of energy use in buildings. The rapid population increase, urbanisation and economy growth in most countries of the world necessitate increase in energy demand and consumption in buildings which on the long run exerts negative impacts on the environment.

In the same vein, Nigeria is currently witnessing rapid growth in population with the current figure of 185,308,154 based on the latest United Nation estimates (Nigeria Population Worldometer, 2016). This increases energy demand for various purposes in buildings and for other economic activities. The Nigeria Vision 2020 intent is to position Nigeria to become one of the top twenty economies in the world by the year 2020 (Accenture, 2009); the vision needs increased energy to drive it to a realistic end. But the current electricity supply in Nigeria does not meet the demand to cater for various needs of the citizens. Figures released by the Federal Ministry of Power in Nigeria (Punch Newspaper, 2015) showed that the country' peak generation as of October 2014 was 3,512.5MW, against a peak demand of 12,800MW (Batagarawa, Hamza, Dudek & Tukur, 2015), (Adegbemi, Adegbemi, Olalekan, & Babatunde, 2013).

The Nigeria climate which is tropical in nature and characterised by high temperature further increases the need for energy use in buildings because of the high solar radiation received throughout the year which causes accumulation of heat in the building interiors. This condition causes thermal discomfort and increases the dependency on mechanical cooling aids such as air conditioners. In order to have energy for various purposes such as cooling,

Adegbie, M. (2016). Low-Energy Building Strategies for a Sustainable Built Environment in Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 33-38

lighting, powering of appliances and to drive the economy, there is a massive use of back-up power generators that burn fossil-fuel because of inadequate power supply in the country. This action has a negative impact on the environment, and with the fact that the nation does not fully harness the available potential to generate power from renewable sources such as the sun, wind, hydro, amongst others; the negative environmental impact will be on the increase.

Incorporation of low-energy strategies to buildings in Nigeria will reduce energy demand and thereby achieve sustainable environment. Low-energy design strategies are methods to earn better energy performance in buildings for the delivery of a comfortable indoor environment and without negative impact on the outdoor environment. These include passive design strategies, use of onsite generated renewable energy and energy efficient technologies (U.S Federal Energy Management Programme 2001). It is believed that when energy is efficiently managed in buildings, the built environment can be sustained.

RESEARCH METHODOLOGY

This paper reviews literatures to elucidate information on the subject of low-energy strategies that can be incorporated to reduce operational energy demand in buildings and thereby achieve sustainable built environment in Nigeria.

BUILDING AND BUILT ENVIRONMENT SUSTAINABILITY

The built environment is the surrounding created out of the ingenuity of man for needs satisfaction and survival. Bartuska and Young (1998) defines the built environment as everything that is made, arranged or maintained by man to fulfil the purpose of needs wants and values. There is an interaction between the natural and the built environment which must be maintained and be balanced at all times to ensure continuous existence on the earth. Brophy and Lewis (2011) stated that building process impacts on the environment in diverse ways through energy consumption, material use, water use and waste generation. These in turn result into problems such as global warming, ozone depletion, loss of natural habitat and biodiversity, soil erosion and release of toxic pollutants. Moreover, Lehmann (2010) listed amongst others, some of the current and most significant environmental problems; these include global climate change, excessive fossil fuel dependency and growing demand for energy in cities. These environmental problems require quick response from all human endeavours in order to preserve and sustain the environment.

The built environment cannot be sustained without sustainable buildings. Sustainability in building requires minimising the consumption of resources such as energy, water and materials while maximising the health, safety and quality of life of occupants and the buildings (Ramah 2005). According to Lehmann (2010), sustainable buildings are buildings that are designed based on the holistic approaches involving five principles; these are:

i. Resource efficiency (reducing energy needs and materials during construction)
ii. Energy efficiency (reducing energy demand in building operation)
iii. Pollution prevention (minimizing pollution, environmental impact and damage to health)
iv. Harmonisation with environment (making the most of the site, reducing embodied energy and resource depletion)
v. Applying integrated and systemic approaches

The energy efficiency approach to sustainable building is of high importance to achieving sustainable built environment. This is because building contributes immensely to the negative impacts on the environment. The United Nation on Environment Programme (2009) proposes improving energy efficiency of buildings as the first target on policy options for reducing emissions from building sectors as buildings account for around one third of energy use and

over half of total greenhouse gas emission globally. Amongst the approaches for achieving a sustainable environment is the energy efficiency in buildings which include low-energy principles in which energy use in buildings can be reduced drastically.

Building Energy Use

Energy use in building is one of the most significant means of energy consumption and greenhouse gas emissions, thereby creating negative impact on the environment. Energy use is associated with the emission of greenhouse gasses which is responsible for global warming and consequently climate change. Peres-Lombared, Ortiz & Pout (2008) reported that there has been a steady increase in the global energy consumption of buildings which steadily emit greenhouse gasses; this has reached figures between 20% and 40% from both residential and commercial buildings in developed countries. Energy is a very crucial and critical resource that a building depends on to function adequately throughout its entire lifetime; energy is used in building to deliver comfortable conditions for occupants, to power appliances, to manufacture building materials and during construction (Rai, Sodagar, Fieldson & Hu, 2011). Tofield (2012) also noted that energy consumed in building during its life time comprises of embodied energy (energy used in building construction), energy-in-use or operational energy (energy used annually to operate the building) and energy used in demolition of building. Cooling and heating energy has been recognised as the most dominant source of energy use in building which is also referred to as operational energy (Tofield, 2012).

Buildings are responsible for a considerable proportion of global energy use (Ashden 2014) and UNEP (2009) reiterates that building sector consumes up to 40% of global annual energy and contributes up to 30% of annual greenhouse gas emissions. In a research conducted by Batagarawa, (2013) on energy use in an office building in Nigeria, cooling loads accounts for approximately 40% of the electricity consumed in the building, while lighting and powering of appliances accounted for 12% & 48% respectively. According to Rai, Sodagar, Fieldson & Hu (2011), building energy use accounts for almost fifty percent (50%) of the total CO_2 emission in the UK. In the same vein, the US Federal Energy Management Programme (2001) argues that buildings in the US consume about 37% of the primary energy and 67% of the total electricity used each year and also produce 9% of global carbon dioxide emissions. This shows that energy use in buildings is high and consequently leads to increased negative impact on the environment. Adoption of energy efficiency approach in buildings will drastically reduce energy demand and consumption.

Meaning of Low-energy Building

Adapting buildings to low-energy is one of the ways to make it energy efficient. Ashdeen (2014) stated that low-energy buildings use a mixture of passive techniques and active systems to deliver a comfortable environment with lowered energy use and related greenhouse gas emissions. Low-energy buildings have decreased energy demand and without deterioration of the indoor climate condition. Low-energy designs in buildings is the inventive use of the basic form and enclosure of a building to save energy while enhancing occupants' comfort as stated by the U.S Federal Energy Management Programme (2001). Low-energy building design combines energy conservation strategies and energy-efficient technologies which result in absolute reduction in the use of fossil- fuel based power. Moreover, building operational energy cost can be saved from low-energy buildings. This savings can be achieved through integrated design solutions.

A low-energy building has fabric energy efficiency that is effective in minimizing the energy needed for cooling and space heating (Tofeild, 2012). Furthermore, installation of renewable energy technologies should not be a substitute for building fabric energy efficiency, but rather

complement it to reduce overall demand for conventional fossil-fuel based energy. It should not compensate or offset operational energy where the fabric is poorly designed; this will lead to unnecessary waste. Low-energy design strategies make use of the building fabric or envelope such as wall, windows, floors and roofs through appropriate design, materials and construction methods to minimise buildings energy consumption, enhance environmental performance and the economy (U.S. Department of Energy Efficiency and Renewable Energy 1999). In the UK, different terms were used to describe low-energy buildings, these includes; low energy house, high-performance house, passive house/Passivhaus, zero carbon house, zero energy house, energy saving house, energy positive house and ultra-low energy house. It is essential to consider low-energy principles at the inception of a building design because it has been recognised as the cheapest way to cut greenhouse gas emissions (UNEP, 2009). Low-energy buildings should consume significantly less energy than the level specified in the building regulation and the key objective of such buildings is energy-efficient design in which minimal energy is consumed throughout the building life cycle (Pedirini, 2003).

Design strategies for low-energy Buildings

One of the principles of low-energy building strategies is the use of passive design strategies. Passive design is an approach to building design in which the building architecture is used to minimize energy consumption (Naresh, 2014). Passive design strategies include passive cooling, passive heating, passive ventilation and daylighting. Passive cooling strategies prevent the building from overheating by blocking solar gains and removing internal heat gains. It includes the use of fixed and operable external shading, thermal mass, low window to wall area ratio (s/w), thermal mass, passive ventilation, nocturnal cooling, stacked windows, passive evaporative cooling and earth-tempering ducts. Low-energy strategies also include appropriate use of building orientation and shape, high performance window, amongst others (Naresh, 2014).

Passive ventilation is another passive design strategy for low-energy buildings in which naturally occurring air flow pattern in and around a building is used to introduce outdoor air into the space. Daylighting as a passive design strategy displaces the electrical energy that would have been used to provide artificial lighting, it maximises the use and distribution of natural diffused daylight throughout a building's interior to reduce the demand for artificial lighting (Baker & Steemers 2005, Naresh, 2014). The active roles of the architect and building engineers during the inception stage of building design is very important so as to incorporate these low-energy design principles. The U.S Federal Energy Management Programme (2001) reported that in the application of low-energy design principles, consideration should be given to factors such as climate, building and space type, internal heat gains from occupants, light and electrical equipment, building size and massing, lighting requirement, hours of operation, costs for electricity and other energy sources. This will allow for the evaluation of buildings' energy requirement and performance as well as right decision making on the appropriate strategies that will produce the optimal energy saving.

Benefits of low-energy design in buildings

There are a lot of benefits to human and the environment when low-energy strategies are incorporated in all building types. There is a reduction in energy demand and consumption; emission of greenhouse gasses is reduced and environmental impacts are lowered. Moreover, low-energy buildings bring improved comfort, health and productivity, energy bills are cut by reduced operational energy and this leads to economic saving (Naresh, 2014). Income is also generated by the integration of renewable energy into buildings. In commercial building sector, low-energy buildings will enhance a more productive workforce, reduced maintenance cost and better rental incomes. The potential financial benefits of low-energy buildings far outweigh any extra initial cost of construction as noted by Tofield (2012). Therefore, low-

energy design strategies should be incorporated with other energy efficient technology and renewable energy in buildings in order to lower the emissions and the negative environmental impacts arising from buildings and thereby sustained the built environment.

In Nigeria, incorporation of low-energy design into buildings will drastically reduce dependence on fossil-fuel based energy and consequently leads to sustainable built environment. The passive design strategies can be employed from the building inception stage, which will reduce energy demand to operate the buildings. The nation has the benefits of harnessing solar energy from the high annual global solar radiation witnessed throughout the year to develop an integrated approach to building designs. This will help in solving the problem of mass use of alternative back-up power generators which releases greenhouse gases and thereby causing damage to the environment.

Conclusion

Adapting buildings to low-energy strategies is essential to having a sustainable built environment since buildings account for a large portion of the global energy use and greenhouse gas emissions. Building design is the first option and the cheapest means to achieving reduced energy demand in buildings, therefore passive design strategies should be considered and be incorporated at the initial stage of all building types. Low-energy strategies in buildings within Nigeria is essential to reduce the dependence on fossil fuel based power to supply energy needed especially operational energy for cooling, lighting and powering of appliances.

The Nigerian government and all the stakeholders in the building industry, especially the architects and the engineers should key in into the incorporation of the low-energy strategies for all building types in the country in order to sustain the built environment.

ABSTRACT

The roles of architects-Nigerian architects-inclusive, in mitigating climate change and global warming in the built environment have been globally identified as invaluable. The extent to which this fact has been accepted in Nigeria is still in much doubt as evidenced by the built structures prevalent in the country; the construction techniques, materials, fenestration and orientation are such that they are not aligned with the local environment. Hence, there is the need for high fossil burning mechanical aids. Interviews, descriptive surveys and questionnaires were used to collect data on the perception of Nigerian architects on climate change and global warming. The data was subjected to statistical analysis using the SPSS (version 20). Findings from the questionnaire survey indicated very unsatisfactory and substandard roles played by the Nigerian architects, which can be attributed to insufficient Knowledge on their part especially as it relates to their roles in designing natural resource consumption intensity in buildings, creating huge opportunities for greenhouse gas reductions. This study concludes that the roles Nigerian architects have played so far can be emphatically improved upon by considering the character of the built environment as a factor which helps in mitigating climate change and global warming.

Keywords: Built environment, Climate change, Global warming, Greenhouse gases, Nigerian architects

INTRODUCTION

Climate change and global warming are perhaps one of the greatest challenges facing the planet today which has brought with it adverse economic, environmental and even health effects on communities where it is pronounced. At the UN Climate Change Conference of parties 21 (COP21) meeting in Paris, participants were of the view that African countries-Nigeria inclusive, are currently suffering from the effects of climate change. This has drastically affected food security, poses a threat to human lives and has caused the destruction of economic and social structures (COP21, 2015).

Climate change is primarily attributed to the trapping of greenhouse gases (GHG_S) within the atmosphere which normally should have escaped. Sassi (2006) in Edward (2006) strongly posits that the planet has warmed and cooled many times during the 4.65 billion years of its history, and at present the Earth appears to be facing a rapid warming, which most scientists believe results, at least in part, from human activities.

In Nigeria, the effects of climate change and global warming may not be too pronounced presently as it is in some parts of the globe, but with current trends, the situation may emphatically change in few decades to come as a result of the growing rate of industrialization, especially as the country is in the move to commence industrial production of commodities. Interestingly, many are afraid that tackling climate change and global warming may be too costly or impossible. However, studies have revealed actions such as the use of low energy materials will not only be cheaper than inaction, but could actually result in economic, environmental, and even health benefits while improving sustainability (Schaub, 2012).

Many studies (Maathai, 2006; UNFCC 2006; CCDI 2007; IPCC 2007, UNDP 2009 and Michael, Nnezi & Adeyemi, 2012) have confirmed that Africa contributes the least to global

Saliu, H. O. & Achimugu, L. (2016). An Assessment of the Role of Nigerian Architects towards Climate Change and Global Warming in the Built Environment. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F.? Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 39-46

warming with Nigeria having about 0.8% but the region is the most vulnerable and most adversely affected by climate change. Smith (2004) opined that the likely rise of sea level for this century is on average, about half a meter, which will have a significant impact. A large percentage of Africa's population is land- locked and coastal facilities are economically significant. In Nigeria for instance, more than 20 million people live along the coastal zone. Nigeria's extensive coastline is already being threatened by a rise in sea-level and human development. This combination contributes to degradation and loss of coastal wetlands and mangroves and increases damage from coastal flooding with serious consequences for fisheries, buildings and tourism.

According to Environmental impact assessment (2005), Commercial and residential buildings account for almost 40% of the primary energy and approximately 70% of the electricity in most parts of the world. The energy used by the building sector continues to increase primarily because new buildings are constructed faster than old ones are retrofitted. Electricity consumption in the commercial building sector doubled between 1980 and 2000, and is expected to increase by another 50% by 2025 (EIA, 2005).

It is saddening to note that current architectural practices in Nigeria tend to worsen the already very bad conditions. Currently, buildings hardly perform up to average without relying on mechanical aids as clearly buttressed by Maina (2010) that in Nigeria, the irony lies in the fact that architects have continued to design buildings and specify the use of mechanical devices like air conditioners. This act which is oblivious to such sobering statistics mentioned above is in the style, spirit, and industrial technology that identifies with Le –Corbusier's machine age architecture.

With considerable global interest and efforts being directed towards the effects of climate change and global warming, it is an established fact that architects-Nigerian architects inclusive - are working towards reducing the causative factors of these phenomena through design and construction processes. Although some practical steps such as more architectural education on the environmental impact of buildings have been taken, it is obvious, judging by the alarming rate at which the climate is changing and the ever increasing global temperature that much still needs to be done.

Architects over the years have reflected on the importance of having good quality environment. The quest for environmental values in architecture, for a harmonious balance between man and his environment is not a new approach. It is so much that for centuries, mankind adopted this approach out of necessity, particularly in vernacular architecture. However, since the industrial revolution, this has increasingly been abandoned in favour of universal architecture, which in many parts of the world, has led to energy intensive buildings.

The effects of global warming and Climate Change are increasingly becoming apparent. Notable in Nigeria today include, famine, diminishing rains, drying rivers and power rationing just to mention but a few. Faced with these dangers, the public and policy - makers alike must become conscious of the need to protect our environment. One response to these issues is to approach architecture in a way that respects the environment. (Oni and Akingbohungbe, 2013). It is in this light that the study sets out to assess the role of Nigerian architects in response to climate change and global warming in the built environment by considering the following objectives:

i. Study the concept and global effects of climate change and global warming in the built environment.
ii. Study the rate at which climate change and global warming has risen overtime.

iii. Evaluate measures adopted by the Nigerian architects to successfully impact and mitigate global warming.

THE CONCEPT OF CLIMATE CHANGE AND GLOBAL WARMING

Climate change is primarily the change in climate that is attributable to the trapping of greenhouse gases within the atmosphere, which normally, should have escaped. In a more recent development, Zoaka (2008) argues that the chief cause of this warming is thought to be the burning of fossil fuels, such as coal, oil, and natural gas, which releases into the atmosphere carbon dioxide and other substances known as greenhouse gases. As the atmosphere becomes richer in these gases, it becomes a better insulator, retaining more of the heat provided to the planet by the sun.

Researchers have employed different methodologies for carrying out studies to investigate global warming. Architecture2030 (2010) posited that the average surface temperature of Earth is just below I5 degree Celsius (59Fahrenheit degree) and believes that over the last century, this average has risen by about 0.6 Celsius degrees (1 Fahrenheit degree). Scientists predict further warming of 1.4 to 5.8 Celsius degrees (2.5 to 10.4 Fahrenheit degrees) by the year 2100. This temperature rise is expected to melt polar ice caps and glaciers as well as warm the oceans, all of which will expand ocean volume and raise sea level by an estimated 9 to 100 cm (4 to 40in), flooding some coastal regions and even entire islands. The EIA (2005) after carrying out an analysis on the changing climate also totally agreed with the aforementioned effects in addition to findings that some regions in warmer climates will receive more rainfall than before, but soils will dry out faster between storms. The potential consequences of global warming are so great that many of the world's leading scientists have called for international cooperation and immediate action to counteract the problem.

Emission of Green House Gasses (GHG_S) by the Buildings Sector

The building sector encompasses residential, commercial and institutional buildings. The sector accounts for 15.3 % of global GHG emissions, including 9.9% for commercial buildings and 5.4 % for residential; CO_2 accounts for nearly all emission as opined by Magdy (2011). Emissions from the building sector are predominantly a function of energy consumption for diverse purposes that are organized into three broad categories: public electricity use, direct fuel combustion, and district heating. Public electricity use include lighting, appliance use, refrigeration, air conditioning, and to some extent space heating and cooking (EIA, 2005).

Furthermore, environmental scientists have often argued that there is an important correlation between building emissions and socioeconomic development levels. In general, building emissions are higher in industrialized countries, both in per capita terms and as a percentage of total country emissions with variances due to climatic factors. Thus, development has an important effect on emissions from the building sector. This implies that building efficiency becomes more significant as countries become more prosperous.

Climate change and global warming timeline

Magdy (2011), stated that the timeline of the phenomenon of climate change and global warming is from 1870 to present and there has being a steady increase in concentrations of CO_2 in the atmosphere from the aforementioned period. Further studies by researchers were able to bring out the fact that for thousands of years, the CO_2 concentrations in the atmosphere have been fairly constant at about 280ppm (part per. Million) in the last 400 years. This corresponds with the start of the Industrial Age which witnessed increase in CO_2 to about 380 ppm (Zoaka, 2008). This was as a result of the use of machinery and factories that led to mass production, which in turn led to the development of numerous environmental hazards.

Architectural Practice and Climate Change

The Architect as a key player in the Building Industry plays a very vital role in combating the effect of climate change on the built environment. According to some researchers (Oni and Akingbohungbe ,2013; Omotoso, 2011 and Serigio, 2008) Architects as key players in the built environment can contribute to the reduction of the energy and demand on resources associated with construction and operation of buildings through the following strategies.

i. Incorporating existing buildings and structures into design schemes as much as possible instead of demolishing such buildings and structures to make way for new buildings.
ii. Collaborating with Mechanical and Electrical Engineers to design for reduced consumption of energy in buildings.
iii. Specifying recyclable, reusable, local, natural, durable and environmental friendly building materials.
iv. Creating high performance buildings that take maximum advantage of natural ventilation and lighting.
v. Planning cities, part of cities and neighbourhoods in such a manner that people can live and work and take leisure within a single environment.
vi. Preserving biologically rich landscapes in master planning.

According to (Ogunsote & Ogunsote,2010) some of the other means of combating climate change include; developing workplace strategies that merge efficiencies with people-focused design, sharing facilities such as copy centers, kitchens and conference rooms, designing meeting areas and large spaces multipurpose and adequate utilization of facilities. It is based on the above mentioned strategies that study assessed the role and practice of Nigeria architects in mitigating climate change in the built environment.

METHODOLOGY

The study adopted literature, alongside interviews and questionnaire survey to assess the roles of the Nigerian architects towards response to climate change and global warming in the built environment. The interviews were carried out on key respondents in an attempt to buttress findings from the literature while structured questionnaires were administered to members of Nigerian institute of architects (NIA) in three selected states in the North – Western branches in Nigeria.

A stratified sampling was used in which all the 400 private firms and institutions (Arcon register, 2015) that employ the services of architects in the branches were identified and analyzed as 318 Private firms and 82 Institutions. The names of the two different samples above were placed in two different bowls and shuffled thoroughly from where 50 percent of each sample (that is, 159 private firms and 41 institutions) were drawn out by the researcher using a random selection method. In the random method, each of the N population members was assigned a unique number. The numbers were placed in a bowl and thoroughly shuffled from where the researcher randomly selects n numbers, totalling 200. The 220 questionnaires were administered to the architects from each of the above selected samples and 200 were returned and used for analysis.

The questionnaire was designed to seek the respondents' opinions on the appropriateness of current architectural practices and the need to reduce the menace of climate change and global warming in the built environment. The questionnaire consists of two parts A and B. Section A consists of the respondents profile while section B generates data on the experiences of the architects on the effects of architectural practices on climate change and global warming. Data from the structured questionnaires were translated into numeric codes by the researcher, and data capture was done by statistical analysis using the SPSS (version

20) computer program. The analysis, presentation, and discussions of the findings from the questionnaires were presented in tables and charts.

RESULTS AND DISCUSSIONS

The result from the survey shows that about two thirds of the architects were master's degree holders largely working in government organizations with about 1-5 years practice experience. Whereas all the Ph.D. respondents 'work in government organizations and have 11-20 years duration of practice (Table 1)

Table 1 Cross Tabulation of Educational Qualification and Other Demographics

		Educational qualification of respondents				
		M.Sc. Number	Ph.D. Number	Others Number	B.Sc. Number	Total Number
Duration of practice	1-5 years	81	0	0	0	81
	6-10 years	54	0	0	0	54
	11-20 years	31	19	0	0	50
	21 years and above	15	0	0	0	15
	Total	**181**	**19**	**0**	**0**	**200**
Place of employment	Government	96	19	0	0	115
	Private Firm	40	0	0	0	40
	Self Employed	45	0	0	0	45
	Total	181	19	0	0	200

Awareness of the global effect of climate change on the built environment

The study examines the level of architect's awareness on the effects of climate change on the built environment which is considered very important in an attempt to seek a solution. The findings from the questionnaire revealed that an appreciative number of the respondents were aware of the danger of climate change and global warming to the built environment. Further investigation through interviews indicated that the awareness is due to media publicity and report from conferences on climate change. This clearly indicates that most architects practicing within the selected areas are conscious of the fact that climate change has an adverse effect on the built environment (see figure 4.1)

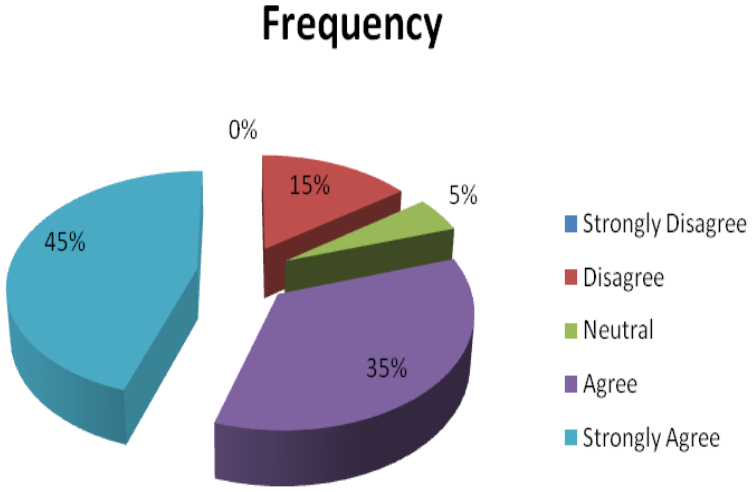

Figure 1 Awareness of the global effect of climate change on the built environment

Architects Response on the Mitigation of Climate Change.

The study seeks to establish the responses of architects in mitigating the effect of climate change on the built environment. Figure 2 below clearly shows that, 70.0% of the respondents rate architect's response on mitigation of climate change unsatisfactory. This finding is not surprising in any-way as interviews and observations indicated that the nature of buildings found in the Nigerian built environment relies more on mechanical aids for optimum operation thereby bringing about increased energy consumption in buildings, which in turn adds to the GHGs in the atmosphere.

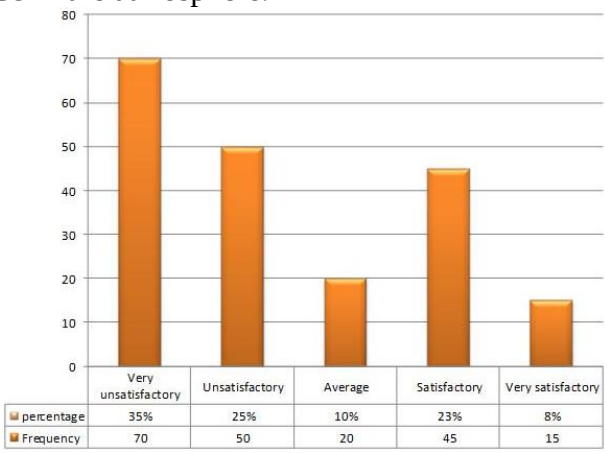

Figure 2: Architects Response on the Mitigation of Climate Change

Collaboration of Architects with Mechanical / Electrical Engineers and other professionals in the building industry to design for reduced consumption of energy in buildings.

The advent of industrial period was characterized by the use of machines in buildings that emits CO_2 to the atmosphere which still manifest throughout the twenty first century; thus, the study seeks to find out the level of collaboration of architects and other professionals (services engineers) in the construction industry. Interviews conducted revealed that most architects limit the scope of their work to the building alone without considering the effect of some of the appliance of machines that would be installed in it by other professionals. This is further buttressed from the analysis of the questionnaire as shown in figure 3 below:

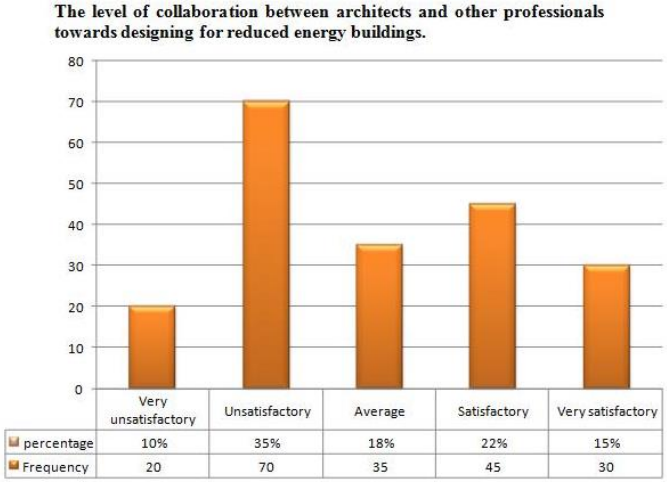

Figure 3: Collaboration of Architects with other professionals (Services engineers) in the building industry.

The Use of local and reusable sustainable building materials

The study discovered from literature that the use of local and re-usable sustainable building materials could reduce the effect of climate change in the built environment and as such,

opinions of architects were sought to know the level at which these materials are used in the building industry via questionnaires, interview and observation. It was found out that the Nigerian building industry largely depends on imported building materials and has totally neglected the use of indigenous materials that are environmental friendly. 70% of the respondents share the same view as seen from figure 4 below.

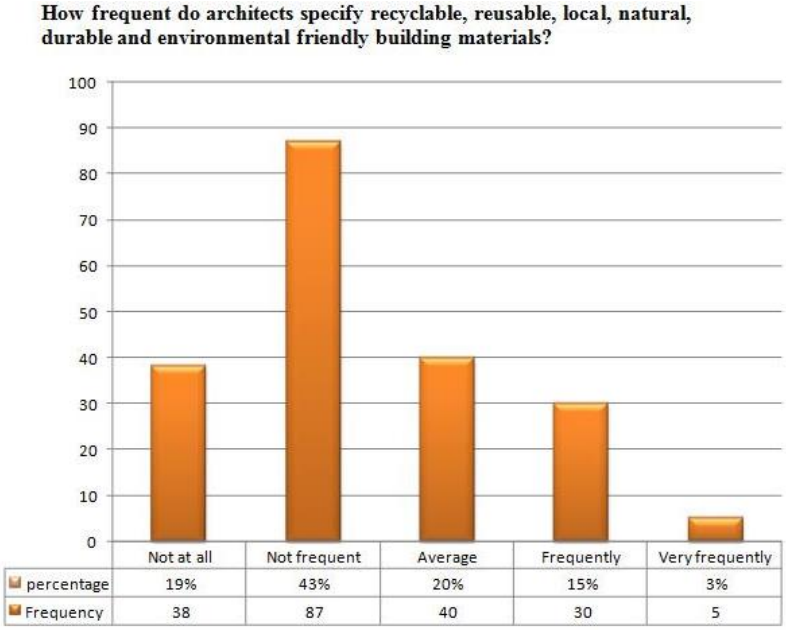

Figure 4: Architect frequent use of local or reusable sustainable building materials

CONCLUSIONS

This paper applied questionnaire survey, and consulted literatures on climate Change and global warming to assess the roles the Nigerian architects have to play in response to climate change and global warming in the built environment: all in a bid to mitigate its effects.

This research was able to buttress the latent fact that the building sector is a major causative factor of climate change and global warming and revealed that the roles the Nigerian architects have played so far can be best described as very unsatisfactory and substandard. From responses gotten, this unsatisfactory result can be attributed to insufficient knowledge on the path of the architects especially as it relates to the available opportunities for GHG reductions in buildings. The results show inadequate knowledge and disinterest of Nigerian architects as to how their change in practices alone can be a major factor in tackling the phenomenon of global warming in the built environment. Therefore, in the light of the aforementioned, it is important Nigerian architects are made aware of their responsibilities in the overall scheme of design and construction, as it relates to low energy buildings, by paying more attention to appropriate specifications, designs, and construction techniques, in order to help bring about minimal resource consumption and reduced pollution in the built environment.

Furthermore, seeing the astonishing facts from this study that the building sector contributes nearly half the greenhouse gases in the atmosphere, it is suggested that;

i. Awareness is created to help the populace make informed decisions concerning the concept of sustainability and how they live considering its measurable effect on global temperature which is responsible for happenings such as floods, droughts, desertification, among others.

ii. The architectural education program should be tailored to prepare fresh graduates towards carrying out and supporting the awareness and implementation of sustainable design. Government should do more in encouraging the use of locally available and Sustainable materials and techniques in building construction.

iii. Nigerian architects should design buildings by making massing, fenestration and orientations work with the local environment, so that buildings could take advantage of passive heating, cooling and natural lighting as this sets in motion the energy consumption pattern over the life of the structure.

iv. Finally, other factors and phenomena whose understanding and application could help tackle the effects of climate change and global warming should be investigated in further studies. These include; Climate change flexibility mechanism, Global warming and population, Nanotechnology and Nano-products at the construction site, as well as attaining Zero carbon city.

ABSTRACT

Energy consumption in buildings accounts for approximately 45% of the world's total energy consumption, leading to a significant proportion of greenhouse gas emissions. This has led to an increasing effort towards reducing energy consumption. An example of such efforts is energy efficient buildings using passive design options. This paper assesses a low cost energy efficient strategy approach to achieving energy efficiency in buildings using passive design options in Nigeria. A critical review of various passive design options and their roles in reducing energy consumption in buildings will be conducted. This approach is necessary due to energy poverty, high energy cost, erratic power supply, over dependence on electrical generators for indoor thermal comfort and other factors. Research has shown that this method can reduce energy consumption in buildings by 40%-60% in comparison to conventional buildings. This paper shows that there is an urgent need for professionals in the building industry as well as other stakeholders to advocate passive design options in Nigeria as a viable step towards achieving high energy performance buildings. This paper concludes by emphasizing the need for Nigeria to start with a low cost energy approach to achieve energy efficient buildings in the short term while aiming for ultra-low energy buildings in the long term.

Keywords: Energy consumption, energy efficient buildings, passive design, thermal comfort

INTRODUCTION

Research showed almost two decades ago that buildings account for nearly 45% of the world total energy consumption (International Energy Agency, 1995). Moreover, the energy consumption in building has exceeded other sectors in different regions of the world. For instance, energy consumption in buildings in the United States is as high as 48% and 76% in terms of total energy and electricity respectively (Perez-Lombard, 2008). Hence, buildings account for a significant proportion of GHG emissions.

Several efforts have been put in place to mitigate the negative impacts of buildings on the environment (BRE, 2004). This has resulted in agreement targeted at developing key strategies and actions to make buildings more sustainable (International Council for Building, 1999; Barrett *et al.*, 1999; Construction Research and Innovation Strategy Panel, 2000). In addition, it has also placed an urgent demand on architects and other professionals in the building industry to design buildings using concepts that consume less energy. Energy efficiency measures have been identified as a viable means of reducing energy consumption in buildings. This method can decrease primary energy consumption in buildings by 40%-60% in comparison to conventional new buildings (Moore et al., 2013).

Despite evidences of climate change in Nigeria, adaptation and mitigation efforts are still rudimentary. Hence, Nigeria is currently faced with an enormous challenge of evolving performance standards, systems, codes and other regulatory means to mitigate, forestall and develop the built environment (Michael, 2013). More efficient use of energy has to be considered as one of the major options for sustainable development in Nigeria and globally (Akinbami and Lawal, 2009).

This paper was born from the need for Nigeria to consider achieving energy efficient buildings using passive design approaches as a viable step towards achieving sustainable buildings. This paper started by explaining the concept of energy efficient buildings and proceeded to identify strategies for achieving energy efficiency in buildings. The reasons why Nigeria should consider achieving energy efficient buildings in the short term using passive

design options were also discussed. The paper later discusses the various passive design options that can be adopted in Nigeria to reduce energy consumptions in buildings. Finally, the findings were summarized and recommendations were made based on the findings.

LITERATURE REVIEW

Energy Efficient Buildings

Energy efficiency refers to using less energy to achieve results otherwise achieved with a certain quantity of energy. It means using energy in a way that reduces the amount required to provide building services (Etiosa, 2009; Chung et al, 2006). It also refers to using less energy to produce the same amount of services or useful output. Energy efficient buildings have been defined as those that strive towards the lowest possible energy requirements with reasonable utilisation of resources through the use of energy efficiency measures (Radhi, 2008).

Energy Efficiency Strategies

Moore et al., (2013) identified a two-level strategic approach developed for the design of energy efficient buildings for the world's four major climatic zones. These are the "Easy Efficiency Strategy" and the "Advanced Efficiency Strategy".

Easy Efficiency Strategy

This approach can reduce primary energy consumption in buildings by 40%-60% in comparison to conventional new buildings or by 70%-80% in terms of existing building stocks. This approach focuses on passive options, which are in low cost compared to the advanced strategy. This strategy is necessary in the short term as it is not adequate to achieve long-term climate protection targets (Moore et al., 2013). This strategy relies majorly on the building envelope through the use of the building orientation, material specification, and other design approaches to reduce energy consumption in buildings.

Advanced Efficiency Strategy

This strategy can achieve energy savings of "up to 90% compared to new building standards" (Moore et al. 2013, p. 1297). Further improvements using active renewable energies can decrease net energy demand to 0% and even beyond.

Passive Design

Passive design has been defined as "design that works with the environment to exclude unwanted heat or cold and take advantage of the sun and breezes, therefore avoiding or minimising the need for mechanical heating or cooling" (Cairns Regional Council, 2011, p.6). It relies on natural processes for cooling or heating to accomplish balanced thermal interior conditions. To achieve indoor comfort conditions in hot climates, focus should be on minimising heat gain into the interior spaces while at the same time enhancing the removal of excess heat. This is the basic principle of passive cooling (Kamal, 2012). In a tropical climate like Nigeria, buildings should be designed to maximise natural lighting and cooling. Moreover, shading, proper building orientation, appropriate building materials and other approaches should be used to discourage both heat gain and storage in buildings.

Major efforts towards achieving energy-conscious design in hot climate regions of the world have centred on the recommendation of passive techniques as the primary means of achieving comfort (Ochoa and Capeluto, 2008). Cairns Regional Council (2011), identified the following major principles for achieving passive design for buildings in tropical climates: avoid heat gain, encourage natural ventilation, make use of natural light and create cool outdoor areas.

Why Energy Efficient Buildings?

Several factors are responsible for advocating energy efficient measures, especially passive design approaches for Nigeria. Among these are the signs and effect of climate change, high energy demand and consumption and housing deficits

Signs and Effects of Climate Change

The effects of climate change as experienced in other parts of the world are now evidenced in Nigeria. A study of Nigeria's metrological data has shown some signs of climate change in the country. Some of the signs of climate change include anomalies in the onset and cessation

of the rainy season, variation in temperature, high impact rainfall, flash floods, disappearance of hail and rising sea levels (Nigerian Metrological Agency, 2012). There is an urgent need for Nigeria to put up adequate measures against the effect of climate change. Part of these measures is to design more sustainable buildings.

Energy Poverty, High Energy Demand and Consumption

Rapid increase in world energy use has raised concerns in terms of supply problems, depletion of energy resources and substantial environmental impacts. It has been projected that energy use by emerging economies (South East Asia, Middle East, South America and Africa) will increase at an average annual growth rate of 3.2% and will surpass that of developed countries (North America, Western Europe, Japan, Australia and New Zealand) at an average growth rate of 1.1% (Pérez-Lombard et al., 2008).

Only about 40% of over 140 million people in Nigeria have access to electricity. A large percentage of households, businesses depend on generators to power their electrical installations. This can be very expensive and a source of environmental pollution (Etiosa, 2009). To achieve comfort in most buildings, generators are required almost on a daily basis due to inadequate supply of electricity. Those who cannot afford the cost of running generators are left with no alternative. There is ample opportunity to reduce energy poverty through energy efficient techniques. This has the potential to enhance comfort in buildings and also free some percentage of the available energy for those in need. This opportunity is yet to be explored due to many reasons among which is the fact that most buildings were not designed for comfort using this approach.

The inadequacy of the power generated in the country to meet energy demand calls for energy efficient culture. Fossil fuels (oil and gas) are the major sources of energy in Nigeria. Hence, for every kWh of energy used, there is a corresponding emission of greenhouse gas into the atmosphere. Despite the energy poverty in Nigeria, the rate of energy consumption is still high and energy policy in the country has undermined the relevance of energy efficiency. Energy efficiency strategies are yet to be properly developed in Nigeria (Etiosa, 2009).

Housing Deficits

It has been projected that Nigeria requres approximately 40 million houses in order to meet its housing deficit in 2020 (Ademiluyi and Raji, 2008; Ademiluyi, 2010; Ogu and Ogbuozobe, 2011). To prevent further impact of buildings on the environment, the goal to overcome this housing deficits must involve sustainable approaches.

The tenure of almost every state government in Nigeria is always marked with the construction of housing units for civil servants which is aimed at reducing housing demands. Previous housing units have been built with little, if any sustainable measures. This paper is intended to guide and create awareness in Nigeria on the need to incorporate sustainable approaches, especially energy efficient techniques to the design and construction of subsequent intervention in housing provision.

METHODOLOGY

A literature review on energy efficient buildings and energy efficiency strategies was conducted in order to identify a suitable strategy that can be adopted in Nigeria. Moreover, reasons for advocating energy efficient measures for buildings in Nigeria were also reviewed. This method was chosen to evaluate the relevance of passive design options in reducing energy consumption in buildings and the need to adopt this method for the tropical climate of Nigeria. Various passive design options were discussed in order to pin down the roles of passive design techniques in achieving energy efficiency in buildings.

FINDINGS AND DISCUSSIONS

Climate is the most important factor in determining the method of achieving energy efficiency in buildings. Other factors include the availability of local building materials, energy efficiency technology and know-how, existing policies and the price of energy (Moore et al., 2013). Hence, each climatic region is to develop approaches for achieving energy efficiency in buildings. For Nigerian climate, which falls under the tropical region, the following passive design options are suggested:

Avoid Heat Gain

As stated earlier, avoiding heat gain is one of the major principles of achieving passive design in buildings. The focus is to reduce heat gain to the barest minimum. To achieve this, factors such as building orientation, building material selection, shading, glazing, insulation and thermal mass will be considered.

Building Orientation

The building should be positioned on site to take advantage of the movement of the sun and the prevailing winds. This also involves the arrangement of rooms in the building. For instance, sleeping areas should be located on the eastern side to take advantage of good morning light. East-facing rooms will also be cooler in the evening and during the night due to the sun path. Recess on walls and fins in addition to other architectural elements should be encouraged to direct cool breeze to the interior spaces. A good understanding of the site will aid a proper orientation of the building for maximum efficiency and thermal comfort.

Building Material Selection

To achieve comfort in buildings in the tropics, building materials with low thermal mass should be selected and used for the construction of buildings. Materials with low heating capacity helps to minimize heat absorption and storage. Neves (2006) argues that some heavyweight materials like stone that possess high effusivity and low diffusivity can be applied to internal spaces in hot-humid climates. These materials can absorb some of the thermal energy present indoors in order to improve indoor thermal comfort conditions. Light colour materials should be chosen, especially for the external walls and roof, as they are very useful in reducing heat flow into the buildings. Simulation results based on a study conducted by Muselli (2010) shows a reduction in cooling energy consumption between 26% to 49% using low-cost white opaque reflective roofs (50m2). A study by Cheung et al. (2005) indicates that a 30% reduction in the solar absorbance of external walls can achieve up to12.6% savings in annual cooling energy demand. Materials that have heat reflective surfaces can be used to reduce heat gain and storage, thereby improving thermal comfort in buildings.

Shading

Shading is an important technique in achieving passive cooling in buildings. Solar shading is an important approach in developing countries because it is cost effective and easy to implement (Kamal, 2012). Shading of buildings and outdoor spaces can lower temperatures during hot periods, improves comfort and save energy. Effective shading design techniques can block up to 90% of the heat generated by direct sun from heating the surface of buildings (McGee, 2013). Shading devices such as overhangs, awnings, louvers shutters, pergolas, which can be part of the building or placed close to the building, can serve as efficient means of achieving passive cooling. Proper window overhangs or awnings are an effective option to optimize south-facing windows and openings during summer. A proper site analysis will aid the placement of shading devices to minimise heat gain and storage. The length of the shading devices (especially overhangs and fins) is an important factor in shading design. Research has shown that the longer the shading devices, the greater the reduction in terms of cooling energy and peak cooling load (Cheung et al., 2005). A study has shown that horizontal shadings of 1.5m long overhangs can achieve 4.06% decrease of cooling electric consumption and a saving of 1.95% of the total electric consumption of a basecase building studied. In the same investigation, vertical shadings (fins) of 1.5m long produced a decrease of 3.92% of the cooling electric consumption and a reduction of 2.20% of the total annual electric consumption (Yu et al., 2008).

Roof shading through the use of concrete cover, plants, canvas, earthen pots and other methods are effective means of reducing heat gain in buildings. Concrete and galvanized roof covers protect the building from direct radiation. These are not very efficient as they hinder the release of heat into the atmosphere at night. Deciduous plants and creepers are good alternatives as evaporation from the leaf surfaces can lower the roof temperature thereby improving thermal comfort in buildings (see Fig. 1). Inverted earthen pots arranged in a closely packed fashion on a flat roof provides a form of insulation, which prevents heat flow

into the building. Some disadvantages of this method are that it makes the roof not usable for other purposes and maintenance of the roof space may be difficult (see Fig. 1).

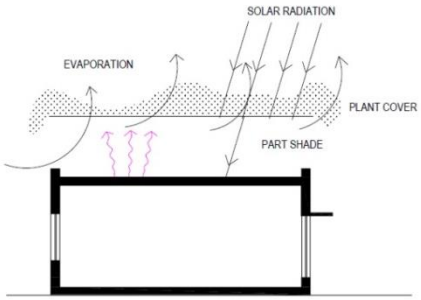

Figure 1.Roof shading using plant cover
Source: Kamal, 2012, p. 87

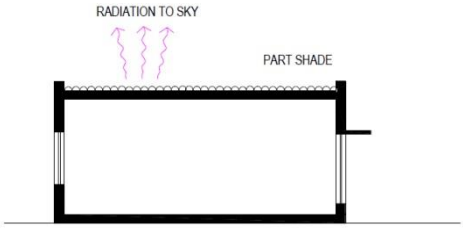

Figure 2.Roof shading using earthen pots
Source: Kamal, 2012, p. 88

An alternative means is to use broken ceramic tiles as the topmost layer of the roof which, helps to reflect incident radiation. Removable canvas cover (especially when painted white) can be mounted at a close distance to the roof to minimize heat gain during the day and removed at night to improve cooling in the building (Kamal, 2012). Roof eaves should be as wide as possible to provide shading for the external walls.

Trees and vegetation and the use of textured surfaces are other means of achieving shading in buildings. Planting of trees and vegetation around the building helps to create a cooler environment owing to the ability of plants to release moisture which cools the air. External air temperatures can be reduced over 50^{o}C through the use of ground cover or lawn around buildings rather than paving (Cairns Regional Council, 2012). See Fig. 3 Textured surfaces have some portions shaded which increase the surface areas of the walls where they are used. This leads to surface coefficient which makes the surfaces stay cooler and cool down faster at night (Kamal, 2012).

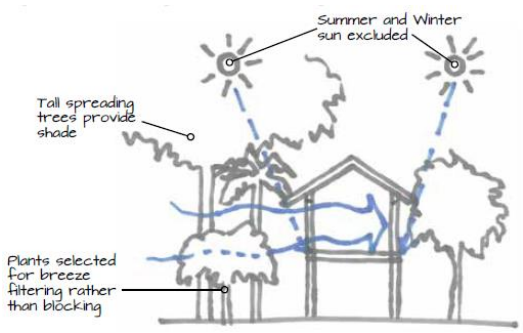

Figure 3. Shading using trees and vegetation
Source: Cairns Regional Council, 2012, p. 11

Glazing

Glazing technologies have recorded significant advances in recent years. Some of the advances include solar control glasses, insulating glass units, low emissivity (low-E) coatings, evacuated glazing, aerogels and gas cavity fills in addition to various improvements in frame and spacer designs (Robinson and Hutchins, 1994).

Where it is difficult to prevent heat gain using external shading devices, advance glazing technologies through the use of treated glass, can be employed to enhance cooling in buildings. For instance, double glazing can reduce heat conduction coefficient of glass and also decrease energy consumption when compared with single glazing based on the same solar heat coefficient. Supergrey glazing, electro glazing, low-E glazing or reflective glazing can increase the reflection of solar radiation to enhance cooling in buildings (Yu et al., 2008).

Insulation

Insulation is a material or combination of materials, which if installed properly, help to reduce the rate of heat flow by conduction, convection and radiation due to its high thermal resistance (Sadineni et al., 2011). Insulation is one of the most effective means of reducing heat gain in buildings. It can be installed in the walls, ceiling and roof to control the rate at which building loses or gain heat.

There are two types of insulation: bulk insulation and reflective insulation. In the tropical regions, reflective insulation installed under the roofing sheets, for instance can be very effective at it does not allow the trapping of heat inside the building. Bulk insulation can be effective when the goal of insulation is to prevent loss of cool air from the building.

Thermal Mass

Thermal mass refers to the ability of materials to absorb, store and release heat energy. Materials such as concrete, brick and tiles that require a lot of heat energy to change their temperatures are said to possess high thermal mass. On the other hand, lightweight materials such as timber have low thermal mass.

Cooling requirements for spaces in buildings depend on convection from internal gains (lights, equipment and people) and the nature of interior surfaces. Owing to the release of significant proportion of internal gains into the interior surfaces, the thermal storage properties of the building and the convective coupling determine building's cooling requirements (Braun, 2003). Thermal mass helps to control the flow of heat energy into buildings thereby reducing energy consumption for heating or cooling.

While thermal mass is preferable in temperate climates due to significant changes in temperature between night and day, low thermal mass is more suitable for tropical climates. If construction materials with high thermal mass are used in the tropics, adequate shading should be provided to reduce heat gain. Moreover, proper insulation should be installed internally minimise heat transfer (Cairns Regional Council, 2012).

Encourage Passive Cooling (Ventilation)

Passive cooling has been defined as "removal/restriction of heat from/to the building environment by using the natural process of rejecting heat in the ambient atmosphere by convection, evaporation, and radiation or the adjacent earth by conduction and convection (Muselli 2010, p.945). It entails maximizing natural ventilation through the use of design in order to reduce heat gain and the need for energy-intensive cooling technologies. Passive ventilation has been described as the cheapest way to cool buildings (McGee, 2013). If the cool outdoor air is properly harnessed through conscious design efforts, cooling can be achieved in some buildings in the tropics without the need for mechanical cooling. Cooling through convection by surrounding air, which serves as a heat sink has been used to achieve comfort condition indoors in hot humid locations (Liping and Hien, 2007). A study conducted by Tantasavasdi et al, (2001) shows that it is possible to achieve thermal comfort through natural ventilation in buildings in Bangkok suburb for 20% period of the year.

This can provide huge savings in terms of energy. To design for effective passive cooling in buildings, some factors are to be considered as the design stage.

Passive ventilation requires a driving force, and sufficient number of openings (fenestration) to produce air flow (Harvey, 2009). Wind is the driving force for passive cooling. Hence, the building orientation should take advantage of the prevailing winds to achieve cooling.

Adequate openings should be provided to improve air flow through the buildings. Windows that reduces the rate of air flow should be discouraged. Design should incorporate verandas, courtyards, atria and other related concepts to enhance wind flow. Design should achieve

cross ventilation, if possible in relevant spaces as this will maximise air flow through the building.

Internal partitions can hinder air flow in buildings. Hence, their use should be minimised in order to maximise air flow within interior spaces. Some spaces can be liked together through the use of archways and curtains or blinds provided for flexibility in use.

Convection air flow should be created through design to remove hot air from buildings. Eave and ridge vents should be provided to let-in cool air and to remove hot air respectively. This process sets up a circulation process that helps to cool interior spaces (Cairns Regional Council, 2012). See Fig. 4

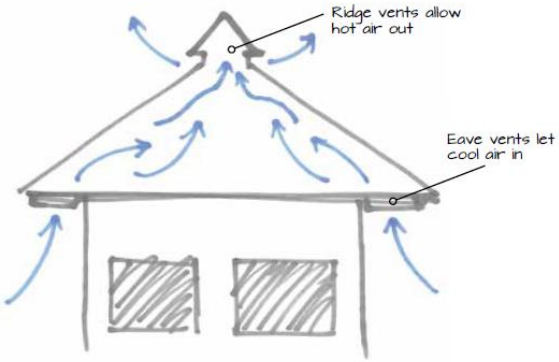

Figure 3. Shading using trees and vegetation
Source: Cairns Regional Council, 2012, p. 11

Encourage Natural Lighting

Natural lighting which is sometimes called day-lighting refers to dependence on sunlight to provide daytime interior lighting. Buildings that are designed to admit maximum amount of natural light into workplaces will save considerable amount of energy required to light those spaces during the day. "Day-lighting can provide 40-80% savings in lighting energy use in perimeter offices, 20-33% savings in combined lighting + cooling energy use, and up to 90% saving deep in room using fiber optics" (Harvey 2009, p. 146).

The efficiency of daylight can be improved through the use of light colours on floor, walls and horizontal surfaces. In addition, internal walls and ceilings should be properly aligned to take advantage of light reflection from light sources. To maximise the benefits of day-lighting, design incorporate strategies to control and heat gain. Design options include protecting glass from direct sun and providing proper insulation to minimise heat transfer. Skylights, atria, light shelves, light tubes, clerestory windows and similar installations can be used to admit natural light into interior spaces as well as enhance its effectiveness (see Cairns Regional Council, 2012).

CONCLUSION

Substantial savings in energy consumption by buildings can be achieved through energy efficient approaches using passive design options. Several passive design options for achieving energy efficiency in buildings were discussed. Passive design options are highly sensitive to climatic factors. Hence, designers should have better understanding of the microclimate of the building site in order to maximise its benefits. Passive design techniques should be advocated to reduce high energy poverty, demand and consumption in the country.

The adoption of passive design approaches in Nigeria will definitely reduce over dependence on mechanical cooling which at most times depends on electrical generators which has adverse effects on the three pillars (environmental, economic and social) of sustainable development.

Architects and other designers in the building industry should consider passive design options as an integral part of building design. Efforts should be put in place to encourage all stakeholders to embrace this concept which is relatively low cost but with many benefits.

Future interventions in mass housing especially by the State and Federal Governments on Nigeria should incorporate this concept to create learning effects.

Nigeria should focus on the application of passive design options to maximise its benefits while aiming at ultra-low energy buildings in the long term.

Socio-economic Consideration of Housing Transformers and Non-transformers in Selected Government Estates in South-Western, Nigeria

Victor Olufemi Adegbehingbe

Department of Architecture, Federal University of Technology Akure, Nigeria
victoradegbehin22@gmail.com

ABSTRACT

Residential buildings in government estates in Nigeria were often built without consultations with the end users, who usually indulge in transforming the houses. This paper carryouts a comparative study on Transformers and Non-transformers in three study estates in South Western Nigeria. Various variables were considered. Data was collected through structured questionnaires administered on 474 transformers and 360 non-transformers. Results were analysed and findings indicated that 57% of the respondents that transformed their building (transformers) are self-employed while 45.5% of those that do not transform their buildings (non-Transformers) are Civil/public servants. This implies that these estates originally occupied by civil/public servants are now mostly occupied by self-employed with more access to funding. On marital status, a preponderance of married persons among the respondents in the study area that transformed their buildings (81.9%) while 40.4% did not transform. This implies that marital status influenced the tendency to transform building since there will be the need to accommodate more household. This study reveals that initial occupants of the study estates are civil/servants but gradually being display by private employed with higher income and had access to more funds. The need to educate the occupants of the study estates were negative influences of indiscriminate building transformation on residential environment is one major recommendation emphasized in the study.

Keywords: Abandoned, Adaptation, Budget, Environment, Performance

INTRODUCTION

Residents of government estates in Developing countries are in the habit of transforming their buildings, since these houses do not conform to their expectations (Tipple 2000). The residential buildings in government estates often times were built without consultation with the users, who usually indulge in making unauthorized alterations, since the houses do not conform to their expectations (Tipple 2000).

Habraken (1975) asserted that no one could live satisfactorily within a fixed environment in which they have no input. Previous studies have revealed that there was shortage of government residential buildings in Akure, Ibadan and Lagos. The few available ones are in poor physical conditions and / or do not conform to the expectations of occupants. Consequently, the result is manifested in growing number of overcrowded houses, increasing pressures on infrastructural facilities, environmental degradation, among others (Tipple 1991).

Continued housing transformations which are triggered by the search for livelihoods among households in formal urban settlements and which are not strictly guided by statutory urban planning are likely to, increase livelihood opportunities at the house level. On the other hand, they can also cause public health problems such as residential and occupational health hazards to the general public (Sheuya, 2004).

While the transformation process can improve the local economy of the estates by accommodating informal sector activities in the houses and plots, this can also contribute to settlement degradation in terms of reduced internal accessibility; an increased burden on the limited infrastructure and services such as water supply, sanitation facilities, and solid waste collection and management system. These, in turn can contribute to noise pollution, poor

Adegbehingbe, V. O. (2016). Socio-economic Consideration of Housing Transformers and Non-transformers in Selected Government Estates in South-Western, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 56-64

lighting and reduced open spaces (Sheuya, 2004).

Residential buildings in government estates in Akure, Ibadan and Lagos only retained their original characteristics due to various activities of the users, which were not accommodated by the original designs. This phenomenon gives rise to significant physical transformation that has taken place in these buildings.

Nigerian government at various levels could not meet the housing need of the people (National Housing Policy, 2004). Even the few ones provided could not meet the expectations of the occupants (Tipple,2000). However, some facilities needed were not provided and some not needed were provided (FGN, 2001).This has made the residential estates to be haphazardly developed to the detriment of the users (Agbola, 1998).This brought about unplanned environment, which made the residential estates physically and functionally not alien with the existing physical planning regulations. Furthermore, most of the physical transformation taking place on the residential estates was not officially approved by planning authorities thus, leading to continuous destruction of unauthorized extensions by appropriate planning authorities. Substantial amount of money earlier invested in carrying out the physical transformation were lost (Nwuzi 1995).

LITERATURE REVIEW

The rapid rate of urbanization in Nigeria is noted to account for the depreciating quality of housing in the country's urban centres The urban centre suffer deterioration in infrastructure and services (Oladapo and Olotuah, 2007). Physical transformation of buildings which usually not authorized had been going on in urban centres of Nigeria. Olarewaju (2004) confirms that within a twenty year period, 1974-1993, residential property changed from 70.94% of the total land use to barely 39% in central Lagos. Similarly Nwuzi (1995) discovers that 76.5% of houses in Diobu, Port- Harcourt were converted and structurally modified from residential to non-residential uses without authorization.

While continued housing transformation which are triggered by the search for livelihood, among households in formal urban settlement and which are not strictly guided by statutory urban planning are likely to increase , they can also cause public health problem such as residential and occupational health hazards (Sheuya 2004). Harrison (1982) was of the concept that while western cities are thinning out, as people move to the suburbs, third world cities are growing denser, infilling their empty spaces and building layers of unsafe structures.

With the Nigeria population growth rate of 2.8%, which is one of the fastest in the world, and rapid urbanization which proportionally rose to 43.3% in 2000 (Report of Presidential Committee on Urban Development and Housing 2001), in the face of massive requirements for housing needs which are estimated to be in the region of demand for 200,000 houses per annum (Mortgage banking Association of Nigeria ,2005). Sheuya (2004) has envisaged that continued housing transformation must be panacea for bridging the gap.

The early works of physical transformations concentrated on the notions of allowing residents to have inputs into their housing situation (Steinberg 1984, Benjamin 1985, and Beinart, 1971).Tipple (2000) asserted that every house is a work in progress and that physical transformers express not just housing needs but that desire for identity, a sense of belonging and a search for status among neighbours. Previous study on Housing Transformation by Tipple and Ameen (1996) in Bangladesh; Tipple and Salim (1999) in Malaysia ; Kardesh (1999) in Egypt; Arimah (1999) in Lagos; Muuzi (1995) in PortHarcourt and Sule (1986) in Calabar, numerous reasons were deduced as to why transformation were carried out. From the simple reason of adding more space to existing structure, to fencing, search for additional income among others, most of the physical transformation were not authorized by relative

public agencies.

Housing transformation is a feature of urban centres of both developed and developing countries. Evidence from literature suggests that substantial transformation of old dwellings even take place in developed cities like New York, London and Toronto, where big Asian communities reside (AI-Naim and Mahmud, 2004).These transformations are effected in their indoor environment in order to acquire spaces that are more habitable. Others involved converting rooms into working space for extra household income.

Mahmud (2003) observed that it is common practice among Asians in Europe to convert rooms into corner shops. For instance, the Indian Sikh families all over England are noted to modify garage into bedrooms or workshop for garments especially by the Sylherty women (a province in Bangladesh) in East London. This transformation by the occupants is economically motivated, to meet their cultural and religious needs.

One major difference in these cities as compared to the third world is climatic factors. The ecological setting makes the physical pattern of these European houses different from their African and Asian counter part as they lack open courtyards within their traditional dwellings. Majority of these low-income earners live in the council or municipality housing units, where by rules are strict and impose with high penalties. Accordingly, such physical transformations are not as flexible as individually owned traditional dwellings (Mai 2008).

The study area is the South-Western, Nigeria which geographically comprises six states namely: Lagos, Ondo, Ogun, Oyo, Osun and Ekiti. The South-Western, Nigeria is located in the tropical rain forest zone (see fig 1); however, the part close to the Atlantic Ocean (the coastal region) shares sub-equatorial climate and receive a high annual rainfall of over 1520mm (Udo 1978). The interior which is the greater part shares Guinea or tropical climate; it has a clearly marked dry and wet seasons and received an annual rainfall of between 1000 and 1250mm (Udo, 1978) The major ethnic group in South-Western, Nigeria is Yoruba, the people share the same culture in respect to language, lifestyle, housing and etc (Udo, 1978). Out of the six states making up the South-Western, Nigeria, three states of Lagos, Oyo and Ondo were selected and the study was carried out in government estates that were first constructed in each of the towns Lagos (Ikeja Housing Estate), Ibadan (Old Bodija Housing estate) and Akure (Ijapo Housing Estate)(Adegbehingbe & Fadamiro 2006).

The south-west region of Nigeria is the most urbanized in the country with 40 percent of the nation's 329 urban centers located there in 1991. The most urbanized states were Lagos, and Oyo with population constituting 93.7 percent, 69.3 percent of their population being urbanized in 1991(CCA 2001).

The Study Area: South-Western, Nigeria

The study area is the South-Western, Nigeria which geographically comprises six states namely: Lagos, Ondo, Ogun, Oyo, Osun and Ekiti. The South-Western, Nigeria is located in the tropical rain forest zone (see fig 1); however, the part close to the Atlantic Ocean (the coastal region) shares sub-equatorial climate and receive a high annual rainfall of over 1520mm (Udo 1978). The interior which is the greater part shares Guinea or tropical climate; it has a clearly marked dry and wet seasons and received an annual rainfall of between 1000 and 1250mm (Udo, 1978) The major ethnic group in South-Western, Nigeria is Yoruba, the people share the same culture in respect to language, lifestyle, housing and etc (Udo, 1978). Out of the six states making up the South-Western, Nigeria, three states of Lagos, Oyo and ondo were selected and the study was carried out in government estates that were first constructed in each of the towns Lagos (Ikeja Housing Estate), Ibadan (Old Bodija Housing estate) and Akure (Ijapo Housing Estate).

The south-west region of Nigeria is the most urbanized in the country with 40 percent of the nation's 329 urban centers located there in 1991. The most urbanized states were Lagos, and Oyo with population constituting 93.7 percent, 69.3 percent of their population being urbanized in 1991(CCA 2001).

METHODOLOGY

Relevant data were obtained by photographic means and field observation to have accurate three dimensional views of the study estates, to capture the extent of physical transformation that took place. The research variables included income, type of building, household size, education level, type of tenure, home based enterprises, other uses for transformed buildings, types of facilities provided in the building within the estate and involvement in the construction and design of transformed buildings. Data obtained from field survey were analyzed statistically at three levels. The first level was univarate analysis using descriptive summary measure and frequency distribution analysis of the variable .Bi – variate analysis which included chi-square test and correlation analysis was the second level while multi-variate regression analysis was employed as the third level.

The primary data were sourced from field surveys using case studies which are residential building survey (extent of physical transformation) and structured questionnaires as the principle research tools. The questionnaire was employed to collect first hand data directly from some household heads that transformed and those that did not transform their building and also the design professionals in charge of the management of the study estates. In addition, relevant research data were obtained by photographic means and field observations to have a nearer accurate three dimensional view of the study area.

The Ikeja GRA had 714 housing units, Old Bodija housing estate had 815 housing unit while Ijapo housing estate had 600 housing units, and since only the household-head were interviewed the three estates selected comprising 2129, constituting the research population. From 2129 housing units, 40 percent of the housing units were selected. In addition, the three public institutions managing the estates were visited to obtain relevant information and maps.

The primary research instrument used was research questionnaires. Three types were employed in this study: The first involved three sets of well-structured multi-choice questionnaires. The first set was used to collect data from occupants of residential buildings in government estate that have extended and altered their buildings (Table 1.0). Information sought included occupation, income, type of building, household size, educational level, and criteria for allocation, type of tenure, source and procedure for payment for the occupied building, age of building. Eight hundred and fifty respondents were randomly selected from the three housing estates of Ikeja, Old Bodija and Ijapo, from which four hundred and seventy four questionnaire were retrieved and analysed.

Table 1 Sampling size of respondents for questionnaires on occupants of selected residential buildings on government estates that have transformed their buildings

S/No	Housing Estate	Town / State	No of Respondents retrieved& analyzed
1.	Ikeja Housing Estate	Ikeja, Lagos State	133
2.	Old Bodija Housing Estate	Ibadan, Oyo State	201
3.	Ijapo Housing Estate	Akure, Ondo State	140
	Total		**474**

The numbers of questionnaire administered on transformed buildings were presented in table 1.

Figure 1: Map of South-West-Nigeria showing States where study areas are located.

FINDINGS AND DISCUSSIONS

Occupation of Respondents

This paper examines the personal and socio-economic characteristics of the respondents (those that transformed their buildings and those that did not) in the three study estates. These include occupation, gender distribution, marital status, income level, household size, educational level, type of building occupied and tenure. The analysis is done, not only in terms of frequency counts of the characteristics for the selected housing estates, but it examined and compared characteristics of those that transformed their building with those that did not.

Table 2 shows the frequency distribution of the occupants that transformed and those that did not transform their building, according to their occupations in the selected housing estates

Occupation Type	Respondent who transformed their buildings		Respondent who did not transform their buildings	
	Frequency	% of respondents	Frequency	% of respondents
Unemployed	12	2.5	13	3.9
Civil/public servant	150	31.6	157	45.4
Self employed	270	57.0	137	39.6
Others	42	8.9	53	11.2
Total	**474**	**100**	**360**	**100**

Source: Adegbehingbe (2011)

Out of the 474 respondents that transformed their building, the table showed that 270 (57%) were self-employed. This is followed by Civil/ Public Servants, with a score of 150 (31.6%). The result of the ANOVA (Table 3.0.) revealed that the distribution of occupants into different categories of occupation varied significantly. This implied that, the majority of the respondents that transformed their buildings were self-employed.

Table 2 Further showed that out of the 360 respondents that did not transform their building, 157 (45.4%) were civil/public servants; this is followed by those who were self-employed accounting for 39.6%. This implied that the majority of the respondents that did not transform their buildings were civil / public servant. This may be due to accessibility of more funding by those who are self-employed.

Table 3 ANOVA for the various occupation types of the respondents

Source of Variation	Sum of Squares	df	Mean Square	F	Sig.
Occupation type	9445.887	8	1180.736	25.230	0.000
Error	842.373	18	46.799		
Total	10288.261	26			

Source: Field survey (2007)

Gender Distribution of the Respondents

Analysis of the sex of occupants of the selected Housing estates that transformed and those that did not transform their buildings as shown in Table 4.0 revealed that 352 males (74.3%) and 122 female (25.7%) transformed their building, while 120 male (28.6%) and 240 female (71.4%) did not transform their building. Since the household heads were interviewed, this result confirmed that male households' heads that transformed are more than female household head. The result of the paired T-test conducted on the gender distribution showed that there is significant difference in the percentage population of male and female respondents (P<0.05) (Adegbehingbe 2011)

Table 4 Gender distribution of the respondents

Sex	Respondent who Transformed their building		Respondent who did not transform their buildings	
	Frequency	% of respondents	Frequency	% of respondents
Male	352	74.3	240	28.6
Female	122	25.7	120	71.6
Total	**474**	**100**	**360**	**100**

Source: Adegbehingbe (2011)

Marital Status of the Respondents

The study analyzed the marital status of the respondent that transformed and those that did not transform their buildings. From the result in Table 5.0., out of the 474 respondents which transformed their buildings, 388 (81.9%) were married. This is followed by 56 (11.8%) that were single. For those that did not transform, 287 (80.4%) were single and 38 (10.6%) were married. Also, the result of analysis of variance ANOVA (Table 6.0) revealed that only the married occupants distinctly differed from other marital status among the respondents in the study area. This indicated that marital status is a factor necessary for transformation since there will be need for more space to accommodate more household members (Adegbehingbe 2011).

Table 5 Marital status of the respondents

Status	Respondent who Transformed their building		Respondent who did not transform their buildings	
	Frequency	% respondents	Frequency	% respondents
Single	56	11.8	287	80.4
Married	388	81.9	38	10.6
Widow	6	1.3	22	6.2
Widower	7	1.5	5	1.4
Divorced	4	0.8	3	0.8
Separated	13	2.7	5	0.6
Total	474	100	360	100

Income Stratification of the Respondents

The distribution of the respondents into different income strata is presented in Table 8. From the table, 77.7% of those respondents who transformed their houses belonged to

the high and upper middle income brackets, whereas 83.5 percent of those who did not transform their houses conversely belonged to the low and lower middle income strata. This indicated that the higher the income the tendency for occupant to transform their building. The result of the Analysis of Variance as shown in Table 8.0 however showed that there is no significant difference in the percentage distribution of respondents into the different income strata (P>0.05). From the results of the Chi-square test, income level of the respondent has a strong association with the type of building occupied by the respondents (P<0.05) (Adegbehingbe 2011).

Table 7 Income Stratification of Respondents

Income Class	Respondent who Transformed their building		Respondent who did not transform their buildings	
	Frequency	% respondent	Frequency	% Respondent

Source: Adegbehingbe (2011)

This paper has a detailed analysis along with interpretations and discussion of the socio-economic consideration of presented Housing transformers and Non-Transformers (respondents) of the selected study housing estates and also examined and compared characteristics of those that transformed their buildings with those that did not.

The occupation of the respondents revealed that majority that transformed their building are self employed (57%), which then confirm that the study estates which were originally occupied by public servants are now mostly being occupied by self employed who are supposed to have more access to fund. Majority of respondents that did not transform (45.4%) their building is civil/public servants (Adegbehingbe 2011).

There was a preponderance of married persons among the respondents in the study area that transformed their building (81.9%) and single persons that did not transform (80.4%). Male that transformed (74.3%) and female that did not transform (71.6%). This confirms that sex and marital status of occupant have effect on building transformation. This confirms necessity to accommodate more people. Majority of the respondent that transformed their building are highly educated (69.0%) while those that did not transform their buildings are also educated. This shows that no notable difference between educational background of transformers and non-transformers. This is due to the fact that access to original buildings on the study estates are for educated occupants (Adegbehingbe 2011).

The result of multiple regression analysis identified marital status (b=0.55), income (b=0.29) and educational level (b=0.193), as the most significant variables that determine the degree of transformation or alteration of buildings on the study estates.

RECOMMENDATIONS AND CONCLUSION

In view of the above research findings, the following recommendations are offered as possible means of improving housing conditions: In the short term, there is an urgent need to increase the number of staff of the planning approval authority in the housing corporation responsible for the management of the study estates, especially those in the contravention section. They should make sure that no modification or alterations are made in a building until these had been approved by the appropriate authority. There is an obvious need to educate the occupants of the study estates on the negative influence of indiscriminate building transformation on the residential environment.

The design professionals in housing corporation responsible for the management of the Estates can reduce the need for housing transformation by ensuring provision for services areas, end users involvement , make use of functional architectural designs, ensure structural flexibilities and appropriate legislative control. If occupants are not satisfied with their houses, there should be alternative housing or availability of other measures to redress the inadequacies by the government.

When approval for transformations is considered, it is recommended that necessary account of the effects of the proposed development on the household should be considered. It is recommended that economic and environmental implications should be considered along with planning and structural consideration.

There is the need to regularly conduct technical audits of all structures on the estates to ascertain their structural stability. Building like's human beings, have life span (Ben –Eboh 2008). There should be more stringent measures to ensure that those showing sign of failure are promptly brought down to make way for new ones.

Government should adopt an essential permissive attitude towards those who transformed their buildings with details to improve the use of space and minimize interference with neighbours especially with respect to ventilation and day light.

Housing transformation is taking place without statutory development control. In other words, it is unguided and is directed by market forces and individuals interests. To guide against this, it is suggested that the state and local government at the appropriate levels should work together with community members to formulate zoning and land use guidelines. In this way, most of the challenges posed by housing transformations including high incidences of plot boundary conflicts and management of solid wastes could be solved efficiently and effectively.

Residential buildings in government estates in Nigeria are often transformed by addition of structures or modification of existing spaces since these buildings do not in most cases conform to the expectations of occupants. Residential buildings were often built without consultations with the end – users who usually indulge in transforming their houses. This study carried-out the analysis of physical housing transformation of residential buildings in selected government estates in south-western, Nigeria in which the socio-economic characteristics of occupants that transformed their buildings were compared with those that did not transform.

It has been established that original owners of the buildings who are civil servants were being displaced by those who were self-employed and had access to more fund and even purchased the buildings. The study has been able to established that sex has no effect on building transformation but marital status has great influence; this study has clearly shown that occupants of the residential buildings transformed their houses mainly to provide comfortable conditions safety and security elements that were lacking in the buildings.

Lack of provision of service areas within the study area is evident from this study and it accounts for numerous home-based enterprises in the study area.

Furthermore, it was observed that transformed building was being used for purposes other than residential. These transformed buildings were used for other purposes due to non-functional architectural designs and inadequacies noted in layout plans.

ABSTRACT

This study examined the evidence of climate change and adaptation strategies among grain farmers in Sokoto state. This paper focused at finding out the farmers' knowledge of climate change and adaptation strategies. Rainfall and temperature data for 30 years were sourced from the Sokoto Rima Basin Development Authority's Rainfall Reading Office, Goronyo and Nigerian Metrological Services (NIMET) Oshodi, Lagos and used for this study. Purposeful sampling technique was used in the selection of 385 respondents. Farmers' perception and adaptation strategies to climate change were obtained by means of structured questionnaire administered to the sampled grain farmers. The results were summarized by means of frequencies and percentages and presented in tabular forms, trend lines and bar charts. The study revealed that farmers' perceptions of climate change issues are in line with the analyzed climate records for the area; the annual rainfall totals favour the cultivation of millet; there is late onset of rain and frequent agricultural drought which affects grain production in the area. This study recommends that the research institutes should produce better adapted varieties of millet and other grains and government should subsidize the seeds to the farmers. Furthermore, there should be adequate provision for irrigation, weather forecasting and other agricultural technological infrastructure, modern knowledge on climate change adaptation and strengthening of the extension services. The study concludes that the climatic characteristics of the study area affect grain production and that adaptation strategies have significant contribution on grain production in the area.

Keywords: Adaptation strategies, Climate Change, Evidence, Grain farmers and Sokoto state

INTRODUCTION

Climate change has become the primary environmental threat of the 21st century. It is now on the global political agenda as never before. The Fourth Assessment Report of the Intergovernmental Panel on Climate Change (IPCC) affirms that climate change is no longer in doubt, IPCC (2007). Although extreme violent weather has occurred throughout history, recent upsurge in climate related hazards is confirming the argument for global warming and climate change, Odjugo and Ikhuoria (2003). The evolving climate change coupled with increasing temperature has been observed to plunge some localities. The IPCC (2001*)* projected that climate change resulting from increased greenhouse gases concentrations has the potential to harm societies and ecosystems, agriculture and forestry, water resources etc. All stages of agricultural production from land clearing and preparation, through crop growth and management to harvesting, storage, transportation, and marketing of agricultural products are subject to the influence of weather and climate. Societies have a long record of managing the impacts of weather and climate related events. Thus, this research focussed on recognising the evidence of climate change in the study area and the grain farmers' adaptation strategies to climate change.

LITERATURE REVIEW

Meaning and Causes of Climate Change

"Climate change is a change in the state of the climate that can be identified (e.g. by using statistical tests) by changes in the mean and/or the variability of its properties, which persists for an extended period typically decades or longer", IPCC (2007). Climate change, in the

Ikpe E, Sawa B. A., Ejeh, Udeh L, Meshubi O. Adekunle & Oladimeji J. S. (2016). Evidence of Climate Change and Adaptation Strategies among Grain Farmers in Sokoto State, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F.? Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 65-74

most general sense –encompasses all forms of climatic inconstancy (that is, any differences between the "long-term" statistics of the meteorological elements calculated for different periods but relating to the same area), regardless of their statistical nature or physical cause, Maunder (1994). Climate change implies a new mean climatic state or climatic normal, Ayoade (2003). The most crucial things about the concept of climate change is not only the time periods involved but also the degree of variability that the change is subjected to as well as the duration and impact of such variability on man and the ecosystem.

Climate change is caused by two basic factors namely natural processes (biogeographical) and human activities (anthropogenic). The natural processes are the astronomical and extraterrestrial factors. The astronomical factors are the eccentricity of earth's orbit, obliquity of ecliptic and orbital procession. The extraterrestrial factors include solar radiation quantity (sunspot) and quality (ultra violet radiation change). A high solar quality and quantity and period of perihelion (when the earth is nearest to the sun), result in heating up of the earth surface which lead to global warming. Volcanic eruptions also lead to both global warming and cooling. Through volcanic eruptions, lot of gases, vapour and particulate matter are emitted into the atmosphere. Such emissions influence the atmospheric chemistry thereby creating short –term cooling and long- term heating of the atmosphere. Prominent examples of such eruptions of great magnitude were Krakatoa eruption in 1883, Mount Agung in 1963, Mount Pinatubo in 1992 and Republic of Iceland in 2011. Researchers (Buba, 2004; Porbeni, 2004; DeWeerdt, 2007 and Odjugo, 2007) have shown that for the past few decades, anthropogenic factors like transportation, industrialization, urbanization, burning of fossil fuel, agriculture, water pollution, changes in land cover and deforestation among others are the major contributing factors to the depletion of the ozone layer and its associated global warming and climate change. Man is at the centre of climate change through activities that add to the amount of greenhouse gases in the atmosphere, Akpodiogaga and Odjugo (2010).

Meaning of Adaptation

The IPCC (2007) defines adaptation as the "adjustment in natural or human systems to a new or changing environment". Adaptation to climate change is a process through which people reduce the adverse effects of climate on their health and well-being and take advantage of opportunities that the environment provides, Saka (2008). Various types of adaptation can be distinguished, including anticipatory and reactive adaptation, private and public adaptation, and autonomous and planned adaptations.

Evidence of Climate Change in Nigeria

Reports from recent literature point to climate change in Nigeria. Ahmad and Ahmed (2000), IPCC (2001), Nigerian Environmental Study/Action Team (NEST, 2003) and Hengeveld and Fergusson (2005) provided indicators that one could use to assess the evidence of climate change in a region. These include increasing temperature, increasing evapotranspiration, decreasing rainfall amount in the continental interiors, increasing rainfall in the coastal areas, increasing disruption in climate patterns and increasing frequency and intensity of unusual or extreme weather related events such as; thunderstorms, lightning, landslides, floods, droughts, bush fires, unpredictable rainfall patterns, sea level rise, increase desertification and land degradation, drying up of rivers and lakes and constant loss of forest cover and biodiversity. A further support of the evidence of climate change in Nigeria by Odjugo (2005; 2009) is the increase in rainfall amount in the coastal areas since the 1970s, and a constant decline in rainfall amount and duration in the continental interior of the semi-arid region of Nigeria. The increasing temperature and decreasing rainfall in the semi-arid region of Northern Nigeria-Sokoto, Katsina, Kano, Nguru and Maiduguri may have resulted in the increasing evapotranspiration, drought and desertification in the region as reported by Odjugo and

Ikhuoria (2003) and Adefolalu (2007). Constant loss of forest cover and biodiversity in Nigeria is linked to global warming and climate change, NEST (2003); Ayuba *et al*., (2007).

The increasing temperature and decreasing rainfall have led to frequent drought and desertification. The Sahara desert is observed to be expanding to all directions trying to engulf the Sahellian region of Africa with annual expansion of 1-10 km, Odjugo and Ikhuoria (2003); Yaqub (2007). Odjugo and Ikhuoria (2003) also observed that Nigeria north of 12^0N is under severe threat of desert encroachment and sand dunes are now common features of desertification in states like Yobe, Borno, Sokoto, Jigawa and Katsina. The migrating sand dunes have buried large expanse of arable lands, thus reducing viable agricultural lands and crops' production. This has prompted massive emigration and resettlement of people to areas less threatened by desertification. Such emigration gives rise to social effects like loss of dignity and social values. It often results in increasing spate of communal clashes among herdsmen and farmers and such clashes resulted in the death of 186 people in six northern states of Nigeria between 1998 and 2006, Yugunda (2002); Yaqub (2007).

In Nigeria, many rivers have been reported to have dried up or are becoming more seasonal, while Lake Chad has shrunk in area from 22,902 km^2 in 1963 to a mere 1304 km^2 in 2000. This shows that what is left of Lake Chad in the year 2000 is just 5.7% of 1963, Odjugo (2007). Awake, (2009) also confirms the fact that Lake Chad has shrunk by 95% since the 1960s. Lake Chad and so many rivers in Nigeria, especially in Northern Nigeria, are in the danger of disappearing. Available evidence also shows that climate change has impacted on agriculture and health in Nigeria, Mshelia (2005); Adefolalu (2007).

Already, Nigerian urban centers have been feeling the impacts of climate change with incessant annual flooding that affect large areas and large number of people. For example, in 2010, flood in Northern Nigeria affected 2 million people in Jigawa State and another 40, 000 people were displaced in Sokoto State where Usmanu Dan Fodio University was forced to close down for weeks as a result of bridge collapse associated with the flood. Similar floods were reported in Lagos where 689 people were to be relocated in Ajegunle as a result of flood, Yekken (2011).

Agriculture and Climate Change

Agriculture is perhaps the most sensitive to climate change related issues of all human economic activities. Changes in the world's climate will bring major shifts in food production. In spite of recent technological and scientific development, weather remains a key variable in agricultural production. Weather and climate affect agriculture and determine the adequacy of food supplies. Climate determines whether or not rainfed agriculture will be successfully cultivated in a given area. Weather and climate act both as a resource and a constraint to agricultural production. The resource value of weather has to be optimized while the hazards posed by weather have to be managed, Ayoade (2002). It is common knowledge that farmers in Sub-Saharan Africa, including Nigeria are struggling to cope with the current climate variability, Chakeredza *et al* (2009).

METHODOLOGY

Study Area

Goronyo is a local government area (LGA) in Sokoto state, Nigeria. It is located along Latitude 13^0 27'11" North and Longitude 05^0 40'35". Its headquarters is at Goronyo, on the bank of the Sokoto River. It has an area of 1, 704km^2. Goronyo is in the dry Sahel, surrounded by sandy savanna and isolated hills. With an annual average temperature of 28.3°C, Goronyo, on the whole is a very hot area. However, maximum daytime temperatures are for most of the year generally under 40°C and the dryness makes the heat bearable. The

hottest months are February to April when daytime temperatures can exceed 45°C. The rainy season is from June to October. The annual rainfall is between 500mm in the north and 800mm to the south. The area's lifeline for growing crops is the floodplains of the Goronyo dam system which are covered with rich alluvial soil, Sani (2005). Goronyo is essentially an agricultural area with traditional mode of production predominating with more than 90 percent of the population engaged in subsistence farming. The main crops produced in the LGA are millet, guinea corn, maize, rice, beans etc.

Climatic data used in this study are daily rainfall and temperature records of Goronyo (1981-2010), and Goronyo's grain farmers' perception and adaptation to climate change. The grain farmers' perception helped to know the sensitivity of farmers to the changing climate and their adaptive strategies to climate change. The daily rainfall and temperature records for the stated period were obtained from the Sokoto Rima Basin Development Authority, rainfall reading office, Goronyo, and Nigerian Meteorological Services (NIMET), Oshodi, Lagos. While farmers' perception and adaptation strategies to climate change were obtained by means of structured questionnaire.

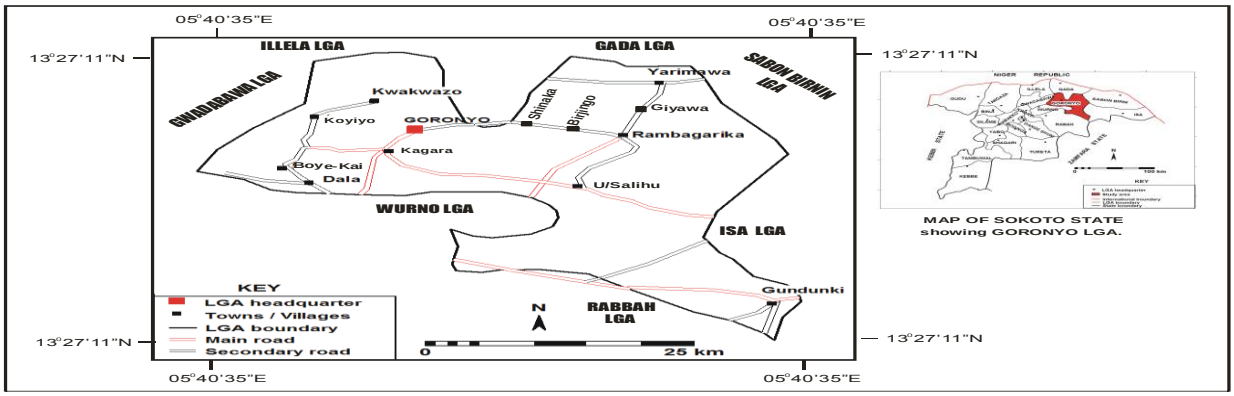

FIG. 3.1: GORONYO LGA SHOWING TOWNS / VILLAGES
Source: Modified from Administrative Map of Sokoto State, 2008

Materials for the Study

The respondents for the questionnaire were the grain (sorghum, millet and maize) farmers in the eleven (11) wards in the LGA. The number of questionnaire used was based on the population of the study area. To determine the sample size for this study, Krejcie and Morgan's (1970) method of determining sample size was adopted which states that, for an area with a population between 75, 000 - 999, 999, the sample size to be used is 382. Since the population of the study area is 182, 296 which fall between these ranges, the sample size of 382 is in order. However, 385 respondents were used to have equal representation in each ward, but only 382 were returned.

Sampling Technique

Purposeful sampling technique was used to determine the respondents after which simple random sampling was used to administer the questionnaire among the eleven wards of the LGA. Purposeful sampling, according to Bernard (2002) "is the deliberate choice of an informant due to the quality the informant possesses." The three hundred and eighty five (385) questionnaires were shared proportional to the population of each ward, but due to the non-availability of population figures for each ward from the 1991 and 2006 census results, the questionnaire was distributed equally among the eleven (11) wards, with 35 questionnaires in each ward. For the purpose of administering the questionnaire, grain farmers above thirty (30) years of age and who must have lived at least twenty (20) years within the study area were identified through the "Sarkin Noma" (Head of the Farmers) and the village Heads. This was done by asking the farmers of their age and how long they have lived in the area. Thereafter the questionnaire was issued. The reason for this decision was

that those within the age bracket have the information needed about climate change. The researcher was assisted by field assistants.

To present the various agricultural adaptive strategies used by the farmers to cope with climate change, percentage analysis was used. The data was summarized and presented in tables, charts, percentages.

FINDINGS AND DISCUSSION

Table 1: Rainfall and Temperature Characteristics of Goronyo, 1981 – 2010

Years	Total Annual Rainfall (mm)	Total Annual Number of Rain Days	Onset Dates	Cessation Dates	Annual Length of Rainy Season (days)	Mean Max. Temperature (^{0}C)	Mean Min. Temperature (^{0}C)

(**Source**, Field survey 2012)

Onset Dates of the rains in Goronyo

The linear trend and trend line equation for the onset dates of the rainy season in the study area are shown in fig.2. It clearly indicates a decreasing trend in the onset dates (that is, the rains are now coming late). The earliest onset date of rain in the study area within the 30 years of study as shown in table 2 is 31st March, (1983). While the late onset date within the 30 years of study is 15th June. The mean onset dates within the thirty years of the study is 11th May.

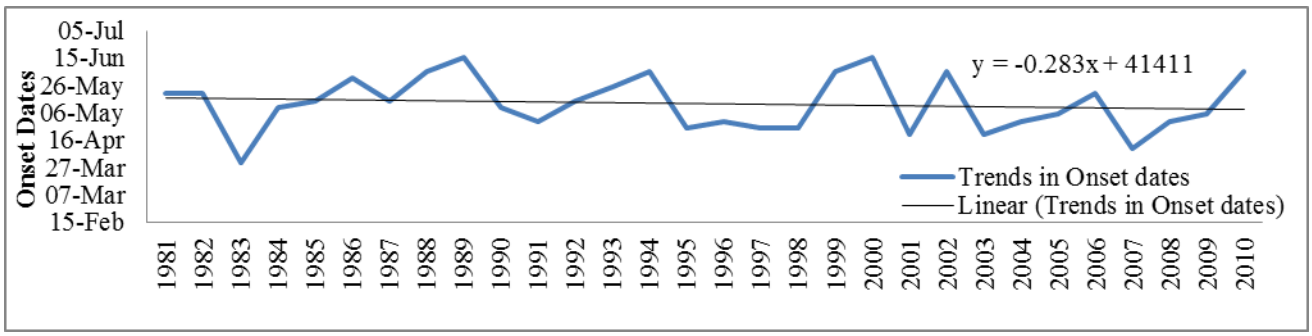

Fig. 2: Trends in Rainfall Onset Dates at Goronyo (1981 – 2010)
Source: Field work, August 2012

Cessation Dates

The earliest cessation date in Goronyo occurred on 5th September (1984), while the latest cessation date occurred (twice within the 30 years of study) on 5th November (1986 and 2009). The average cessation date of rainfall in Goronyo within the thirty years of study is 7th October. As shown in table 1, cessation dates in the study area within the 30 years of study occur between 5th September and 5th November. These periods of anomalies, that is early cessation may affect the production of grains in the study area.

Length of Rainy Season

The linear trend and trend line equation for the length of rainy season is shown in figure 3. From this figure, it is observed that the trend line for the length of rainy season is increasing. The linear trend line equation for the length of rainy season is y = 0.858x + 135.5. This positive trend line equation further indicates that the length of the rainy season is on the increase in Goronyo. The highest length of rainy season within the 30 years of study was recorded in 2007 (199 days out of the 365 days of that year), while the shortest length of rainy season was recorded in 1988, with 92 days. The mean length of rainy season (days) is 149 days.

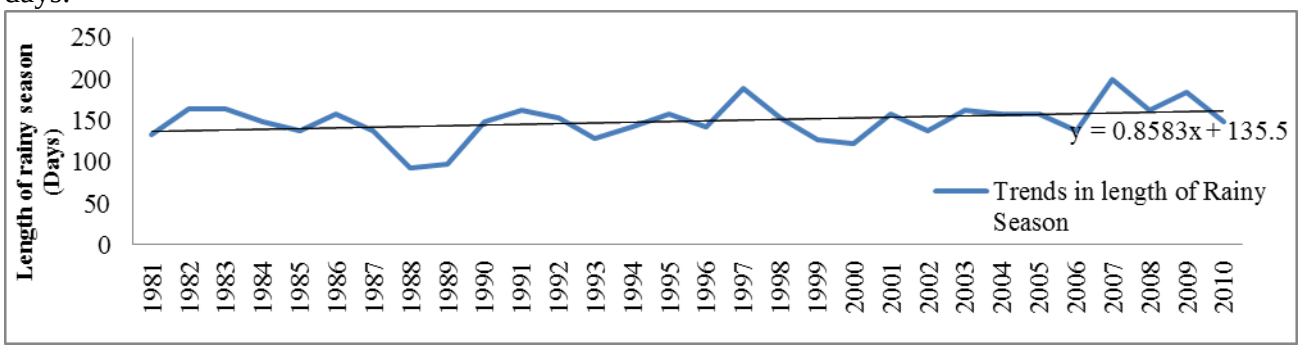

Fig. 3: Trend in Length of Rainy Season at Goronyo (1981 – 2010)
Source: Field survey, August 2012

Number of Rainy Days

Table 1 indicated an upward trend in the number of rainy days. The annual number of rainy days in Goronyo ranges between (12-30 days). The highest annual total number of rain days is 30 days and was recorded in 1997 and 2008. While the lowest number (12 days) occurs in 1994. The mean annual number of rainy days in the study area is 21 days. Researches shows that millet requires the minimum of 60-70 days of rain for effective cultivation and yield, sorghum requires 80 rainy days and maize 80-100 rainy days. Going by the records of rainy days presented in table 1, the length of the rainy season in Goronyo may not favour the cultivation of crops having tap root system such as millet, sorghum and maize. Hence, the need for an adaptive strategy to climate change scenarios in Goronyo. Amongst the three crops- millet, sorghum and maize, the number of rainy days pattern in Goronyo favours millet production most. This is why millet remains the favourite crop and most cultivated among the grain farmers in Goronyo because characteristically, millet is better adapted than most other crops to dry infertile soils, high temperatures, low and erratic precipitation, short growing seasons and acidic soils with poor water-holding capacity.

Annual Rainfall

Trends in the total annual rainfall of Goronyo for the period of thirty years are presented in figure 4

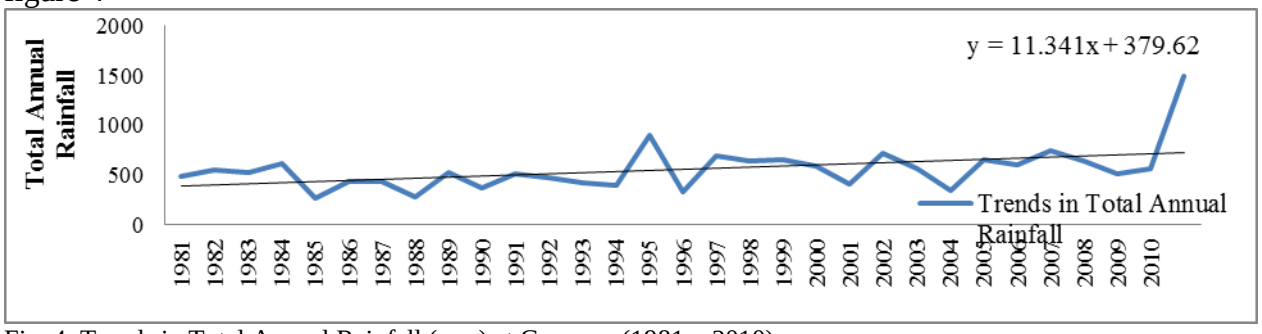

Fig. 4: Trends in Total Annual Rainfall (mm) at Goronyo (1981 – 2010)
Source: Field survey, August 2012

The trends in fig. 4 show an increasing annual rainfall amount. The best fit trend line equation is y = 11.34x + 379.6. The positive equation implies that annual rainfall is on the increase. More so, in table 1 the highest rainfall was recorded in 2010 (1,496.5mm), while 1984 had the least rainfall (263.4mm). The mean annual rainfall during the period of the study is 563.6mm. This amount is lower than the minimum required for the cultivation of sorghum and maize in the study area. Millet requires the minimum of 300mm of rainfall, sorghum 400-600 and maize 500-750mm. It then implies that millet yield was low in the years where annual rainfall was 300mm. Following the annual rainfall record in table 1, 1984 and 1987 are bad years for millet production as the annual total was less than 300mm for millet production. While 1984, 1987, 1989, 1993, 1995 and 2003 were bad years for sorghum and maize production.

Major Adaptation Strategies to Climate Change by Farmers

It is no doubt that adaptation strategies can reduce the impacts of climate change and increase benefits. As shown in figure 6, crop rotation, mixed cropping, use of improved seed varieties, shifting cultivation, access to water for irrigation, use of organic and inorganic fertilizer, access to credit loan are the major adaptation strategies to climate change adopted by farmers in Goronyo.

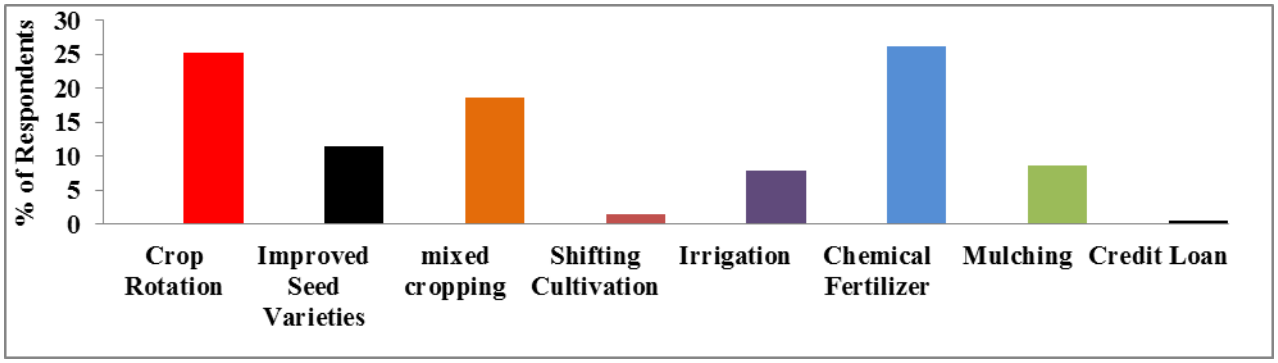

Fig. 5: Farmers' Strategies to Adapting to Climate Change in Grain Production
Source: Field survey, August 2012.

The questionnaire administered on the grain farmers contained a list of adaptation options for the farmers to choose from and then open ended questions for the farmers to itemize other viable adaptation strategies in the study area. The questionnaire was uniformly applied in the eleven wards of the study area. As strategies to adapting to climate change in grain production, 25.2% of the farmers practice crop rotation; 18.6% practice mixed cropping; 15.5 percent uses improved seed varieties; 1.5 percent use shifting cultivation; 7.8 percent use irrigation/fadama farming; 32.2% use chemical fertilizer (chemical fertilizer helps to improve crop yield); 3 percent use mulching with crop residue and animal dung; 0.2 percent use credit loan as a means of diversification of the economy for livelihood and only 0.5 percent stated that no adaptation method is best fit.

CONCLUSION

The study has achieved to a reasonable extent the aim of carrying out this study on the evidence of climate change and adaptation strategies among grain farmers in Goronyo LGA of Sokoto state. Over the 30 years examined, rainfall is characterized by large inter-annual variability. The annual total rainfall favours the cultivation of millet than sorghum and maize. In addition, the study also revealed that the length of the rainy season in Goronyo is too short for the effective cultivation of grains without employing adaptive strategies. Summarily, the characteristics of rainfall and temperature in the study area are not consistent. Major Adaptation strategies of farmers in Goronyo are: Crop rotation, mixed cropping, use of improved seed varieties, shifting cultivation, intensification of irrigation or fadama farming and use of organic and inorganic manure among others. The study also showed that a decrease in rainfall is likely to push farmers to delay their planting dates. Factors that enhances the farmers' adaptive capacity to climate change includes: the farmers' farming experience, the farmers' ability to perceive changes to weather and climate indices, access to credit loan etc.

RECOMMENDATIONS

Following the findings made in the study within the 30 years covered, the following recommendations are made:

i. Since the annual rainfall totals favours the cultivation of millet, grain farmers should focus more on millet cultivation so as to maximize millet yield in the area.
ii. Grain farmers should adopt viable adaptation strategies such as: improved seed varieties, Irrigation farming (since the study area is close to the Goronyo dam), credit loan, mixed cropping, crop rotation, shifting cultivation etc
iii. Government policies should therefore ensure that farmers have access to improved seed varieties, chemical fertilizer, water for irrigation and affordable credit as these increases the resilience of farmers to climate variability.

iv. The Goronyo dam should be developed and opened up for farmers' use as most of the farming activities in the study area is carried out around the Goronyo dam area, mostly maize cultivation.

ABSTRACT

This study assessed the public perception of climate change and its impacts on health and environment in Zaria city and its environs. The objective of the paper was to find out the level of awareness by the public on climate change and its impact on health and the environment. Simple random sampling technique was used in the selection of 400 respondents in the study area. The public perception of climate change and its impact on health and environment were obtained by means of structured questionnaire. Results were analysed and presented in tabular forms, percentages and pie charts. This study revealed that 82% of the respondents are well aware of the dynamics of the local climate. Age, gender, occupation and the educational level of the respondents affected their knowledge of climate change. The electronic media (television and radio) is the major source of awareness of climate change. Based on the findings of the study, some recommendations were made which include the need for a comprehensive environmental education by the government and non- governmental organizations to educate the public on the causes and effects of climate change on health and the environment; studies on climate change, adaptation and other environmental issues should be integrated into the primary and secondary school curriculum among others. This study concluded that climate change has negative impacts on health and the environment in the study area.

Keywords: Climate change, Environment, Health, Public perception and Zaria

INTRODUCTION

Global climate change has become one of the most visible environmental concerns of the 21st century. Climate change endangers human health, affecting all sectors of society, both domestically and globally. The environmental consequences of climate change, both those already observed and those that are anticipated, such as sea-level rise, changes in precipitation resulting in flooding and drought, heat waves and degraded air quality, will affect human health both directly and indirectly. Addressing the effects of climate change on human health is especially challenging because both the surrounding environment and the decisions that people make influence health. The World Health Organization defines "environment" as "all modifiable physical, chemical, and biological factors external to the human host, and all related behaviors that are critical to establishing and maintaining a healthy livable environment," Interagency Working Group on climate Change and Health (IWGCCH, 2010).

There is abundant evidence that human activities are altering the earth's climate and that climate change will have significant health impacts both domestically and globally. While all of the changes associated with this process are not predetermined, the actions we take today will certainly help to shape our environment in the decades to come. Some degree of climate change is unavoidable, and we must adapt to its associated health effects; however, aggressive mitigation and adaptation actions can significantly blunt the worst of the expected exposures. Climate change and health issues transcend local and national borders, and climate change health impacts in a community are likely to affect health in the neighborhood as well. Famine, drought, extreme weather events, and regional conflicts—all likely consequences of climate change—are some of the factors that increase the incidence and severity of disease,

Ikpe E, Sawa B. A., Ejeh, Udeh L, Meshubi O. Adekunle & Oladimeji J. S. (2016). Analysis Of Public Perception Of Climate Change And Its Impact On Health And Environment In Zaria City And Its Environs In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 75-81

as well as contributing to other adverse health impacts, making it imperative to address climate change-related decision making at local, regional, national, and global levels. The complicated interplay of these and other factors must be considered in determining the scope and focus of both basic and applied research on climate change and health. Climate change, in the most general sense –encompasses all forms of climatic inconstancy (that is, any differences between the "long-term" statistics of the meteorological elements calculated for different periods but relating to the same area), regardless of their statistical nature or physical cause, Maunder (1994). Climate change may be due to natural changes or to persistent chemical changes in the composition of the atmosphere or in land use. Climate change is the end product of a changing climate. Climate change is said to exist when the level of climatic deviation from the normal is very significant over a long period of time (preferably centuries) and such deviations have clear and permanent impacts on the ecosystem, Odjugo (2009).

Perception is a process by which organisms interpret and organize sensation to produce a meaningful experience of the world. It is the process by which we receive information or stimuli from our environment and transform it into psychological awareness, IPCC (2001). According to Merriam-Webster dictionary (2014) Perception is "awareness of the elements of environment through physical sensation. It is the ability to understand or notice something easily". Perception is our recognition and interpretation of sensory information. Perception also includes how we respond to the information. Doss and Morris (2001) opine that the perspectives of the local people, the way they think and behave in relation to climate, as well as their values and aspirations have a significant role to play in addressing climate change. In spite of this, traditional people are only rarely considered in academic, policy and public discourses on climate change, though the impact of impending changes of climate is greater on them, Adefolalu (1986). It is interesting to see that people infer about a certain situation or phenomenon differently using the same or different sets of information. Knowledge, interest, culture and many social processes seem to shape the behaviour of an actor who uses the information and tries to influence that particular situation.

The Intergovernmental Panel on Climate Change, IPCC's (2007) Fourth Assessment Report summary for Africa describes a trend of warming at a rate faster than the global average, and increasing aridity in many countries. Climate change exerts multiple stresses on the biophysical as well as the social and institutional environments that underpin agricultural production, IPCC (2007). "The great moral dilemma posed by climate change is clearly revealed in the differences in risks posed to health and survival, both between and within populations, and between present and future generations. The risks to human health provide one of the strongest signals of the profound significance of climate change as a threat to the planet's life support processes. There is much evidence that climate change is proceeding faster, and with more unexpected manifestations, than predicted by climate scientists a decade ago (e.g. Rahmstorf et al. 2007; Steffensen et al. 2008). Various positive feedback processes (able to accelerate the warming) are occurring, as "tipping points" are reached. Examples include the melting of Arctic sea-ice, which reduces the albedo (reflectance) of the Arctic surface, and the increase in atmospheric water vapour (a greenhouse gas) due to warming-enhanced evaporation. Hence, risks to human health may rise sooner and more widely than has been anticipated, as in the latest Assessment Report of the Intergovernmental Panel on Climate Change", IPCC (2007).

"Research on the health effects of Climate Change has focused largely on direct physical health impacts, principally death and injury from extreme-weather events, impacts of increased temperatures and heat waves, spread of vector-borne disease, air quality and respiratory illness, and changes in food and water quality and availability. The WHO

estimates that Climate Change already accounts for more than 60,000 deaths globally from climate-related natural disasters every year, along with at least another 100,000 deaths from malaria, malnutrition, and child diarrhea. It is anticipated that there will be changes in airborne pollutants, leading to increased respiratory problems. The incidence of some infectious diseases, such as gastroenteritis, is predicted to rise, and there will be changes in the distribution and intensity of mosquito-transmitted diseases, such as malaria, yellow fever, and dengue fever. Research has suggested that the risks of diarrheal disease may be augmented by the increased temperatures that result from Climate Change. One study showed that for every degree of increase in temperature, the rate of hospitalization of children with diarrhea increased by 8%. It has also been predicted that gastrointestinal infections, which are already common in our community, are likely to increase with higher temperatures. The more vulnerable members of our community will be most affected by climate-related illnesses. These include the elderly, who cope less well with changes in temperature, and young children, whose developing lungs are susceptible to ambient air pollution"- Asekun-Olarinmoye E. et.al (2014).

The potential child-health impacts of severe weather include drowning, gastrointestinal disease, malnutrition, and psychological trauma. Health indicators in children, such as infant mortality rate and under-five mortality rate, are already unacceptably high in Nigeria. More importantly, the prevalence of childhood malnutrition in rural areas has been reported to be much higher than in urban settings in Nigeria. The health impacts of Climate Change on children, especially rural children, who are most often marginalized, will be an additional burden, Asekun-Olarinmoye E. et. al (2014).

One of the greatest impacts of climate change is the worsening condition of extreme weather events like drought, flood, rainstorms, windstorms, thunderstorms, landslides, avalanches and tsunamis, among others, Odjugo (2001). Odjugo (2008) noted that the frequency and magnitude of wind and rainstorms did not only increase, they also killed 199 people and destroyed property worth N85.03 billion in Nigeria between 1992 and 2007. Odjugo (2010a) shows that climate change has led to a shift in crops cultivated in northern Nigeria. Climate Change would also directly or indirectly affect population and human settlements in Nigeria. In general, about 15% of the country's population is presently affected by climatic variation and sea level changes. With climate change, between 50% and 60% of the population would be affected. The excessive heat, increasing water stress, air pollution and suppressed immune system occasioned by climate change will result in increasing incidence of excessive death due to heat exhaustion, famine, water related diseases (diarrhea, cholera and skin diseases), inflammatory and respiratory diseases (cough, and asthma), depression, skin cancer and cataract, Odjugo (2010b) & Deweerd, (2007).

METHODOLOGY

Study Area

Zaria is located at approximately 11° 3¹ north of the equator and on longitude 7° 42¹ East of the Greenwich meridian and at about 660m above sea level. It is the second largest city in Kaduna state after Kaduna town. Zaria is one among the 23 local government areas in Kaduna state. It is surrounded by Sabon Gari local government area (LGA) to the north, Soba LGA to the east and Giwa LGA to the west. The climate of the study area is a tropical savanna climate, with distinct wet and dry seasons (Aw climate Koppens classification). Zaria experiences six (6) months of rainy season and six (6) months of dry season. The rainy season is from May to late October, while the dry season is from early November to April, this is as a result of the interplay of the two dominant air masses within the region i.e. the tropical continental air messes (cT) and Tropical maritime air masses (mT) (Iguisi and

Abubakar, 1998 in Yusuf and Shuaibu 2012). The mean daily maximum temperature is at the peak in April and about 39ºC while the mean minimum temperature rises from its lowest value in December to January to its highest in July to August (Ojo, 1982 in Yusuf and Shuaibu 2012).

The soil type of the study area is alluvial soil, also the area constitute dark vertisol referred to as "fadama" soil (Hausa) this soil is classified as hydromorphic soil. The region generally falls within the Guinea Savannah vegetation. The climax climatic vegetation of the area ought to be northern Guinea Savannah, but because nearly all vegetation within the stream system has been degraded due to man's activities such as intense cultivation, fuel wool felling, the real climax vegetation is almost absent. The drainage system focuses on River Galma and Kubanni River. River Galma is a major tributary of River Kaduna and Kubanni River, on which Ahmadu Bello University Dam is situated.

Sources of Data and Sampling technique

Questionnaire was the main source of primary data for this study. The number of questionnaire used was based on the population of the study area. To determine the sample size for the study, the Krejcie and Morgan's (1970) method of determining sample size was adopted which states that for an area with a population between 75,000 - 999,999 the sample size to be used is 382. Since the population of the study area is 408,198 persons by the 2006 census, which falls between these ranges, the sample size of 382 is in order. Meanwhile, 400 respondents were used. Interview and personal observation were also used to source for data. Simple random technique was used to administer the questionnaire to the 200 males and 200 females in the study area. Analysis and presentation of information from the questionnaire was done using percentages, charts and tables.

FINDINGS AND DISCUSSION

Awareness of Climate Change

It is true, that the issue of climate change is no longer news but a reality as its signs are all around us today. Awareness is having a knowledge or understanding of a subject, issue or situation. Adaptation to climate change requires that the public first notice that the climate has altered. The public then need to identify potentially useful adaptations and implement them. Table 1 shows the public awareness to climate change issues.

Table 1: Public awareness of climate change issues

Awareness	Respondents	Percentage
Yes	328	82
No	72	18
Total	**400**	**100**

Source: Field Survey 2008

The above table shows that 82% of the public are aware of climate change issues in Zaria and its environs.

Table 2: Age and knowledge of Climate change issues

Age (year)	Climate change (%)	Global warming (%)	Ozone depletion (%)	Green house gases (%)
Less than 20	75	62.5	43.8	62.5
20 – 29 years	92	92.8	88	88.8
30 – 40	82	78.6	78.6	75
41 – 50	69.5	78.3	69.6	73.9
51 and above	75	75	62.5	62.5
Chi square test	0.000*	0.000*	0.000*	0.000*

Note* significant at 0.05

Source: Field Survey 2008

The age of the respondents affects their knowledge of climate change. Those that are between the ages of 20-40 years are better informed about climate change issues as shown in table 2.

Table 3: Education and knowledge of Climate change issues

Education	Climate change (%)	Global warming (%)	Ozone depletion (%)	Green house gases (%)
None	40	40	46.6	26.6
Primary	63.3	60	70	66.6
Secondary	71.8	68.8	78.1	75
Tertiary	94.2	94.2	93.1	94.2
Traditional	83.3	80.5	72.2	75
Chi square test	0.000*	0.000*	0.000*	0.000*

Note* significant at 0.05

Higher level of education is often hypothesized to increase the probability of adopting new strategies (Adesina and Forson 1995). Indeed, education is expected to increase one's ability to receive, decode, and understand information relevant to making innovative decisions (Wozniak 1984). The educational levels and levels of awareness of the respondents are presented in table 3.

Table 4: Occupation and knowledge of global climate change issues

Occupation	Climate change (%)	Global warming (%)	Ozone depletion (%)	Green house gases (%)
Farmers	82.6	60.8	60.8	56.2
Traders	76	80	68	44
Students	78.9	84.2	78.9	84.2
Professionals	77.7	77.7	77.7	66.6
Civil servants	92.5	87.5	90	87.5
Others	94.4	88.8	83.3	88.8

Source: Field Survey 2008

Table 4 illustrated that occupation affects ones knowledge of climate change. Farmers and civil servants are better informed about climate change issues.

Table 5: Gender and knowledge of global climate change issues

Gender	Climate change (%)	Global warming (%)	Ozone depletion (%)	Green house gases (%)
Male	83.9	76.9	75.5	69.9
Female	82.4	66.6	64.9	61.4
Chi square test	0.000*	0.000*	0.000*	0.000*

Source: Field Survey 2008

The survey revealed that gender affects ones knowledge on global climate change issues as males are better informed about climate change issues in the study area.

Sources of Awareness on Climate Change

Of the many sources of information available to the respondents on climate change related issues in Zaria city and its environs, electronic media is the most important, followed by the school, printed materials and personal observation. This is displayed in table 6.

Table 6: Sources of information on climate change issues

Sources	Respondents	Percentage (%)
Interacting with friends	30	7.5
School	50	12.5
Printed materials	40	10
Electronic media	112	28
Personal observation	40	10
All of the above	108	32
Other sources		
Total	**400**	**100**

Source: Field Survey 2008

Table 7: Public Perception Of The Impacts Of Climate Change

Perception	No. Of Respondent	Agreed (%)	Disagreed (%)	Undecided (%)
Rainfall Amount Fluctuates Year In Year Out	400	77	18	5
Temperature Getting Warmer	400	70	21	9
Number Of Rainy Days Have Reduce	400	67	22	11
Rain Episodes Are More Stormy	400	63	21	17
Floods After Rain Are More Common	400	74	21	5
Harmattan Period Is Now Shorter	400	47	38	13
The Changing Climate Has Led To Crop Infestation And Diseases By Pest	400	67	17	16
High Temperature Encourages The Breeding Of Mosquitoes And Easy Spread Of Diseases	400	70	20	10
Excessive Heat, Increasing Water Stress Etc. Resulting From Climate Change Causes Famine, Water Related Diseases, Inflammation And Respiratory Diseases.	400	75	15	10

Source: Field Survey August 2012

The public perception on weather and climate change indices was analyzed; 77% of the respondents perceived that rainfall amount fluctuates; 70% noticed that temperature is getting warmer; 67% observed that number of rainy days have reduced; 63% noticed that rain episodes are more stormy; 74% agreed that floods after rain are more common and only 47% stated that the harmattan period is now shorter; 67% agreed that the changing climate has led to crop infestation and diseases by pest and 64% believed that high temperature resulting from climate change encourages the breeding of mosquitoes and easy spread of diseases.

FINDINGS AND DISCUSSION

i. Majority of the public (82%) are well aware of climate change issues.
ii. Public perceptions of climatic variability are in line with climatic data records reviewed in the literatures.
iii. The study further revealed that age affects knowledge on global climate change issues as those between 20 - 40 years have better knowledge and practical experience of climate change issues.
iv. More so, education and occupation is a major determinant of the level of awareness of global climate change issues as those with tertiary education, students and civil servants are better informed about climate change issues.
v. Electronic media is the main source of awareness on climate change issues.
vi. Climate change affects the biophysical and socio-economic aspects of the environment.

RECOMMENDATION

Following the findings of the study, the following recommendations are made:

i. Since the electronic media is the main source of awareness on climate change issues, the government and relevant organizations should utilized the advantage of the public media to educate and inform the general public on climate change issues and its devastating impacts on human health and environment.
ii. Studies on climate change, adaptation strategies and other environmental issues should be integrated into the primary, secondary and tertiary curriculum.
iii. Further studies of the science of climate change and its potential impacts in Nigeria is important in creating awareness and providing the background information for targeting policies adequately

ABSTRACT

The importance of maintaining a healthy and sustainable environment cannot be overemphasized. Over the years, human have continued to deplete the natural environment at a faster rate than it can be replaced. Desertification, problems of pollution, loss of green areas, improper solid waste disposal systems have become recurring decimal in Nigeria urban centres. This degradation has been attributed to ignorance, poverty, overpopulation and greed amongst other. A major contradiction of the 21st century is the exceptional economic growth and technological advancement which, while benefiting many people have unleashed inexorable social and environmental impact on humanity. While cities continue to grow, there is the need to plan and effectively manage this growth so that human relationship with the built environment will not continue to degrade the environment. This paper through an elucidating literature review examines the roles of green infrastructure at tackling the challenges of environmental degradation in Nigeria. Green infrastructure consists of spatially or functionally connected areas which maintain ecological coherence as an essential condition for healthy ecosystems. This paper proposed that the purpose of effective green infrastructure planning and management is not only to reconnect species populations but also to mitigate further environmental degradation and as well enhances the quality of life in the built environment.

Keywords: Environmental degradation, Green infrastructure, Natural resources, Sustainability, Urbanization

INTRODUCTION

The concern about environmental degradation to a large extent stems from the universal concern about sustainable development arising from natural resource exploitation and utilization. Although high population increase and economic developments has been fingered as a factor in environmental degradation, so much weight has been given to the social problem of depleting the green spaces as a major factor in environmental degradation (Egger, 2006; Gutman, 2007; Fadamiro and Adedeji, 2014). Challenges of environmental degradation is today becoming more prominent not only among developing countries of the world but, ubiquitous globally. Indeed, the intertwining relationship between urbanization, the problem of sustainable development and urban green resource exploitation is crucial as it is paradoxical.

However, the need to control environmental degradation in Nigeria is to achieve a sustainable environment which is in line with Goal 15 in the newly developed Sustainable Development Goals (SDGs) so that Nigeria will also conform to the global quest for developing nations sustainably. Very prominent among the definitions of sustainable development is that of the World Commission on Environment and Development (WCED, 1987) which sees sustainable development as the developments that meets the needs of the present without compromising the ability of future generations to meet their own needs.

Also, Haggag and Elmasry (2011) referred to a sustainable development as a socio-ecological process characterized by the fulfillment of human needs while maintaining the natural environment. The idea of sustainable development involves enhancing the quality of life, thus allowing people to live in a healthy environment, with improved social, economic and environmental conditions (Ortiz et al, 2009). However, the advancement in technology,

Dipeolu, A. A. & Fadamiro, J. A. (2016). Mitigating Effect of Green Infrastructure on Environmental Degradation in Nigeria Urban Centres. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 82-90

exceptional economic growth and the quest to cater for the rapid human population growth have unleashed inexorable social and environmental impact on humanity in Nigeria and other nations of the world. This therefore requires urgent approach to stabilize the environment and institute measures which can make the built environment to develop sustainably and tackle further degradation.

Green infrastructure has been suggested as a viable ecosystem network that is capable of creating environment that is cool, clean and habitable for different species of plants and animals as well as comfortable built environment. Countryside Agency (2006) in the UK asserted that green infrastructure comprises the provision of planned networks of linked multifunctional green spaces that contribute to protecting natural habitats and biodiversity, enable response to climate change and other biosphere changes, enable more sustainable and healthy lifestyles, enhance urban liveability and wellbeing, improve the accessibility of key recreational and green assets, support the urban and rural economy and assist in the better long-term planning and management of green spaces and corridors.

This article therefore emphasized that effective green infrastructure planning and management is capable of mitigating further environmental degradation and can provide viable strategies for achieving sustainable environment in Nigerian cities. Specifically, the article attempts to answer the following research questions pertaining to environmental degradation in Nigeria: 1) what are the causes and consequences of environmental degradation in Nigeria? 2) How can green infrastructure respond to challenges of environmental degradation and provide ecological networks for developing Nigerian cities sustainability? This research is potentially significant due to the emphasis in the global fight for environmental sustainability, and the Nigerian environment lacking prompt strategies at combating environmental disasters. The study was carried out through desktop research methods; these include searching for relevant documents and research articles from peer reviewed journals over the internet, gathering and collating relevant information from published and unpublished articles, consulting journals database resources like the Hinari initiatives and others freely available on the internet. Information gathered were reviewed, discussed and presented descriptively with appropriate recommendations and conclusion.

Study Area

Nigeria, a country located in West Africa with a population of about 150 million people and an area of 923,000 square kilometers, lies between 04 16^0 and 13 53^0 North of Latitude and 02 40^0 and 14 41^0 East of longitude. The country is bordered in the west by The Republic of Benin and in the East by Chad. It also shared border with the Niger Republic in the North and in the Southern part by Cameroun. It has 36 administrative states, a Federal Capital Territory (FCT), It has 774 Local Government Authorities (LGAs) and 6 main geo-political zones (Muhammad, Salisu and Umar, 2014).

Nigeria is rich in biodiversity as the country is well endowed with a variety of plant and animal species like many other nations of the world. There are about 7,895 plant species identified in 338 families and 2,215 genera (Federal Government of Nigeria, FGN, 2010). To take advantage of the biodiversity as well as the rich vegetation which ranges from the mangrove and thick forests in the South, followed by Savannah and the Sahel in the middle belt and the North respectively, Nigerian Economy is dominated by Agriculture. The paradox of Nigerian Agricultural economy is such that while it is producing food for the economic growth, the desire to expand agriculture has brought serious degradation to the environment.

SUSTAINABLE DEVELOPMENT GOALS

The Sustainable Development Goals (SDGs) was adopted on September 25th 2015 when countries of the world gathered to review the formal Millennium Development Goals (MDGs) which ended in 2015. The Sustainable Development Goals, officially known as *Transforming our world:* the 2030 Agenda for sustainable development are an intergovernmental set of aspiration goal with 169 targets. These set of goals are targeted to end poverty, protect the plant, and ensure prosperity for all as part of a new sustainable development agenda. There are 17 goals in all some which are: No poverty, affordable and clean energy, climate action, zero hunger, good health and well-being etc. Each goal has specific targets to be achieved over the next 15years. Specifically, Goal 15 is sub-titled LIFE ON LAND: *protect, restore and promote sustainable use of terrestrial ecosystem, sustainably manage forests, combat desertification, and halt and reverse land degradation and halt biodiversity loss*. This goal is of great relevance to the topic under discussion. If environmental degradation is appropriately tackled, this will contribute positively to the achievement of goal 15 in the Sustainable Development Goals.

Understanding Environmental Degradation

The United Nations, UN (1997) refers to environmental degradation as the deterioration of the natural environment through human activities and natural disasters. The term environmental degradation implies that environmental resources such as land, soils and vegetation are reduced to a lower rank taking into account the fulfilment of given demands. Following this definition, Reed (2007) defined environmental degradation as the reduction in value of the environment to meet its ecological and socio-economic needs. It includes issues such as deforestation, desertification, land degradation, loss of biodiversity, various levels of pollution, climate change, sea level rise and ozone depletion. Also, Omofonmwan and Osa-Edoh (2008) submitted that environmental degradation implies "abuse of the environment" due to improper resources management. The emphasis of these definitions is on proper accountability in the management of earth's abundant natural resources and the systematic uses so that earth resources will not easily go into extinction and can be available for the coming generation.

Although environmental degradation is not a new concept, but it is rapidly gaining more attention now than before because environmental problems are now occurring at a much faster rate, therefore not leaving enough time for the environment to recover and regenerate (Owolabi, 2012). Apart from its effects in Nigeria, environmental degradation is causing great havoc globally with the effects becoming much pronounced in developing countries especially due to the fragile economy strength and development in such areas. Statistical evidence of the effects of environment degradation by the United Nations have estimated that, of the 8.7 billion hectares of arable land, pastures and forests worldwide, nearly 2 billion of them have been degraded over the past 50 years, of which 18% are of forest land, 21% are of pasture land and 37% are of arable land (Haaften et al., 2004 cited in Muhammad et al., 2014).

Concept of Green Infrastructure

Green Infrastructure is a concept originating in the United States in the mid-1990s that highlights the importance of the natural environment in decisions about land use planning. Since then, the concept has spread rapidly through UK, Europe and other continents of the world. Howard, cited in Mell (2011) stated that the UK sees green infrastructure develop through the ideas of garden cities and the protected designations of green spaces. While in Europe, the development of green infrastructure has been linked with the development of the

urban greening agenda and the need to develop integrated green space effectively within high density landscapes (Beatley, 2009). However, in contrast to the UK and Europe, Benedict and McMahon (2006), affirmed that the North American green infrastructure development has its foundations in landscape conservation.

Green infrastructures are resilient landscapes that support a multitude of ecological, economic and social functions without compromising the sustainability of a resource base. They may comprise a number of different landscape elements that vary in size, composition, and function (Mell, Roe and Davies, 2009; Mazlina, Zalina and Khalilah, 2015). What characterises green infrastructure resources are their ability to meet a wide variety of needs – sometimes termed 'ecosystem services - in diverse urban, urban-fringe and rural locations (See Table 1). Green infrastructures have been proposed to promote access and connectivity, function sustainably across different spatial areas, be planned strategically and holistically, support diverse ecological, economic and social needs, and to promote a more holistic approach to landscape management (Benedict and McMahon, 2006; Davies et al., 2006; Kambites and Owen, 2007). Recently, green infrastructure development has started gaining prominence in Nigeria even though; this development is still very slow compared to the situations in the developed world. Many states in Nigeria are emphasizing the need to green up the environment. For example, there are designated sites in Lagos, Oyo, Rivers and Kano states where green infrastructure projects can be appreciated.

Table 1: Classification of Ecosystem services of Green Infrastructure

Consequences of Environmental Degradation in Nigeria

Nigeria's cities are often criticized as having sprawling, low-density development, over-use of non-renewable natural resources, social inequities, including poverty and economic hardship and pollution of air, water and soil (Balogun et al., 2011; Isah, 1998). Therefore, environmental sustainability has faced critical problems in Nigeria. Several factors ranging from increasing population, demolishing of natural resources, environmental pollution, unplanned land use and several others are responsible for this (Balogun et al., 2011). The need for corresponding development that can take care of the rapid population growth and the over dependence on agricultural activities in Nigerian economy has seriously degraded both the natural and the built environment. Environmental degradation of varying types and degree are very rampart in Nigeria. Muhammad et al. (2014) noted that coastal erosion, water pollution and marine biodiversity loss are typical in the southern coastal areas of Nigeria while the central states suffers from salinization and acidification of soils and sediment discharge on lower Niger-Benue catchments. Deforestation, salinization and loss of plant diversity are most widespread in all parts of Northern Nigeria. The increasing intensity of agricultural activity due to population growth may be the most important factor influencing this process.

Unkempt environments, poor road network, lack of proper refuse disposal, smoke from refuse burning are very ubiquitous in most Nigerian cities (See figures 1 and 2). Whereas these environments can be landscaped sustainably, they are often neglected and these increased degradation of the built environment and consequently impeding the sustainability of the natural environment. Regionally, cases of flooding, rainstorm, oil spillage, drought, erosion and many other dysfunctional environmental phenomenons have become routine

occurrences in Nigeria (Dipeolu, 2015). For example, the routine floods in the South Western Nigeria (See figure 3), the deep erosion in the South Eastern Nigeria, the extreme weather conditions that generate heat and drought of the desert in Northern Eastern Nigeria, have all been traced to the excessive depletion of most forest areas in Nigeria and these poses threat to quality environment (Balogun et. al., 2011; Fadamiro and Adedeji, 2014; Dipeolu, 2015;). In Niger Delta region, the cumulative practice of environmental degradation arising from pollution of land, gas flaring, oil spillage and release of various carbon contents during oil exploration (See figures 4a, 4b & 4c) have contributed a lot to climate change and other challenges in the environment. Instead of leaving these challenges to continue to threaten human existence, green infrastructure projects implementation can urgently rescue the sustainability of the built environment from collapsing.

Responses of Green Infrastructure to Environmental Degradation Challenges

Carbon Sequestration

This is the process of removing excess carbon dioxide (CO_2) from the atmosphere through engineering processes, chemical processes and biological or agricultural processes. Carbon sequestration is required so as to slow the atmospheric and marine accumulation of greenhouse gases (Which are the major constituents of global warming inducing agents) which are released by burning of fossil fuels into the atmosphere. In agricultural sequestration, plants absorb carbon dioxide during growth and release oxygen which is needed for man effective respiratory system. It simply implies that the more the green spaces in the environment, the less the amount of carbon dioxide that will be present in such an environment since there will be rapid competition for the few available carbon dioxide for the survival of the green plants in such environment (Tzoulas et al., 2007; Mazlina et al., 2015; Dipeolu, 2015).

Abatement for Air Pollution

Availability of green infrastructure facilities within urban centre aids adequate abatement for air pollution. Many impurities within the atmosphere are easily trapped by green infrastructure facilities like grasses, street trees, community forest, city farms, woodlands and other functional green spaces within the urban centre. Green infrastructure facilities (as abatement for air pollution) will be needed especially in areas where there are huge amount of fuel burning activities, major traffic ways, industrial compounds and various manufacturing sites laden with heavy power generating equipments.

Access to Tree Corridors

Green infrastructure like street trees, create opportunity for the provision of sidewalks, trails, and private streets, connected to transit stops and an interconnected street network. This consequently provides mobility options and helps to reduce pollution by reducing vehicle trips. It also encourages walking, bicycling, and other mobility options within the urban centres.

Restoring Lost Urban Environmental Greening

Urban environmental greening is an integrated citywide approach to the planning, care and management of all vegetation in a city to secure multiple environmental and social benefits to urban dwellers. It is the practice in which a significant percentage of urban environments are allowed to maintain adequate vegetal cover such as trees, shrubs, vines, flowers, grasses and other form of (vegetal) ground cover (Sorensen, 1997; Dipeolu, 2015). Effective green infrastructure enhances the restoration of the initial lost environmental greening which had occurred as a result of the need to cater for economic, industrial and human population explosion. As the green spaces increase in the built environment, it contributes to having facilities that enhance sustainability in the built environment and brings gradual reduction environmental degradation.

Improves quality of life in the built environment

Green infrastructure plays a very prominent role at improving the urban environment. It is a viable strategy to create access to nature within the built environment as it encourages rapid urban environmental greening by maintaining green open spaces and enhancing appreciable vegetation cover in the built environment. Past literatures have linked natural settings and green spaces to have positive effects on human health. Most of these studies confirmed that activities around green spaces produced positive psychological and physiological effects for human restoration from directed attention fatigue (Kaplan, 1995; Lau and Yang, 2009; Tzoulas et al., 2007; Mell, 2010; Mazlina et al., 2015).

Improves quality of air in the built environment

Plants and trees have a positive impact on the air human being breathe. Plants produce oxygen as a by-product into the environment which human being need oxygen to survive. Highways produce carbon, first by the construction process, but more significantly over time is the carbon produced by combustion of petroleum-based fuels by the vehicles using the highways. Highways are great air pollutants. But plants and especially trees have a much more positive impact on air quality (Coder, 1996). In addition, trees, plants and lawns have huge impacts on temperatures and energy use, especially in urban areas. A landscape lowers local air temperatures by transpiring water and shading surfaces. Because trees lower air temperatures, shade buildings in the summer, and block winter winds, they can reduce building energy use and cooling costs.

Possibility of Green Roofs on Buildings

Green roofs are building roofs that uses living plants as the exposed surface. They are very prevalent in Europe and in the United States but are just been introduced to Nigerian building industry. The advantages to a green roof are that it can reduce energy use by moderating temperature on the roof and surrounding areas. It also can systematically reduce storm runoff volume and peak flow rate by holding and releasing storm water slowly. A green roof can also restore the ecological and aesthetic value of urban open space by replacing a stark conventional roof with a green, softer roof line (PLNA, 2013). With more green roofs in Nigerian environment, it implies more green spaces, more access to nature and consequently more quality of life in the built environment.

CONCLUSIONS AND RECOMMENDATIONS

Man's capability to transform his environment can bring the benefits of economic development and an opportunity to enhance the quality of life. But this same power, incorrectly applied, can also cause very serious harm to the natural environment and consequently to human life. Due to anthropogenic activities, the earth surface is being significantly altered in some manner and man's presence on earth and his use of land has had a profound effect on rather all meteorological/climate parameters (Balogun et al., 2011). There should be no delay in tackling the task of solving these environmental problems, as this degradation has cumulative impact. Delayed remedial action will cost considerably more and the damage will become irreversible. (Chaudhary, 2011).

This article has seen green infrastructure as a network of multifunctional greens pace, both new and existing, both rural and urban, which supports the natural and ecological processes and is integral to the health and quality of life of sustainable communities. Through proactive planning, design and management it has been shown that green infrastructure can reduce carbon, promote renewable energy, improve air quality, control flooding, serve as wind breaker, moderate local micro-climates, enhance biodiversity, improve water management, facilitate more sustainable modes of transport, promote healthy communities, contribute positively to the quality of place and control further environmental degradation. Effective

green infrastructure planning and implementation is therefore considered to be very relevant in achieving Goal 15 in the Sustainable Development Goals.

In light of this, the study recommends that Nigerian government at all levels should be more proactive in implementing policies for effective green infrastructure planning and management, more orientation programs for citizens on proenvironmental attitudes towards sustaining the built environment and professionals and other stakeholders should be encouraged to collaborate with the government to win the current war against abuse of both the built and the natural environment. With this appropriately utilized, environmental degradation challenges in Nigeria can be sufficiently tackled.

ABSTRACT

The importance of having acceptable indoor environmental quality in building interiors have been well established in rating systems like BREEAM and LEED. However, in a developing nation like Nigeria, where rating systems are under consideration and adequate provision for power is a challenge, retailers in commercial buildings tend to provide power generating sets on their own, more so the influence of vehicular traffic on indoor environment is also of concern to researchers. In the development of a green building rating system for Nigeria, models need to be developed as to the patterns of carbon monoxide (CO) levels in commercial buildings in the country. The purpose of the quantitative study is to assess the level of CO in the terraces of buildings in the Obanla district of Akure in October 2015. Eighty commercial cum residential buildings was assessed in the Ijomu, Obanla commercial axis in Akure, the capital of Ondo State, using dSense Portable CO Meter - a hand held CO monitor, on a once a week measurement, for a month. The implication of increased exposure of CO levels usually from generator fumes and vehicular traffic could lead to reduction in the oxygen carrying capacity of the blood. Results showed that the average one hour measurements for eighty positions were 1.225ppm for week one, 1.775ppm for week two, 1.475ppm for week three and 4ppm for week four. These average levels are lower than the WHO indoor air requirement of 30ppm for 1 hour and the USEPA (NAAQS) 35ppm outdoor air 1 hour average.

Keywords: carbon monoxide levels, green building rating system and indoor environmental quality

INTRODUCTION

World Congresses of States especially the United Nations, UN Conference on Sustainable Development, Rio+20 (UN, 2012; the Earth Summit, 2015) have raised concerns on the sustainability of the environment, such issues as depletion of renewable and non-renewable resources, pollution of air, water and land, soil degradation and high level of waste generation have been of concern to researchers (Day, 2004; Roaf, Fuentes & Thomas, 2007).

In advanced nations, the concept of green buildings and rating of buildings' have been explored as a practice that can reduce impacts of the building industry on the environment (Brophy & Lewis (2011); Atkinson, Yates & Wyatt (2009). One of the basic principles of the established Building Research Establishment Environmental Assessment Method (BREEAM) is the health and Wellbeing aspect, which aggregates up to 15% of the rating for any building (Sleeuw, 2011, p.6; Potbhare, Syal, Arif, Khalfan, & Egbu (2009, p.110). Furthermore, levels of pollutants such as carbon monoxide (CO) and particulate matter level, all contribute in one way or the other towards rating the interiors of buildings. Other factors considered are carbon dioxide (CO_2) level, light level, humidity and temperature of building interiors. Also these environmental issues have raised concern(s) on the productivity and health of users in the interior of buildings and thus have increased the health risk of users of buildings, particularly the presence of CO sometimes leading to death of occupants, specifically where power is sourced through petrol electricity generators.

In developing nations such as Nigeria and Akure South Local Government Area precisely, research into assessment of CO levels are limited, especially in relationship to buildings, hence the importance of this work.

Afolami, A. J.; Ogunsote, O. O.; Elnokaly, A. & Okogbue, E. C. (2016). Assessment of Carbon Monoxide Levels in a Commercial District of Akure, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 91-96

LITERATURE REVIEW

Carbon Monoxide Levels and Health of Building Occupants

The purpose of the quantitative study is to assess the level of CO in the terraces of buildings in the Obanla district of Akure in October 2015 between 9am and 10am on selected days, this time was based on the previous work by Adegoke, Balogun, Odiase & Tate (2015, pg. 21), the authors observed 8am – 10am as one of the two peak periods of ambient CO concentration in Akure metropolis. Also, Farayola & Egunjobi, (2015, pg. 46) also noted that "CO concentration levels were significantly higher during the day than in the night" and concentrations of CO was observed to be higher in more densely populated areas than in the less densely populated areas. The Obanla research area is one of the down town, traditional area of Akure. The Ondo State Building and Subdivision Regulations (1984, Section 77-79) specifies that where natural ventilation is not feasible, mechanical means of ventilation can be procured for buildings to improve the health and safety of occupants. Section 80 of the regulations (Op. Cit), informs about noxious vapours, but no specifics about carbon monoxide (CO) is discussed in the regulations. The research questions raised are: What is the CO level in the terraces of buildings in Obanla – Oke Ijebu area of Akure down town? Is the air quality of these buildings in compliance with in country and international requirements?

Table 1: Comparative carbon monoxide exposure levels from different standards

S/N	Organization	Period	CO levels	Notes
1	ASHRAE	8hrs	9ppm	Standard 62.2 (2013)
2	USEPA	8hrs	9ppm	NAAQS (outdoor air)
		1hr	35ppm	NAAQS (outdoor air)
3	ACGIH	8hrs	25ppm	Threshold limit value
4	NIOSH	8hrs	35ppm	Recommended exposure limit
		15min	200ppm	Short term exposure limit
5	OSHA	8hrs	50ppm	Permanent exposure limit
6	WHO	24hrs	6ppm	Indoor air
		8hrs	9ppm	Indoor air
		1hour	30ppm	Indoor air
		15min	87ppm	Indoor air
7	NBC (2006)	1hour	200ppm	Car garages and connecting spaces
		8hrs	50ppm	Car garages and connecting spaces

Source: NBC (2006), Carbon monoxide levels and standards (n.d.)

Figure 1: research area bounded by Oke Ijebu Street, Obanla Street and Oba Adesida Road, Akure, Courtesy of Google Maps (2015)

Carbon monoxide is an odourless, colourless gas and it is a bye product of burning gasoline and natural gas. Common sources of CO are usually from automobiles, coal, oil and electricity generators. The site of action of CO is the haemoglobin in blood to which the

carbon monoxide attaches, leading to a loss of its oxygen carrying capacity and subsequent toxic effects" (Connell, Hawker, Warne & Vowles, 2005, p.8). CO is hazardous to persons with heart or circulatory problems, or people with damaged lungs or breathing passages (ASHRAE, 92.1, pg. 29)

Environmental Sustainability

The Encyclopaedia of life support systems describes sustainability in terms of "protecting the planet's life support systems to ensure longevity for humans and other species". The term 'development' was further explained as "progress in social well-being or improvement in the quality of life". While working towards this progress, it is important to take note that the ecological system is both global and finite, thus "observing nature's limit is important in order to prevent an irreversible depletion of the life support systems" (Bell & Cheung, 2002). Sustainable development is that which "meets the needs of the present without compromising the ability of the future generations to meet their own needs" (World Commission on Environment and Development (WECD, 1987). This is by far the most widely quoted definition of sustainability.

Kwami and Adi (2012) advices that governments, professionals and educational institutions should embrace sustainability in their programmes in order to advocate for social, humanitarian and environmental factors to be paramount in their day to day responsibility towards the people. Sustainability is seen as a panacea to everyday problems such as excessive rainfall leading to flooding which displaces people, disrupting businesses and family relations, a vivid example is the flooding in Kano State, Nigeria where residents in declared risk zones where further affected due to lack of enforcement (Nabegu, 2014, p.25), whirlwind and tornadoes in the United States, excess heat on sunny days and sometimes in the night causing discomfort, the cases of urban heat island in our city centres due to activities of humans (Taha, 1997, p.101), drought in the northern part of Nigeria, erosion leading to deep gullies in the eastern part of the country and ocean encroachment in the coastal state of Lagos, Nigeria. Sustainable design considers the urban fabric, thus designers makes it a point to deliver only buildings that fit local context (Bay & Ong 2006, p.226).

Green Building Rating System

There is a growing awareness of the term green buildings and green building rating systems in emerging nations (Potbhare, V., Syal, M., Arif, M., Khalfan, M.M.A. & Egbu, C., 2009, pg.100). In Africa, South Africa and Egypt are countries that have existing green building councils and rating systems (GBCSA, 2016; EGGBC 2016). However, in Nigeria, the development is at best still at the discourse level within the professional bodies, for example, several conferences such as Architects Colloquium have focused majorly on sustainable development for the economy (Adabamowo & Kusimo, 2008; Prucnal-Ogunsote, Okwoli & Ude, 2011).

A green building is a building that considers and then reduces its impact on the environment and human health (Yudelson, 2009). A green building in the United States and Canada is generally considered to be one certified by the Leadership in Energy and Environmental Design (LEED), green building rating system of the U.S. Green Building Council (USGBC) or Canada Green Building Council (CaGBC). Buildings generally consume too many resources to be overlooked laments Porter (2004), thus green buildings are designed to use considerable less energy and water than a conventional building and have fewer site impacts and generally higher levels of indoor air quality. Sensible House (2013) concretizes the idea of green buildings under five sub headings: energy, materials, health, water/landscape, design.

The establishment of a Green Building Council for Nigeria can be jump started by setting up a multidisciplinary committee at the level of the Nigerian Institute of Architects, Architects Registration Council of Nigeria, and other Registration Councils of the built environment disciplines; the Town Planners Registration Council, Council for the Regulation of Engineering in Nigeria, Council for the Registration of Builders, Quantity Surveying Registration Council of Nigeria, Surveying Registration Council of Nigeria, Chartered Project Management Institute of Nigeria. This idea by Ogunsote et al (2011) suggests firstly setting up web portal managed by various disciplines in the academia, the building industry and government agencies, the web portal of the Green Building Council should be hosted by the World Green Building Council website. The Stake holders according to US Green Build 2015 Expo flier usually includes: architects, engineers, interior designers, landscape architects, builders, code officers, building owners, contractors, developers, educators/schools, facility managers, financial service providers, government agencies, green building thought leaders, utilities.

Green building rating systems are defined as "tools that examine the performance or expected performance of a whole building and translate that examination into an overall assessment that allows for comparison against other buildings" (Fauler & Rouche, 2006). The aim of any building environmental assessment system according to Adegbile (2013) is to set criteria against which to rate a building and then to provide a score or descriptive rating for that building. This rating shows the building's environmental credentials which usually have commercial implications in terms of promoting sustainability image. Fowler and Rouch (2006) in the executive summary to the report for the General Service Administration (GSA) of the United States of America, advises that using a green building rating system allows for comparison with other GSA Buildings, other Federal Buildings and the US Building market and also as a means "to track GSA's progress towards designing and operating the best buildings for their occupants". In addition, the report assumes that "the rating systems reflect the values and priorities of the developers and countries". Maton (2013) suggested adoption of the LEED system of rating buildings in Nigeria because of the flexibility of LEED. Also Adegbile (2013) suggested the use of LEED in Nigeria, more reasons might need to be put forward towards the adoption of LEED in Nigeria, acceptance of LEED hook line and sinker may be a simplistic solution to the problem. Ultimately, sustainability will be measured based on local conditions (GRIHA, 2014). Green building rating systems promotes the use of simple techniques, passive energy principles that makes buildings more suitable for users for example; orientating the longer side of buildings in the East – West direction, the use of courtyards, atrium and cross ventilation (Brown & Dekay, 2001). Technological solutions is also encouraged; making use of alternative to grid power through photovoltaic (PV) cells, Task lighting, light control devices (Oyedepo, 2012), rainwater collection (Brophy & Lewis, 2011).

METHODOLOGY

The study made use of data collected through on site measurements as primary source, while secondary data was collected through published journals and standards. On selected days at exactly 9am, on the spot assessment using the dSense Portable CO Meter – a hand held CO monitor was used to collect data. This was recorded in a memo pad and later transferred to a Microsoft excel table which was later analysed using descriptive tools; tables and graphs.

The purpose of the quantitative study is to assess the level of CO in the terraces of buildings in the Obanla district of Akure, the terraces were selected as an initial aspect of the work and subsequent studies would be based on interiors of selected non-residential buildings. Furthermore, the terraces were selected because of the issue of access. It is easier to gain

access to terraces of commercial buildings, since it is considered as a semi-public space, this is because potential customers have the liberality to pause for a moment, deciding whether there is a need to enter the shops or not.

Precautions: as advised by CO meter operation manual (n.d.)

i. Allow CO meter to run self-test in a neutral environment, free of CO, since high CO may cause failure in passing self-test
ii. It is important to have backup batteries should in case low battery indicator comes up during the test
iii. Keep the meter away from electronic interference, which may cause erratic reading

FINDINGS AND DISCUSSIONS

The points that are known to constitute possible higher levels of CO can be studied to detail. Such as the Car park exit point into Oke Ijebu Street from the public car park area, the motorcycle repair/ park point and the vehicular inlet area to Obanla street from Oke Ijebu Street.

Table 1: Purpose of building in the study area

S/N	Building Types	Quantity	Percentage
1	Commercial	49	61.25
2	Commercial/residential	31	38.75
Total		80	100

Two types of buildings were found in the study area: commercial buildings amounted to 61.25% (Table 1) and residential rooming buildings with the rooms closer to the streets converted to commercial purpose 38.75%. Two buildings were under construction and was not included in the project.

Table 2: Building floor levels in the study area

S/N	Building Types	Quantity	Percentage
1	Bungalows	62	77.50
2	One Storey	16	20.00
3	Two Storey	2	2.5
Total		80	100

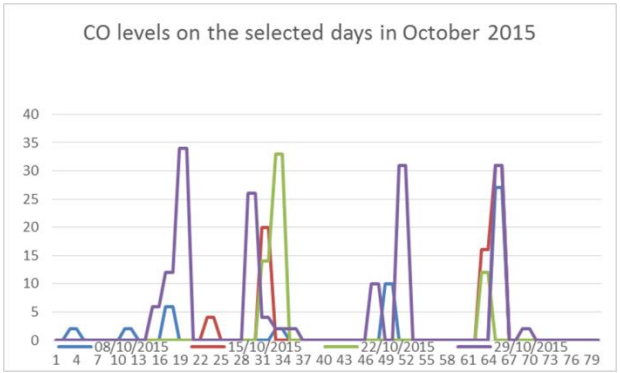

Figure 1: CO levels in station 1 to 80 on the selected days in October 2015.

Bungalows recorded as high as 77.50% of the buildings studied (see Table 2). One storey buildings accounted for 20% while two storey buildings were 2.5% of the lot. Comparatively, there is considerable increase in the level of concentration between study position 13 – 20, 28 – 34, 46 – 52 and 61-67. The highest reading occurred on 29/10/2015, as high as 34ppm. The average CO concentration levels for one hour at the eighty positions were 1.225ppm for week one, 1.775ppm for week two, 1.475ppm for week three and 4ppm for week four. These average levels are lower than the WHO indoor air requirement of 30ppm for 1 hour and the USEPA (NAAQS) 35ppm outdoor air 1 hour average.

CONCLUSION

The study shows that there are certain positions that have the possibility of high CO concentration levels (as high as 34ppm) in the study area – positions 13 -20 and 46 - 52. The study further shows that comparatively, certain positions in the study area for the four weeks have consistently high CO level emissions – positions 28 – 34 and 61 - 67. On the average, it was discovered that the one hour average is lower than WHO (indoor) and NAAQS (outdoor requirements). This shows that although previous studies have indicated that vehicular traffic and generator fumes increase CO levels in the environment, the levels are still within permissible limits in the study area.

Sustainable Site Planning; A Soil Conservation Strategy for Residential Developments in Lagos, Nigeria

Akagwu Mamajaunkwun

Department of Architecture, Federal University of Technology, Akure, Ondo State, Nigeria
majaakagwu@yahoo.com

ABSTRACT

The concept of sustainable has taken center stage as a key to addressing several tropical development problems. The residential built environment is a complex environment consisting of both artificial and natural elements. Soil conservation and management problems usually arise in residential areas in situations where the artificial elements largely dominate the residential plot. The research through the collection of primary and secondary data from questionnaires administered, observations, literature and case studies revealed that most developed residential plots in the study area have larger areas covered with artificial site organization elements. This research aimed at employing the principles of sustainable site planning in increasing the amount of natural elements or sustainable artificial elements of residential tropical plots in Lagos, Nigeria. It reveals that planning and monitoring were the major problems that brought about covering of large areas of residential plots by the built structure. This research recommended that the element of percentage covered by sustainable landscape elements should be provided as part of the components of site analysis for building approval. The building code should be strictly adhered to during the development of residential plots, especially with the aspect of setbacks and local development and planning authorities should be more vigilant, transparent and transparent in monitoring and ensuring standards. This research concluded that sustainable site planning for tropical residential developments in Lagos, Nigeria is the basis for ensuring available and conserved soil space around residential structures.

Keywords: Built environment, Residential area, artificial elements, Natural elements, setback, and Sustainable site

INTRODUCTION

It is imperative that building owners and developers maximize the restorative impact of site design and building infrastructure while meeting the projects other demand (World Building Design Guide Sustainable Committee, 2013).

The major natural component of outdoor residential building development is soil and this component serves as the base for the development of all other components, both natural and artificial. Hence there is a need to stabilize this component, so as to enhance the functionality of all other components that it supports including the residential building structure which it surrounds. Sustainable site planning involves majorly sustainable landscaping of outdoor building spaces and this encompasses a variety of practices that have been developed in response to different environmental problems. One of such environmental problems is the issue of erosion. Due to the severity of its ecological effects and the scale on which it is occurring, erosion constitutes one of the most significant global environmental problem we face today (Toy et al, 2002).

Aim and Objectives

This research aims at tackling erosional soil management issues with setbacks of buildings in residential areas through the application of sustainable site planning principles. In other to achieve this aim, the research employed the following objectives:

i. to establish, through literature, the concept, origin, objectives and functions of sustainable site planning;
ii. to examine the various erosion types and soil conservation strategies for erosion control in residential developments;

Akagwu M. (2016). Sustainable Site Planning; A Soil Conservation Strategy for Residential Developments in Lagos, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 97-104

iii. to identify and study the different sustainable landscape and building roof design solutions employed in sustainable site analysis that enhances erosion control;
iv. to articulate the concept of sustainable site planning, with special emphasis on measures that will lead to the achievement of soil conservation around residential buildings;
v. to propose through Site analysis and Sustainable landscape design, percentage areas for different landscape elements to enhance soil conservation and erosion control in residential areas.

CONCEPTUAL AND THEORETICAL ISSUES

Sustainable Site Planning through Sustainable Landscaping of Outdoor Residential Developments

According to Bob (2011) a site plan has least environmental impact while still meeting the client's project goals. It's sustainable if it meets project needs and budget and at the same time reducing environmental impact. Site planning refers to the organizational stage of the landscape design process. It involves the organization of land use, zoning, access, circulation, privacy, security, shelter, land drainage and other factors, by arranging the compositional elements of landform, planting, water, buildings and paving in site plans.

Kerry (2007) emphasizes that during site planning and design process, it is important to study ways to integrate sustainable elements such as recycling materials, innovative storm water management practices sensitive to site layout, native (or naturalized) landscape materials and site lighting into a complete site package. Kerry (2007) further emphasized that it's not all about writing about the benefits of exterior natural spaces on human wellbeing, but how planners and designers should integrate the basic infrastructure required for today's projects into a sustainable site plan that also incorporates natural areas or green space.

Sustainable Site Planning Through Employment of Sustainable Landscaping Solutions

i. Soil management techniques, including composting kitchen and yard wastes to maintain and enhance healthy soil that supports diversity of soil life.
ii. Recycling of products such as glass, rubber from tires and other materials top create landscape products such as paving stone, mulch and other materials (United States Environmental Protection Agency, 1998).
iii. Permeable paving materials to reduce storm water runoff and allow rain water to infiltrate into the ground and replenish ground water rather than run into surface water (Interlocking Pavement Institute, 2008).
iv. Creating and enhancing wildlife habitat in urban environment (Harker et al, 1999).
v. Reduction of storm run-off through the use of bio swales, rain gardens green roofs and walls (Robinette and Sloan,1984).
vi. Bio filtering of wastes through constructed wetlands (Campbell and Ogden, 1999)

Soil Conservation in Residential Developments through Erosion Control in Open Spaces around Buildings

Soil conservation is a set of management strategies for prevention of soil being eroded from the earth's surface or becoming chemically altered by overuse, acidification, salinization or other chemical contamination (Dave and Favis, 2014). Erosion refers to the actions of exogenic processes (water flow or wind) which remove soil and rock from one location on the earth's crust and transport it to another location where it is deposited (Blanco, 2010). Due to the severity of its effects and the scale on which it is occurring, erosion constitutes on of the most significant global environmental problem faced today (Toy, 2002a). Land degradation is a process in which the value of the biophysical environment is affected by a

combination of human induced processes acting upon land (Conacher et al, 1995). According to Toy (2002a), water and wind are now the two primary causes of land degradation; combined, they are responsible for about 84% of the global extent of degraded land. Physical processes which may result from rainfall produce four main types of soil erosion (Toy, 2002b). Splash erosion which is generally the first and least severe stage in the soil erosion process, which is followed by sheet erosion, then rill erosion and finally gully erosion (Zachar, 1982).

In splash erosion, the impact of a falling rain drop creates a small crater in the soil, ejecting soil particles. If the soil is saturated or if the rainfall rate is greater than the rate at which water can infiltrate into the soil, surface runoff occurs. If the run off have sufficient flow energy, it would transport loosened soil particles down slope (Food and Agricultural Organisation, 1965). Sheet erosion is the transport of loosened soil particles by overland flow. Rill erosion refers to the development of concentrated flow paths which function as both sediment source and sediment delivery system for erosion (Nearing, 1997). Gully erosion occurs when the runoff water accumulates and rapidly flows in narrow channels during or immediately after heavy rains or melting snow, removing soil to a considerable depth (Poesen 2007). Most common in urban developed areas are the splash, sheet and rill erosion types and gully in rear cases due to obstructions and flow paths created by different structures in the urban environment, except for cases of neglect.

Some residential development erosion control parameters employed include:

a. **Perimeter Run off Control**; trees, shrubs and ground covers are effective perimeter treatment for soil erosion prevention by insuring any surface flows are impeded. A special form of this perimeter treatment is the use of a grass way that both channels and dissipates runoff through friction, impeding surface runoff and encouraging infiltration of the slowed surface water (Lumina Technologies, 2002)
b. **Windbreaks**; these are created by planting sufficiently dense rows of trees at the windward exposures. Evergreen species are preferred to achieve year round protection; however, as long as foliage is present the seasons of bare soil surfaces, the effect of deciduous trees may also be adequate (Mingyuan et al, 1998).

MATERIALS AND METHODS

The research was undertaken at Genesis Conceptual Perceptions Limited, an architectural research and construction firm, in Newsite Estate, Satelite town, Lagos, Nigeria between 2014 and 2015; it covers residential areas in Amuwo-Odofin Local Government Area in Lagos Nigeria.

Population Sampling Size and Technique

Descriptive research Approach was used for the study in which field survey was conducted using well-structured questionnaires as the main research instrument. In addition to that critical field observations were also done. The survey was carried out by random sampling of stakeholders of the residential development. The study population includes; the designers, developers and owners of structures in the estate.

The population size for the study is 167 and out of this 40 was structurally sampled out. This is because out of the 167 residential plots in the study area , nothing less 5 – 10 is owned or developed by the same Developer/Building owner .40 questionnaires were structurally distributed so as to avoid certain degree of repetition, 37 were returned and used for the analysis. The questionnaires solicited substantial information on sustainability and sustainable site analysis in relation to the achievement of erosion control and enhanced soil conservation and management in residential development in Lagos Nigeria from the

aforementioned respondents based on their knowledge and experience. The opinions sampled included the respondents understanding of sustainable site planning, erosion control around buildings, benefits, problems and measures of achieving soil conservation around the built residential environment. The questionnaire had 3 sections namely; section, A, B and C respectively. Section A (this is to assess how different group of individuals involved in construction in the study area perceive the concepts in study) contained respondents profile, section B solicited information on sustainable site planning and section C on erosion control.

Methods of analysis and presentation

The method used for analysis was a descriptive analysis, involving the use of percentages, mean scores and ranking of some factors.

Table 1: Professions of Respondents

Profession	Number Distributed	Number of Responses	Percentage Responses
Architect (Building Designer)	14	14	100
Builder (Building Developer)	16	15	93.75
Civil Servant (Building Owner)	5	5	100
Business (Building Owner)	5	3	60

Field Survey 2014

DATA PRESENTATION, ANALYSIS AND DISCUSSION

Data Presentation and Analysis

Results obtained from the research are presented under the following appropriate headings and sub headings.

Breakdown of Respondents: 92.5% of the questionnaires distributed were returned. This level of return was achieved because a conscious effort was made to retrieve questionnaire from respondent personally. Reminders in form of text messages and phone calls were made also to respondents before collection .Table 1 shows that the breakdown of the questionnaires from 37 respondents. Architects (Designers) returned 100%, Builders returned 93.7%, Civil Servants returned 100% and Business Owners returned 60%. From Table 2, it can be observed that all the respondents claimed to have heard of erosion control. Table 5 shows the responses from questionnaires on the measures of achieving sustainable residential sites in Lagos Nigeria. The result shows that minimizing the development of open spaces averaged 3.27, meaning it is important, while linking natural areas averaged 2.9 (important), control of rain/storm water runoffs through improved grading and landscaping averaged 3.86 (important), minimizing impervious surfaces using permeable flooring averaged 3.57 (important), reducing and controlling runoff impact from roofs using roof gutter system averaged 2.86 (important), increasing awareness of the concept of sustainability and sustainable site planning averaged 3.68 (important), encouraging sustainable design and construction practices averaged 3.68 (important) and encouraging tree planting to create covering over exposed soil averaged 3.57(important). Table 4 shows responses from questionnaires on the benefits derived from sustainable site planning .Table 5 is about the problems achieving sustainable site planning in residential developments in Lagos, Nigeria.

From the above presentation, the study reveals that the respondents believe that the measures outlined in the questionnaire are important for the achievement of a sustainable built residential environment through sustainable site planning. This invariable means that there is a need to design and develop residential plots in the area in ways that are less impact on the residents, building structure and the environment

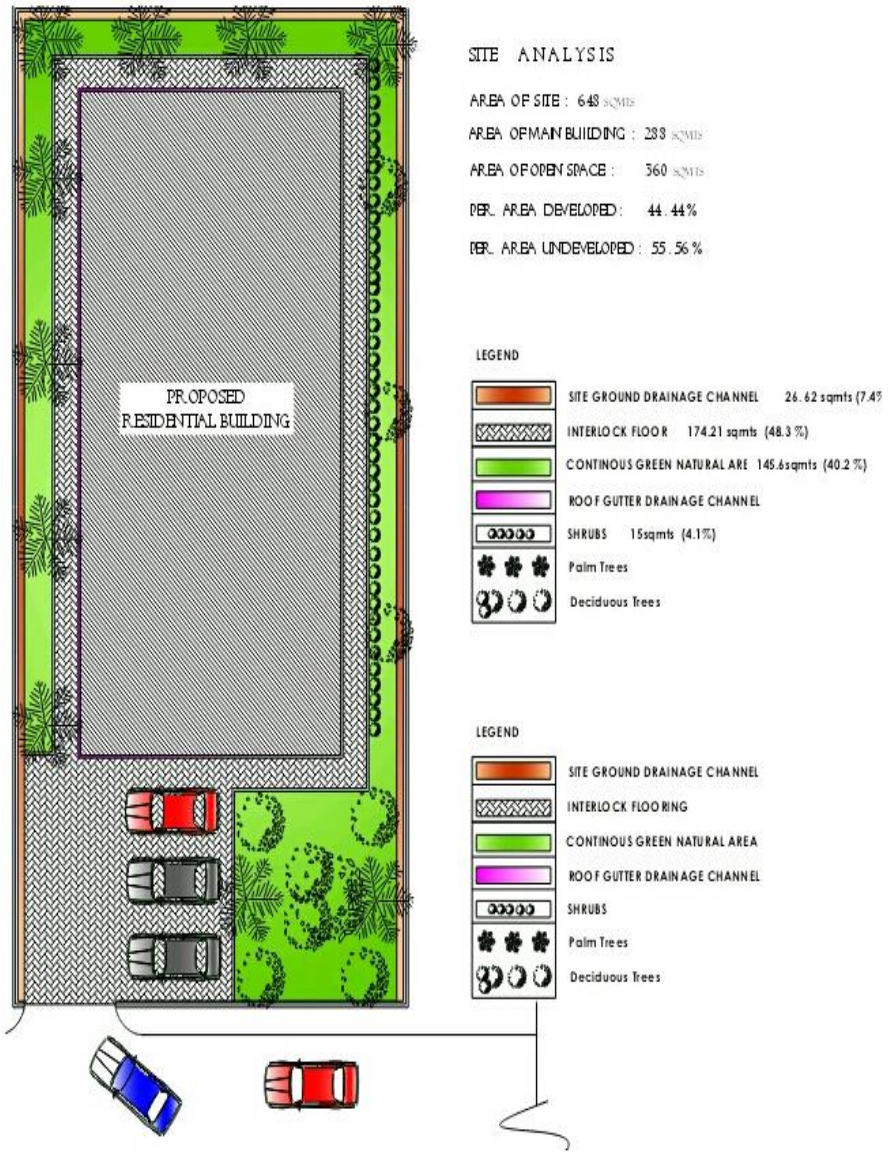
The entire benefits derived from soil conservation and sustainable site planning for residential development were seen important. This implies that the soil is an essential element for site planning and needs to be managed in a manner that it enhances the entire outlook and

functionality of the residential plot. Out of the problems/Challenges stated, the most agreed was lack of compliance with relevant existing statutory documents, urban construction policies and monitoring issues from monitoring authorities which has led to erection of most buildings occupying major set-back areas designated for sustainable landscaping and a soil conservation.

Observations of Soil Erosional Effects on Structures

Fig. 1 *showing common soil erosional effect of the building structure at the study area*

RECOMMENDATIONS



The study recommends that;

i. There is a need to effect sustainable site planning percentages on site plans through percentage areas occupied by landscape soil conservation elements during design, as part of the Government approval criteria for residential building approval.
ii. There is also a need for Amuwo-Odofin Local Government should revive its monitoring agencies to ensure strict adherence to set back rules and regulations.
iii. There should be a proper enlightenment of stakeholders and the general public on the need to sustainable plan their environment so as to enhance building structure and environment through erosion control.

CONCLUSION

The study reveals that a greater percentage of the respondents who are stakeholders involved in the development of Newsite area of satellite town, Lagos are aware of the concepts of sustainability and sustainable site planning as ways of achieving erosion control and management in the area. It further reveals that the issues of cost, design, monitoring and implementation were major problems hindering the development of sustainable sites in the area.

Therefore the study concludes that through the implementation of the proposed sustainable site development parameters presented in the study and a cooperative process involving building owners, designers, developers, government and its agencies sustainable sites would emerge and increase in New site area of Lagos. Achieving this will invariably improve the environmental outlook and quality of the neighborhood, creating a standard for other neighborhoods within and outside Lagos.

ABSTRACT

Studies have shown that building designs contribute greatly to the magnitude of fire in building with severe consequences on safety of life and property. Hence, fire safety is an important consideration in building design which architects seek to fulfil at the early stage. Knowledge of fire safety amongst architects can aid the design of safer buildings in terms of fire protection. Fire safety designs are expected to meet the provisions in Approved document B of the UK Building Regulations which specifies basic fire safety requirements. The main objective of this paper is to explore the educational underpinning of architects with respect to designing fire safe buildings. This paper is based on literature review and interviews conducted among architects both in academia and in practice to ascertain the need for fire safety education in architecture, and as a working knowledge for practicing architects. Findings showed that architects undergo fire safety education under different modules, but not as a distinct course. Fire safety education provides architects with basic understanding of fire safety principles, and to determine when to consult fire experts. Recommendations include creating a separate course on fire safety and if taught as part of other modules, more time/ depth should be allocated to its contents.

Keywords: Architects, Building design, Education, Fire safety

INTRODUCTION

Fire according to Cote and Bugbee (1988) is a serious threat to people, and the principal cause of death in building, beside falls, which is also responsible for a large number of deaths in building related incidents. Among the momentous dynamic forces such as earthquake and windstorm, devastations from fire are about 20 times those from earthquake and wind disasters (Walls, 2007). Fire accounts for almost half of the insurance policies claims against fire and multiple perils (Cote and Bugbee, 1988; Association of British Insurers (ABI), 2014; Hogendoorn, 2016) and a leading source of property loss and its contents (ABI, 2009; Haynes, 2015). The ability of a building to either confine or fast-track the growth of fire depends on how it was designed. For instance interior finishes might facilitate or restrict the spread of fire. Likewise walls, duct systems, barriers and routes can either allow or compartmentalise fire. Occupants' routes might or might not be protected, lighted, signage, of sufficient size, as well as the provisions of fire detection and suppression facilities or otherwise (Cote and Bugbee, 1988).

Fire safety is one among several other considerations such as functionality, aesthetics, human comfort, structural stability, cost-effectiveness, constructability, maintainability, and sustainability, etc (Kodur, et al, 2012; Park, 2014), that building designers must fulfil at the early stages of building design process (Stollard, 1989; Fire Sector Federation, 2015). This is to ensure safety of the building users in the event of a fire incident, as well as the protection of the built property using active and passive measures. For a building design to be effective in terms of satisfying both architectural and technical objectives, fire safety must be integrated early on in the building design process (Lawson, 1990, Stollard, 1989, Lataille, 2002). Arguably, the duty of guaranteeing the fulfilment of fire safety objectives rests with the architect (Stollard, 1986; Abraham and Stollard, 1999; Stollard, 2014). Kodur (2012) highlighted that:

"Most of the passive fire protection design for structural framing remains within the project architect's responsibility, with little if any input from a fire protection or structural engineer" (Kodur, et al 2012. Pp 826).

Although architects are not trained to be fire scientists, it is important for them to be aware of the fundamental principles of fire safety (Abraham and Stollard, 1999; Stollard, 2014) because of their roles as principal designers. Architects should also ensure they are

Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 105-114

acquainted with specific safety issues of a structure being planned, as well as obtaining necessary advice and information from fire specialist early in the design stage (Megri, 2009). The necessity for safety awareness especially for fire safety is due to the fact that the design and construction of a building contributes substantially to the severity of fire in building (Stollard, 1986; Stollard, 1989; Sagun et al, 2014). For example, in the inquiry into the Summerland disaster, it was reported that 20 out of 34 recommendations had to do with the building and the design process. The knowledge of designers with respect to the combustibility of the materials was faulted in the following areas (Rasbash et al., 2004):

i. Oroglas acrylic sheeting or poly methyl methacrylate, is a form of plastic materials whose quality is of low fire resistance and can easily be degraded was used for constructing the wall and roof of the building (Rasbash et al., 2004; University of Birmingham, 2016);
ii. The rear part of the amusement arcade to the top of the building was adjoined on the oroglas with a wall of Galbestos cladding. The cladding was covered with resins which makes specimen prone to a radiation of 12kW/m^2; and
iii. A 300 mm wide cavity with a length of 12 m, which contains fibreboard called Decalin was used between sheet steel outer wall and the amusement arcade. The decalin was of low rating in terms of spread of flame test in the BS 497 part 7.

In addition to the materials used in the building, delayed evacuation, locked exit, lack of escape stairs contributed to the fire deaths during the incident.

Another notable example is the fire that occurred at the Faculty of Architecture building, Delft University of Technology, Netherland, in 2008. The incident showed some effects that building design has on fire development. The fire as reported by Meacham et al. (2010) and Park (2014) started around 9:00am on the 6th floor of the South tower, but quickly spread to the 11th floor which leads to the failure of the North tower after approximately 8 hours. Even though the building was said to have satisfied Local Fire Regulations for existing buildings, other features contributed to the speedy development and vertical spread of the fire. These features include (Park et al, 2014):

i. The large open space in the design studio area sustained oxygen which allowed the fire to grow fast at the beginning of the fire development;
ii. Combustible acoustic material at the bottom of the mezzanine floor which aided the fast heat release rate (HRR);
iii. The 30 minutes fire barrier could not confine the fire within the fire origin room. The fire developed more rapidly that it could not be controlled by the fire service;
iv. Horizontally continuous exterior windows served as means of horizontal fire propagation making the fire to spread around the fire barriers; and
v. The 4.95 m tall exterior window height was high enough to facilitate large flame extension which could annul 2.05 m vertical separation in the international Building Code requirement. The extended flame height out of the opening reached was reported to be more than 7 m.

Figure 1 shows an extended flame over two-story high (left), and the right picture displays the rapidity of fire spread within 12 minutes from when the left image was captured (Park, 2014).

Figure 1: Faculty of Architecture Building, Delft University of Technology Netherland, 2008 Source: (Park, 2014)

The two examples cited above provide insight into how some building design features and the material choices impact on the seriousness of fire in buildings.

This work seeks to find out among other things the level of importance accorded to fire safety in the design process as well as the extent of fire safety awareness that is currently available among architecture students, and practicing architects. This work further explores the training that building designers currently undergo to identify deficiencies and efficiencies that affect fire safety considerations in building design. The motivation for this research comes from the fact that the design and construction of building contributes substantially to the severity of fire in building (Stollard, 1986; Stollard, 1989). Stollard (1986) reviewed a number of major fire incidents including the Summerland of 1973, Fairfield of 1974, Coldharbour of 1972, Woolworths of 1979, and Bradford City Football ground of 1985 and established that the design of those facilities play a major role on the magnitude of fire after ignition and consequences for occupants.

LITERATURE REVIEW

Current Approaches to Building Design

Building design process is an uninterrupted series of actions by design team members such as architects, structural, mechanical, electrical and fire safety engineers, to achieve a comprehensive building design (Park et al, 2014). Laseau (1980) describe the process as a chain of transformation from ambiguity to information. The design process according to Balcomb and Curtner (2000) involves four stages which include: pre-design (PD), schematic design (SD), design development (DD) and construction documents (CD).

Design stages are realised using two patterns which can be either: conventional linear design or integrated design. In the linear design approach, architects primarily manage the design progress and request engineers and other consultants to take part when the design has advanced (Gane and Haymaker, 2009). This method is effective for a small and uncomplicated building projects, that are carried out by few stakeholders usually with little budget, and where it is not necessary to undertake major building performance analysis and evaluation (Park et al, 2014). Integrated design on the other hand is used for large size building project where, interested parties in the projects such as the client, the project manager, architects and other consultants come together early on in the design process to share project information. This process allows for identification of required building performance and reduces any possible clashes that may arise later in the design stages.

In the past few decades, enormous transformations had been observed in the design and construction of fire engineered buildings such as transport termini, airports and high-rise buildings. This is due to rising demand for efficient space, greater comfort level and safety (Megri, 2009; Wilkinson et al, 2013). Megri (2009) maintained that fire safety plays a major role in building operations and should be properly coordinated with other subsystems early in the design stage to provide efficiency, reliability and performance. He further stated that consideration for fire protection is carried out by the architects in conjunction with the structural engineers. While architects design the building layout-including the exterior and interior walls, structural engineers produced structural calculations that meet fire safety regulation. In addition, inclusion of an experienced fire engineer in project design team according to the National Institute of Building Sciences, (2015) is crucial at all stages of the design to occupation. This is to ensure the construction of a reliable and safe building for occupants' habitation.

Need for fire safety education and training

The need for education and training on fire safety arose from different reports in literature (National Commission on Fire Prevention and Control (NCFPC), 1973; Barham and Roberts, 1995; and Watt, 1998). This includes creating a common understanding among designers and consultants involved in building design to be adequately equipped with the currently available fire safety information and their applications. This common understanding could prevent any form of delay that could come up during the design process (The fire safety studies group, 1992). In addition, fire safety was reported to be lagging behind other consideration such as aesthetic and cost in building design (NCFPC, 1973; Watt, 1998; Lo

and Yuen, 1999). Watt argues that the gap between building and fire safety design was due to fire safety analysis not meeting up with rapid innovation in building design, as well as inadequate attention being given to fire safety by architects and engineers. He opined that as a result of insufficiency of formal education in fire safety for architects and engineers, a lot of information necessary for effective fire safety application appeared to be unheeded. For instance in architectural curricula for most schools, students are not taught any course specifically on fire and life safety design (Watt, 1998).

Fire safety education

Fire safety education involved providing people with good knowledge of fire prevention and protection. The Mid and West Wales Fire and Rescue Services (2015) use the term fire safety education with respect to the following:

i. creating awareness among young people on the need to be mindful of fire hazard in home;
ii. Give necessary information that can help people prevent, detect and escape from fire;
iii. Cautioning children to overcome the peer pressure of getting involved in crime such as arson and hoax calls.

Fire safety education can be an effective and empowering tool for intervention with fire setting behaviours among children if properly utilised (Kolko, 2002). For operators of business premises fire safety education deals with issues such as false alarm due to malfunctioning of fire detection system poor maintenance and insufficiently trained staff (Rielage, 2009). In some cases fire safety awareness is created through different means. For instance, the distributions of free fire alarms to communities that have high prevalent rate of fire incidents (Parmer et al, 2006).

Fire safety education is important in many ways. For example, the National Fire Protection Association (NFPA) runs education programmes that are focussed in educating individual representing different age groups about the practices of making responsible choices concerning health and safety (Gamache et al., 2011). Similarly, the Fire Service College runs training programmes to develop the capability and expertise within UK Fire and Rescue Service, emergency services and other categories of respondents (Fire Service College Limited, 2015). However, the example included here highlights the breadth of fire safety education encompassing a range of stakeholders representing specialist emergency services on the one hand to the general public on the other. Thus, the architectural practitioners may or may not be covered as a stakeholder group. This forms the focus of this research, to shed light on how exactly fire safety design training is imparted or conducted.

If people have good knowledge of fire, the number of fire related fatalities in buildings may be greatly reduced. For the aforementioned reason, it is a valuable project to train people on the various ways of preventing fire. Cote and Bugbee (1988) asserted that fire safety education have impacted positively in subsiding fire hazards. They also highlighted that the advantage of public fire education outweigh the cost that may be incurred in creating such awareness. The main purpose of public fire education is to enhance people's awareness, support and participation in fire prevention activities. Local fire department contribute to this process in the form of periodic inspection of building of various occupancy types, fire safety materials distribution, presentation of fire safety material to the public as well as presenting fire safety educational programmes in schools (Cote and Bugbee, 1988).

Fire safety training

Lawrence Webster Forrest (2015) defines Fire safety training as "the process of instruction and learning between trainer and trainee for the efficient application and management of evacuation procedures for a building". Training on fire safety is often provided to prevent injuries and deaths that could result from fire incidents. The general knowledge of fire safety among people helps in determining the level of training that could be provided. The effectiveness of fire safety training programmes such as 'fire Ed' (carried out by the Oklahoma City Fire Department) and 'kid safe' (conducted by the Melbourne Fire Brigade, Melbourne, Australia) led to the provision of fire safety information and skills for young people. It also contributes to reducing fire deaths and more use of fire alarms in homes and workplaces (Huseyin and Satyen, 2006). In order to achieve a fire safe design, Buxton (2011)

suggested that a good working knowledge of the building regulations dealing with fire safety is required of architects, even when there may be opportunity for consulting fire experts. In her opinion, architects should not leave all activities regarding fire performance technology to fire engineers, as such seeking knowledge of building materials and how they affect designs becomes necessary.

METHODOLOGY

To carry out this task, a number of stakeholders who have roles to play in the education of architects (principal designers) as well as those governing the practice of architecture in the UK were identified. Under these categories falls the professional body – the Royal Institute of British Architects (RIBA), and the Schools of Architecture. A significant numbers of trained and qualified architects go into professional practice of architecture, designing buildings which are expected to comply with building and fire regulations such as ADB and BS 9999 etc. The architects in practice formed the third group of stakeholders who are considered in this work. Then the next two are those that enforce the provisions of the building regulation from the conception design stage through construction and operation of the building. They are the Building Control Officers, and the Fire Prevention Officers (Communities and Local Government, 2007). The Fire Prevention Officers are the Statutory Consultee for Regulation B5 (access for firefighting personnel to building) during the design and construction stages, their statutory functions of enforcing the regulatory reform fire safety order (2005) commence after a building have been completed and occupied. Further information on the interviews is given in the next section, the interview design. Table 1 shows the profile of research participants including their years of experience, post and their places of work.

Table 1: Profile of the Research Participants

Note: AA - Academic Architects; PA- Practicing Architects

Interview design

For this research, interviews were conducted to find out amongst other aspects the relevance of fire safety education, its coverage in the curriculum, specific topics where fire safety is considered, mode of delivery and intended learning outcomes. Information generated from the interviews is expected to provide insight on how the current approaches to fire safety in architectural education contribute to shaping the understanding of fire safety issues amongst the future practitioners, and assessing the adequacy of the approach to fire safety problem during the building design process.

Stakeholder samples were obtained using stratified random sampling. The suitability of this sampling method was due to the spread of population into distinctive groups, or strata (Fellow and Liu, 2008). The selection of each of the stakeholders was based on their various roles within the study area. Four members of academic staff from various schools of architecture identified as Educational Institution 1, 2, 3…n, comprising of two heads of school, and two academics were interviewed. Two of the interviews (AA1 and AA4) were conducted face to face, while the other two (AA2 and AA3) were carried out over telephone. Three of the interviewees consented to audio recording of the interview, but fourth respondent declined recording. Consequently, little information was obtained from the participant AA4 even from the note taken during the meeting, as not all questions were responded to, therefore analysis with regard to participant AA4 was be restricted to the area

where information were provided. For the practicing architects (PA), 6 participants were interviewed, 1 was carried out by telephone while 5 were conducted face-to-face in the location preferred by the participants, mostly in the offices of the participants except one that volunteered to be interviewed outside the office. 3 Building Control Officers participated, 1 of which was conducted by telephone and the rest face to face. The last stakeholders interviewed are the fire prevention officers, all the interviews were conducted face to face in the various offices of the participants.

Similar questions were asked during the interviews for the various stakeholders, but sometimes additional questions do arise from answers given by respondents for clarification of responses and detailed understanding. This approach is categorised differently by in literature. While Valenzuela and Shrivastava (2008); McNamara (2009); and Tuner (2010) consider it as standardised open-ended interview, Davies and Beaumont (2010) and Open University (2015) on the other hand referred to it as semi-structured interview. This method enables a quicker interview that can be analysed and compared straightforwardly. It is in contrast to the closed, fixed response type of interview where interviewees select answers to questions from same set of options (Valenzuela and Shrivastava, 2008). The standardised open-ended interview according to Baker (2012) allows the interviewer to further probe unexpected responses to obtain more information.

FINDINGS AND DISCUSSIONS

Under this section, findings from the analysis of data collected are discussed under the following sub-headings:

Relevance of fire safety education in architectural programme

This section highlights the importance of fire safety in architectural education in the UK. Views and opinions of architects both in academia and in practice were sought to gain insight on fire safety related courses are taught amongst the various Schools of Architecture. There are different views among architect concerning what they studied of fire safety while in the school of architecture. Some of the practice and academic architects confirm dealing with some aspects of fire safety to the level of awareness, and compliance with the building regulations (PA4), others were of the view that nothing of fire safety were done (PA5, AA4).

The relevance of fire safety education was expressed by the various participants in terms of creating awareness among students, and how other design criteria can be integrated in building design to ensure a fire safe building. Fire safety knowledge is mostly needed in practice where actual designs that will comply with building regulations are carried out. Designing out fire in buildings is key to reducing fire risk where possible. With fire safety awareness, architects highlight necessary steps and measures to be employed to mitigate fire risk, where it is not possible to design out fire (PA4). Some of the critical fire safety issues that are considered during the building design process include the provisions of adequate means of escape for safe evacuation of building occupants, as well as protecting the building to allow for people escape and intervention of fire and rescue services.

Understanding fire safety will enable students to know where to seek information on fire safety design, developing a proposal that is fire safe (AA2), as well as getting a good grasp of building regulations and its application in design (AA3). These include understanding the guidance document, the approved document B both for domestic and non-domestic buildings, and the Department of Communities and Local Government Guidance on fire risk assessment for various types of buildings. Some of these buildings comprise of Offices and shops; sleeping accommodation; educational premises; places of assembles – both large, medium and small; health premises; places of entertainment such as cinemas and theatres; and fire safety risk assessment covering means of escape for disable persons (University of Reading, 2008).

The significance of fire safety was emphasised as an aspect that examiners check for the understanding of architectural students. For instance in studio courses students are expected to prove how their designs comply with regulatory requirements including fire safety as explained in the Part B of the Building regulations for England and Wales. It is one of the

determining factors for students' success in examination even as it may not be a stand-alone module.

"... fire safety is one of the key things that external examiners look at, as a sort of evidence that they understand the building regulations" (AA 1).

In addition, Fire safety awareness is necessary as part of architectural professional ethics to comply with the building regulations and standards (RIBA, 2005; RIBA, 2007; Architect Registration Board (ARB), 2009; and Sadri, 2010). The aspects of building design feature which need to conform to the regulation include accessibility and fire core. Equivalent solutions are negotiated for, if it is not possible to produce an efficient design using the guidance in the approved document B of the Building regulations 2010. As part of personal and professional responsibility, it was also stated that architects ensure the safety of users of the buildings designed by them (AA1).

Fire safety content in architectural programme

Essentially, architectural curriculum is grounded on the design studio that is concerned with learning by doing, a process that is achieved through lectures and critique sessions, through which students express their understanding based on discussions with teachers, friends and colleagues (Utaberta, et al., 2011).

The general opinions of the interviewees from educational institutions and from architectural practitioners are that there is very little content of fire safety related topic in architecture. The topics are not treated as an individual subject rather as part of other technical courses such as Building construction and studio works. In studio students learn by doing, and are expected to present their work before peers and teachers, in a form that can be built to conform to all existing standards and regulations that apply to the project type.

Participant PA2's view supported the opinions of academic architects' stakeholders concerning the content of fire safety in architecture and went further to state that fire does not really feature in the architectural education in the university. The participant's view also agrees with others such as AA2 and AA3 that advocated for on the job fire safety related trainings. When asked if a participant's interest in fire safety was inspired by education in the school of architecture, the response of PA2 was as quoted below:

"No I can honestly say that has nothing to do with it, absolutely nothing to do with it... I can still say there is still very little in terms of fire engineering in schools of architecture...fire doesn't from my understanding of what people are going through now, it doesn't really feature at all...I don't think it (fire safety) sits well in the architectural training, in terms of the formal training at the university. I basically believe it is far more successful on the job training, because you can see the relationship far better" (PA2).

The aforementioned statement does not rule out the necessity of having the basic knowledge of fire safety in the widest engineering terms. The fire safety taught elements of curriculum was stated to be within the range of 1.25% to 3% of the total course contents (AA1, AA2, AA3). It is covered within an estimated duration of 3 to 6 hours in a year. This issue might have prompted Gillie and Morvan (2006) and others in proposing course content that could improve the fire safety engineering knowledge among architects and engineers. Although it was stated that the duration could be more when one considers time spent by student for independent learning (AA3).

All the interviewees agreed that fire safety is not run as a distinct course. For example, participants AA2 was of the opinion that it should not be a stand-alone module stating that the purpose of architectural education is to improve critical abilities of an architect, rather than filling them with knowledge. Although the respondent is entitle to his opinion, the research argues that a separate fire safety module may enhance a better understanding of the basic principles of fire safety. The next section indicates the module where fire safety topics are taught in architecture schools.

Modules with fire safety topics in the architectural programme

This section seeks to find out where to locate fire safety related topic within the curricula of various Schools of Architecture. The collected data shows that the modules under which fire safety topics are taught include: technical lectures (AA2), tectonics modules, professional

studies, and all studio modules for undergraduate degree (AA3). In the Masters of Architecture (MArch), it is usually taught as a lecture in the design studio (AA1). Some of the architects in practice interviewed could not recall precisely the module under which they studied fire safety (PA4, PA5, PA6). However, PA4 stated to have learned in the School of Architecture in the past three decades, how to provide adequate means of escape, the principles of travel distances, compartmentation, fire resistance of structures as well as fire doors and partitions, although not to the level of fully complying with the building regulations (PA4).

The participants AA1, AA2, and AA3 were all of the view that the modules with fire safety topic prepare majority of students with the understanding of basic principles. The available information in the module may not be enough to be used on real building in practice. According to PA2:

"*Fire does not from my understanding of what people are going through now; it doesn't really feature at all".*

The above quotation was supported by one of the academic architects (AA4) who opined that there is no fire safety education in architecture. According to the participant AA4, things like calculation of exit width, numbers of escape routes are not carried out by architects. He further stated that design education do not cover evacuation and collapse of building during fire. The participant however admitted that architect do consult fire engineer during preliminary design stage, and where necessary modify the design based the outcome of such consultation.

For some schools of architecture that fire safety related topics were admitted to be taught, the impact of such course(s) on architecture students include: knowing how fire safety problem in design is solved; and whose assistance that may be required to provide effective design solutions. Practical experience about understanding how these modules get applied to real buildings was suggested for students, whereas continuous professional development (CPD) was highlighted as a veritable means of acquiring fire safety education in practice (AA2, and AA3). This is in agreement with Cerda (1981) who supported that Continuing professional development serves as a mean of providing up-to-date information for architects on specific types of building, new materials and methods as well as new legislation. CPD helps to further develop the basic knowledge on fire safety acquired from the school of architecture (Stollard, 1986).

The teaching of Fire safety in the school of architecture is carried out as part of studio, technology courses by structural engineer, and/or as part of building services by either a building services engineer or environmental engineer (AA3). Part time lecturers working in design firms sometimes bring in their practical experience in the real world to support students' understanding of design for fire safety.

"*…bringing their expertise to the holistic design process… and demonstrate to the design of building"* (AA3)

Methods adopted in teaching include technical lectures, practical demonstration, one to one tutorial, informal discussion and studio reviews (AA1). Assessment of fire safety part of a module is through Portfolio submission, in which they will need to make drawing or diagrams that show where the exit route is, the travel distances, and correctly label the fire rating for building element.

Tools used for fire safety education and training

The tools used for promoting fire safety training include; combination of lectures and studio where students learn by getting involved in activities (AA3), group discussions and physical demonstrations through which students contribute to the learning process, rather than being told what to do (AA1). Fire safety teaching is also enhanced through the guidance of technically competent tutors (AA2). Technical competence of tutors entails trainers having sufficient skills on the use of wide range of training techniques to present training materials to students eithers on one-to-one or to group of learners (Buckley and Caple, 2009). Architect in practice enhance their skills by attending fire safety seminars (PA3), seeking relevant information using the internet, research projects, British Standards, AD B, as well as

consultation with the Building Control Officers / Approved Inspectors (PA5). The use of Microsoft excel was mentioned as a tool that some architects used for calculating sizes and width of escape stairs and fire doors for building with large population, in compliance with the provisions of Building Regulations and the British Standard, BS 9999.

Suggestions for improving the existing modules

Interviewee AA3 encourages improvement to the modules, but made no specific suggestion as to improving fire safety related modules. AA2 was of the view that critical understanding of fire safety should be left to the time of architectural practice. Therefore, made no suggestion for any improvement besides knowing who to consult when a need arise. AA1 advocated for creating a summary of the main principles required to understand fire safety and using pictures to present alternative solutions. AA4 made no suggestion since the respondent is of the view that fire safety is not part of architectural education.

CONCLUSION

This investigation has revealed that there may be no need for a separate module to be created on fire safety education and training for architecture students. However, majority of the participants supported on the job training through continuing professional development (CPD) to enhance architecture graduates fire safety design skills. The overall opinions show that the current provision for education and training is adequate to provide the type of fundamental skills that students require, and students are told where to ask for help if necessary. Practicing Architects also believed that they have knowledge of fire safety sufficient to allow for effective fire safety design. They are willing to engage fire engineers, should the need arise, especially for complex design projects. Although some architects have conflicting opinions on the need for creating a module on fire safety within the architecture programme, future work in this study area shall seek to verify the reliability of the various assertions.

Integrating Green Infrastructure to Enhance the Environmental Quality of High Density Residential Areas in Zaria

Musa Lawal Sagada

Department of Architecture, Ahmadu Bello University, Zaria
msagada@abu.edu.ng

ABSTRACT

Urbanisation in Nigeria has been characterised by the concentration, rapid growth of population in certain towns and cities which has put enormous pressure on land and its management. Its consequent effect is the inability of the towns and cities to provide adequate facilities infrastructure that will accommodate and cope with the population growth which has negative impact on the urban environment. This paper examines ways through which Green Infrastructure (GI) can be integrated into High Density Residential Areas (HDRA) as a means of improving and enhancing the quality of the environment. This study employed the case study approach to make a descriptive assessment of some High Density Residential Areas in Zaria, Kaduna state and to suggest ways of integrating GI for enhancing the environment. It is established that the quality of the urban environment can be improved and assist in eliminating urban slums. This study observed that the use of gray infrastructure in the study area is not sustainable, because it is costly to maintain. The quality of the environment can be enhanced by the use of GI elements such as trees, impervious walkways, rainwater harvesting. It recommends that governments and urban managers can encourage and motivate house owners in the HDRAs to embrace aspects of GI to improve their environment by giving them some incentives.

Keywords: Environmental Quality, Green Infrastructure, High Density, Residential Areas, Urban Environments

INTRODUCTION

The urbanisation process in Nigeria, since the 1970's has been characterised by the concentration and rapid growth of population in certain towns and cities which are majorly administrative, commercial or educational centres. The growth in the population of these centres (most of which were created by administrative fiats to serve as headquarters of local governments or capitals of newly created states as a result of the various political restructuring of the country) is caused by the migration of people from other places in search of better opportunities that are presumed to abound.

According to Onibokun and Faniran (1995), the population increases account in part for the rapid expansion of cities. Most often these cities and towns do not have the capacity to provide the necessary infrastructure and other urban services such as adequate housing environment to cope and accommodate the physical expansion taking place with same speed. Among the effects of urbanisation according to Nubi and Ajoku (2011) is that enormous pressure is often placed on the land and its management. The authors observed that in cities like Lagos, rapid urban population growth has resulted in unprecedented urban sprawl as a result of the failure of the government agencies that are empowered to monitor and control development to cope with the expansion.

The rapid population growth and expansion of the cities without proper monitoring and control of development always brings about negative impacts on the general urban environment and most especially it affects the well - being of users in the residential environment if not properly managed. The draft National Urban Development Policy (NUDP, 2004), notes that Nigerian towns are growing without adequate planning. Lanrewaju (2012) affirms that environmental conditions in cities deteriorated due to the rapid growth of the cities and the attendance inability of social services and infrastructure to keep pace with the rate of growth. The rapid growth of cities are therefore characterised by being overcrowded with poor quality housing in certain quarters, poor or nor drainages, un - cleared waste dumps

Sagada, M. L. (2016). Integrating Green Infrastructure to Enhance the Environmental Quality of High Density Residential Areas in Zaria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 115-123

and proneness to flooding. Lanrewaju (2012) reports that, millions of Nigerians live in sub-standard and sub – human environment plagued by slum, squalor and grossly inadequate social amenities.

The urban settlements in Nigeria are segregated into three major categories namely the Low Density Residential Areas, the Medium Density Residential Areas, and the High Density Residential Areas. There are also the Special Residential Plots and the Comprehensive Development, (Abuja Development Control, 2007). This study examines the possibilities of integrating Green Infrastructure into the High Density Residential Areas which is often the most vulnerable and neglected areas in terms of infrastructural development and provision urban amenities as a means of enhancing the quality of the environment. The objectives of the study is to evaluate the elements of green infrastructure that can be used in enhancing the quality of the residential neighbourhood, and to suggest and to recommend those components of GI that can be used in the neighbourhood.

Characteristics of the High Density Urban Residential Areas in Nigeria.

The high density residential areas in most towns and cities in Nigeria is characterised (either by design or by default) by the provision of cheap housing for certain section of the urban population. According the Ogunleye (2014), the types of building in the area are mostly multifamily (tenement) buildings which comprise mainly of single rooms and room and palour. Majority of the residents are either artisan, petit – traders, skilled and unskilled labourers. The area is generally plagued by overcrowding, little or no infrastructure, most of the roads are not tarred and drainages are either not existent or have blocked. Past researches in housing studies (Filani, 1987, Agboola, 1998) have shown that most urban centres in the country are characterized by high density buildings, acute sanitary problems, and pollution of air, surface water, noise and solid wastes.

The quality of housing in the area is generally low, most of which are in need of major maintenance. Coker, Awokola, Olomolaiye & Booth (2007) points out that, housing in the high density residential neighbourhood have the worst property and environmental characteristics.

Fig. 1 satellite imagery of a sector of Sabon Gari a high density residential neighbourhood
Source: Google Earth

The houses are built on rectangular plots measuring 15mx30m or 450sqm. The buildings are often compacted on a plot thereby giving no room to ancillary uses. The division of the land into various plots did not make provision for other uses other than residential purposes, that is why no provisions for other land uses (like open spaces) are hardly made. Plate 1 shows the satellite imagery of a high density residential layout.

Green Infrastructure

Green Infrastructure according to Benedict and McMahon (2002) is an interconnection of network of green space that conserves natural ecosystem values and functions that provides

associated benefits to human population. Foster, Lowe & Winkelman (2011) see green infrastructure as more often related to environmental or sustainable goals that cities are trying to achieve through a mix of natural approaches. Green infrastructure can be a centre piece of smart regional and metropolitan planning; ensuring communities have a liveable environment, with clean air and water, for generations to come American Society of Landscape Architects (ASLA, 2012). The United States Environmental Protection Agency opines that, "Green infrastructure is an approach that communities can choose to maintain healthy waters, provide multiple environmental benefits and support sustainable communities". The approach uses vegetation and soil to manage rainwater where it falls and also mitigate flood, air quality management and enhances the aesthetic quality of the environment among others. According to New York Environmental Protection, (2015), Green Infrastructure describes an array of practices that use or mimic natural systems to manage urban storm water runoff.

The Study Area

Zaria the second largest town in Kaduna State has become an important educational centre in Nigeria. It houses many Federal and State institutions of higher education including the Ahmadu Bello University, and many others. Zaria is one of the traditional towns in the north that which came under the influence of the "Lugard" colonial planning policy whereby urban units were created outside the traditional wall city. These urban units are, the European Reservation Area (now referred to as Government Reservation Area), Sabon Gari, and Tudun Wada were based on segregation (Urquhart, 1977). Other settlement like Samaru grew as a result of the establishment of the Ahmadu Bello University, Zaria.

The paper looks at Sabon Gari and Samaru which are two high density residential areas within the Zaria Urban Area. Sabon Gari (plate II) was laid out in 1911 in a grid plan with few plots measuring 50 by 100 foot arranged in blocks and separated by 100 foot or 50 foot roads. According Urquhart (1977) the then Governor directed the area should be planned for the occupation of Railway labour and petty traders using the construction camps. Presently, Sabon Gari provides accommodation for all categories of people, ranging from traders, factory workers, civil servants, artisans, skilled and unskilled workers. The housing in the area which provides cheap accommodation is mostly multifamily (tenement) buildings consisting of single rooms in row and room and palour, built on 15mx30m plots of land.

Sagada (2013) observed that the area is highly built up with scarce or no tree cover, the absence of which often makes residents and pedestrians to have experience of discomfort, especially during heat period. Further study of the area, reveals that within the residential areas, there are no parks, play areas for children, nor designated green areas.

Fig. 2 A section of Sabon Gari through Dogon Bauchi and Club streets
Source: Google Earth

The main streets like Aminu Road, Dogon Bauchi Road and Club Street, part of Lagos Street and Old Hospital road are asphalt covered with artificially constructed open side drains some

of which have been blocked either by silting or dumping of refuse, other streets in the area are untarred and without side drains. There is a clear absence of sidewalks and other urban furniture along the streets (plate III). Table 1 gives an assessment of the urban infrastructure in Sabon Garia and Samaru.

Fig. 3 A street view of Club Street in Sabon Gari
Source: Field work, 2015

The present location of Samaru (plate IV) was mapped out in 1947 and served as settlement for settler labourers. Oyedele, (1989) points out that, the growth of the population resulted in the building of houses for renting, a practice that became a dominant aspect in the area. Like most high density residential area in Nigeria, it is highly built up with scarce or no tree cover, there are no parks and play areas for children, nor designated green areas.

Fig. 4 A satellite image of a part of Samaru neighbourhood
Source: Google Earth

The main streets like Basawa, Iya and Danraka roads in the area are covered with asphalt and artificially constructed open storm water drains on each side. However, majority of the roads in the area are untarred. Generally, there is a clear absence of sidewalks, trees and other urban furniture along the streets. Plate V, is a view of an asphalt covered street in Samaru showing the side drainages and pedestrians.

Fig. 5 A street view of Samaru
Source: Field work, 2015

Table 1 Assessment of urban infrastructure in Sabon Gari and Samaru

Item	Description	Remarks
Roads	Most of the roads in the study areas are wide with a Width of 12m and no sidewalks and some few have Side shoulders of 1m wide. Less than 30% of the roads Have asphalt cover	width of road can reduced to create permeable side walk and pedestrian walkways
Sidewalks	Sidewalks are non-existent, in some cases there are side Shoulders of 1m wide on both sides of the road where it is Covered with asphalt	the area can benefit from the introduction of Permeable side walk
Drainages	over 60% of the storm water drains and gutter have been Covered by sand and are not functional	green streets can use where the drains Have collapsed to Absorb storm -water runoff
Trees and Hedges	trees and hedges are sparsely planted in the area	this is the most common green infrastructure element that every house can adopt
Rainwater Harvesting	rainwater harvesting is practically non existent	residents can be encouraged

Method of study

The study adopted a case study approach to provide a descriptive assessment of the quality of the physical environment of the two residential areas. Case studies can be employed as a source of providing practical information that leads to potential solutions to problems. According to Francis (2010), the case study is a well-documented and systematic examination process, decision making and outcomes of a project, which is undertaken for the purpose of informing future practice, policy, theory, and /or education. Yin (1994) had shown that case studies can be done alone or together.

Information was obtained by carrying out a survey and physical assessment in order to understand the areas being studied. The survey also provided a description of the physical characteristics of the environment of the areas, through the use of photographs and sketches.

Integrating Green Infrastructure

The growth of towns and cities if not properly controlled and managed can present the risk of creating unliveable and unhealthy living environments. According to Ely and Pitman (2014 p3), "the contention that human habitats need to be healthy and friendly places that use and recycle resources wisely, are clean, safe and accessible, are protected as far as possible from extreme weather conditions and where natural systems are not only recognised and valued for the critical functions and services they provide, but assisted in delivering these services." However, for the towns and cities to properly function there have to be good and functioning infrastructures, roads and to move vehicles, transmission lines to distribute electricity, sanitary sewer systems to remove wastewater to safeguard public health, and storm water systems to prevent roads and homes from flooding. Much of the infrastructure whenever they are available are built in the traditional approach by using grey infrastructure, there is little or no consideration of the relationships between the built and natural environments. The repair and installation of grey infrastructure is becoming increasingly expensive for the authorities to sustain.

Similarly, Benedict and McMahon (2006), point out that more 40% of total urban land is covered by impervious surfaces as roads, parking and buildings. The use of green infrastructure at city scale is therefore important in improving environmental conditions. Perini and Rosasco (2013) points out that vegetation plays and important role in the human

psychological well-being inside dense cities. Green areas provide recreational facilities and improve resident's quality of life.

The elements of green infrastructure that can be employed and used to enhance the quality of the high density residential area include the following: permeable walkways, swales, bio retention pool, rain gardens, green roofs, planters and hedge, and trees.

Most of the streets and roads in the Sabon Gari and Samaru residential neighbourhoods are in bad conditions, with a minimum width of 12m. Provisions are made only for vehicular transit; there is no provision for pedestrian walkways and tree covers, neither are waste bins installed. Most often the pedestrians have to struggle with motorist for space (Plates III, V). However, several intervention processes can be carried out by integrating elements of green infrastructure to enhance the environmental quality.

i. **reduction of the street width by introducing permeable pavement and walkways:** The roads in the residential neighbourhoods are wide enough measuring about 12m, this can however be reduced to 7m by the provision of permeable pavements and sidewalks on both side of the road (see Plate VI). The Permeable pavement installations allow rain water to percolate into the ground. The maintenance of many green infrastructure practices can be done by hand and does not require expensive machinery to keep them operational, Rowe and Bakacs (2012).

Fig. 6 Example of the use of permeable sidewalks and green lane in residential neighbourhood.
Source: Field work, 2015

ii. **Planting of trees and hedges**:
The addition of trees to a landscape is one of the simplest green infrastructures techniques (see plate VII - IX). Tree canopy can reduce storm water runoff by intercepting rainfall, as well as by improving storm water infiltration in soils. Trees and hedges are the simplest elements of green infrastructure and can be easily incorporated into the neighbourhood to enhance its quality and environmental appeal. According to United State Environmental Protection Agency (2011) Street trees and trees planted along building exteriors can lower surface and air temperatures through shading and evapotranspiration. Shaded surfaces are likely to be 20 – 40°F cooler than those that are non-shaded, which reduces electricity demand for cooling in summer.Street and landscaping trees also reduce wind speeds, slowing heat loss in winter.

Every compound in the study area can be requested to plant a minimum of two (2) shade providing trees in front of their houses. This will provide shaded surfaces for pedestrians, reduce outdoor temperatures, enhance the visual quality of the environment, reduce wind speed and dust during the harmattan season and improve storm water infiltration during the rainy season.

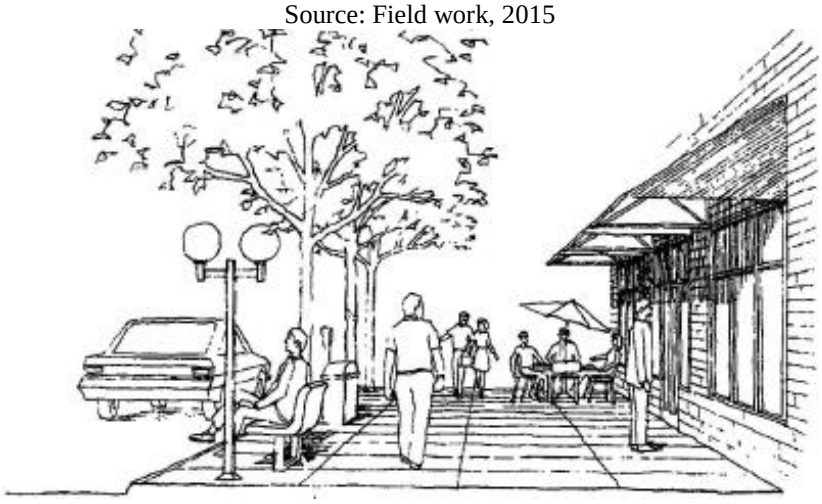

Fig. 8 Use of trees to provide canopy on sidewalks in residential neighbourhoods.
Source: Streetscape Urban Design Elements

Fig. 9 Use of trees and shrubs to provide canopy on sidewalks in residential neighbourhoods.
Source: Streetscape Urban Design Elements

iv. **Bioretention cells**, or **rain gardens**

These are shallow landscaped depressions that utilize soil and both woody and herbaceous plants to remove pollutants and infiltrate storm water runoff (USEPA, 1999). Bioretention cells consist of different zones that perform specific functions for treating and infiltrating storm water. Bio retention cells can be installed either in residential properties or parking lot islands, and even in areas with high clay content by amending the soil with sand and compost and installing an under drain.

iv. **Rain water harvesting:**

Rain water can be harvested and stored in underground tanks during the raining season and the same water can then be utilized in the dry season to water flowers and hedges. USEPA (2011) States that rain water harvesting will help to reduce the amount of run-off water going into the surface drainage. Water harvesting and reuse includes practices such as rain barrels and cisterns that can reduce energy use by saving on the need to use highly treated drinking water for outdoor water and other non-potable uses.

Most of the houses in the study area have either gabbled roofs or hipped roofs of corrugated roofing sheets. For the hipped roofs, rain barrels, and re - use drums and cisterns can be placed along the roof valley, while a metal or plastic collector channel should be placed along the roof eaves to receive and channel rain water to rain barrels. Similarly, for the gabble roofs, metal or plastic collector channel can be used toreceive the rain water along the eaves and channel it to a down pipe into the rain barrels.

v. Green Roofing

According to Architectural Record, (2003) there is an easy and largely forgotten place to restore green infrastructure in urban regions at a fraction of the cost of open space - rooftops. Traditional urban rooftops are black tar, and thus they absorb huge amounts of heat in the summer, contributing to the urban "heat islands" that have been demonstrated to measurably alter weather patterns around urban centres. USEPA (2011) points out that, the green roof offers a myriad of environmental benefits including providing improved air quality and preventing storm water runoff from entering the area's already taxed combined sewer system. The ASLA green roof retains about 80 percent of annual rainfall and significantly reduces the amount of nitrogen entering the watershed. The report further points out that, the green roof provides an extra layer of insulation for the building, reducing building energy use by as much as 10 percent during the winter months and temperatures on the roof itself measure 59 degrees cooler than a conventional black roof.

Rooftops in the study area are silver - coloured corrugated galvanized iron roofing sheet which reflects a large part of the incident solar radiation thus raising the ambient temperature. Green roofs will therefore offer a lot of benefits including the reduction of storm water runoff, reducing the incidence of urban heat island and improved air quality.

CONCLUSION

Embracing and adopting the use of aspects of green infrastructure in the high density residential neighbourhoods in our urban areas is an economic way of enhancing

environmental quality in the study area by increasing the size of green areas. In addition it makes it visually acceptable by reducing the size of paved area and reduced cost of road construction because the width has been reduced. Similarly, tree planting by the roadside will create a walkable conducive microclimate for pedestrians and reduce the possibility of an urban heat island arising.

ABSTRACT

Prior to the late 19th-century, sunlight was considered as the primary day-time lighting system for buildings. Classical and other early architectural designers manipulated daylight and incorporated various strategies to make it more efficient. Although lost to the discovery of electricity and the Industrial Era, the energy crisis of the last few decades has spurred renewed focus on daylighting. Literature shows multiple daylighting options for architects which have been extensively reviewed. But a model daylight retrofitting principle is lacking. This paper seeks to bring to the fore the need a strategy for incorporating efficient daylighting as a post-construction strategy towards achieving sustainable designs. This study involves a partial comparative analysis of ten (10) daylight strategies on a residential building with daylighting challenges. A retrofit rating was developed from the analysis and used as a guide to select the best daylight strategy for the retrofitting process. This paper recommends that retrofit projects be embarked upon to incorporate ample daylight using a step-wise method to rank the various strategies available. This way the benefits of daylighting can be fully maximized.

Keywords: Comparative Analysis, Daylighting, Design, Retrofitting

INTRODUCTION

The 21st century has been the age of globalised innovative advancements in technology. This extensive development has however resulted in a rise in global energy demands. Although there have been attempts all over the world to reduce energy demand and emissions, buildings presently account for approximately 40% of global energy consumption and play an important role in the energy market. (Nejat, Jomehzadeh, Taheri, Gohari, and Majid, 2015; World Energy Council, 2013). This suggests that significant reduction in global energy consumption can be achieved if we alter the way we design and maintain our buildings.

However, Xing, Hewitt, and Griffiths (2011) and Ibn-Mohammed, Greenough, Taylor, Ozawa-Meida, & Acquaye, (2013), surmise that for now, buildings' energy demand is still predicted to continue growing worldwide in the coming decades. IEA (2013) put forward that for the past forty (40) years, the energy demand from buildings (including residential and commercial buildings) has grown by 1.8% per year. The scenario implies that the global trend is worsening. Despite the scarcity of petroleum products, energy demand in Nigeria has been on the steady rise due to increase in economic development and the population growth (Emodi, & Boo, 2015).

The residential sector constitutes the third-largest major energy consumer in the world, representing 27% of total consumption (Laustsen, 2008). Steaming the tide of the global energy crises thus requires significant attention in this sector. Renovation and retrofitting are concepts that provide the architect an opportunity to enhance the sustainability attributes of buildings, particularly with regards to energy efficiency. These post-construction processes allow for major or minor modifications or repairs to homes. In most cases these involve masonry, electrical, plumbing or fitting and installation changes. Clients seldom engage architects for daylight retrofitting.

The Daylighting Challenge

Sunlight was considered as the primary day-time lighting system for buildings before the discovery of electricity. Classical and some other early architectural designers manipulated daylight and incorporated various strategies to make it more efficient. Although lost to the

discovery of electricity and the Industrial Era, the energy crisis of the last few decades has spurred renewed focus on daylighting. But a model daylight retrofitting principle is lacking. The significance of which will assist both architects and building owners to harness more of the daylight and reduce energy consumption.

BACKGROUND

In making a case for the increase in daylight considerations, the debate has been significantly advanced by researchers advocating significant benefits of daylighting. According to Edwards & Torcellini, (2002), the integration of daylighting into the building as an architectural statement and energy savings strategy, gravitates into benefits which extend beyond structural functionality and energy conservation. Their proposition is that utility costs and building occupants well-being are heightened by improving daylight admission. The assertion that daylight integration has gains beyond the confines of architecture and energy was earlier put forward by Hathaway, Hargreaves, Thompson, and Novitsky, (1992). They stated that human biological functions are dependent on the highest levels of natural light while Robbins (1986) had also earlier surmised that on a psychological dimension, daylighting facilitates the desire for building occupants to have contact with the outside living environment.

Furthermore, workers in daylight and full-spectrum office buildings have reported an increase in general well-being, with specific gain including health, reduced absenteeism, increased productivity, financial savings, and preference of workers (Pellegrino, Cammarano, & Savio, 2015; Franta and Anstead, 1994). Similarly, daylighting has been to improve the academic performance of students (Nicklas and Bailey, 1997), and there is consensus among researchers that spatial quality can be enhanced through natural light to afford psychotherapeutic care to building users (Edwards & Torcellini, 2002; Vischer, 1986; Verderber, 1983). Thus, the conclusion is that the therapeutic qualities of indoor environments can be enhanced by daylighting.

Daylighting Strategies:

Literature shows multiple daylighting options for architects which have been extensively reviewed. These options in some cases utilise mechanical systems to help transport daylight from openings into the building. This significant difference in these systems determines issues like the cost, complexity, amount of embodied energy, and effectiveness.

In achieving a classification for daylighting systems, there are several approaches taken by researchers. Some researchers focus on the strategies that involve the entire building design while others focus on the manipulation of daylight through various openings. According to Belakehal, Aoul, and Bennadji (2004), daylight admittance into functional spaces can be achieved by the use courtyards with various configurations (totally and/or partially covered) – giving special considerations for the building type; semi-open spaces; skylights; different shapes of windows (recessed, screened, and small sizes) and some constructional and aesthetic details. These passive strategies represent the preferable way to harness sunlight as they do not directly add any extra cost to the energy requirements of the building, seeing that they do not consume energy in operation.

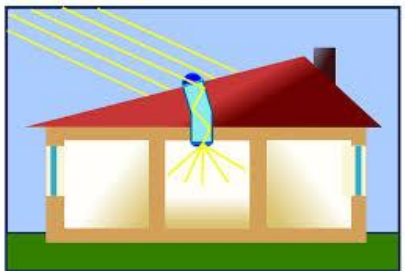
(4) Toplighting



(5) Light Pipe

(6) Light Tube

Fig. 1 – 6: Types of Daylighting Strategies
Source: Google images

Boukekri (2008) detailed strategies for daylighting from a purely design point of view, integral with the building envelope. He classified these as sidelighting and toplighting. He highlighted the use of side windows, the clerestory system, combined side systems, light shelves, louvre systems, prismatic systems, and anidolic zenithal collector system as sidelighting options. He then listed the skylight and light pipe systems as toplighting options. Although these are basically window design options, the variety shown in design, materials, integration and technology has guided their classification as individual daylighting strategies. Core daylighting and atriums can also be used to light interiors as investigated by several researchers and highlighted by Ander (2003).

It is important to note that in practical application, some of these strategies discussed above can take on both passive and active controls. In the passive configuration, they will not require energy in operation, while in the active configuration they require energy for mechanical parts. For example, there are passive and active windows and lourve systems as well as.

DESIGN EXAMPLE

i. Introduction

The methodology for this investigation required the selection of a residential unit with sufficient daylight challenges. The various daylight strategies identified by researchers were ranked based on a rating index to guide selection. The index outlined the terms as passive

design, performance, and DIY (Do-It-Yourself) technique as positive indicators and embodied energy, demolition requirements and cost has negative indicators.

The residential unit selected for this study is a 4bedroom semi-detached bungalow located in Akure Ondo State, Nigeria. This region of south-western Nigeria was selected owing to the fact that it is characterized with abundant sunlight all year round. The building type was selected so as to present a typology with inherent daylighting challenges sufficient to raise the concern of the building dwellers.

ii. Orientation

The building orientation is such that it is slightly off the North-South axis. This exposes the longer axis of the building to daylight to the East in the morning and to the West in the later hours of the day. Although this orientation may increase solar heat gain –which can be solved by passive shading, it maximises the daylighting potential the site offers.

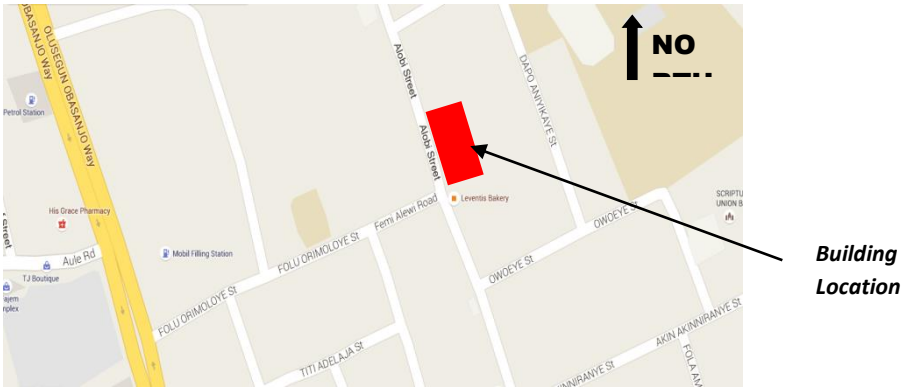


Figure 2: Building Site Plan:
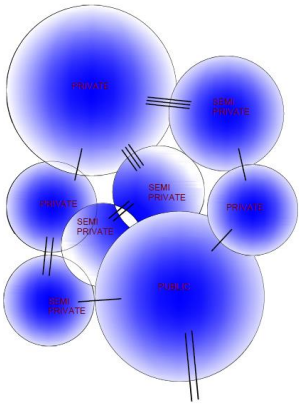
Source: Google Maps

iii. Zoning

The diagrams below show the building zoning and spatial arrangement. They give an idea of the client's general requirements and design.



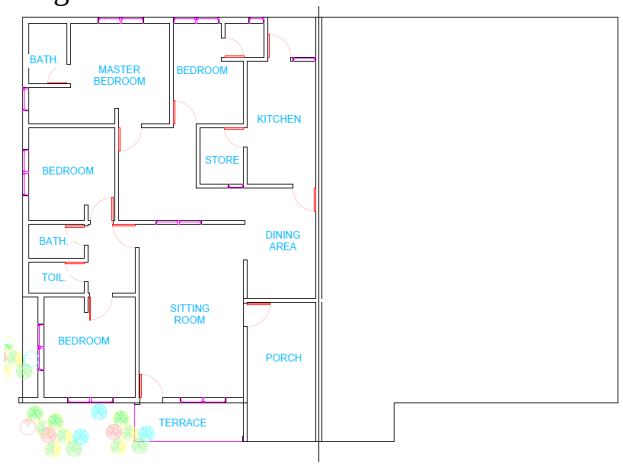


Figure 3: Building Zoning; Figure 4: Building Floor Plan

BUILDING DAYLIGHTING CHALLENGE

Step 1: Identify poorly lit areas on the plan

This was done on the floor plan and shows the exact situation of the plan. The function and area of the space, as well as the surrounding spaces are critical to guiding the manipulation scheme.

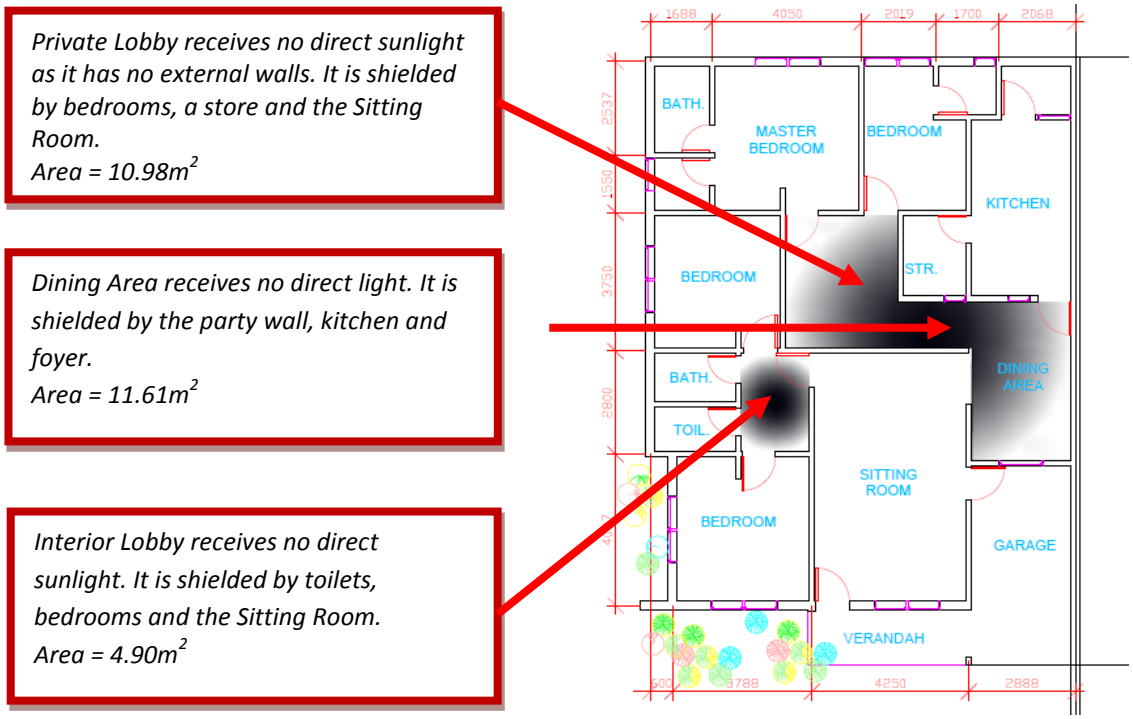

Figure 5: Outline of Poorly lit areas
Source: Researcher's Work

Step 2: Retrofit Rating

A table was developed based on literature survey and practical construction experiences to develop a simplified rating system for home-owners. The chart defines a comparative analysis of the daylight strategies in available to designers and evaluates the possibly of implementation. Using the chart will assist in the choice of which strategy to adopt in the Daylighting retrofit as well has save time and finances. The goal will be to find which strategy is most practical-unique to the design, and has the highest benefit to the building owner.

Table 1: Retrofit Rating (A)

DAYLIGHT STRATEGY		RETROFIT RATING								AVE
		POSITIVE				NEGATIVE				
		Passive	Performance	DIY	Sum	Embodied Energy	Demolition required	Cost	Sum	
1.	Courtyard	✓	✓ ✓ ✓	x	4	✓ ✓	✓ ✓	✓ ✓	6	5
2.	Semi-open spaces	✓	✓ ✓	x	3	✓ ✓	✓ ✓	✓ ✓	6	4.5
3.	Sidelighting	✓	x	x	1	✓	✓	✓	3	2
4.	Toplighting	✓	✓ ✓	x	3	✓ ✓	✓	✓ ✓	5	4
5.	Corelighting	✓	✓ ✓	x	3	✓ ✓	✓	✓ ✓	5	4
6.	Atrium	✓	✓ ✓	x	3	✓ ✓ ✓	✓ ✓	✓ ✓ ✓	8	5.5
7.	Light Shelves	✓	✓	✓ ✓	4	x	x	✓	1	2.5
8.	Light Tubes	✓	✓ ✓	✓	4	✓ ✓	x	✓ ✓	4	4
9.	Light pipe	✓	✓ ✓	✓	4	✓ ✓	x	✓ ✓	4	4
10.	Skylight	✓	✓ ✓	x	3	✓ ✓ ✓	✓	✓ ✓	6	4.5

Guide to colour-coded Retrofit Rating Table

Each tick on the table represents a "one" mark of a maximum of 3, while an "x" represents "zero". The table is divided into the green (positive) columns and the red (negative) columns; the sum for each is indicated next to it. A high green score indicates that the strategy is rated high while a low green score indicates that the strategy is rated low. In contrast, a high red score indicates that the strategy is rated low while a low red score indicates that the strategy is rated high.

Positive Ratings

i. **Passive:** strategy will rely on no active means (i.e no electric power)
ii. **Performance:** effectiveness in daylight admission (i.e. a comparative index based on other strategies on the table)
iii. **DIY:** degree of independence from hired skilled labour (i.e. DO-IT-YOURSELF)

Negative Ratings

i. **Embodied Energy:** average amount of energy required to effect this strategy (i.e. a comparative index based on other strategies on the table)
ii. **Demolition required:** degree of demolition required to install this strategy.
iii. **Cost:** relative cost –whether high, low or average required installing thus strategy.

Step 3: Selection of Daylight Strategy

Table 2: Retrofit Rating (B)

DAYLIGHT STRATEGY		Sum (G)	Sum (R)	AVERAGE
1.	Sidelighting	**1**	**3**	**2**
2.	Light Shelves	**4**	**1**	**2.5**
3.	Toplighting	**3**	**5**	**4**
4.	Corelighting	**3**	**5**	**4**
5.	Light Tubes	**4**	**4**	**4**
6.	Light pipe	**4**	**4**	**4**
7.	Semi-open spaces	**3**	**6**	**4.5**
8.	Skylight	**3**	**6**	**4.5**
9.	Courtyard	**4**	**6**	**5**
10.	Atrium	**3**	**8**	**5.5**

Source: Researchers work

Based on the comparative analysis, the table shows that "sidelighting" has the lowest average rating of 2 and "atrium" has the highest of 5.5. The summary table however shows that "sidelighting" has the lowest (worst) green performance on the index and the lowest (best) red performance. While "Atrium", has a high (good) green performance on the index and the highest (worst) red performance.

This scenario guides the architect in selecting a strategy somewhere in the middle of the table. While the perfect option will be a strategy with a high green score and a low red score, (e.g. Toplighting) the alternative option will be a strategy with an average green and average red performance. This will help to maximize on the gains and minimize the losses. Thus, the use of Light pipes or Light tubes may also be selected and recommended to the client for the daylight retrofitting.

RECOMMENDATIONS AND CONCLUSIONS

Daylight retrofitting requires a methodological procedure which can be done with sufficient professional expertise. It is however simple to educate building clients so that they can make an informed decision on the type of strategy to adopt. To advance this, architects are required to be vastly knowledgeable about current daylighting strategies. Further research will however be required to appraise client preference of various daylighting strategies and environmental impact. Summarily, daylighting provides an increase in natural lighting, reduction in artificial lighting needs, increase in health benefits, and passive aesthetics. Incorporating it yields present and future gains for building occupants

ABSTRACT

Housing energy consumption accounts for almost 36% of total primary energy use in Libya of which cooling and lighting are the main source of demand. This study reviews passive control methods employed in traditional dwellings of Ghadames that highly contribute to enhance indoor thermal and visual comfort. Designing for natural ventilation and daylighting in harsh environment poses a greater challenge to building designers. Twenty one traditional dwellings were surveyed to assess building designs and performance in terms of daylight and natural ventilation interoperability. This study conducted field surveys comprising measurements of indoor/outdoor temperatures while concurrently investigating inhabitants' thermal feeling through both direct semi-structured interviews and questionnaire. In addition, drawings were made to demonstrate the design elements and techniques used to minimize extreme outdoor temperatures and best make use of daylight. Findings indicated that skylight openings play an important role in promoting day and night ventilation. The opening's position and size have to be carefully studied to prevent excessive direct solar heat gains and induce air movement across internal spaces. The field surveys showed that occupants were thermally satisfied in naturally ventilated dwellings having considered that fixed ceiling fan is used at late afternoon when indoor temperature starts to rise gradually. Also the use of light color roofs and walls is recommended which is approved to enhance interior lighting and increase the outdoor albedo ratio. Embedding passive design measures in traditional dwellings can be very effective and cheap in reducing the cooling and lighting demand; the impact on future housing development is also discussed.

Keywords: traditional architecture, natural ventilation/lighting, passive design features

INTRODUCTION

The demand in energy has seen an increase of over 26% in the last five years in Libya within the domestic sector, expected to be even higher by 2017 (GECOL, 2012). Cooling loads and lighting are the main energy consumers in buildings in hot regions particularly in summer seasons. Roaf et al. (2009) mentioned that for thousands of years traditional societies have managed to live in comfort dwellings using natural and simple means to cool or heat spaces. The window design plays a major part in controlling the ventilation and lighting of dwellings on which other interrelated aspects (solar heat gain, heat loss, privacy and security) may depend on (Wilson, 1999). Although there is sufficient detailed design guidance on daylight and natural ventilation issues in CIBSE publications and other related sources, there yet especial cases in extreme climatic conditions may require additional revision. Therefore, understanding the general climate and the micro-climate conditions in particular could help building designers offer better control of indoor built environment. The most important element connecting the indoor and outdoor world is openings in terms of thermal and visual interaction. This element plays many roles including the supply of daylight, the view to outside world, control of air exchange, noise and acts as a glare protector and climate moderator, as well as contributing to energy efficiency in buildings (Wilson, 1999). McCluney (2008) believes there are many benefits of good daylighting design in buildings, starting from enhancing the users' visual and thermal comfort to worldwide issues like global warming and dwindling of fossil fuel energy supply. In the US lighting alone accounts for 30% to 50% of all energy consumed in buildings and 20% to 40% saving in lighting and cooling can be achieved by utilizing daylight and natural ventilation system (Boubekri, 2008). A number of studies highlighted the performance of some

Alabid, J.; Taki, A. & Painter, B. (2016). Control of Daylight and Natural Ventilation in Traditional Architecture of Ghadames, Libya. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 131-140

architectural elements employed in vernacular architecture such as the Arabic *Mashrabiya* and its environmental implication on visual connection, users' privacy and natural ventilation systems (Hansen, 2008). Hansen also stated that only few studies considered integrating such passive strategies into contemporary architecture and these have the potential to synergize buildings, microclimatic conditions and interrelated human activities. Henriques, et al. (2012) focus on developing a responsive skylight system with a mechanism response to indoor and outdoor environmental conditions, synthetically imitating the natural biological system of daylight control.

METHODOLOGY

The study conducted field surveys evaluating the traditional dwellings' performance and control of daylight and ventilation investigating how satisfied occupants are within this naturally ventilated (NV) indoor environment. The nature of the study necessitates carrying out qualitative surveys involved semi-structured interviews of 4 professionals and 7 house owners, personal observations and meanwhile a questionnaire was distributed in 16 neighbourhoods to include 85 respondents to quantitatively evaluate the residents' opinion and preference of their thermal and visual indoor environment. In addition, 21 traditional dwellings were visited during summer 2013 and 2014 and simultaneously temperature measurements were taken inside and outside dwellings. The study also used CBE thermal comfort tool to predict the neutral comfort temperature and zones of these investigated dwellings comparing the two models with actual votes of subjects participated in the surveys. *EnergyPlus* is used for daylight analysis and architectural drawings were made to demonstrate design techniques and methods employed in traditional dwellings

CLIMATE

It is well known that indoor environmental conditions in buildings depend highly on outdoor climatic conditions. Thus, housing designs should consider climate analysis in a very early stage in order to make buildings responsive, healthy and friendly to the environment. Literature is rich in discussing the implications of climate on the design of homes particularly of those who study vernacular architecture such as Singh, et al. (2009). Climate has an immediate impact in forming old cities and related effects on local community traditions and way of life and the choice of adaptation methods to deal with surrounding environment (Ben-Hamouche, 2008). Libyan climate classified into three main regions; the coastal region "hot and humid", Mountain region "cold zone" and desert region "hot and dry" but also there are subsidiary regions may found within those mainstreams as stated in Bukamur (1983).

Ghadames Oasis lies in the Libyan Sahara desert "hot and arid climatic zone" characterized by high average temperatures and temperature variations, very directional solar radiation, clear sky most of the year, almost no rainfall, very low humidity and hot dusty winds occurs occasionally in summer. It is very extreme climate conditions especially the diurnal swings of temperatures in summer times where temperature may rise over 47˚C during the day and drops down to 20s˚C at night and can drops below 0^0C in winter. It is always important to know the wind shadow and sun patterns of the region throughout the year for effective passive optimization of building designs. However, in Ghadames direct exposure to sun and wind is not desirable especially in summer when scorching sun and high solar radiation rates as well as sandy and hot windstorms are the case.

Site & Urban Structure

Old settlements in a wide range of climates have been produced in different architectural styles based upon the local climatic conditions and inhabitants' way of life (Singh et al., 2009). The urban fabric of the old town of Ghadames is highly compact and dense with a clustered type of building design. It has been existed for over 400 years ago and re-erected

several times as local builders gained experience over time by trial and error. The discovery of the artesian spring called Eyn El-lfaras (horse's lake) was the impetus of the town existence that built on an Oasis of an area of 310.3 hectares surrounded by massive sand-dunes and mountains according to (Ealiwa, 2000). One can notice that there are underground water-streams passing underneath the urban fabric of the town ending at green fields surrounding the town. On a city scale, the urban plan of the old town indicates a hierarchal structure from public wide scale to private family space concerning every single issue in community life. Elwefati (2007) described the urban structure of the old town as a covered connected city as majority of roofs are interconnected whilst streets and alleyways also covered in order for shade, privacy and security to be ensured.

Yet, natural ventilation and daylight are among the issues concern local builders and users which carefully were employed in accordance with interior space requirements and moreover upon inhabitants' need for protection from undesirable outdoor conditions. Littlefair et al. (2000) underlined the role of urban morphology, building geometry, street patterns and other local features like vegetation play in natural ventilation field. However, local builders have recognized such effect and adopted certain building techniques to maintain sufficient access of fresh air and daylight in dwellings throughout the year. And the only way to ensure this mechanism is to rely on skylight openings. Open courtyard was not ideal due to the sandstorms that hit the area from time to time. Therefore, there is a modified microclimate in the town differs from the regional synoptic climate brought by its urban structure as well as the massive green fields that contribute to mitigate the extreme regional climate by preventing the buildings from direct sandy winds and vegetation helps promoting thermal stability and increasing humidity rates. The urban stratification of the town and its individual dwellings shows a great coherence to the natural world surrounded formed upon social and environmental considerations making the entire city works as a one unit. Figure 1 demonstrates a curved and centralised urban structural design of the old town surrounded by over 36 thousands of palm trees and part of the new town with an open rectangular kind of western style of city urban design.

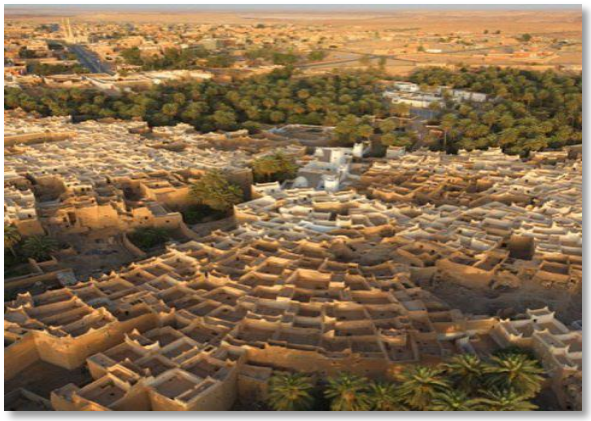

Figure 1: view of the urban settlements of old and new towns of Ghadames

DATA ANALYSIS

House Design

The visit to the old settlements involved drawings to capture the most common architectural design and features of different dwellings besides the investigation of indoor thermal conditions. Surveys found that traditional dwellings somehow have similarity in form, layout and interior space organization irrespective of the dwelling size. According to Ealiwa (2000) the traditional house plot area ranges from 25m² to 50m² whereas the total floor area of the house may also varies from 70m² to 80m². Figure 2 demonstrates the location of the modelled house within the compound and its space organization. As this drawings of typical traditional

house show, the majority of houses consists of three storeys stratified according to social and environmental requirements.

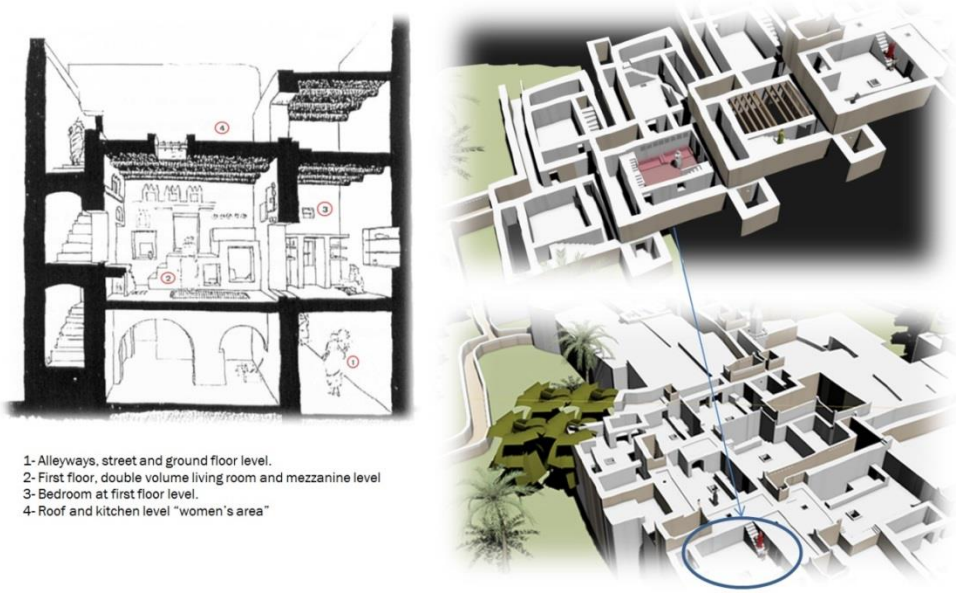

Figure 2: architectural details of typical traditional house

Socially, privacy is very important issue for local community and therefore ground floor allocated for visitors and storage purpose. The first floor is the semi-private space where family may invite someone and also part of it still considered as private area for sleeping and practicing certain cultural affairs. The third floor is only for women use where the kitchen is located and a shed used in summer time at cool nights. Thermally, ground floor found to be cooler and the higher the level the warmer it gets. The living room is built in a double volume with a height of 4.5m to 5.5m. The relatively high ceiling space enhances the air circulation and helps remove the heat gained through the roof structure during the day.

Comfort & Users' Thermal Sensation

According to a number of studies, thermal comfort requirements may vary from region to region and even between individuals. Therefore, it is important to understand the building users' thermal perception in order to determine the proper indoor conditions that natural or mechanical systems may deliver. Brager & De Dear, (2001) compared The upper limit of comfort zone in ASHRAE Std. 55 which is 26˚C that base on 0.5 cloth rate (clo) and 50% relative humidity (RH) to the new adaptive comfort standards (ACS) which is based on climatic data and 80% acceptability limit of subjects. To some extent Brager and De Dear's study agrees with a number of studies conducted in North African context including current work suggesting that adaptive approach in hot regions so often allows warmer indoor temperatures in naturally ventilated dwellings during summer, which may refer to psychological and physiological adaptation of the human body to surrounding environment. The air movement is a significant parameter in human thermal comfort and how effective may depends on other physical environmental parameters. For example, in warm humid conditions, higher indoor air speed is preferred (Tablada, et al. 2009). On the other hand, in hot dry climates lower air speed and mean radiant temperatures could enhance indoor thermal comfort as Ealiwa, (2000) and Al-Jared, (1991) concluded.

As figure 3 demonstrating the comfort temperature records for naturally ventilated buildings show that neutral comfort temperature for subjects falls within the acceptable band in adaptive model and stepped aside in Predicted Mean Vote (PMV) model. This findings may underpin the study carried out by Honnekeri, et al. (2014) that explains the case users' expectation towards particular thermal environment which sometimes overrides other

psychological or physiological factors. The study found that in naturally ventilated dwellings occupants are thermally satisfied preferring to be slightly cooler despite air temperatures of 32˚C and relatively low air speed that ranges between 0.04 m/s to 0.08 m/s. In air conditioned dwellings, the majority wanted no change to the indoor thermal conditions with temperatures recorded at 21˚C to 25.5˚C and air velocity of 0.12m/s to 0.25m/s. According to the equivalent temperature reduction method (ETR) suggested by Lechner (2014) there is only necessity to increase air velocity when relative humidity is higher to maintain the same thermal sensation. This may explain the tolerance for higher air temperatures and relatively low air speed of those who live in naturally ventilated dwellings of Ghadames.

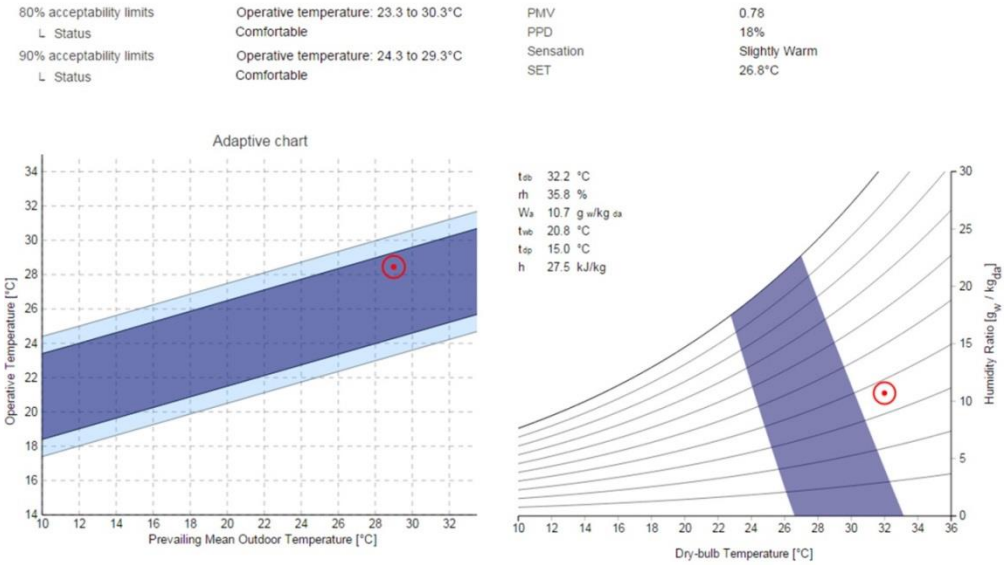

Figure 3: Thermal comfort zone in CBE tool for MPV and adaptive models

Natural Ventilation

Clancy, (2013) has stated in CIBSE knowledge series – KS17 that ventilation is very important component in human thermal comfort and highlighted certain reasons for which ventilation is mainly needed:

i. providing fresh air for metabolism, dilution and removal of pollutants from space
ii. extracting contaminants at source (e.g. extract systems for kitchens, bathrooms, industrial processes and fume cupboards)
iii. satisfying combustion needs for appliances such as gas cookers, boilers and unvented heaters
iv. distributing conditioned air (for heating or cooling)
v. space pressurization to inhibit the infiltration of pollutants from outside or from one space to another (e.g. preventing integrated circuits within cleanrooms from being contaminated by dust particles)
vi. pre-cooling building fabric (e.g. night venting of naturally ventilated spaces)

For naturally ventilated dwellings it may seem quite challenge for designers to ensure all is achieved particularly in extreme conditions. However, Ghadames traditional dwellings show an incredible application of natural ventilation systems in homes considering all mentioned above by Clancy. The house is so often surrounded by adjacent houses from three or four sides with light-wells interposed in between. These light-wells play an important role in ventilation especially during summer. The position of those voids designed mainly according to both the room location and privacy issue. Air speed was measured in different locations within the house and found to be higher the closer to those openings at an average of 0.12 m/s whilst lower in the middle of the living room at an average of 0.06 m/s which may explain why occupants use ceiling fan in this room at that position. Minimum exposure of external

facades helps reducing the direct solar heat gain whereas the greater thermal mass structure the more the amount of heat transferred through building fabric is delayed, which means less heat extraction from the space to cool the air down as shown in figure 4.

The skylight aperture is the soul of the building structure acting as an artery for daylight and air movement daily cycle linking inhabitants with the outside natural world. During the day air enters the house through relatively small room voids approximately 15x25cm crossing all other spaces to leave the house via the 1m² roof aperture. Vice-versa at night time as outdoor temperature is getting lower, cool air begins to penetrate through the skylight opening and warm air leaves through the same opening via stack ventilation effect and more recent a fan ceiling is used to enhance the air circulation. Al-Zubaidi, (2002) and others have mentioned how roof is an important component in traditional house of Ghadames for women do home cooking and some other family traditional customs. The main reason that kitchen was placed on the roof is to extract heat and smoke away from the house and therefore there is no heat generated from home appliances and such activities inside the dwelling.

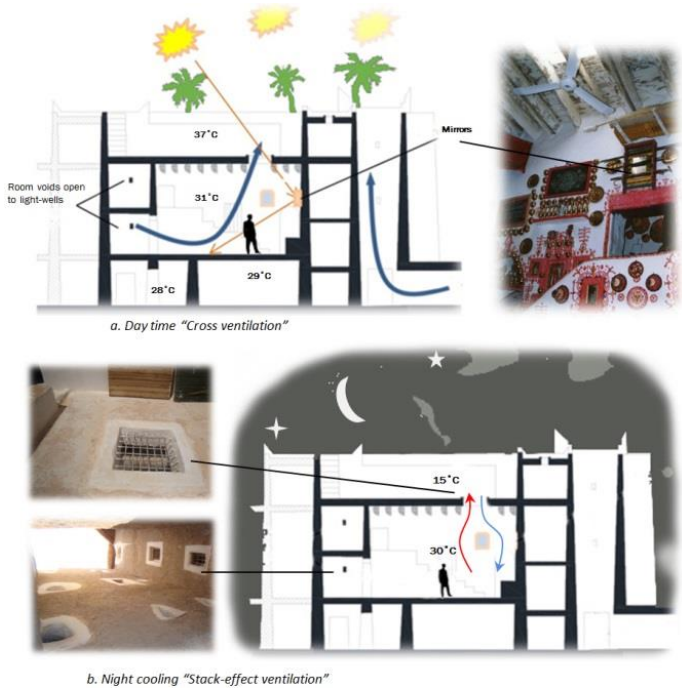

Figure 4: Natural ventilation, design and methods "traditional house"

Daylight

Boubekri, (2008) defined the daylight or sunlight as a vital component to life that plays fundamental, biological and psychological functions to humans and other creations on earth. Daylight is also known as natural light which is the amount of solar radiation stemmed from either the sun "direct sunlight" or the sky "diffused light". Scientifically, as figure 5 demonstrates natural light is the visible wavelengths on the earth surface which ranges from 400 to 760 nm (Thomas, 2006). Obviously, considerable factors can affect the availability of natural light such as the geographical location, weather conditions and the time of the day and year, and notwithstanding the spatial design and the particular use of the space has a significant impact on the required amount of daylight.

Recent studies concerning with daylight design in residential buildings have developed possible passive solutions to provide an adequate amount of daylight to buildings in order to optimize its energy efficiency and consequently for human well-being and productivity. Carter, (2014) and some other researchers have studied the use of tubular daylight guidance system (TDGS), that was introduced in the last decade of the last century and became widely

used in a wide range of buildings. The polycarbonate collectors are located at roof level to capture direct and indirect sunlight which may enhanced by additional reflective devices such as mirrors where sun conditions may not be predominant. Despite TDGS being 50% more expensive method than electric systems and compared to conventional roof lights and windows, it is still considered as passive tubular daylight system and have capacity to deliver deeper daylight into areas that cannot be covered by conventional means.

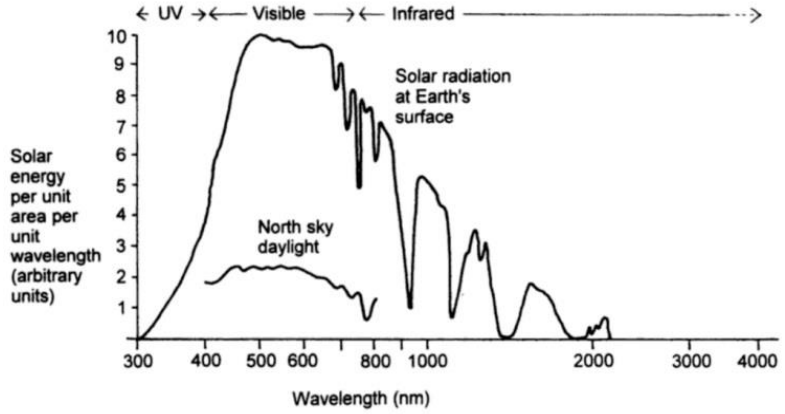

Figure 5: The visible solar radiation on earth surface ... source (Thomas, 2006)

Similarly, but over 200 years ago traditional dwellings of Ghadames employed such passive design technique installing skylight aperture at roof level to lit the interior with the use of reflective mirrors and brass motifs to deliver the daylight into deep areas. Figure 6 shows the use of these reflective devices on internal walls not only for decorative propose but rather to optimize indoor visual environment. The figure also shows dynamic simulation of daylight analysis using EnergyPlus tool to compare the average of daylight inside the living room with and without reflective surface. As may figure 4 illustrated the position and size of external openings and one can notice that roofs and internal walls are painted with white colour to intensify reflected solar radiation, as the lighter the colour and more reflective the surface the less heat will pass through the roof. Due to clear sky in desert regions and high solar radiation which creates extreme brightness that more likely to cause glare, therefore the size of external openings is minimized whilst sky diffused light is optimized to avoid overheating and discomfort occurrence. Sealed and porous plank shutters have been used to cover roof aperture according to weather conditions and another shutter type to prevent from insects invading buildings during some seasons.

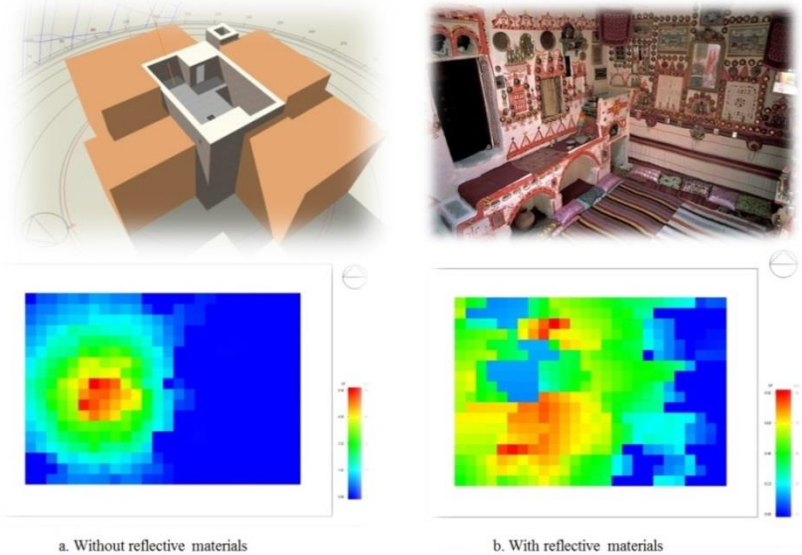

Figure 6: Daylight analysis in living room of traditional house

The sunlight's motion incorporated through the design of the old town's streets and alleyways. The repetition of shaded and sun-lit zones resembles a natural phenomenon of day followed by night, which is experienced in sequence as one walks through these alleyways during the day as shown in figure 7. These streets and walk paths were designed for minimum exposure and daylight requirements, inhibit the amount of direct sunlight and diffused reflections. Thus, during the hottest summer days while outdoor air temperature was around 44˚C it was recorded in these shaded paths at 28˚C to 31˚C.

Figure 7: Design methods and distribution of daylight in alleyways

Ground Water Cooling Strategy

In fact, not only minimum exposure to outdoor environment contributes to alleviate the extreme outdoor conditions but also water systems passing underneath the town alongside those alleyways have a great impact on indoor microclimate. These canals designed to work in gravity fed system starting from the water source "Eyn El-lfaras" passing the town urban structure to end up at fields surrounding the town. The water contributes to humidify the indoor air and brings cool breeze into pedestrian paths and light-wells attached. Figure 8 demonstrates the process of using the water from the domestic use point to the green fields.

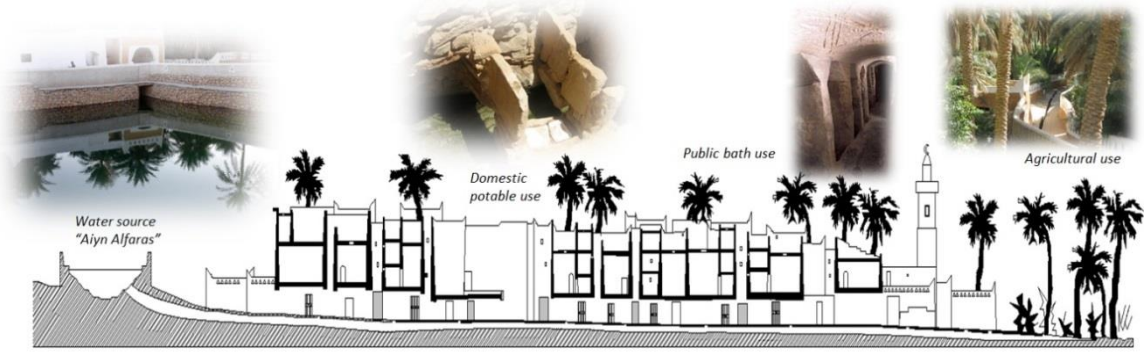

Figure 8: Gravity fed water system and distribution in old town

However, the water flow promotes air circulations and introduces air currents into the indoor atmosphere that can clearly be noticed at the junctions of alleyways and those opened voids to the water streams. The air enters the alleyways through the wider main streets may have been passed over the canals and subsequently cooling it via latent heat exchange and humidity in the air may increase though.

CONCLUSION & RECOMMENDATION

Good design of daylight and natural ventilation could result in considerable avoidance of energy consumption in buildings. The benefits of that are not only saving energy operating costs rather than achieving the desirable natural environment in buildings. And to do that

building designers should have an understanding of the design methods and techniques found in vernacular architecture that harness the climatic conditions to work to its advantages. The purpose of this work is to shed light on various techniques used in indigenous settlements of Ghadames to naturally control the indoor thermal and visual environment. Obviously, uncountable benefits can be achieved by incorporating various passive design techniques and bioclimatic features into future developments which some may underline here:

i. Considering a compact type of settlements in such climate conditions that provide less exposed external surfaces which mean more shadings and less solar heat gain rate.
ii. Ensuring high thermal mass structure in order to stretch the time lag reducing the heat transfer rate per unit of the surface into internal spaces.
iii. Paying more attention to external openings and promote the concept of roof and skylights rather than vertical windows to;
    - Promote stack ventilation
    - Minimize direct solar and heat gain through openings
    - Achieve appropriate daylight distribution
    - Prevent from undesirable hot sandy winds during summer
    - Respect cultural norms and preserve local identity
iv. Applying mutual shadings from adjacent buildings helps reducing solar heat gains.
v. As the visible solar radiation is high in the region so that size of openings on external facades can minimized to avoid issues such glare and discomfort.
vi. Narrow shaded streets and pedestrian paths will act as cooling ducts that vents away hot dusty air which may contribute to enhance the heat loss via winds to the outside environment.
vii. Light-wells behave as environmental modifier for heat exchange and provision of natural light and adapting such concept in future housing development can solve number issues like heat islands and reduce energy costs for lighting and ventilation.
viii. Covered public routes and squares ease residents' movement during the day at which car parking locations may be connected to in future developments.
ix. Having live plants within the dwelling and an enclosure of green belt around settlements helps stabilizing the outdoor microclimate for instance absorbing CO_2, provide more shades and filters out hot dusty air which in turn have an impact on indoor environment.
x. Creating wet surface within the building or surroundings cools the air via latent heat extraction that may passes over intermittently-wetted surface and also increasing its humidity rate.
xi. Introducing double volume space e.g. living room or covered indoor courtyard with roof openings promotes the night ventilation system by trapping cooler air at night and stratifies air presence during the day.
xii. Reflective external surface by painting it white could help increase albedo rate and reduce the heat gain and transfer through the building structure into interior spaces.

Analysing the Importance of Climate Forecast Information for Transhumance Pastoralists in Katsina State, Nigeria

Idoma Kim.[1*]; Ikpe, Elisha[2] & Sawa, B. A.[3]

[1]Department of Geography, Ahmadu Bello University, Zaria, Nigeria
** kimidoma@gmail.com*

ABSTRACT

Undoubtedly, climatic variability wields remarkable influence on the livelihoods and well-being of Pastoralists in the semi-arid regions of Nigeria. Hence, scientific weather forecasts can help increase the resilience of communities to unpredictable weather events and seasonal patterns. The study examined the value of climate change prediction for transhumance pastoralists in Katsina State, Nigeria. Specifically, the study investigated pastoralists' access to weather forecasting and early warning information, main sources of climate forecast information and barriers to pastoralists' utilization of climate information. Multistage sampling technique was used to select 367 respondents for the study. Data were analyzed using percentages, frequencies and tables. The results showed that pastoralists generally lacked access to timely climate forecast information. More than half of the pastoralists affirmed that the main sources of climate information were the radio, extension services, television and pastoralists 'personal observation. In conclusion, the study contended that climate forecast information is crucial to pastoral economy; however, timely access to reliable forecasting and early warning information would enhance capacity of pastoralists to adapt to climate variability. Hence, adequate training of extension workers and farmers on the interpretation and use of forecasts is necessary to enhance effective dissemination and utilization of climate information.

Keywords: Climate, Forecast, Information, Pastoralist, Transhumance

INTRODUCTION

Climate change has turned out to be most critical issue at the global level, regional and local level to such a point that it is considered as the severest challenge for the mankind in the present century (Kumar, 2014). Consequently, there is an emergent concern that climate variability and change, coupled with other environmental, social and political pressures, may overpower resilience of pastoral systems (Francis, et al., 2015).

Hence, the expected global temperature increase, more intense rainfall and more frequent droughts will have overwhelming effects on pastoral livelihoods. The economy of the vulnerable areas also declines in the event of these misfortunes considering that droughts and diseases resulting from floods affect the health of livestock which is the major source of livelihood for the pastoralists (Geoffrey, 2010). To navigate these risks, pastoralists need better and more complete information on both climate (long-term patterns over months or years) and weather (short-term changes in conditions).This would enable farmers and pastoralists take crucial crop, livestock, land and water management decisions before and during growing seasons.

Although, their decisions should be based on indigenous climate knowledge, but as precipitation patterns alter there is an increasing need for science-based climate information. But then farmers and pastoralists lack access to reliable forecasts on probable rainfall patterns in coming rainy seasons, and knowledge about the full range of technologies that they could use to ease production under increasingly challenging conditions. Consequently, it is problematic for them to make operational decisions, which results in increasing food insecurity and vulnerability, and persistent or even increased poverty.

In Nigeria, principal sources of climate services include; the Nigerian Meteorological Society [NMETS], academic institutions such as universities, non-governmental organizations and research institutions.

Kim, I.; Ikpe, E. & Sawa, B. A. (2016). Analysing the Importance of Climate Forecast Information for Transhumance Pastoralists in Katsina State, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 141-148

Although several studies have been carried out on adaptation to climate change in developing countries [Nhemachena, (2007); Ojiako, Manyong and Ikpi, (2007); Selvaraju, Subbiah, Baas, and Juergens (2006); Idrisa, Ogunbameru, Ibrahim and Bawa,(2012); Onu, (2006)], these studies do not look at the significance of Climate Forecast Information (CFI) and its linkage to adaptation to climate change by farmers and pastoralists.

In view of that, this study seeks to fill this lacuna and contribute knowledge to the general adaptation literature by analyzing the importance of climate forecast information for transhumance pastoralists in Katsina state, Nigeria.

The specific objectives of this study were to:

i. identify the socio-economic characteristics of respondents in the study area
ii. analyze how pastoralists in Katsina State accessed weather forecasting and early warning information.
iii. examine the pastoralists main sources of climate forecast information
iv. assess how access to climate forecast information influenced pastoralists adaptation decisions
v. assess barriers to utilization of climate forecast information in the area of study

LITERATURE REVIEW

Pastoralism and Climate Variability

According to Okoti, Kung'u, and Obando (2014), pastoralism is a complex livelihood system seeking to maintain an optimal balance between pastures, livestock and people in uncertain and variable environments. Pastoralism, therefore, is a subsistence system based primarily on domesticated animal production for meat, milk, hides and blood (Encyclopedia Britannica, 2009). The way of life of pastoral herders depends largely on mobile grazing of livestock. They practice differing levels of mobility, from sedentary herds that move within a locality, to transhumant herders who move between particular locations on a regular basis, to nomadic herders who have high mobility without regular patterns. (Blench, 2001; Joshi, Jasra, Ismail, Shrestha, & Wu, 2013)

Therefore, Nori, Taylor, and Sensi (2008) noted that pastoralism plays a crucial role in supporting local livelihoods, in contributing to national and regional economies as well as in in providing diverse ecological services in some of the world's poorest countries. However, its capacity to adapt to change is facing many challenges, including those posed by climate change.

Although long-term impacts are difficult to predict and are bound to vary from one location to another, most climate change models predict rising temperatures and decreasing rainfall in many dry land areas (Hesse and Cotula, 2006). Consequently, Bai and Bent, (2006) remarked that the quality, quantity and spatial distribution of natural pastures are mainly shaped by rainfall. Predicted changes in rainfall patterns are bound to result in increasingly scarce, scattered and unpredictable pastures. Furthermore, the number, distribution and productivity of permanent pastures and water points, which are so critical for livestock survival during the dry season, are bound to decline (Hesse and Cotula, 2006) Berhanu and Beyene (2015) also maintained that scarcer resources, coupled with current levels of demographic growth, are likely to lead to stronger competition between pastoral communities and between these and other groups - possibly resulting in conflict and even violent clashes. As a result, access to pastures becomes more difficult, leading to loss of livestock and of livelihoods.

Supporting the aforementioned, Oxfarm (2008), Seo and Mendelsohn, (2008) opined that there are also significant negative consequences including loss of livestock through heat stress or colder seasons; increase in animal pests and diseases; loss of land to agricultural

encroachment as the rise in rainfall raises the productive potential of the dry land areas; an increase in frequency of flooding, and the spread of human and livestock diseases that thrive during the wet season; declined animal performance such as growth, milk production, and reproduction. The resultant effects have been food insecurity in the most parts of Arid and Semi-Arid Lands (ASALs).

In the sub humid zone of Nigeria, infectious diseases continue to be the most common cattle health hazard. The principal ones are rinderpest, foot-and-mouth disease, and contagious bovine pleuropneumonia. These have led to the deaths of many livestock.

Weather Forecasting and Early Warning Information in Pastoral Communities

According to Dinku, et al., (2014) advance knowledge of climate information is important in helping farmers and pastoralists make decisions on resource allocation and type of agricultural enterprises in a season. Climate information coupled with agro-advisory services offers greater potential to enhance capacity of pastoralists to adapt to climate variability and climate change. The effects of climate change and increased climate variability mean that farmers and pastoralists have to make crucial management decisions based on available climate information (Mase and Prokopy, 2014)

However, they are hampered by their lack of access to science-based forecasts of the coming season, and also their lack of knowledge about the full range of crop and livestock management options that could help minimize rainfall-related risks (Mugabe, Admassu, Sall, Omolo, and HanKponou, 2011). Hence, Radeny, et al., (2015) opined that making available timely Seasonal Climate Forecasts (SCFs), which offer crucial information ahead of the next growing season helps livestock keepers to make informed decisions on when to migrate with livestock, destock and restock as well as adoption of livestock breeds that are more productive.

Similarly, Hansen, Challinor, Ines, Wheeler, and Moron (2006) admitted that forecasts can provide advance information so that farmers can adjust critical agricultural decisions, thereby improving efficiency, and enabling them to adopt the most suitable coping strategies An Early Warning System (EWS) involves the provision of timely and effective information, through identified institutions, which enables individuals exposed to a hazard to take action to avoid or reduce their risk and prepare for effective response (Shakespear and Godwell, 2014)

Consequently, for pastroral communities to be prepared, there should be early warning systems in place to disseminate information so that pastoralists take necessary action in advance. However, (Vermeulen, Aggarwal, Ainslie and Angelone, (2010) posited that many of the promising opportunities provided by early warning and climate information have not been fully exploited. Conversely, Dinku, et al., (2014) noted that the availability and access to such information and the ability to use it, is a serious challenge in most rural areas across the continent.

METHODOLOGY

Description of the study area

The precise location is between latitude 11˚7' 49"N, 13˚05' 22"N, and Longitude 6˚52'30"E and 9˚20'40"E and a total area of 24,192 km² (Patrick, 2012). It borders Zazzau Emirate in the south, Kano in the East, Daura in the Northeast, the kingdom of Maradi in Niger Republic in the North and Sokoto Emirate in the west. Katsina state has thirty-four (34) Local government Areas. See (Fig.1). Katsina State has a total land area of 23,938 square kilometres.The projected population of the state was put at 7,452,629 in 2014 from the 2006 figure at a growth rate of 3.2 percent. Majority of the population are Hausa/Fulani Muslims. The climate is semi-arid with average annual rainfall of about 689mm falling between May

and September. The major economic activities of the people are farming, livestock rearing and marketing of agricultural products (Umar and Musa, 2015 ; Ikani, 2015).

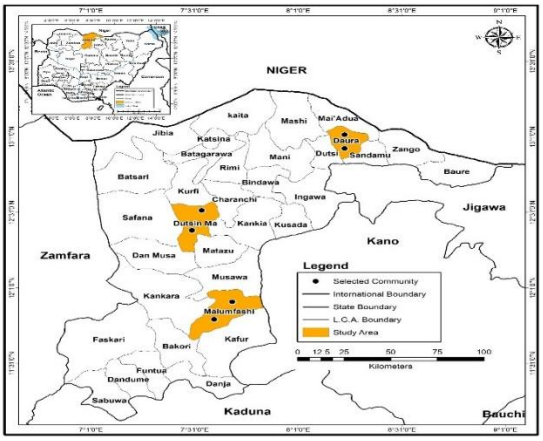

Figure 1: Map of Katsina State showing Study Area
Source: Adapted from the Administrative Map of Katsina State

Sampling Method

A multi-stage sampling method was used to select respondents for the study. Hence, one LGA from each senatorial zone was purposively chosen, two wards from each LGA were systematically chosen and two settlements from each ward were purposively selected (Table 1).

Based on Krejcie and Morgan's (1970) table of sample size determination, 367 pastoralists were interviewed .This is because the population of sampled communities is 7, 266(see table1) and according to Krejcie and Morgan's table could have a sample size of 367. Consequently, a total of 367 copies of the questionnaire were administered, while 300 (96 in Daura, 107 in Dutsin-ma and 97 in Malumfashi LGAs) copies of the questionnaire were retrieved representing 81.74%. Focus Group Discussion was also employed for data collection. The data obtained were analyzed using descriptive statistics and chi-square analyses.

Table1: Sample Size for Questionnaire Administration

Katsina State Senatorial Zones	Selected LGAs	Selected Wards	Selected Settlements	Population 1991	Projected Population 2013	Proportion of questionnaire
Katsina North	Daura	Madobi Sabongari	Tudu RumaSanda	478 717	925 1387	47 70

FINDINGS AND DISCUSSIONS

Socio-Economic Characteristics of Respondents

Table 2 expresses the socio-economic characteristics of respondents in the study area. Regarding gender, nearly all the pastoralists (90%) were males. This implies that pastoral activities in the study area is male dominated. Various studies (Idrisa, Sulumbe and Mohammed, 2007; Onu, 2006) found that gender plays significant role in having access to production resources and hence utilization of information. Hassan, (2008) asserted that male-

headed households are often considered to be more likely to get information about new technologies and take on risks than female-headed households.

The age distribution of respondents has indicated that 20% of respondents (i.e. majority) were between the ages of 20 -24 and greater than 50 years. This by implication suggests that pastoralists in the study area were made up of young and fairly old people with over 70% having cognitive herding experience of 20 -30 years. This has further shown that the study area has large number of able-bodied farmers who have a greater tendency to utilize agricultural information/innovations (Obinne and Oche, 2001).

With reference to marital status, the results revealed that 80% of the pastoralists were married with a mean house hold size of 17 persons, whereas only 4% were widowed. Marital status has implication for utilization of agricultural information and technologies since married people are willing to seek information about improved technologies so as to enhance the welfare of their families (Idrisa, 2009).

On the basis of education, table 1.4 has expressed that pastoralists were literate to varying degrees. It has shown that majority (over 36%) had Islamic education. Education influences farmer's information utilization. Educated people are expected to perform certain jobs and functions with higher efficiency and are also more likely to utilize information and new technologies in shorter period of time than uneducated people (Ofuoku, Uzokwe and Ideh, 2006).Considering the income level of respondents, table 2 has illustrated that majority (33.33%) earned between 201,000 to 300,000 annually.This investigation further disclosed that in general pastoralist communities in Katsina state had medium economic status and hence may possess the financial muscle required to purchase and utilize ICT facilities.

Table 2: Socio-Economic Characteristics of Respondents (N=300)

Access to and Use of Forecasting and Early Warning Information

About 78% of the pastoralists affirmed that it was important for them to know about expected amount and distribution of rainfall as well as temperature trend in the subsequent season. Regarding questions on the awareness of the pattern of rainfall and temperature in the succeeding season, about 40% of the pastoralists claim to have knowledge. Concerning drought and violent storms, approximately 30% avowed that they got timely warning.

Main Sources of Climate Forecast Information

Sources of weather forecasting and early warning information include modern methods, traditional knowledge and farmers' observation. However, this research focused mainly on access to forecasting information from modern methods. More than half of the pastoralists stated that they receive weather forecasting information through personal assessment of weather parameters.

Furthermore, the pastoralists ranked radio as the most important channel for accessing information. This is followed by extension services and television. On the reliability of the modern forecasting information, majority (78%) admitted that the information was only 'reliable once in a while'.

Role of Forecasting Information in Farm Decision- making

Undoubtedly, a farmer has various decisions to make in the course of farming. Consequently, the pastoralists were asked about factors that mostly influence farming decisions. Three factors were cited and ranked in this order: Input costs, weather and climate information and output price expectations. These investigations indicate that weather and climate information is an important determining factor in farming decision in the study area.

Again, the pastoralists were asked to rank farming decisions that were mostly influenced by climate forecast information. The most important decision were knowing when to migrate, harvest water, collect fodder and choosing animal species as well as having more knowledge. Additionally, pastoralists ought to have information and knowledge on how to apply the forecast information received. Disappointingly, 56% of the pastoralists asserted that they did not have knowledge on how to effectively utilize the climate information received.

Barriers to Utilization of Climate Forecast Information

In the study area, the major challenges to weather information utilization included among others lack of timely advance information (42%), inappropriate and non-context specific information (35), undependability of information (13%) and wide spread illiteracy (10%). The preceding assertion is corroborated by Speranza, Kiteme, Ambenje, Wiesman, and Makali,[2010] that communication of climate information to support adaptation actions in Africa is hindered by several contextual factors: social-cultural, content-related and technological barriers. In addition, a study conducted by Gwimbi (2009) in Gokwe District of Zimbabwe, revealed that more than 70 percent of the surveyed farmers lacked access to timely Weather forecasts.

CONCLUSION

The present research found that there was a general lack of access to timely rainfall forecast, temperature trend and early warning information on droughts and violent storms. Some of the key channels that transmitted the information were the radio, extension, the television, and the farmers enquiring directly.Pastoralists acknowledged radio as the most important channel. Besides, the forecast and early warning information were perceived as not being very reliable. Although it played an important role in the decision-making process of pastoralists, particularly, when deciding the time to migrate in search of pasture, collect and store fodders and choosing livestock varieties. A severe constraint for pastoralists was lack of

complementary information, inputs, and technology that could be used to adjust their livestock management practices consistent with forecasts. The forecast and early warning information is imperative as it acquaints individuals and communities on the need to take action

RECOMMENDATIONS

Government and Non-governmental Organizations should:

i. Enhance farmers' timely access to reliable forecasting and early warning information
ii. Help in improving reliability of forecasts and early warning information through upgrading and maintaining meteorological stations and equipment, and enhancing the skills of the personnel.
iii. Adequately train extension workers and farmers on the interpretation and use of forecasts
iv. Enhance the knowledge and capacity of farmers in terms of general preparedness and adaptation to climate variability and change through provision of complementary information, inputs and technology

Impact of Cities Physical Development on the Aged Lifestyle in Akure, Nigeria

Onanuga, Omotayo Adebayo

Department of Architecture, Federal University of Technology, Akure, Nigeria
oaonanuga@futa.edu.ng

ABSTRACT

In Nigeria, the practice of aged support is solely anchored on the traditional practice of adult children to care. However, recent trends show that the aged now live alone in indecent houses that lacks housing related services and environmental benefits. Cities development patterns and infrastructure are presumed to be responsible for the non-cohabitation between the aged and their families in the cities as the aged find it difficult to adapt to the city lifestyle due to its non-compliance to their culture and communal life. This study therefore investigates the city defect on aged communal lifestyle and suggests how the situation can be mitigated. Qualitative data was collected through structured interview aided by voice activated tape recorder. Two categories of the aged were interviewed, those who reside permanently in the city and those that have come to live with their adult children. The aged who were at least 70 years of age, oriented to person, place, and time, were asked to participate alongside their adult children where necessary. Observations of the environment, and the participant expressions were utilized in combination with the aid of relevant literature on the subject matter. This study upheld the presumptions that city development pattern is a disadvantage and therefore concludes that it is to the uttermost benefit of the aged if urban development conform to the communal lifestyle of its inhabitants as this will improve family unity and give the aged the sense of belonging.

Keywords: Aged lifestyle, Akure, city development, communal life, Nigeria

INTRODUCTION

Old age is a status quo that is pervasive to every living creature. This age has a peculiarity of low strength and agility to cater and sought for themselves their daily needs. The need for some form of care, assistance and special consideration to residence provision increases as people move into older age, particularly for those aged 75 years and over (National Research Council, 2001). The customary practice of family support, which has been solely affixed on the capacity and willingness of adult children to care for their elderly parent in Nigeria is increasingly coming under threat of contemporary transformation in life styles and expansion of expectation (Omokaro and Ibrahim, 2011). It is of general view in Africa that children and relations must do their best to care for their elderly as it is part of African tradition.

Living is becoming more challenging lately owing to the general downturn of economy, a blame casts upon poor governance and actualization of the dividends of democracy in Nigeria, thereby makes the adult children in the family to have migrated to developed countries and cities in search of economic advantages, educational opportunities, and diversity of experiences that large cities provide. The need to keep the aged close to their adult children also have necessitated the relocation of the aged to the cities where their adult children live for proper care and close monitoring of their health as they grow older. Nevertheless, it has been observed that it does not take long before these aged return to their various old locality where care is far from them and their livelihood is been threatened.

The physical characteristic of the built environment is presumed to be responsible for the inability of the aged to fit into city environment as it is sensed that the pattern of the aged activities and lifestyle contradicts the planning of the urban cities from a holistic point of view. Rural communities where most elders grew are sparsely populated areas outside of large urban centers that have defined social, economic and cultural traditions associated with their region or community (Woods, 2005). The city development of the present generation does not conform to this well-established lifestyle and interest that the aged pattern of life have long been fashioned towards.

Onanuga, O. A. (2016). Impact of Cities Physical Development on the Aged Lifestyle in Akure, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 149-157

To assist ageing in a place, consideration needs to be given not only to housing options but also to transportation, recreational opportunities, and amenities that facilitate physical activity, social interaction, cultural engagement (Wahl & Weisman, 2003) through the span of the aged remaining existence. Therefore, it can only be said that the aged is considered by understanding their communal lifestyle and investigation on how the physical development of a city can contribute to the sustainable ageing in the relocated areas.

The continuity theory of Neugarten, Havighurst, and Tobin (1961), as also supported by Atchley (1989), posits that successful adjustment to old age requires continuing life patterns across a lifetime. This continuity and a connection to the past are maintained through a continuation of well-established habits, values and interests that are integral to the person's present lifestyle. The aim of the study is therefore to investigate the physical development in the selected neighbourhood in Akure and its implication on sustainable ageing in the neighbourhood to ensure healthy living conditions for the aged. The objectives set to achieve this are to investigate the communal lifestyle of the aged in their old locality; access the level of physical development and infrastructure in the selected neighbourhood; evaluate ageing in selected neighbourhood in Akure; and access how the physical development contributes to sustainable ageing in the selected neighbourhood in Akure.

It is expected that the objectives itemized will enlighten on the challenges the physical development in the built environment poses on aged well-being in the society, and the need for government and key decision-makers to put in consideration the measures for ageing in place and out of place to make the environment sustainable to aged, giving them the sense of belonging, and thereby strengthening the family bond in the society.

LITERATURE REVIEW

In research, the focus is mainly on attempts to systematically probe a subject matter in order to uncover the cause and effect, the magnitude of a problem and its impact (Omokaro, 2010). The objective is to explain the multi variant nature and workings of the matter under discussion (Ibrahim and Omokaro, 2011) which in this case would be addressing the importance of bringing families together through proper city planning that considers all stages of life, with more consideration on the aged health as optimal aging involves staying active and managing to resist the shrinkage of the social world by maintaining the activities of middle age for as long as possible.

The Theories of Aged Right

As the most populous country in Africa, Nigeria currently has the highest number of aged or elderly people in Africa (Kinsella & Velkoff, 2001; Ajomale, 2007; UN, 2005). With the largest population in Africa and the seventh in the world, it is estimated that by the year 2050 the population of Nigerians aged 60 and above will constitute nine percent (9) of the entire population (UN DESA, 2015). This growth in the number of older people was explained as the increasing expectation of life, which results from improving living standards, better nutrition. These aged were able to attain this level of age because before they aged, they were able to seek out for themselves their necessary needs.

The four major theories that expresses the obligation of the children to the required care of old age people are (1) the developmental theory of sociology (2) the structural function theory (3) the role theoretical perspective and (4) the exchange theory (Omokaro and Ottong, 2004). The developmental theory of sociology has postulated that the care given to the aged should be based on cultural, systematic and learned behaviours, while the Structural Functional theory posits something related as it argues that care giving behaviour by adult children is systematically learned and developed through socialization and internalization of

cultural norms. The Role Theoretical perspective also postulates that care giving is a normative requirement and social role prescription, while the Exchange Theory perspective posits that care of the elderly by adult children is based on the norms of reciprocity and filial obligation. These four major theories that concentrated on aged care points toward a paradigms that the adult children owe society and their parents, provision of services and social values, and the customs of society confer legitimacy on the moral rights of elderly parents to such services (Omokaro et al, 2004). No wonder the adult children in Nigeria when interviewed felt strongly that care should be given to the aged by their children and expressed that it is even a taboo for a child not to attend to his aged parent's needs. One of the adult children interviewed in Lagos, Nigeria stated that dumping the elderly in seclusion from their relations is not fashionable as the elderly want to maintain their natural environment till their dying day which they believe gives a sense of belonging, freedom and responsibility to the elderly (Obasoro, 2011).

Decreased physical agility which is associated with old age necessitates their dependence on others for tasks such as shopping, bathing, housework, cooking among others. This poor physical health could also be made worse with mental health problems such as depression (Heidrich, 1998) caused by loneliness. Dean, Kolody, Wood and Matt (1992) affirmed the fact that elderly people who live alone has higher level of depressive symptomatology. Bower (2000) notes that it is tough to grow old when one lives all alone and without satisfying contact with either friends or relatives as such isolation carries an added burden in that it sharply boosts a person's chance of developing Alzheimer's disease or related brain ailments associated with advancing age.

In view of this, the need for the aged to move alongside their adult children to the cities arose as their stage in life requires close monitoring. Although this decision is necessary as it will help in moving the aged close to their adult children for proper care, but the urban city form of development have been frustrating the idea due to its non-compliance to culture and the communal lifestyle of the aged.

Aged Communal Lifestyle

Globally, the two major sets of people that dwell in today's cities either migrate from one locality or the city could have been their one time rural community. A larger percentage of the aged in Nigeria hail from one rural settlement or the other. These rural settlements are known for their disperse settlement style which does not actually conform to any pattern. It gives room to good spacing of residential houses, creating more of open spaces for gathering, recreation and sporting activities, green areas of good creature display that brings about innovation, pure and clean air good for body system among others.

Prior to the colonial era in Nigeria, open spaces played vital roles in the lives of the people in the traditional setting in the villages and towns, mostly in Yoruba land (Iloeje and Emenike, 2014). These open spaces serve as common places for connection of spaces, they also serve as area for social interaction, communication and share of ideas. The people of same community will group themselves together in peers to interact, play games and share memories. Sometimes the aged of the community will gather the children together for moral teaching, passing down the cultural and the historical information that is associated with the community to the children. The aged were never alone even when the adult children have left to farm as they will group themselves together to chat and relate.

It is easier to reason and discuss together as the whole community do feel concerned about their neighbour wellbeing, and their built environment encourage neighbourhood interaction. The houses are without fences, thereby encouraging even a distance chat between neighbours.

Theft and other criminal activities are found wanting in those settlement as everyone felt responsible for the neighbours wellbeing.

People in the rural settlement tend to live longer breathing unpolluted air and eating fresh food crops. There are numerous natural elements and green plant that relax the mind and boost creative thinking. Also the rural environment encourages walking ability over a long distance as the streets are connected through path ways. Most time in the evening, after the children might have returned back from farm, the aged will walk down many streets with their children singing and discussing.

The rural environment is not densely populated, therefore the number of vehicles are minimal and noise level is drastically low. This encourages the aged to rest well at any time of the day they deem fit, thereby positioned their health in good shape. This to mention a few are the characteristics of the life that most of the aged were brought up with, a lifestyle seen very different from what we have in many cities in the country. The lifestyle of the cities is characterised by fenced off buildings, doors steps road connection, pollutions due to the industrial discharges, noise from every angle.

METHODOLOGY

Structured interview questions were the data collection instrument adopted for this study. This methodology appears to be one of the most productive means of collecting qualitative data (Henderson, 1991) as it gives the respondent the opportunity to express themselves to the fullest. The aged interviewed were of two categories. The first set was the aged that have lived in the study area before it became a city and the second set were those that have migrated to the study area from a different locality. Due to the non-conformity of the aged to city lifestyle, the second set were fewer in numbers in the study area and therefore making the first set the dominant of this study. Nevertheless both group tended to reason along the same line as their salient points were quite related. This is not unexpected as it is known that today's city was once a rural settlement of the first group of the aged.

Information was also sought from relevant literature in order to exhume the in-depth knowledge of factors underpinning the aged views. This is needed to proof the credibility and the authenticity of the results. The aged who were at least 70 years of age, oriented to person, place, and time, as judged by the researchers, were asked to participate alongside their adult children. Application of the age screening criteria and the fenced off method of building development in the study area led to the limited population of 40 participants in all. Observations of the participant, the activities, the setting for interviews and their expressions were utilized. A voice activated tape recorder was used to record each resident's answers so as to capture all the responses.

The Research Study Area

Akure is a city in the Southwestern region of Nigeria and the capital of Ondo State. It is the economic nerve centre of Ondo State and a leading producer of mineral resources and food crops in Nigeria. It is located on the intersections of Latitude 7^{o} $17^{'}$ and Longitude 5^{o} $14^{'}$. It comprises of Akure South and Akure North Local Government Area. The study was carried out at the Aule housing estate in Akure south local government, Akure. Akure south LGA has an area of 331 km² and a population of 353,211 at the 2006 census (Fig 1). The maximum mean global radiation which occurs around (14:00hrs LT) varies in the course of the year from 512 W/m2 in the wet season to 543 W/m2 in the dry season (Falodun & Ogolo, 2007). In a seven year average (between 2001 and 2007), Akure received statistical mean daily sunshine hours of 5.21 hours (Afolami and Fadairo, 2014) and the recorded measured values for relative humidity of Akure in 2007 was close to 100% for the rainy season months

(Adediji and Ajewole, 2008). Average rainfall measurement for year 2010 review in the South West States (including Ondo State) was 2,000mm to 3,000mm (NIMET, 2010; as cited by Afolami and Fadairo, 2014).

FINDINGS AND DISCUSSIONS

Responses of the participants indicated that the most popular activities were sitting at home, and sometimes at daybreak, interacting with children. This finding was understandable in light of the fact that most of these activities were un-socially inclined and the study areas lacks neighbourhood relationship due to the house built pattern.

The investigation focused on the planning pattern of the study area as to discover its conformity to the culture and communal lifestyle of the aged living in that environment. Based upon the analysis of the data collected, three (3) themes were deduced from the communal lifestyle of the aged which were consequently tried on the environmental design of the study area. The themes are as follows:

i. The neighbourhood environment
ii. The house type
iii. Space planning and recreation

The Neighbourhood Environment

It was observed that nature does not exist in the study area any longer as the environment is connected with hard asphalted road network with no sidewalks. The participants explained that this was not the case in pre-modern times, when human settlements either integrated or co-existed peacefully with the nature. This statement is related to Kaveh (2012) study when he notes that during modern era of human development, growth of towns and cities displayed a separation between nature and human activities. The building surrounding was of hard landscapes of either over-site concrete or stone paved. Most of the natural infrastructure has been destroyed due to the city development that is said to focus on making life more convenient, with drive through services. One of the guiding design principles outlined with reference to the best qualities of the traditional neighborhood design from Congress for New Urbanism stated that "Neighborhoods should be compact, pedestrian-friendly and mixed use"(Urbanism, 2007). In a related study, Jacobs (2007) described the four necessary physical conditions for dynamic urban life as multifunctional neighborhoods, short blocks and

connected street systems, varied age residential areas and a high concentration of people. All this have been and made evidence in the traditional architecture that encompasses the culture of a community in accordance with the lifestyle of its people.

The cost of disregarding nature has extended also to quality of life. As stated by one of the aged, he emphasized that the disregard of nature in urban design of the study area in terms of housing type and choice of material, neighborhood planning, and infrastructure planning among others have make the area inhabitable. Among what was stressed by the respondents in neighbourhood planning is the difficulty in walking down the road. Inefficient transit service and precarious walkable environments was observed to have been another barrier to the adaptability of aged to the city planning as the urban areas remain largely auto-oriented and difficult to traverse on foot. Over the last three decades, both research and practice have provided substantial evidence confirming that walkability is essential for improving social integration, enhancing urban quality of life and maintaining physical health (Doyle, Kelly-Schwartz, Schlossberg, 2006). Evidence to date suggests that adults living in more walkable neighbourhood (ie, higher residential density with mixed land use and connected street networks) have higher levels of transport-related walking, overall physical activity and a lower body mass index (BMI) than those in less walkable neighbourhood (Doyle et al., 2006; Saelens, Sallis, and Frank, 2003).

This came to be due to the lack of pedestrian walkway as regards road planning in one hand and recklessness of the vehicular drivers on the other hand. Walking is so essential to the aged for it is the only possible exercise that their ability can tolerate as it offers relatively little risk of injury. Research has affirmed that each exercise session appears to be additive in reducing the risk of infection over time (Nieman, 2001; Hu et al, 2004; Davey, 2000; Laverty et al, 2015) and those positive changes in the immune system occurs during moderate exercise. Sidewise this, during the time that the adult children that the aged are residing with would have gone to their places of work and the grandchildren to school, the aged could like to take a walk to relief loneliness and boredom. This culture is common in the traditional setting as it improves neighborhood relationship. It is therefore not advisable for the aged to walk by the road side due to the absence of pedestrian walkway and inconsistency in driving of the motorists to avoid the unexpected.

Aside this, the new social crime that concentrated on the aged is also not helping matter. Senior citizens or the aged are now been kidnaped to extort money from their adult children, a situation that is lately rampant and seems uncontrollable. To avoid distress, most aged are always being restricted of movement in the neighbourhood. The study area is also known for its high sun intensity, the reason behind its slogan as the sunshine state. Therefore, the choice of hard landscape pattern adopted in the study area have resulted in an unbearable heat in both the interior and the exterior of the environment as it was stated by the respondents, causing discomfort to the elderly.

House Type

Housing, a subset of traditional architecture, evolves from the culture of a community in accordance with the lifestyle of its people, the materials for construction available, and technical possibilities open to them (Gardi, 1973; Olotuah and Ajenifujah, 2009). Advocates of housing pattern that evolves from a people lifestyle described it as pleasant, private, and safe. They claim that it creates a sense of togetherness and tight-knit community among their residence. Moreover, the residential development in the study area has long deviated from this trend as stated by the older participants, they now provide a lifestyle and higher quality standards of living as it may seems with a homogenous social groups. This new pattern of residential development in a community is what researchers termed “Gated

Community/Society" (Teipelke, 2011). Exclusive amenities like swimming pools, children playgrounds, and other recreational facilities were added advantage of the present way of development but the gating phenomenon is not without costs (Al Shawish, 2015). Being self-sufficient and large enough, it detaches those living inside from the outside world; on the other hand, it denies access to the outside world (Ayna, 2011).

As it was deduced from the interview, the aged tends to have the same feeling in this regard, a phenomenon that they stated posed isolation and gives the feeling of been cut off from the world. As stated by Mrs Ajayi (aged 81),

> *"I have stayed more than five years here in Akure but hardly know well even this area I am. My daughter forbid me of walking around, said it's risky. So I took pleasure in walking round the house while I listen to what goes on in the environment. Due to this high fence I could not deduce what is going on around, and when it feels weird, I will return to my room awaiting the return of my daughter."*

Mr Adewale, a retired civil servant staying in his personal residence also expresses the discomfort that the high level fence poses. He explained that the high fence became necessary due to the insecurity state of the country. According to him, he stated that the present life pattern in the estate have created an isolation of neighbourhood and eradicated neighbourhood relationship. He commented that he and his neighbor next to his door steps only do meet accidentally or during the monthly landlord association meetings.

Previous research has identified a wide range of indicators of social isolation that pose health risks which includes living alone, having a small social network, infrequent participation in social activities, and feelings of loneliness (Waite and Cornwell, 2009). The isolation of individual neighborhoods from each other and from the public spaces that the new pattern of residential development is associated with is completely unacceptable and hard to adapt to by the aged. As other cities in the world have their reasons for the adoption of this pattern of development (Levent and Gülümser, 2007; Touman, 2002), the respondents allied their reason to security improvement. Meanwhile, this development type has restricted the aged in their everyday life and most time confined them into a room creating a lifeless, blank, and windowless walled streets between them and the society. This in return has led to the loss of public life, limits their experience of the city, and consequently resulted in life frustration.

Space Planning and Recreation

The benefits of quality recreation spaces in a neighborhood include encouraging people to be more physically active, enhancing opportunities for social interaction with others, and relieving stress and mental fatigue, thereby improving the health of its users. (Richardson, 2013). The African concept of recreation as well as physical exercises includes acts such as dance, acrobatic and gymnastic displays during cultural festivals and other related occasions. These activities are usually done for enjoyment and refreshment as well as finance in some situations. Many of these activities are carried out in special places earmarked for recreation; however in the absence of these special spaces, children, youths and adults in the society have had to improvise (Ajenifujah-Abubakar and Ojo, 2015). It is the major determinant of their life consciousness as a basis for the adoption of value and attitude that influence their behaviour in other aspects of life. Among the measures which have received considerable attention in recent years in understanding measures that contribute to an enhanced quality of life for institutionalized elders are recreation/leisure activities (Teague & MacNeil, 1992). Although these aged have past their prime in terms of physical activity and strength, but their first-hand knowledge of historical events, wealth of experience and hindsight, makes them veteran advisors to the young.

CONCLUSION

The study has revealed a major shortcoming in development, highlighting the particular plight of the elderly population, who by choice of not their own making, cannot move about freely and can only engage in restricted leisure activities within the confines of their immediate physical environment. The healthy functioning of a natural system, including their life-sustaining processes, depends on all species participating in a coordinative way. If cities are built in such a way that children could play in creeks, the families could watch the sunset and the night sky, and sometimes there is quietness, the feelings of change of environment from ones locality would be eliminated and the city dwellers would begin to know nature again. Respect for cultural and ethnic diversity and the recognition of multi-cultural leadership are important inputs to a healthy city. For the benefit of actualizing the focus on proper care for the aged, the unionism of the aged with their adult children has to be attained. The family union could be achieved if adequate consideration is given to the aged communal lifestyle during city planning to make the environment sustainable to them and thereby improve their sense of belonging in the community. To accomplish this, the lifestyle pattern of the aged and their birth community needs to be understood and a way to balance the city development to conform to the communal lifestyle of the people has to be addressed.

The Influence of User Perception and Social Sustainability on Architectural Design

[1]Ejeh, Ekoja David; [2]Adedire Johnson & [3]Salihu Murtala Mohammed*

[1, 2 &3] Ahmadu Bello University, Zaria
** archejeh@yahoo.com*

ABSTRACT

Social sustainability is understood as creating a successful place that is founded on what people need from the places they live and work. Research in social sustainability suggests that this combines the design of the physical realm with the design of the social world. Architecture on one hand has contributed a great deal in the design of the physical realm. On the other hand a variety of social concepts like place making, perception, sense of place, livability, and community resilience to mention a few have significantly contributed to the design of the social world. However, very little attention has been given to the effect both realms have on the other. It is with this in mind that this paper set out to highlight the influence of user perception and social sustainability on Architectural design. To achieve this, this paper assessed students' perception in the design of architectural studios with Ahmadu Bello University as a case study. Through a review of relevant literature, a theoretical background was established between social sustainability, perception and architectural design. Furthermore, themes in form of design requirements were identified and validated by focus grouped discussions. Questionnaires (65) were used to collect primary data from the student respondents to assess their perception in the design of architectural studios. Results showed the priority of the user needs in the design of Architectural Studios. In addition, the students' perception helped to clearly show a strong link with the concept of user perception and social sustainability in Architecture. This paper recommends that, due to the subjective nature of social sustainability with respect to its location and the constant demand to satisfy user needs, the concept of user-perception should be incorporated in architectural design as a major tool in the architectural design process.

Keywords: Architecture, Design, Social sustainability, Sustainability, Perception

INTRODUCTION

In recent times, there has been a lot of demand on the concept of sustainability. In every discipline and profession the concept of sustainability has taken a major focus and is incorporated in fundamental aspects. In 1987, the world commission on environment and development sought to address the problem of the conflicts between the environment and development goals and thus coined a definition of sustainable development.

> *"Sustainable development is development which meets the needs of the present without compromising the ability of future generations to meet their own needs". (WCED, 1987)*

This definition highlighted the displeasure on a global scale of large projects, which were at the expense of local peoples and the natural resources. Due to the destructions of the ecosystems many were subject to displacements and vulnerable to job loss (Carley and kirk, 1998). Thus the mandate in 1987 recognized the strong bond between the people, the planet and wealth and advocated and still advocates that policies fully consider these three components to ensure that none negatively impact the others. Furthermore, this mandate has given birth to extensive discussions and interpretation of the concept of sustainable development based on these three components otherwise known as economic, environmental and social components of sustainability (Harris et al., 2001, Reed, 1997).

According to Mebratu (1998), these three components of sustainability have provided a complicated platform for understanding the Brundtland definition of sustainability. Over the past twenty years, the three components were intended to encompass sustainable development. However, sustainable development has been compartmentalized as an environmental issue (Paper, 2012). In addition, there has been a general orientation of

Ejeh, E. D.; Adedire, J. & Salihu, M. M. (2016). The Influence of User Perception and Social Sustainability on Architectural Design. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 158-163

sustainable as economic growth by both the developed and developing countries. This has not only highlighted the neglect of the social component but has also pointed the priority given to economic and environmental components of sustainability whilst neglecting the social aspects of sustainable development.

Put differently Variance, Perkins and Dixon (2011), pointed out that for the past two decades the social mandate of the sustainable development, which strongly represents the human dimension has been neglected due to a focus on bio-physical environmental issues and the increasing emphasis on economic growth.

Research has shown that despite the extensive body of literature on the social aspects of sustainability, there are still a gap and a need for a better understanding of the meanings and interpretations of this concept, especially when considering it from an interdisciplinary approach (Weingaertner and Moberg, 2011). However this paper would focus on an interpretation of social sustainability in Architecture. With this in mind, this paper set out to highlight the influence of user perception and social sustainability on architectural design. To achieve this aim the following objectives were outlined:

i. To establish a theoretical background between social sustainability, perception and architectural design
ii. To identify variables for assessing user perception in the architectural design
iii. To highlight the influence of user perception on architectural design

Meaning of Social Sustainability

Many definitions in Literature suggests that there is no single definition to social sustainability. However definitions that exist have been derived according to specific disciplines. For example, Konning (2002), maintains that social values such as culture and social justice should be focused on in providing social sustainability. Also, Littig and Griessler (2005) stressed the relationship between nature and the society in providing social sustainability. They added that this relationship can be further understood as "work in the society" and "needs".

Though there is a list of definitions a recurrent concept highlighted in the literature of social sustainability is …meeting human needs. Kefayati and Moztarzadeh (2015) in their study of developing effective social sustainability indicators in Architecture highlighted that social development are designed to improve the quality of human life and consider measures to meet human needs. Consequently, Nastaran, Qasemi and Hadizadehzargar (2013), opined that these strategies pay attention to the welfare needs, cultural and psychological needs, the need for adaptability and the need for growth and development, which are regarded as important human needs in the new society.

Contrary to the views of Sachs (1999), Godschalk (2004), and Chiu (2002, 2003), in identifying different aspects of social sustainability and connecting and connecting them to sustainable development, Vallance, Perkin and Dixon (2011) suggests that social sustainability, drawing from the Brundtlandreport provides an opportunity of reconciling peoples' need with the bio-physical environmental management goals through economic development. They further explained that these needs were either tangible or less tangible necessities of life and if not met would hinder bio-physical environmental concerns.

Thus we can conclude that social sustainability is one of the key component in the drive for sustainable development. In addition, human needs are seen as very pivotal in achieving social sustainability. These needs may be regarded as tangible as in welfare or less tangible as in psychological and cultural needs among others. Therefore human needs are a dimension in social sustainability.

Social Sustainability and Architecture

As stated previously, social sustainability can be seen as the focus of the present and future generation that is meeting human needs and improving the quality of life among others. An equivalent response in Architecture to this definition is to create a responsive Architecture that is consistent with the basic needs and behavior patterns of humans to improve the corresponding spatial qualities for all segments in the society (Kefayati and Mozatarzadeh, 2015). What is known as social sustainability today in Architecture is derived for the socio-cultural approaches in Architecture. Consequently, Architecture with an approach to social sustainability focuses on the design of spaces that are compatible with the culture, behavior and methods of human life for the maximum time possible and is suitable for human life for prolonged times. This clearly shows the strong relationship between social sustainability and architecture in achieving human needs. Thus a socially sustainable architecture is one that designs based on the study of human needs and behaviors in a way that there is a relationship between man and the built environment. Put differently, human needs and behavior must be reflected in the design for it to be socially sustainable.

Over the years, research has proved that human behavior has been carefully studied to propose varieties in the practice and execution of architectural design. Most books on Architectural design have guidelines and principled that caters for range human behaviors in Architectural building products. However this is not the case with human needs which are dynamic and cannot be streamlined to specific guidelines.

User Perception and Human Needs

Environmental psychology is the study of transaction between individuals and their physical settings (Clifford, 2007a). He further stated that environmental psychology has fundamental psychology as a process which included concepts like perception of the environment, spatial cognition and personality (Clifford, 2008).

Perception as a concept is not absolute, reason being, individuals perceive and view things in different ways. Perception is the process of using the senses in understanding, acquiring and mentally interpreting information about the surrounding environment and situation (Demuth, 2013). The consideration of the users' perception in the building is a very crucial component in obtaining a good design. This concept of perception to some certain degree has been adopted and developed in post occupancy evaluation (P.O.E.). This has assisted professionals in assessing the performance of buildings.

Demuth (2013), and Eysenck and Kean (2008), listed a few theories relevant to the concept of perception. They include:

i. Gibson theory of Direct perception
ii. Constructivist theories of Perception
iii. Gregory theory
iv. Computational theories of perception

A careful look at this theory, one would observe that experience is key in obtaining meaningful perception.

The concept of user perception is not new in world of architecture and design, it has to do with how the users or occupants of a space perceive or feel about the space they are in. Applying the concept of user perception will help during the design and planning stage in a design process to accurately provide spaces that are functional and that meet the needs of the user of the space. It also helps in assessing the performance of the buildings after construction as seen in post occupancy evaluation. It describes the opinion of a set of people already using

a space in order to accurately provide spaces in a new design or to guide professionals during the renovation or maintenance of that space. It is from this concept of assessing the user perception of users of a space that the concept of post occupancy evaluation emerged.

User needs in buildings are the likes and desires of the building occupants (the people who use and work in buildings everyday but usually have no active part in designing and managing them). It is crucial to recognize and establish the fact that user needs are growing and increasing by the day as man and his environment evolve and discover possibilities that were not known before, from basic activities that are carried out in buildings to more diverse activities. This increase is a product of changes in weather and climate, technological development and advancement, social and economy factors, increase in world population, increase in crime rate and terrorism, increase in the occurrence of natural disasters. As a result of these factors, professionals in the building industry are making efforts to provide more sustainable, efficient and secure methods and systems in designing, constructing and operating buildings to meet the needs of the building users. This is in line with the concept of social sustainability.

Contribution of assessing user needs in the design of buildings

Building designs that focus on the users and catering for their needs will naturally perform better than buildings that are just designed off the shelf without proper study and research and application of this research in the design process. In some projects, these researches are done and carried out by the professionals but it is evident that in a number of buildings been built today that very little of the information gotten from the studies are used. This shows the dearth in the use of social sustainability in architecture. However, user needs, to a certain degree has been met in residential buildings than in the other types of buildings, because the client who in most cases is the user or occupant of the building is more directly involved in the planning and design of the building. This is not the case in other types of buildings like the institutional buildings. It is with this in mind that this paper set out to establish a link between user perception and social sustainability in Architectural design.

METHODOLOGY

After a thorough study of the concept and developing a conceptual framework through relevant framework, this paper decided to prove empirically the link between user perception and social sustainability in the design of architectural studios. Thus, architecture student perception were assessed in the design of architectural studios. First, after a study of relevant literature basic design considerations for Architectural studio design were outlined. Ogunsote and Prunscal-Ogunsote (2012), gave a summary of the design requirement of Architectural studio design based on their study of leading architectural schools in the world. They include; sufficient space for a standard workstation, working surfaces, exhibition spaces, social spaces, computer laboratories, natural lighting and ventilation, study rooms and discussion rooms, standard space requirement per square area for each student, conveniences, adequate storage facilities, dining areas, modeling space, uninterrupted power supply, intranet and internet connectivity model gallery. These considerations were used as themes in assessing the students' perception in the design of architectural studios. They were validated using focused group discussions.

Data assessing the perception of student was obtained through a structured questionnaire administered to students of the department of architecture, A.B.U., Zaria. The Zaria school of architecture has four (4) levels with over five hundred (500) students. Considering time, available resources, accessibility and most especially experience, the 400 level students were chosen as the representative sample. The sample population comprised the 400 level students of the Zaria school of architecture, reason being that they have had the highest level of

experience and training at the undergraduate level. A total number of 65 questionnaires were distributed and 60 collected. Data from the structured questionnaires were translated into numeric codes by the researcher and data capture was done by statistical analysis using SPSS (version 2 1) and Microsoft excel (2010) computer programs. The following presents the findings of the study.

FINDINGS AND DISCUSSIONS

Table 1: Students' Perception in the design of an Architectural Studio

	Design Consideration of Architectural studios	Level of Importance					Average Mean Value	Rank
		5	4	3	2	1		
1	Uninterrupted Power supply	49	8	2	-	1	4.73	1st
2	Digital Architecture laboratory	44	13	2	-	1	4.68	2nd
3	Internet Connectivity	45	11	1	3	-	4.62	3rd
4	Conveniences	36	17	6	-	1	4.44	4th
5	Work station for illustration of ides among students	33	21	5	1	-	4.42	5th
6	Alternative Power Source	36	17	4	2	1	4.41	6th
7	Storage facilities	28	24	5	3	-	4.29	7th
8	Exhibition and Gallery space	28	21	8	2	1	4.19	8th
9	Group discussion and Study Rooms	30	18	7	2	3	4.17	9th
10	Intranet Connectivity	26	20	8	6	-	4.11	10th
11	Combination of Digital and manual workstations	19	24	13	4	-	4.10	11th
12	Customized or personalized work station	25	19	7	4	5	3.92	12th
13	Sinks for washing equipment	13	28	10	9	-	3.89	13th
14	Professional laboratories	16	23	17	2	2	3.83	14th
15	Rest Relaxation area, Snack Bar, Sleeping Niches	17	16	13	12	2	3.57	15th
16	Digital Workstations only	6	14	28	10	2	3.20	16th

18	General workstation	8	14	25	6	7	3.08	18th

Source: Researcher, 2015.

Table 1 shows the analysis of students' perception in the design of architectural studio. A look at the table above, the priorities of the architecture students' needs in the design of an Architectural studio in Ahmadu Bello University, Zaria can be clearly seen. The students rated 'uninterrupted power supply', 'digital architecture laboratory', 'internet connectivity', and 'work surfaces for illustration of ideas' amongst the topmost priority with average means of 4.73, 4.68, 4.62 and 4.42 respectively. While 'digital workstations only', 'Manual workstations only', and 'General workstations' as the lowest with mean averages of 3.20, 3.16 and 3.08 respectively.

From the results, it can conclude that other than validate the themes used in the design of architectural studios; the students' perception clearly outlined the priorities of their specific needs in the design of Architectural studios. Thus we can infer that there is indeed a strong link between user perception and social sustainability in Architectural design.

CONCLUSIONS

This paper set out to establish a link both conceptually and empirically between user perception and social sustainability in Architecture. Through the study of relevant literature starting from the Brundtland report and other views on sustainable development, it was established that social sustainability has been neglected when compared to the other components of sustainable development (environmental and economic). However, it was proven that the social component of sustainability contributes equally to sustainable development. Furthermore, one important theme that was used to describe social

sustainability was 'meeting human needs'. Through environmental psychology, the concept of user perception was seen an effective way to assess these needs in architecture. From the research carried out it was proven that user perception goes beyond validate user needs in architectural design but clearly prioritizes these needs thereby by creating a strong link between user perception and social sustainability in Architectural design. It is recommended that user perception be used as a key component in teaching and practicing architecture thus incorporating social sustainability. However further research should be carried out to incorporate more concepts in the practice of social sustainability in Architecture.

Challenges in Conducting Field Studies in Nigeria: The Built Environment Sector

Ramatu Aliyu

Developing World Built & Natural Environment Research Unit, Leicester School of Architecture, De Montfort University, Leicester, UK

ramatualiyu@yahoo.com

ABSTRACT

Research activities across all sectors generally have their challenges. However, the Built environment sector presents peculiar challenges, particularly with regards to field research, which need to be highlighted and documented to serve as reference for future researchers in the sector. Field research is a way of unearthing valuable information gathered preliminarily from a focused area guided by known template and using accepted research methodology while adhering to strict ethical guideline. It affords the researcher a huge opportunity to have a first-hand experience of the research terrain and an experimental contact with the population of interest to the researcher. A further significance can be found in the influence that filed work can have on the epistemological positioning of the researcher, as it facilitates observation and interpretation of the real world. Additionally, fieldwork can be a tonic and a morale booster for the researcher, providing clarity and purpose for the research, and helping to shape the research questions and possible solutions. However, the experience encountered during fieldwork can be sector and country specific, depending on research, institutional, educational, and physical infrastructure in place. In the built environment sector generally, and developing countries in particular, the challenges faced by researchers on field studies cannot be taken for granted. These challenges can be significantly ameliorated if researchers form the habit of documenting their experiences in their thesis to guide subsequent researchers embarking on field studies in the sector or country. This paper through a documented personal experience and critical literature review brings to fore the challenges encountered during fieldtrip by researchers in the built environment sector of Nigeria and the need to be abreast with such challenges while taking up any research topic in the field of the built environment in Nigeria. It is expected that future researchers in the built environment sector in Nigeria and developing countries generally will benefit from this study.

Keywords: Built Environment, Field Research, Challenges, Nigeria, Developing Countries

INTRODUCTION

Field work is a good significant part of a good research. As widely known, field studies is a way of extracting that valuable data collected primarily from a defined area guided by known template and using accepted methodology. Access to quality data facilitates important discoveries and allow hypothesis to be verified or refuted, helping to shape the response to a research question. However, access to quality data is a major challenge in the built environment sector, which implies the physical environment in this context, particularly in the developing countries. The challenges are more acute in Sub-Saharan Africa and Nigeria is no exception. On Over and above, the relative under development of the built environmental, sector of the economy in Nigeria such as lack of local manufacturing of components needed for the development of the physical environment especially the construction sub sector results in little synergy with the economy; leading to over dependent on importation of construction materials and resulting in little opportunity for research in the development of indigenous building materials. According to the immediate past Minister of Industry, Trade and Investment Dr. Olusegun Aganga (in 2014), Nigeria spends over N500bn ($3.3b) on importation of building materials yearly, which he said may increase to $15b in the next few years. It is in view of this that as a built environment professional and a researcher in this field; I saw the need to highlight and document experiences with data collection to serve as a guide for future researchers in the sector.

Aliyu, R. (2016). Challenges in Conducting Field Studies in Nigeria: The Built Environment Sector. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 164-169

Challenges of Field Studies

Finding an appropriate balance between the requirements of ethical research and the requirement of academic success can be challenging, particularly for novice researchers. Participants such as the respondents as well as established authority as the case may be may request that researchers withhold publication of result for a period of time so as not to undermine local initiatives. In particularly, with sensitive cases, participants may request that researchers not publish the findings at all, leaving researchers in a compromised position in terms of their professional advancement. This can put doctoral researchers in a position of unexpected professional vulnerability –potentially jeopardizing the timely completion of their programs.

All these should be made visible by the graduate school in such a way that possible challenges in fieldworks be included in the generic courses designed for researchers. The tensions in this regard can further be explicitly addressed by creating easy access to research school for ease of consultation during field works surprisingly too. In many cases, research participants can become actively involved in all stages of the research due to personal or cultivated interest in the research topic. Some research participants become so involved to the extent of resources contribution, thereby leading to exerting control and undue influence in the direction of the research. This brings to fore the position that "power can be democratically shared vis-à-vis participatory involvement". However the extent/ modalities has been repeatedly called into question (Gilles & Alldred, Page 43).

Major challenges that researchers generally confronts are summarized thus

i. Restricted access to key actors in the sector.
ii. Residual negativity based on poor practices and ethical abuses of past researchers.
iii. The cumbersome nature of government bureaucracy and protocols.
iv. Difficulty of working in politically charged contexts.
v. Risk factor in working in war zones.

These are explained below as follows:

Restricted Access to Key Actors

In a number of cases, potentially interesting participants failed may fail to return repeated calls. And in the end, the researcher would have no option other but to accept their tactical refusal to engage in dialogue on the subject matter., although Although some researchers may found find the lack of response to various queries somewhat dis-hearting, one would be more grateful to those who did consent to respond or to engage in an interview. It is equally most fulfilling too. However, whether the lack of interest on the part of policy makers reflects logical constraints, skepticism towards the researcher interest or some other reasons remains unknown.

Cumbersome Nature of Government Bureaucracy and Protocol

Foucault's interpretation of power as multidirectional, "Operating from the top down and also from the bottom up" (Dreyfus and Rainao, 1983 p.185), is useful here. Certainly, a multi-directional understanding of power does not preclude the possibility of domination or oppression (in this case, in the context of potentially unequal researcher – participate relations) but rather, acknowledges the potential for interviewers to resist domination. Perhaps, the most obvious – and relatively low risk-way that interviewers (both marginalized and elite) resist domination is through non-participation; or would behoove novice researchers to keep at the fore that participants access is a privilege and not an entitlement and to adjust expectations – and assumptions – regarding participation accordingly when planning research process. This would greatly enhance the researcher's delivery capacity in a timely and effective mannerly; with minimum stress possible.

Residual Negativity Based On Poor Practices and Ethical Abuses of Past Researchers
Interview access can also be denied for reasons completely unrelated to the project (and researcher) in question. Poor practices and ethical abuses of past researchers can legitimately result in limited access to respondents or interviewers. Misconduct by researchers can harm a participant community and spoil future research opportunities.

Field Work during Politically Charged Period
Generally, conducting fieldwork during electioneering year is particularly difficult within a politically charged context. Skepticism creeps in and respondents / interviewers become much more reluctant to respond and much more restrictive with the level of information given. Respondents in some instances relate the researcher with electioneering campaign as well as become hostile. In some instances they relate the researcher with bad governance – believing you are a government agent or worker.

Risk Factor – Field Working In War Zones
Conducting research field work in war zones can be extraordinary challenging especially if it is deemed a war zone, conflict ridden and unsafe by international media. This is in the context of not being able to perform normal actions performed daily at a time of peace, This otherwise simple daily actions become challenged by chaos of warfare. Activities such as eating, drinking, finding shelter and protecting oneself from harm can often become recurring struggles, necessary for survival. As such, the usual challenges of empirical research are intensified and are accompanied by various new contests, many of which interconnect the broad categories of methodology, practice and ethics. Some of these new challenges such as the difficulty in receiving funding, the importance of the researchers ethnicity or nationality in conjunction with the wider potential danger of transporting research notes are in essence simple functional dilemmas that merit only a passing reference.

There are however, certain new challenges that deserve particular attention as they developed alongside other research contests, amplifying methodology and ethical qualms. These challenges concern both access to information in the war zone, as the rapidly changing nature of the conflict produces new practical and ethical contest and the character of the researcher, the conflict presenting them with new challenges during which they must rely upon their own judgment (Hellbart, Hellman-Rajanayagam and Koff 2010: 374/380). Summarily, therefore, the difficulty of this imperative element of fieldwork process is heightened in war zones for many reasons. Firstly, the scientific side to academic fieldwork is near devastated as solid accountable statistical data is almost impossible to accumulate. Methodological norms proficiently applied to research in stable settings for decades are difficult to employ in conflict areas. Systematic data collection through surveys and other tools fail due to war – time population movement, significant number of potential participants in hiding and the security situation dictating from where and whom result can be obtained (Ibid: 356, Barakat, Chard, Jacoby and Lume 2002: 993).

Challenges of Research in the Built Environment
For the built environment researchers whose objective is to engage in participating community based field research, the availability of filed work references (including densification of relevant, timely and topical issue as well as community willing to participate in research) is a minimum prerequisite for success. Nevertheless, no matter how prepared one is during the build-ups to conducting field works, one would always be surprised by the degree of professional challenges experienced during the field work stage of the research process. Furthermore, one would be equally surprised to find little methodological or theoretical guidance within the existing research literature, relevant to doctorate field work challenges in general. Meanwhile, doctoral field works in the built environment in particular

remains an under researched area -one seldom addressed in literature. It therefore, follows that a worthwhile research in the built environment in Nigeria is hampered by a number of factors.

The Traditional Built - Environment Professions Educational System:-
The existing educational patterns in the built environment schools do little in creating an attractive research environment for students; by emphasizing intuitive design methods and de-emphasizing academic thought and values. ..The professions in the built environment have over the years attached status to practitioners and conferred only limited recognition for academic and research pursuits, (Sterling, 2009). However integrating designs, research and practice can be viewed as a new strategy for achieving a productive dialogue about the visual environment (Sanoff, 1991). More so as there is a growing dynamism and complexity in modern buildings, environment and building codes as well as the society.

Inadequacy In Human Resources:– It is admitted in the 2004 report by the Nigeria University Commission that human resources to conduct research in Built Environment disciplines are still present in Nigeria Universities and Research Institutes, but their capacity in terms of competence, commitment and population is inadequate. This problem is further compounded by the excessive brain drain currently being experienced in the country leading to very few hands left to attend to the daunting environmental challenges.

Paucity of Research Funds:- This is a leading factor hampering research and development in Africa generally and in Nigeria specifically; particularly in all professions under the Built Environment sector. According to NUC report of the impact assessment of Research Grants and related activities in Nigeria Federal Universities, 2009, fiscal resources needed to fund and sustain research are meager and where allocations for such are made and available, they are often misappropriated It is also on NUC record that for the past one and half decades, Nigerian Universities expended over 98 percent of recurrent expenditure paying salaries and allowances and 2 percent on maintaining services, with zero allocation for research. Meanwhile, of the total funds granted for research nationally, between 1990 and 2003, less than 20 percent were actually allocated to NUC by Government as shown in table1herewith, and out of these, less than 50 percent was actually allocated to the Universities, and out of this allocation, less than 3 percent of the money was utilized for research. However, research activities over the years have been self-funded, that is, the money spent comes from parents and the meager salary / income of the researchers (graduate students, staff-in training, academic staff or self-determined individuals and professionals. This is a fiscal cranium where research can never thrive and will be stifled.

Table 1: Research Grant Allocation and Releases from 1990- 2003.

S/N	Year of Release	Allocation	Amount Released
1	1990	24,000,000.00	22,075,371.00
2	1991	51,266,530.00	16,645,034.00
3	1992	14,500,090.00	17,472,972.00
4	1993	122,182,102.00	122,182,102.00
5	1994	132,213,817.00	98,662,255.00
6	1995	155,534,575.00	73,973,806.00
7	1996	153,842,000.00	50,583,686.00
8	1997	194,013,732.00	122,020,447.00
	1998	215,618,453.00	149,993,549.60
9	1999	302,735,543.00	183,501,468.00
10	2000	448,127,780.00	612,666,910.00
11	2001	206,410,910.00	206,410,619.00’
12	2002	Not available	Not available
13	2003	73,435,618.00	73,435,618.72
	Total	2,146,657,150.00	1,799,637,713.32

Source: Okebukola P. (2004)

Weak Research – Industry Collaboration.

The link between theoreticians and practitioners is not well fostered. If its were well fostered, research solutions would have for long emerged to the quibbles in the built environment professions. It is believed that fruitfulness of any research on the human environment would be predicted on continuous feedback with a cooperative collaboration between researchers and professionals who often utilize such research products,(Okebukola P. (2004).

METHODOLOGY

The study made use of data and information from both primary and secondary source. Primary data were collected through my experience during the field work in the Federal Capital Territory (FCT) while carrying-out a research in "Designing for Sustainable Communities in Abuja, the Federal Capital Territory of Nigeria" – during which the six Area Councils in the FCT were the primary research fields. Secondary data includes relevant information from related studies such as published research works and findings as well as documentations by the National Universities Commission of Nigeria.

RESULT

Summarily therefore, the researcher in the built – environment sector of Nigeria should be prepared to face the under listed challenges especially in the Federal Capital Territory,

a. Limited data availability.
b. Lack of academic capacity
c. Socio-political confrontation ie skepticism on motive for questioning
d. Socio-cultural barriers to free gender interacting with strangers.
e. Difficulty in accessing quality or key respondent of interest due to bureaucracy and protocol.
f. Lack of fellable funding for the project in general.

RECOMMENDATIONS

After carefully studies studying and experienced experiencing the challenges of conduction conducting field-work in Nigeria with particular focus on the Built Environment sector, the paper recommend as follows:-

i. Government through the various Agencies and development partners should be more responsible to the funding of researches in the country in general and the built-environment sector in particular. This is because it is through research that effective policies are formulated that enhances sustainable development.
ii. The built-environment schools should not only be practical in the structuring of its courses structure but should also be research oriented in order to prepare and propel students to a future endeavour in the research world.
iii. Both practitioners and academics should create synergy in the area of data collection and achieving of research findings for referencing.
iv. The researcher in the built-environment sector should have adequate exposure in literature review so as to be duly prepared for the numerous challenges that abound in the field when carrying out fieldwork.

CONCLUSION

Revealed in this paper are the challenges often encountered by researchers, especially in the built environment sector while conducting fieldworks. These challenges are easily surmountable if researchers are abreast with the possibilities of encountering them. In addition, the paper reveals that fore knowledge of these challenges reduces stress usually encountered by researchers in the sector.. It is further shown that the built environment sector

has paucity of research reference materials; due partly to the design structure of their training programs as well as the zero budget allocation to research in Nigeria Universities over the years.

However, It is acknowledged by societies that research forms the basis for meaningful development; specifically so in the built environment sector where research brings about innovations in construction materials and techniques. Therefore. Meaningful development in the sector is possible, only if the educational system is repositioned to address adequately the challenges faced by researchers in the built environment sector

ABSTRACT

One of the tools proven to help reduce the incidences of cost and time overruns in construction project delivery are building procurement methods. It is however very challenging to select the appropriate method for maintenance of residential buildings because of the difference in client objectives. To address this problem, this study evaluated the procurement methods used for residential building maintenance, factors influencing the choice of procurement methods used in the delivery of maintenance work and; assessed the performance impact of the adopted procurement methods in terms cost, time and quality. Seventy (70) identical questionnaires were distributed to randomly selected clients, professionals in the construction industry and maintenance officers. Data collected were subjected to analyses using frequency, percentage, mean score and Relative Importance Index. The study revealed that the method mostly employed for procurement of residential building maintenance was the direct labour or in house method (MS = 4.02) while the use of traditional method (MS = 2.89) ranked second. The major factors that influenced the choice of procurement methods for residential building maintenance were cost and time certainty (RII = 0.862) and productivity and efficiency (RII = 0.814). The procurement methods with the highest performance impact were direct labour method (MS = 4.18) and public private partnership method (MS = 3.63) in terms of time; direct labour method (MS = 3.95) and public private partnership method (MS = 3.63) in terms of cost; and direct labour method (MS = 3.81) and design and build method (MS = 3.75) in terms of quality. This study recommends the use of direct labour method for residential building maintenance because of its high performance impact in terms of cost, time and quality.

Keywords: Delivery, Dilapidation, Maintenance, Procurement methods, Residential building

INTRODUCTION

The rapid growth in population recorded in many nations of the world has necessitated the construction of various buildings which serve as a vital requirement for the survival of mankind. Hence, the development of residential buildings to meet the growing demands of the populace has become a worldwide initiative (Ghattas, Gregory, Olivetti and Greene, 2013).

Buildings generally, are structures which serve to provide shelters for man, his properties and activities (Oseghale, Ikpo and Ajayi, 2015). Buildings provide humanity with a great variety of accommodation in form of residence, churches, mosques, offices, schools, hospital and others (Oke, 2011). Buildings, either as temporary, permanent structures need to be properly planned, designed, constructed and maintained to obtain the desired satisfaction, comfort and safety (Obiefuna, 2013). Experience has shown that most of these buildings if left unmaintained begin to dilapidate. Therefore, once a building is commissioned, it becomes very important to ensure that its operating efficiency is maintained. This is actualized through maintenance of buildings.

Ogunmakinde, Akinola and Siyanbola (2013) defined maintenance as stated in BS 3811 as the work or combination of actions associated with initiation, organization and implementation carried out to retain or restore an item to an acceptable standard. Similarly, maintenance has been defined as the process by which buildings are kept usable at a predetermined standard for use and benefit of its users (Mydin, Ismail and Ulang, 2012).

Folorunso, T. A.; Akinyemi, T. A. & Farayibi, O. O. (2016). Evaluation of Procurement Methods Used for Residential Building Maintenance in Ondo State, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 170-177

Maintenance of buildings is needed to enhance the durability, improve quality of life, protection of human health and environment. Maintenance which involves numerous skills influenced by occupancy and the performance level of the expected building, aims at effective and economic means of keeping the building and services fully utilizable (Central Public Works Department, 2000). Consequently, maintenance procurement strategy which calls for high skills is ultimately required in order to keep the building in a good condition.

Straub (2004) described procurement strategy as the overall method used to take a building project from its early planning phase to the completion and occupation by the building users. Maintenance procurement method refers to the method through which the necessary maintenance works are executed (Adenuga and Dosumu, 2012). Davis, Love, and Baccarini (2008) further described procurement methods as organization system through which responsibilities and authorities are made available to organizations and individuals with well-defined elements that constitute the construction project. Procurement methods used for construction projects are classified as the traditional, design and construct, management and collaborative (Graham, Craig, Peter, Peter, and Angela, 2008).

Research evidence has shown that there is a considerable flexibility in the adoption of the use of the many available maintenance procurement methods (Royal Institute of Chartered Surveyors, 2009; Adenuga and Dosumu, 2012). Hence, clients tend to employ the use of those procurement methods in which they are most familiar with while neglecting differences between the types of projects (Eriksson and Westerberg, 2011). However, not all these procurement methods are suitable for a particular project type, based on the difference that exists in client objectives and priorities (Davis, Love and Baccarini, 2008). Moreover, selecting the appropriate procurement method from the available types have been ascertained to help reduce the incidence of time and cost overrun in building construction works, the disputes that may arise and the likelihood of project success (Love, Skitmore and Earl, 1998).

Shirly, Azlan and Anuar (2012) asserted that it is now more challenging for decision makers to select the most appropriate procurement method for a specific building as different types of procurement methods suit different types of project. This challenge therefore stands as a major drawback to effective maintenance of buildings in Nigeria. A critical assessment of the performance impact of the available procurement methods for maintenance of residential buildings is expected to serve as a pointer to building users when considering selecting the appropriate procurement method for residential building maintenance. Therefore, the challenge of decision making as regards the most appropriate procurement stands to be abolished.

Hence, this research evaluates the procurement methods used for residential building maintenance in Ondo State, Nigeria; evaluates the factors influencing the choice of procurement methods used in the delivery of maintenance work and; assesses the performance impact of the various adopted procurement methods in terms cost, time and quality.

LITERATURE REVIEW

Maintenance of Building and Its Variants

Maintenance refers to the combination of all technical and associated administrative actions intended to retain an asset in or bring it to a state in which it can perform its required function (Royal Institute of Chartered Surveyors, 2009). The maintenance of a building begins once the building is completed by the contractor and handed over to the client and since human beings depend on buildings for their comfort and economic survival, maintenance of these buildings therefore becomes important (Ogunmakinde, 2013). Shirly *et al*. (2012) claimed

that a building that has proper operation and maintenance will only continue to be a valuable asset.

Maintenance carried out on buildings has been generally classified as corrective and preventive. Preventive maintenance on the one hand, represents the works undertaken in anticipation of failure; on the other hand, those undertaken upon the event of failure are referred to as corrective maintenance (Waziri and Vanduhe, 2013).

Maintenance of buildings has seen many improvements one of which entails the use of diverse procurement methods and in spite of the recent improvements in building technology; all buildings deteriorate from the time they are completed. The rate of deterioration depends on a number of factors (such as the right choice of materials, suitable construction techniques, adequate specifications for construction and installation works and effective supervision) which are not all under the control of occupants (CPWD, 2000).

Procurement Methods for Building Maintenance Works

Procurement as defined by Akinola, Okolie and Akinola (2013) is the acquisition of appropriate goods and services (which may involve a bidding process) at the best possible cost of ownership to meet the needs of the purchaser in terms of quality, time and location. In the same vein, Adenuga and Dosumu (2012) described procurement as the overall method used by clients or representatives to arrive at a tender figure and other operation towards the selection of a contractor to deliver a project at an agreed time and conditions. Maintenance procurement is therefore employed to undertake the maintenance of building works. In Nigeria, the Public Procurement Act 2007 established the Bureau of Public Procurement as the regulatory authority responsible for the monitoring and oversight of public procurement, harmonizing the existing government policies and practices by regulating, setting standards and developing the legal framework and professional capacity for public procurement.

Procurement process is characterized by its simplicity in theory, balancing quality, time and cost priorities but complicated in practice by legislation, the need to achieve value for money, demonstrates accountability and coordinates consultant and contractual roles and obligations to achieve a satisfactory income (Cunningham, 2013). Several methods of maintenance procurement are available (Adenuga and Dosumu, 2012; RICS, 2012; and Shirley *et al*., 2014). Kumaraswamy (1998) noted that classes of procurement methods have evolved from traditional method of division of labour and specialization to modern methods of collaborative and fast track procurement systems and therefore classified procurement methods into traditional, design and build, and construction management.

According to Davis et al. (2008), in the traditional method, the design works is accepted by the employer as distinct from the construction work; the construction works are usually the responsibility of the contractor while design and cost control functions are executed by consultants. In the design and construct procurement method, the responsibilities regarding the design of specific elements of the projects are saddled on the contractor. Hence, the contractor has input in the design of the project. Quite a number of management procurement methods exist and they are the management contracting, construction management and design and manage. In the case of management contracting, the contractor has contractual connections with all the works contractors and all construction work is the contractor's responsibility (Graham et al., 2008). As described by Davis et al. (2008), 'management contracting differs from construction management in the sense that works contracts, although arranged and administered by the management contractor, are direct between the clients and works contractor'. As regards the design and manage contract, the contractor is paid a fee and assumes responsibility, not only for works contractors, but also for the design team responsibility (Graham et al., 2008).

A study conducted by Adenuga and Dosumu (2012) revealed that for building maintenance works in Lagos State, Nigeria, the procurement strategies most commonly adopted are direct labour, lump sum contract and traditional contract, cost reimbursement contract and measured term contract. In Nigeria, execution of maintenance works is mostly left for the maintenance department to handle on direct labour basis contract while jobs of higher amount are given out in form of maintenance contracts to mostly unqualified maintenance contractors (Kunya, Achuenu and Kolawole, 2007). However, research evidence has shown that the strategy adopted for procurement of maintenance of building works is a function of many factors (Davis *et al.*, 2008; Adenuga and Dosumu, 2012; RICS, 2012). Deciding the method to adopt for a given project is very difficult and challenging because of the disparity in the priorities and objectives of clients which needs to match with the procurement strategy adopted (Davis *et al.*, 2008).

Generally, the strategy chosen for maintenance procurement is often dependent upon the extent to which the host organization seeks detailed involvement in the task, which in turn is informed by the maintenance management structure (RICS, 2012). Furthermore, a study conducted by Adenuga and Dosumu (2012) revealed that time duration, cost of project and risk allocation, price competition and flexibility of contract are major factors influencing the choice of maintenance procurement methods. Davis *et al.* (2008) also concluded that client experience and knowledge project characteristics (location, size and complexity), legal factors were factors influencing the choice of strategies for maintenance works.

It is however worthwhile to note that despite the available studies conducted on building procurement strategy and the procurement strategy for maintenance works, researchers have failed to evaluate the procurement methods employed for the maintenance of residential buildings.

METHODOLOGY

Primary data obtained through questionnaire survey were utilized for this study. Information obtained from the questionnaire were procurement methods used for residential building maintenance works, factors influencing the choice of procurement methods and performance impact of the various procurement methods in terms of cost, time and quality.

The population for this study comprised clients, consultants, maintenance officers and professionals in the construction industry in Ondo State, Nigeria. Seventy (70) identical questionnaires were distributed to randomly selected clients, maintenance officers and professionals in the construction industry in Ondo State, out of which fifty seven (57) were duly completed and retrieved for the study, and this constituted eighty one (81) per cent response rate. Data obtained for this study were analyzed with frequency, percentage, mean score and Relative Importance Index using IBM Statistical Package for Social Sciences (SPSS) 20 software.

FINDINGS AND DISCUSSIONS

Summarized in Table 1 are the characteristics of respondents in Ondo State. These are professions, nature of firm/organization and year of experience. Majority of the respondents 27 (47.37%) were Builders. The professional distribution is expected since Builders are majorly involved in maintenance of buildings. Investigation into the nature of firms revealed that 20 constituting 35.09% were contracting firms, 16 constituting 28.07% were consulting firms, 10 constituting 17.54% were clients and 11 constituting 19.30 were Government establishments. This indicates that all types of firms involved in the maintenance of buildings were adequately represented in the study. This study further sought information on the years of experience of the respondents and the result of the analysis revealed that over 89% of the

respondents had working experience of not more than fifteen(15) years. This implies that these respondents have adequate experience and knowledge of current procurement techniques for building maintenance works.

Table 1: Characteristics of Respondents.

Profession	**Frequency**	**Percentage**
Builder	27	47.37
Sub-contractor	5	8.77
Client	2	3.51
End user	4	7.02
Estate Manager	1	1.75
Quantity surveyor	7	12.28
Maintenance officer	6	10.53
Others	5	8.77
Total	57	100
Nature of Firm	**Frequency**	**Percentage**
Contracting	20	35.09
Consultancy	16	28.07
Client	10	17.54
Government	11	19.30
Total	**57**	**100**
Year of Experience	**Frequency**	**Percentage**
0-5 years	18	31.58
6-10 years	22	38.6
11-15 years	11	19.3
16-20 years	4	7.02
21 years and above	2	3.51
Total	**57**	**100**

Presented in Table 2 is the result of the analysis of the procurement methods employed for residential building maintenance in Ondo State. The method mostly employed for procurement of residential building maintenance was the direct labour or in house method (MS = 4.02). Next in frequency of use was the traditional method (MS = 2.89) while public private partnership (MS = 1.89) method ranked third. Ranked least among the procurement method employed for residential building maintenance was the design and build method (MS = 1.49). The direct labour or in house method mostly employed for the procurement of residential building maintenance implies that most clients are likely to prefer this method because of savings in terms of cost which is of benefit to the client wishing to embark on maintenance of residential buildings. The ranking of direct labour or in house method as the most employed procurement method for residential buildings therefore corroborates the work of Adenuga and Dosumu (2012) which revealed that procurement strategies most commonly adopted for general building maintenance works is the direct labour method.

Table 2: Procurement Methods employed for Residential Building Maintenance Work.

Maintenance procurement methods	N	Mean Score (MS)	Rank
Direct labour or in house method	57	4.02	1st
Traditional method	57	2.89	2nd
Public private partnership method	57	1.89	3rd
Outsourcing method	57	1.79	4th
Labour only method	57	1.68	5th
Partnering method	57	1.65	6th
Design and build method	57	1.49	7th

Presented in Table 3 is the result of the Relative Important Indices of the factors that influence the choice of procurement methods employed for maintenance of residential buildings. Ranked highest among the factors influencing the choice of procurement methods for the maintenance of residential buildings was cost and time certainty (RII = 0.862); next in

rank was productivity and efficiency (RII = 0.814) while technical competency (RII = 0.754) was ranked third. Ranked least among the factors that influence the choice of procurement methods employed for maintenance of residential buildings was arbitration/dispute resolution (RII = 0.278). The average RII was 0.627.

The factors that influence the choice of procurement methods employed for maintenance of residential buildings with RII higher than the mean RII (0.627) were cost and time certainty, productivity and efficiency, technical competency, risk allocation and avoidance, price competition for ensuring a low price and quality level of work and aesthetics. Factors with RII lower than the mean were flexibility in accommodation design change, motivation, availability of competent contractor, technology, complexity, expatriate and arbitration/dispute resolution. The factors with RII greater than the mean RII are considered to be very important and of high consideration when selecting appropriate procurement method for maintenance of residential buildings. The ranking of cost and time certainty as the most important factor that influence the choice of procurement methods employed for maintenance of residential buildings suggests that when clients are considering selecting procurement methods for use, they tend to adopt procurement methods with less procurement cycle time and this results in time savings, hence, cost savings. This result is in consonance with the work of Adenuga and Dosumu (2012) which reported that time and price certainty were major factors influencing the choice of building procurement methods.

Table 3: Factors Influencing the Choice of Maintenance Procurement Methods.

Criteria	Mean	Relative Importance Index (RII)	Ranks
Cost and time certainty	4.31	0.862	1st
Productivity and efficiency	4.07	0.814	2nd
Technical competency	3.77	0.754	3rd
Risk allocation and avoidance	3.75	0.750	4th
Price competition for ensuring a low price	3.58	0.716	5th
Quality level of work and aesthetics	3.54	0.708	6th
Speed (during both design and construction)	3.51	0.702	7th
Flexibility in accommodation design change	3.05	0.610	8th
Motivation	3.04	0.608	9th
Availability of competent contractor	2.98	0.596	10th
Technology	2.96	0.592	11th
Complexity	2.42	0.484	12th
Expatriate	1.49	0.298	13th
Arbitration/dispute resolution	1.39	0.278	14th
Mean RII	0.627		

Summarized in Table 4 is the result of the mean scores of the performance impact of the various procurement methods in terms of time. Direct labour or in house method (MS = 4.18) was ranked first; next in rank was public private partnership method (MS = 3.63), while outsourcing method (3.35) was ranked third. However, least ranked among the performance impact of procurement methods for residential building maintenance was partnering method (MS = 3.16). The result implies that in terms of time, the direct labour or in house procurement method is considered to have the highest performance impact. Hence, adopting this procurement method for residential building maintenance will amount to time savings which will in turn constitute cost savings.

Presented in Table 5 is the result of the mean scores of the performance impact of the various procurement methods in terms of cost. Direct labour or in house method (MS = 3.95) was ranked first; next in rank was public private partnership method (MS = 3.63), while design and build method (3.56) was ranked third. However, least ranked among the performance impact of procurement methods for residential building maintenance was Labour only method (MS = 3.23). The result implies that in terms of cost, the direct labour or in house

procurement method has the highest performance impact. It is therefore deemed to be the most appropriate strategy for the maintenance of residential buildings.

Table 4: Performance Impact of Procurement Methods in Terms of Time.

Procurement methods	Mean Score (MS)	Rank
Direct labour or in house method	4.18	1st
Public private partnership method	3.63	2nd
Outsourcing method	3.53	3rd
Design and build method	3.35	4th
Traditional method	3.28	5th
Labour only method	3.23	6th
Partnering method	3.16	7th

Table 5: Performance Impact of Procurement Methods in Terms of Cost

Procurement methods	Mean	Ranks
Direct labour or in house method	3.95	1st
Public private partnership method	3.63	2nd
Design and build method	3.56	3rd
Outsourcing method	3.53	4th
Partnering method	3.49	5th
Labour only method	3.23	6th
Traditional method	3.16	7th

Presented in Table 6 is the result of the mean scores of the performance impact of the various procurement methods in terms of quality. Direct labour or in house method (MS = 3.81) was ranked first; next in rank was design and build method (MS = 3.75), while public private partnership method (3.63) was ranked third. However, least ranked among the performance impact of procurement methods for residential building maintenance was traditional method (MS = 3.19). The result implies that in terms of quality, the direct labour or in house procurement method has a very high performance impact of the maintenance of residential buildings and thus represents the most appropriate strategy that should be adopted for maintenance of residential buildings.

Table 6: Performance Impact of Procurement Methods in Terms of Quality

Procurement methods	Mean	Ranks
Direct labour or in house method	3.81	1st
Design and build method	3.75	2nd
Public private partnership method	3.63	3rd
Outsourcing method	3.44	4th
Partnering method	3.39	5th
Labour only method	3.23	6th
Traditional method	3.19	7th

CONCLUSION

This study concludes that the direct labour or in house procurement method is the most frequently employed procurement method for the maintenance of residential buildings. Despite the fact that the direct labour or in house procurement method is characterized by some shortcomings such as project abandonment resulting from lack of contractual obligation; it continues to be a relevant procurement method in Ondo State. Furthermore, there is usually no standard labour and there may be inadequate incentive for workers involved in direct labour procurement.

The study further concludes that cost and time certainty, productivity and efficiency, technical competency, risk allocation and avoidance, price competition for ensuring a low price and quality level of work and aesthetics are major factors influencing the choice of procurement methods employed for the maintenance of residential buildings.

Furthermore, when it comes to cost, time and quality, most clients prefer the adoption of direct labour or in house procurement method for the maintenance or residential buildings. This study therefore recommends the use of direct labour method for residential building maintenance because of its high performance impact in terms of cost, time and quality. Furthermore improved utilization of emerging procurement methods designed to fast track residential building maintenance projects and promote teamwork is highly encouraged in order to have better maintenance results.

Towards Achieving Low Cost Housing: Use of Traditional Building Materials (A case study of Fayose Estate, Ado-Ekiti, Nigeria)

Victor Olufemi Adegbehingbe

Department of Architecture, Federal University of Technology, Akure, Nigeria
victoradegbehin22@gmail.com

ABSTRACT

There is a widespread shortage of housing in several urban areas in Africa. This shortage is growing both from the increase in rural-to-urban migration rates and the relatively high cost of urban building materials. In Nigeria, it has become obvious that most of the urban residents live in dehumanizing housing environment while those that have access to standard housing do so at abnormal cost. The fact must also be faced that government and people do not have the capital resources to construct convectional buildings. Given the limited resources available for low-cost housing programs, and the limited funds of the families who acquire such housing, it is important that the cost of construction and buildings be kept to a minimum by the use of appropriate technique and materials. This study critically appraises some local building materials available in Nigeria. Research revealed such materials as Stone, Timber, Laterite, Bamboo, Mud, Thatch, Cornstalk amongst others, are readily available and relatively cheaper than the convectional materials imported from outside the country. However, only stabilized laterite bricks and bamboo are discussed in details in this paper. The neglect of these materials should be discouraged. This study pays attention to the use of these materials as an alternative to the foreign materials, in other to reduce the increasing cost of housing and encourage more housing construction in the country and a comparative cost of stabilized laterite bricks and sandcrete blocks were carried out. This comparison is to further establish the fact that the use of our local building materials can go a long way to lessen the cost of construction. It also offers some recommendations at accomplishing housing delivery using indigenous building materials.

Keywords: Housing environment; housing materials; urban building materials; low- cost housing; traditional building materials

INTRODUCTION

Low cost housing can be considered affordable for low and moderate-income earners if household can acquire a housing that (owned or rented) for an amount up to 30% of its household income (Miles 2000). In developing countries such as Nigeria, only 10% of the population are high-income earners, who are able to afford normal housing units, the low-income groups in developing countries are generally unable to access the housing market (Adegbehingbe, 2011). Cost effective housing is a relative concept and has move to do with budgeting and seeks to reduce construction cost through better management, appropriate use of local building materials, skills and technology but without sacrificing the performance and structure life (Tiwari et al, 1999). It should be noted that low cost housing are not houses which are constructed by cheap building materials of substandard quality. A low cost house is designed and constructed as any order house with regard to foundation, structure and strength. The reduction in cost is achieved through effective utilization of locally available building materials and technique that are durable, economical, and acceptable by users and not requiring costly maintenance (Miles, 2000).It is also about the usage of traditional building materials, local skills, energy servers and environment-friendly options (Kumar, 1999, civil engineering postal, 2008).

According to Olayiwola, Adeleye and Ogunshakin (2005), the provision of housing as for long been seen as a government concern and the Federal Government has tried in different ways to tackle the nation's housing problems. A breakdown of government activities reveals

Adegbehingbe, V. O. (2016). Towards Achieving Low Cost Housing: Use of Traditional Building Materials (A case study of Fayose Estate, Ado-Ekiti, Nigeria). In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 178-189

that during the past few years, a series of constructive program and far reaching actions were taken by the government to combat the housing problem. However, it is a fact that the housing problem is far from being solved, and this can attributed to flaws in the strategies adopted by the government. Such flaws include: Government intervention through direct housing construction; even though the government possesses the resources and managerial capacity to embark on direct home construction, it should not have done so given the past experiences to the high cost and slow pace of construction of government projects. Apart from the fact that the Ministry of Housing and Environment was faced with many challenges which affected its performance level, the houses built were usually very expensive which put them beyond the reach of the low-income group, and they did not meet the requirements of the people e.g. provision of one bedroom houses for low group when the average family size is put at 6 persons.

Secondly, the adopted practice and system of granting loans makes it difficult for the really low-income people to benefit. The bulk of the mortgage loans went to the family in the upper class, making it necessary to re-examine the loan policy of the country.

Thirdly, other means of encouraging housing construction were not given adequate attention. For example the government agreed to lay emphasis on the provision of basic infrastructure in various layouts on which individual could build their own houses, but this was not done. Also, cooperative societies were not given much encouragement as planned.

Fourthly, many government housing projects were embarked upon without effective program of action and appropriate institutional arrangement for their execution. This means that the project lacked adequate and sound planning which led to their failure. Adequate shelter for all the people is one of the pressing challenges faced by the developing countries, Nigeria is currently facing a shortage of about 20.65 million houses. The dream of owing a house particularly for low-income and middle-income families is becoming a difficult reality. Hence, it has become a necessity to adopt cost effective, traditional.

Fifthly, there was too much corruption in high quarters. Often times, money meant for house project are diverted into private hands thereby allowing the project to suffer.

Finally, the problem of party policy in Nigeria has affected the Federal Housing Project extents. For instance, the uncooperative attitude adopted by some state government is simply because a different party other than their own controlled the federal administration. These states saw themselves as competing with the Federal Government and did all they could to slow down the pace of the Federal Housing Projects. In a nutshell, one may conclude that lack of financial prudence, public integrity and accountability, incompetent and ineffective administrative machinery, mass importation of foreign technology, material, personnel and inflation, as well as incomprehensive study of the nation's housing requirement has led to the low performance of public housing in Nigeria. This paper focuses on how the use of our traditional building materials can aid affordable housing delivery scheme in the country, with more emphasis on two major materials: stabilized laterite bricks and Bamboo.

Classification of available building materials

According to Adekoyejo (2005), building materials refers to those requisite raw substances used for erecting or constructing structures (shelters), after undergoing processing using available finance, technology of production and personnel (professionals) to achieve building

products, which are assembled to put in place the required or desired shelter, house or other structures.

According to Adekoyejo (2005), the identified available building materials could be classified as follows;

i. Convectional Building Materials
ii. Improved Building Materials
iii. Indigenous/Traditional Building Materials.

i. Convectional Building Materials; these are materials were transformed from their raw state and applied in building construction using modern methods or techniques. They are produced locally using imported techniques or directly imported as finished products. Such materials include; cement, steel, burnt bricks, precast concrete slab, glass, and plastic.
ii. Improved Building Materials; these are materials of improved quality, transformed from its original raw state through further research and development effort toward providing alternatives to expensive imported materials. Examples of such are bricks, Bamboo-crete, laminated-leaf composite boards, clay tiles, lightweight concrete with oil-palm clinkers and coconut shells.
iii. Indigenous Building Materials: these are materials from its raw state, which are transformed and applied by local technological means, such as earth, stone, timber, bamboo and organic products. These materials were widely used in the pre-independence era.

A review of traditional building materials in Nigeria

Traditional materials that are used in their natural conditions, or slightly altered by primary energy without any industrial influence. They could also be referred to as materials from its raw state, which are applied by local technological means. They include wood, stone and pebble, earth, thatch, bamboo and organic products. They could also be referred to as local materials. Local materials are the resources that can be found readily in large quantity at a particular location or area at a certain time. It could also be referred to as materials that can be used to fabricate a finished element. Gooding and Thomas (1995), identified that the traditional building materials common in Developing Country maybe considered to fall into four broad groups; un-stabilized soil, fired brick, wood and stone.

Traditional building materials should be;

i. Locally sourced
ii. Affordable
iii. Readily available
iv. Renewable.

Most traditional buildings in Africa and particular in Nigeria generally are made from the following traditional materials;

i. Bamboo; from palm tress
ii. Mud; from selected earth
iii. Mud and Stone; earth mixed or used as mortar
iv. Stone; used as masonry works and mortar
v. Cornstalk; found in guinea corn

Compressed stabilized laterite bricks

Many things are done with Laterite after it has been dried. An example is the addition of cement (about 5-10%) to stabilize the blocks and make it stronger and thus produce landcrete or sun-dried blocks or ordinary blocks in a process similar to adobe. The compressed stabilized Laterite block is the modem descendant of the moulded earth block, more commonly known as the adobe block. The term "Compressed Stabilized Laterite Bricks"

(CSLBs) is also a name used to cover a wide range of derivative building materials from Laterite/soil/earth in which a stabilizer or soil additive has been added to alter the properties of the soil and to improve its engineering properties including compaction, density, bearing strength and safety (i.e. fire)

.According to Arumala and Gondal (2007), compressed stabilized Laterite bricks are safe alternatives to masonry. They are low cost and can be designed to be earthquake resistant. They are non-toxic, are sound resistant, fire-resistant, and insect-resistant. Furthermore, research has also shown that compressed stabilized Laterite bricks have excellent insulating properties - reducing heating and cooling costs. In addition, they are inexpensive, strong, made with locally available materials and are dimensionally uniform. Also, workers with little prior building knowledge and experience can be used for the wall construction. They are resistant to sound transmission, fire, insect damage and durable if properly protected. Little energy is needed for their production compared to other wall systems and soil is an environmental friendly material.

Other Products

i. Floor tiles: the main type of floor tiles from laterite is called quarry tiles. These are laterite quarried out of the ground with sands removed and made to plastic and therefore rolled out and cut into different sizes .e.g. 100m* 100m, 150*150m.
ii. Roof tiles: this is another product of Laterite which has limited use in Nigeria because of shortage of supply and fixing technique.
iii. Sanitary wares: water closet, basins are produced with the application of modem technology. Pipes are also possible for sewage and other related purposes.

Production of stabilized laterite bricks

This can be done traditionally and in the factory or workshop

i. Preparation; traditionally, it could be moulded by hand and formed into a plastic state by adding water. In the factory, it is ground by rollers to eliminate large structures like sands. It is passed through a sieve to finalise the elimination and later, water is added to it during the rolling process.
ii. Shaping; traditionally, it is done in a box mould. In the factory or workshop it is extruded and cut into different shapes. Laterite is fired out from roller machine and it comes out with force in a rectangular form. This is later cut into required rectangular shape as it goes through by conveyor's belt.
iii. Drying; traditionally, it is sun-dried since it has to be dried before it can be used. In the factory it is artificially dried by the use of warm air passing through the kiln. Also tunnel dryer, by passing it through a tunnel with a dryer is another system. This normally takes about 24hrs because rapid drying makes the brick liable to crack.
iv. Firing; this is carried out by traditional kiln. The process here is the ordinary firing for about three days to produce three types of dried blocks which are used as follow high dried blocks used for foundation.
    a. Medium dried blocks used for load bearing walls.
    b. Less heated blocks used for partitioning walls.

There is also a different type of kiln being used in the factoiy. An example is the Hoffman kiln which is also called continuous kiln. It is divided into four compartments and each compartment is built with bricks and containing about 20,000-40,000 bricks. There is the process that as one-third is fired, one-third is drying, and one-third cooled. Fadamiro (1996), Ogunsemi (1996).

Application of laterite in Building construction:

The specific areas of application of Laterite as a building material in the components of a

typical building are as follows;

i. Foundation
ii. Walls
iii. Floors and
iv. Roof

Advantages of the application of laterite

i. It is readily available in large quantities.
ii. It has favourable climatic performance in most regions due to its high thermal capacity, low thermal conductivity, and high fire resistant ability.
iii. The use of Laterite is suitable for most part of the building, because it is easy to work with, even without the use of special equipment.

Disadvantages of the application of laterite

i. They have low resistance to abrasion and impact if not sufficiently stabilized or reinforced.
ii. They have not been generally accepted amongst institutions and social groups because of numerous examples of poorly constructed and poorly maintained earth structures.
iii. Disintegration occurs due to excessive water absorption, arising from swelling and shrinkage (if not sufficiently stabilized) leading to cracks.

Bamboo

Bamboo is a group of perennial evergreens in the true grass family *Poaceae,* subfamily *Bambusoideae,* tribe *Bambuseae.* It is a type of grass with a hard, woody, hollow stem. Giant bamboos are the largest members of the grass family.

It is also one of the traditional building materials with potentials for variety of application. It is a perennial plant found mostly in tropics and some temperate region. Bamboos are some of the fastest growing plants in the world. They are capable of growing 100 cm (39 in.) or more per day due to a unique rhizome-dependent system. However, the growth rate is dependent on local soil and climatic conditions. They shed their leaves annually and grow new branches. They can provide an ecological alternative to wood as a structural, siding and flooring material. There are several varieties of bamboo; some are as short as one foot (30 cm) in height while others can grow to ten times that size. The root structures of bamboo plants vary and they are often scientifically classified by root type. Many different climates support bamboo, although it is commonly associated with the tropics.

Bamboo is being currently looked upon as an alternate low cost material for the enormous housing problem faced by several developing countries. It is an extremely hard substance,although it should be chemically treated to prevent insect infestation and rot. Since it is a quickly growing grass and can grow in dense conditions, it is considered one of the best renewable resources on the planet. It is a green building material.

Apart from its use in building construction, bamboo can also put to several uses. Bamboo is commonly used as a food source. Bamboo has a crisp texture and light, sweet flavour. It generally assumes the flavour of ingredients it is combined with, so bamboo shoots are often used as fillers in Asian cuisine. While some bamboo can be eaten raw, some varieties must be cooked to remove some toxic elements. The giant panda enjoys it too; pandas subsist almost completely on bamboo plants. Bamboo was used to create the earliest suspension bridges in China and today it is used in a variety of building projects. It has also been used to craft boats, zeppelins and airplanes. Bamboo is also used to make a variety of household goods. You can find furniture, dinnerware, sporting goods, jewellery and handbags comprised of it. It has also been used for flooring, cutting boards, wind chimes and nearly any other good that

is commonly made of wood.

Bamboo is a beautiful landscape plant and is often used to create a privacy screen. However, it must be planted with a bamboo specific root barrier to keep it from spreading into other areas. It reproduces as quickly as it grows so it can quickly take over a garden.

It is important to note that the "lucky bamboo" many people have growing in their homes is not actually a member of the bamboo family; instead it is a Dracaena, an easy to grow house plant.

Characteristics of Bamboo:

i. Bamboo is the fastest growing plant: Bamboo timber can be harvested every year Bamboo is a natural water-control barrier Bamboo generates 30 percent more oxygen Bamboo can restore degraded lands vi. Bamboo plants are further characterized by long life span of the culms/hollow stalk and the development of woody tissues/fibres. The height of the clams of some species reaches 35m or more within the first 6 months of growth, but it takes about three years to develop the required strengths for construction. Full maturity is generally realized after 5-6 years of growth.
ii. Bamboo as a potential environmental friendly material for housing and construction has the following advantages in its application.
iii. High tensile strength compared to that of mild steel.
iv. High strength to weight ratio and high specific load bearing capacity.
v. Requires less energy for production.
vi. Service life of bamboo can be enhanced by suitable preservative treatment.
vii. Can be converted into panel and composite material possessing enhanced strength properties suitable for structural applications.
viii. Bamboo also possesses high residual strength to absorb shocks and impacts - highly suitable material for construction of houses to resist seismic and high wind forces.
ix. Bamboo is very efficient in sequestering carbon and contributes to the reduction-of green house.

Uses of Bamboo

Bamboo is useful in the following areas;

i. Medicine; Bamboo is used in Chinese medicine for treating infections and healing. It is a low-calorie source of potassium. It is known for its sweet taste and as a good source of nutrients and protein.
ii. Musical instrument; Bamboo's natural hollow form makes it an obvious choice for many instruments, particularly wind and percussion. There are numerous types of bamboo flute made all over the world, such as the dizi, xiao, shakuhachi, palendag, jinghu.
iii. Constructions; bamboo has been applied in building construction in areas such as bamboo reinforcing bar, bamboo fencing, and so on.
iv. Transportation; it is surprising to see that bamboo has been put into other uses such as bicycle making, trailers, e.t.c.
v. Clothing; Clothing from bamboo is soft and comparable to cashmere. Bamboo has natural antibacterial and anti fungi qualities that help the plant fight off disease and insects. These properties come from a naturally occurring substance in bamboo called Kun. Because these qualities are not lost during processing or washing, bamboo fabrics are able to retain these qualities and do not hold odours like some fabrics do.
vi. Water processing; Bamboo as a versatile material is demonstrated by its use in water desalination. A Bamboo filter is used to remove the salt from saltwater.
vii. Cooking; The shoots (new bamboo culms that come out of the ground) of bamboo are edible. They are used in numerous Asian dishes and broths.(wikipedia.org)

Photo survey of Fayose estate, ikere-ekiti, Ekiti state (Fig. 1- 5)

Gallery of the arrangement of buildings in the Estate

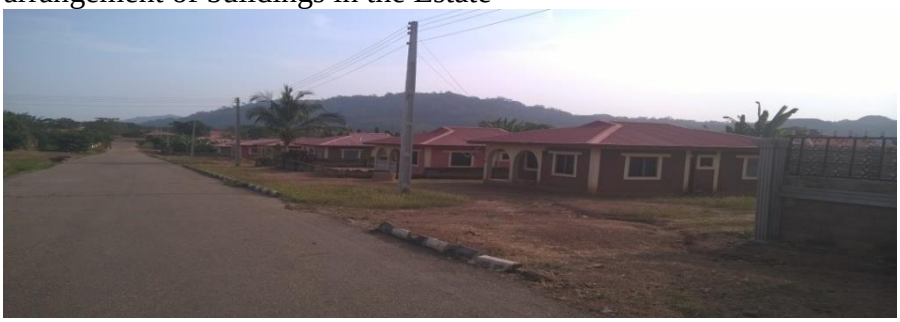

Fig. 1: Picture showing bricks used as a wall material as well as road network to some portion of the estate

Fig. 2: Picture showing unapproved Fencing work under construction using Sandcrete blocks

Fig. 3: Picture showing proper ventilation of the buildings

Fig. 4: Picture showing open space at back of a building transformed to another building using sandcrete blocks

Fig. 5: Picture showing new construction still at Foundation stage

The fundamental features of the components of the buildings in the estate are as following:

i. Walls: the materials used for the walls are mainly medium dried Laterite bricks. The bricks were mainly used for load bearing walls. Few of the residents applied paints on their walls while others just left it bare.
ii. Roof: Timber was used for the roof structural members and the convectional roofing materials (galvanizes aluminium roofing sheet) was used for the building.

METHODOLOGY

The study made use of data and information collected from both primary and secondary sources. Primary data were collected through physical investigation of some buildings that were made use of traditional building materials in the study Estate (Fayose Estate) located on the outskirt of Ikere- Ekiti, Ekiti state, a state in south west, Nigeria. At the time of this study, the estate is made up 180 units. Each housing unit is a single detached three/two bedrooms bungalow (photo survey above). The most common traditional building material employed for the construction of buildings in this estate is the stabilized Laterite bricks. These bricks were used mainly for load bearing walls, the only wall materials used for each building in the estate.

In order to achieve cost reduction (which is the essence of this study),all the walls of the buildings(180units)in the study estate(Fayose Estate),which constitute the major part of a building are constructed with Laterite bricks which makes cost reduction significant as the buildings were constructed in mass and this is illustrated in this study by carrying out the cost analysis of stabilized Laterite bricks with sandcrete blocks because they are the common walling materials used for construction in Nigeria. This comparison is to further establish the fact that the use of our local building materials can go a long way to lessen the cost of construction (even if it's only by a few percent) because analysis has also shown that although stabilized Laterite bricks are relatively cheaper than sandcrete blocks, the percentage difference in cost guideline for housing affordability is a housing cost that does not exceed 30% of a household's gross income (Struyk, 2005; Wikipedia, 2007).

Comparative cost of stabilized Laterite bricks and sandcrete blocks

In this study, the cost of constructing a wall using stabilized Laterite bricks were compared with that of sandcrete blocks because they are the common walling materials used for construction in Nigeria.

The analysis shows that stabilized Laterite bricks are cheaper than sancrete blocks; the percentage difference in cost did not swing away people from using sandcrete blocks. However the percentage difference in cost could be significant when many buildings are constructed in a given location as in the study estate (Fayose Estate, in ikere, Ekiti state). This study emphasis on reducing the cost of construction, because when cost of construction are reduced, in the long run, it directly or indirectly affects rental fees.

In this study, the plan of one of the two bedroom bungalow constructed on the study estate is used for the analysis below:

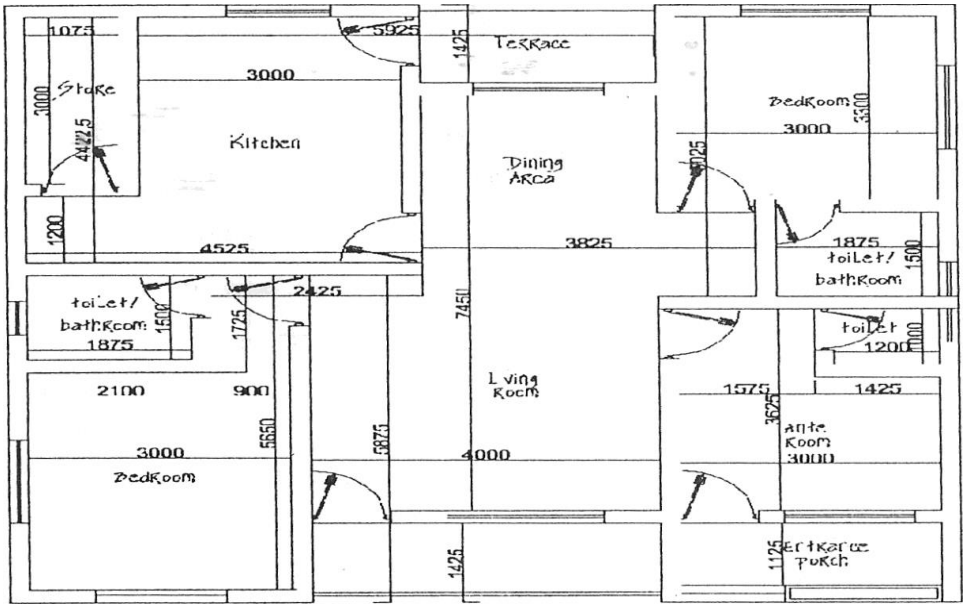

Fig 1 Plan of a Two Bedroom Bungalow on the study estate

The plan was developed taken into consideration the family size of an average Nigerian (1-6) and level of salary of the low- income and middle-income earner. It also adopted a simple shape, which will cost less during construction. The plan consists of the following facilities;

i. Ante room
ii. Living room
iii. Dining area
iv. Two bedrooms (en-suite)
v. Kitchen and a store

Unit Cost of Sandcrete Blocks

There are two types of hollowed sandcrete blocks. The first one is of the dimension 450mm *225mm*225mm. This size is typically referred to as the 9 inches block while the second type of sandcrete block is of the dimension 450mm*225mm* 150mm. This size is typically referred to as the 6 inches block. This size of block as at the time of this research (July 2015), cost #150.00 while the 9 inches block cost #190.00. Using the typical two bedroom plan as an example, it was discovered that approximately 10 sandcrete blocks will be required to complete one square meter of wall construction. The typical two bedroom plan is 200 square meters. Therefore, a total number of approximately 2000 blocks will complete the building.

Table 1 showing unit cost of sandcrete blocks

$1m^2$	10 sandcrete blocks
$200m^2$	2000 blocks

Unit Cost of Stabilized Laterite Bricks

Arayela (2000) noted that about 4% cement stabilization would generally be adequate to soils in the South Western part of Nigeria He also affirmed that the variation from his experiment was between 2.5% and 4%. It was discovered that one bag of cement will produce about 190 units of Laterite bricks. The size of Laterite bricks produced is of dimension 290mm x 140mm x 95mm. It was discovered that 4 Laterite bricks will take up one hollow sandcrete block. Therefore, about approximately 40 bricks would be required for one square meter of wall construction. As at the time of this research, a normal sandcrete brick cost #190 while the stabilized Laterite brick (i e bricks that contain additives as cement) cost #35.00 (researchers market survey) Therefore the number of Laterite bricks for the total completion of the two bedroom en-suite was therefore calculated as an illustration to be 8,000 bricks as shown in table 2.0 below

Table 2 *showing Unit Cost Of Stabilized Laterite Bricks*

1 Sandcrete Block	4 Laterite Bricks
Lm^2	10 Sandcrete Blocks
Therefore, 10 Sandcrete Blocks	40 Laterite Bricks
Lm^2	40 Laterite Bricks
$200m^2$	8,000 Bricks

Analysis of typical two bedrooms constructed at the study estate

Analysis of quantity of materials

Table 3 Comparing Laterite Bricks and Sandcrete Blocks In Terms Of Quantity

Wall construction	Sandcrete blocks	Laterite bricks
1	(450 x 225 x 225)mm	(290 x 140 x 95)mm
	No. required per m"	No. required per m^2
Wall area: $200m^2$	2000 blocks	8,000 bricks

Analysis of cost of materials

Table 4 Comparing Laterite bricks and Sandcrete Blocks in terms of cost

Sandcrete Blocks		Laterite Bricks	
Cost of 1 sandcrete block	# 150.00	Cost of one Laterite brick	#40.00
1m2	10 blocks	lm^2	40 bricks
$200m^2$	2,000 blocks	$200m^{13}$	8,000bricks

Comparative Cost Analysis of Laterite Bricks and Sandcrete Blocks

Table 5: Comparing Laterite bricks and sandcrete Blocks (9 inches) in terms of cost

	Sandcrete Blocks	Laterite Bricks
No required	2000	8,000
Cost per unit	# 190.00	#35.00
Total cost of wall construction	# 380,000.00	#280,000.00

Note: the cost per unit of these materials is based on the market price in Akure as at the period of this research (July 2015).

FINDINGS AND DISCUSSION OF RESULT

The cost analyses as carried out in the tables above shows that Laterite brick is the cheapest for wall construction. Investigation on site shows that it is possible to mobilize labour and equipment to the site if sandcrete block and Laterite bricks were to be used. Though both types are capable of being made on site, the raw materials and labour for Laterite walls are relatively cheap and gotten from site or close to the site.

As at the period of this research, (July 2015) a bag of cement cost #1900(Dangote cement) . The cost analysis carried out in the tables above, does not include the cost of mortar. cost of labour, transportation cost and so on, it only includes the cost of the material seeded for the internal and external walls. Both wall materials require mortar, but the quantity of mortar required for sandcrete as a wall material will be more. Sandcrete block walls will also require plastering and finishes (such as paint, tiles, and so on) to make the wall aesthetically pleasing to the eye. Brick walls require little or no finishes. The fact must therefore be faced that in the long run, the cost of construction using sandcrete blocks will be more than the construction cost using Laterite bricks, as indicated in tables1-5 above.

To further reduce the cost of this typical two bed room building the application of the following traditional building material is recommended below:

Substructure: Normal strip foundation
Superstructure (Walls): Materials for external and internal walls is the Laterial bricks.
Superstructure (Roof): Bamboo purlins and rafter should be laid on fibre or micro-concrete roofing tiles.This is of 20% cement and 80% sand.

Doors and Windows: wooden panel doors are to be used, while windows are to be louvers.
Finishes (Walls): Bricks which require little or no finishes
Finishes (Floor): The bamboo flooring system could be adopted instead of normal floor tiles. Bamboo floors are durable as the timber floors.

RECOMMEDATION AND CONCLUSION

It is my belief that the following suggestions/recommendations will help significantly in solving the unaffordable housing problems in Nigeria.

The use of laterite bricks should be encouraged as it is cheaper, more readily available and the production process is environmental friendly.

The usage of bamboo and other natural fibres such as oil palm fibre, palm kernel fibre and coconut palm fibre should be encouraged as possible substitutes for steel reinforcement and steel mesh.

The aesthetics of stabilized Laterite bricks should be improved in order to attract more users.

The government and other organized private sectors should invest on the development and application of our abundant local materials. A good example of this is that of the study estate(Fayose Estate in Ekiti State)..

Government and organized private sectors should also have confidence in the results of research findings in Nigeria and adequately support their practical applications.

Finally, government officials as well as wealthy Nigerians in our society should also embark on the use of these local materials for the construction of their houses, office complexes and the likes rather than the imported building materials. This will encourage a great majority of the populace to do the same.

This study established that Laterite bricks are sustainable and cheaper alternative to sandcrete blocks. Thus, in order to provide housing for a greater majority of Nigerians, our locally sourced building materials (such as the Laterite and the Bamboo), should be encouraged as they are relatively cheaper, more readily available, requires little or no finishes (as in the case of Laterite bricks) and their production process is environmental friendly.

Also, the lifecycle of a brick generates very minimal waste, equating to approximately 1.2 per kg of the product. Other benefits include high thermal mass with balanced and responsive conditions for cold and hot periods, good sound insulation properties, and ability to absorb and diffuse water vapour and absorb odours SICCM (2010).

Assessment of Thermal Comfort Level of Some Selected Lecture Theatres in Federal University of Technology, Akure

Ganiyu, S. A.[1*] & Ojo, T. E.[2]

[1&2]Department of Architecture, Federal University of Technology, Akure, Nigeria
[*]ganiyusikiru@gmail.com

ABSTRACT

Solar radiation consists of light and heat energy in the form of electromagnetic waves given off from the sun to the earth surface. Heat from the sun often raises internal temperature in buildings which in turn leads to thermal discomfort of the building occupants. This often negatively affects the ability of man to effectively carryout the expected activities within buildings and, thus, reducing man's productivity. It therefore becomes imperative to look for ways of tackling some of these challenges, especially in academic buildings where students are expected to learn in a conduicive environment throughout the day. This research examines the various negative effects of heat on the thermal comfort of students in some selected Lecture Theatres within the Federal University of Technology, Akure (FUTA). Three Lecture Theatres were chosen for case studies, namely: Big Lecture Theatre, '3-in-1' Lecture Hall and SEMS Lecture Hall. From the analysis of the case studies and questionnaires administered to users of the theatres, it was discovered that the users often experience serious thermal discomfort, especially in the afternoon due to excessive solar radiation and overcrowding by the students. Some of the recommendations for controlling excessive solar penetration into the lecture halls, in order to enhance thermal comfort of users while learning or carrying out other educational activities include the use of effective shading devices, adoption of good building form, good building orientation, appropriate use of building materials and the use of vegetation for landscape around the theatres.

Keywords: building orientation, heat, shading devices, solar radiation, thermal comfort

INTRODUCTION

The main purpose of designing buildings is to provide a comfortable environment for the inhabitants of such buildings. In Nigeria today, ensuring spaces are at desired temperature largely depends on mechanical air conditioning which requires high amounts of energy that is presently insufficient in the country. Therefore, there is the need to provide a comfortable indoor climate with minimum energy utilization. It is worth noting that a comfortable thermal environment makes people healthy, both physically and psychologically, and this will positively influence productivity.

In schools, students can comprehend well only within a very narrow range of temperature, hence the need for research into the selection of materials and methods that will help make school buildings habitable and conducive for students' learning purpose.

Thermal Comfort in Educational Buidings

The American Society of Heating, Refrigerating and Air-conditioning Engineers (ASHRAE, 2001) defines thermal comfort as the condition of mind that expresses satisfaction with the thermal environment. Thermal comfort exists when a body's heat loss equals its heat gain or vice versa. Deep body temperature is about 37°C, while the skin temperature can vary between 31°C and 34°C under comfort conditions (Audris & Steven, 2007). Understanding the indoor thermal comfort helps Architects and Building designers in providing a comfortable environment, devoid of negative impart to the health of users of such buildings.

The thermal performance of a building determines how well a building can modify the prevailing outdoor climate to create a unique indoor environment. Many factors such as

Ganiyu, S. A. & Ojo, T. E. (2016). Assessment of Thermal Comfort Level of Some Selected Lecture Theatres in Federal University of Technology, Akure. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 190-196

shape, orientation, absorption of solar radiation, window to wall ratio, materials, etc., contribute to the way buildings are able to respond to their external environment.

Studies have revealed that reducing moderately high classroom air temperatures by providing sufficient cooling, improves the performance of students and that moderate changes in room temperature, even within the comfort zone affect student's abilities to perform mental tasks requiring concentration, such as addition, multiplication, and sentence comprehension. Therefore it is important not only to look at the energy consumption and Indoor Air Quality, but also at the thermal comfort performance of schools (Wim, Gert and Mark, 2011).

The skin should always be at a temperature less than the deep body, and the environment should be below the skin temperature in order ensure a sense of physical well-being. The table below summarizes the critical body temperatures.

Table 1 Showing critical body temperatures

Skin temperature	Deep body temperature	Regulatory zone
Pain: 45°C	42°C	Death
		Hyperthermia
	40°C	Evaporative Zone
		Vasodilation
		Comfort
31- 34°C	37°C	Vasoconstriction
		Thermogenesis
	35°C	Hypothermia
Pain: 10°C	25°C	Death

Source: Audris and Steven, (2007)

Effects of Solar Radiation in Lecture Theaters

Solar radiation from the sun could be a source of delight and other times discomfort of building occupants. The effects of solar radiation on the comfort of building occupants include: extreme luminance resulting in glare and extreme heating resulting in discomfort.

Extreme Luminance Resulting in Glare

Glare can be caused by a direct view of the bright sky from the interior of a building. It can be an impediment to vision and even a direct hazard as in when on a stair way. Glare is a direct function of both the size of the window and the brightness of the sky seen through it and an inverse function of the brightness of the room interior. It can therefore be reduced by cutting down the size and brightness of the visible patch of sky and by increasing the interior brightness by the judicious use of surface areas of high reflectance so as to reduce contrast in brightness of light which is the major cause of glare in buildings.

Extreme Heating of Building Interior Resulting in Thermal Discomfort

Thermal discomfort in buildings often occurs when heat stored up in some building elements or properties of occupants in the building transmit absorbed heat accumulated through solar radiation into interior spaces of buildings. This results to people residing in the building experiencing increase in body temperature and subsequently sweating. Thermal comfort can be maintained when the heat generated by human metabolism is allowed to dissipate, thus maintaining thermal equilibrium with the surrounding.

THE STUDY AREA

The buildings used for the purpose of this research were three lecture theatres selected from the Federal University of Technology, Akure. They were studied to ascertain how their designs were able to control the effects of solar radiation thereby enhancing the comfort conditions of the users of the buildings. The selected lecture theatres are: Lecture Theatre 1 (Big Lt), 3-in-1 Lecture theatre, and SEMS lecture hall.

Lecture Theatre 1 (Big LT)

The lecture theatre, known as Big LT, is located in Obanla between the School of Engineering (SEET) and School of Agriculture (SAAT) of the Federal University of Technology Akure. The lecture theatre can accommodate 300 students at once.

Fig. 1: A side view of the the Big LT showing the horizontal fins and the eave projection
Source: Ojo (2013)

Merits

The use of vertical fins reduces the penetration of solar radiation into the theatre. Number and positioning of the windows provides good ventilation and enhances thermal comfort of in the theatre. The use of Celotex material for the ceiling reduces the penetration of heat from solar radiation into the building just as vertical fins of about 75mm thickness and 750mm projection attached to windows control the penetration of solar radiation into the theatre. The roof gutter eave projection of about 750mm serves as horizontal shading device to complement the shading provided by the vertical fins. The presence of some trees close to the theatre provides a level of shade for the building (see Fig. 1).

Demerits

The orientation of the building is bad because the longer side of the building is positioned in the East-West direction. As a result of this there is penetration of solar radiation into the interior space of the building thereby leading to excessive heat gain in the building in the afternoon hours of the day resulting to thermal discomfort.

'3 in 1' Lecture Hall

The '3 in 1' lecture theatre is located behind the PGD Research Laboratory (Phase1) and adjacent School of Science (SOS). The building is a combination of three prototype halls with a central reception yet to be roofed.

Fig. 2: Showing The Approach View Of The '3 In 1' Lecture Hall With Verandas Serving As Horizontal Shading Devices.
Source: Ojo (2013)

Merits
The interior of the lecture halls are relatively cool owing to the colour of wall paint used inside the building and the effective use of hard and soft landscaping elements outside the building as shown in Plate 2. The building has horizontal shading devices in the form of verandas 1200mm wide and eave projection of the roof. The number and positioning of the windows provide parallel ventilation for the space which in turn enhances thermal comfort of students.

Demerits
Due to the Y shape form of the building some of the halls are exposed to solar radiation in the cause of the day thereby leading to thermal discomfort in the afternoon to evening hours of the day. The absence of trees among the landscape elements minimizes the effectiveness of the soft landscape.

SEMS Lecture Hall
The hall is located behind the School of Earth and Mineral Sciences (SEMS), FUTA. The building has three lecture halls.

Fig. 3: Showing a side view of the SEMS lecture hall. Source: Ojo (2013)

Merits
The use of the vertical fins helps in reducing excessive heat gain in the building. Effective combination of hard and soft landscape and vertical fins of 225mm thick by 600mm projection as used between the windows, as well as the roof eave projection and verandas at the entrance into the halls aids thermal comfort of users. Window blinds were also provided in one of the halls because in some hours of the day the hall was exposed to penetration of solar radiation. Plate 3 shows the effective use of shrubs and flowers to enhance therm comfort in the building.

Demerits
Some of the lecture halls are exposed to solar radiation penetration at some time of the day due to the shape and orientation of the building.

FINDINGS AND DISCUSSION

For the purpose of this research, questionnaires were administered to a total of 110 students in all of the three lecture theatres to determine comfort level, thermal discomfort (intense heat) and time of the day thermal discomfort is experienced. Results were graphically represented as follows:

Comfort Level

In terms of comfort level below is a table showing a breakdown of data of respondents in each lecture theatre examined.

Table 2: *Showing data for the comfort level of respondents in the theatres*

S/N	Lecture theater	Highly comfortable	Comfortable	Not comfortable
1	Big Lt	-	19	21
2	3 in 1 Lt	1	20	19
3	SEMS Lt	10	15	5

The Table 2 above shows that none of the respondents in Big Lt was highly comfortable, 19 (47.5%) of them were comfortable and 21 (52.5%) of them were not comfortable while learning or carrying out other educational activities.

In the case of the 3 in 1 Lecture Theatre, 1 (2.5%) of the respondent was highly comfortable, 20 (50%) were comfortable and 19 (47.5%) were not comfortable. The provision of sufficient windows in each of the three lecture rooms here facilitated good ventilation which was felt on visit to the building.

Data from the SEMS Lecture Hall indicate that 10 (33.33%) of the respondents were highly comfortable, 15 (50%) were comfortable and 5 (16.67%) of themwere not comfortable. The positioning of the windows and ventilation generally was good just as the case of the 3 in 1 Lecture Theatre.

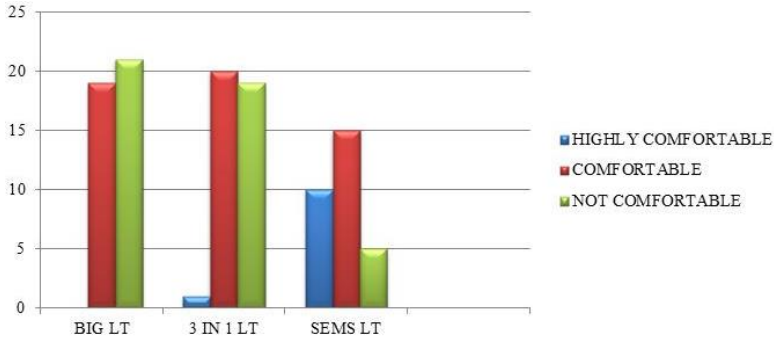

Figure 4: A chart showing the comfort level of respondents

Thermal Discomfort (Intense Heat)

In terms of thermal discomfort, 40 respondents stated that they often experience intense heat during the day. The same was observed in the other two lecture theatres, where a large number of respondents affirmed that they experienced similar thermal discomfort.

Table 3: Showing thermal discomfort data of respondents

S/N	Lecture theater	Yes	No
1	Big Lt	40	-
2	3 in 1 Lt	13	7
3	SEMS Lt	17	13

From Table 3 above, it can be deduced that most of the respondents in each of the lecture theatre experience thermal discomfort in all the three buildings.

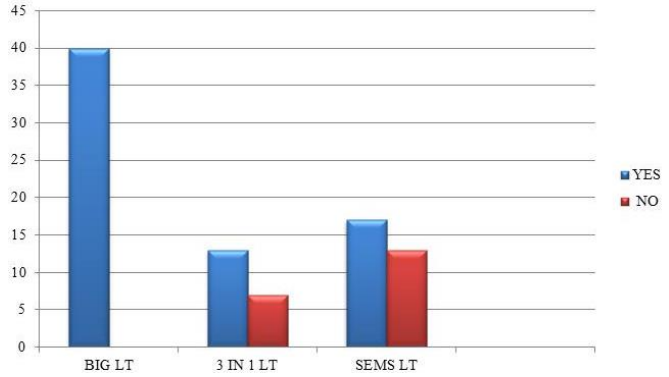

Figure 5: *A chart showing thermal discomfort data from the respondents*

Time of the Day Thermal Discomfort is experienced

In each of the theatres, thermal discomfort was observed to be experienced by virtually all of the respondents in the afternoon hours between 12pm – 4pm as shown in Table 4.

Table 4: Showing the time thermal discomfort is experienced in the theatres

S/N	Lecture theater	10am – 12 pm	12 – 4pm	4 – 6pm
1	Big Lt	4	35	1
2	3 in 1 Lt	-	30	-
3	SEMS Lt	2	15	-

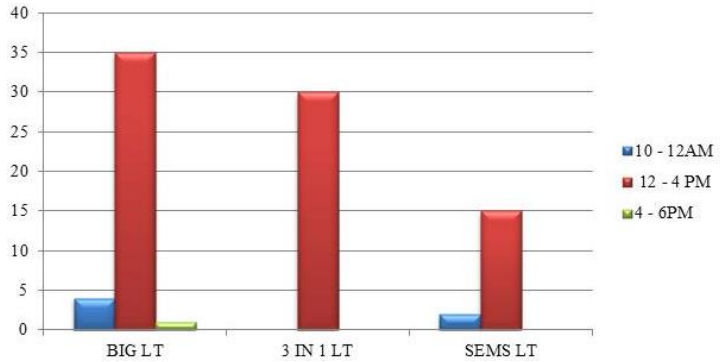

Fig 3: *A chart illustrating time of the day thermal discomfort is experienced in each of the Lecture theatres*

From the research carried out, it was gathered that factors responsible for poor thermal condition of lecture theatres include: bad orientation of theatres such as the Big Lt, bad form of the 3 in 1 Lt and ineffective vertical fin design, as in the case of the SEMS lecture halls.

RECOMMENDATIONS

From the information gathered through the research carried out, here are some recommendations that are of great importance to be considered for enhancing thermal comfort of students during the design of lecture theatres:

i. Shading devices should always be used on windows facing the east and west sides of buildings to reduce the penetration of solar radiation into the theatres so as to enhance students' thermal comfort while learning in school.
ii. Roofs should be of light and reflective surfaces to reduce solar heat gain through the roof.
iii. Materials used for the construction of wall should be of light weight and low thermal capacity. Wall finishes should be light in colour to reflect solar radiation.
iv. Building orientation and form should minimize the area of the building exposed to solar radiation all through the day. It is best for the longer sides of buildings to be positioned along the east-west axis.
v. Spaces should be provided around buildings for plants such as shrubs, lawns, trees among others as this will help in reducing solar heat gain in the building.
vi. Theatres where students are been taught should not be over populated but should always be occupied by the number of students the space was designed to accommodate.
vii. Internal shading devices such as blinds can be used in existing school buildings where some classes are exposed to solar radiation penetration due to ignorance or negligence on the part of the designer.

CONCLUSION

Apart from the need for acoustic and visual comforts in educational buildings, it is imperative for building designers to give great attention to thermal comfort of students who are to occupy the buildings. Learning in good acoustic, visual and thermal comfort conditions help

in improving students mental ability to comprehend what they are been taught in school and their academic performance. The use of the identified methods of solar radiation control in buildings as showcased in this paper will help in reducing the reliance on mechanical equipment in enhancing thermal comfort of building occupant.

ABSTRACT

Construction industry is the largest employer of labour, and more importantly; it is one of the largest contributors to economic growth in many nations. However, this industry has been troubled with a lot of drawbacks that impede its achieving as much as it ought to achieve. Building Information Modelling (BIM) is a new paradigm employed in the delivery of construction projects in most developed world, and it has proven to mitigate various hitches that have bedeviled the industry for ages. This paper therefore seeks prominent works of researchers, experts' opinions and the apparent benefits that have been gained in the employment of BIM in construction industry for project delivery in many developed economy. These facts are further confirmed by the survey carried out in this study among professionals and specialties in the industry. This paper thus, submits that Building Information Modelling (BIM) should be integrated into higher education curriculum as an antidote for the various hitches that confront the construction industry in Nigeria. Hence, facilitating an adequate BIM adoption in the construction industry in Nigeria will invariably boost building project delivery in terms of time, cost, quality and management of construction project and also mitigate against shortcomings of the traditional delivery processes.

Keywords: Antidotes, Building Information Modelling (BIM), Delivery Process, Education, Hitches, Nigerian Construction Industry (NCI)

INTRODUCTION

Construction industry plays an important and vital role in the socio-economic growth of a country. The industry contributes significant improvements in the overall GDP of a nation and positively influences the quality of life by providing necessary infrastructure such as housing, roads, hospitals, schools and other basic facilities (Abdul Rahman et al., 2013). Furthermore, construction industry is one of the most challenging industries in this present age, but it still remains within low reliable rate of profitability, little investment in research, education and development, of which the Nigerian Construction Industry (NCI) is not an exception. In addition, the problem of training beginners for replacement of aging work force and people without adequate modern technological training is among the issues raised by the Construction Task Force Report (1998) as cited in (Ahmad, 2013).

Building Information Modelling (BIM) is a modern delivery tool that is widely in use in the construction industry. It is said to be the international benchmark for efficiency in Architectural, Engineering, and Construction (AEC) and a host of other building services. It is the platform that brings about collaboration and integration of environmental professionals and all other stakeholders. Ibrahim affirms that every professional practice have particular tasks needed to achieving a successful BIM platform (Ibrahim and Krawczyk, 2003). Thus, BIM can now be said to encompass all phases of project development from investment conceptual stage through to architectural, civil/structural, mechanical/electrical, cost evolvement and analysis, procurement, tendering and award, construction to completion and occupation, facility maintenance and operation, and finally, the demolition of the building with a positive resultant returns on investment at the end of its life span. These are very enormous and cumbersome tasks that can be rolled into a series of integrated tasks for easy

Yusuf B. Y., Ali K. N., Embi M. R. & Tukur R. B. (2016). Building Information Modeling Integration to Education as an Antidotes for Nigerian Construction Industry (NCI) Hitches. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 197-205

project delivery with the use of BIM. Of course, it can be argued that these various tasks have been initiated and executed successfully before the introduction of BIM, but BIM is a coordinated and integrated method where time, money, decision making and precise predictions of project characters are of advantage. Besides, more potentials of BIM are still yet to be exploited and explored (Abubakar, 2012).

Recent studies revealed that construction industry is vital to the economic growth of most developed countries (Macdonald, 2012) and that maximum utilization of BIM benefits cannot be fully harnessed because of lack of adequate manpower in the sector. The education sector, especially higher education is still behind in balancing the differences of the industrial needs in terms of manpower to the current turn-out (Macdonald, 2011b).

Objectives of study

This paper sets out to evaluating the NCI performance and the global practices in the construction industry. It is also to unveil the inherent benefits of BIM adoption in some countries of the world and how it profits economic growth and industrial practises. The objectives of the study is therefore to: 1- establish the needs for paradigm shift in the NCI so as to meet-up with the best of global practises; 2- highlight the importance of building information modelling (BIM) as an antidote for alleviating most of the challenges in the NCI; 3- show BIM education integration to higher institution of learning in Nigeria as the best alternative to mitigating the NCI problems of this age. In line with these objectives, this paper tends to adopt literature review of benefit deliverables that are characteristics of BIM when fully adopted while also noting that the impediment against achieving these objectives is lack of adequate knowledge of BIM. This is therefore the motivation necessary for integrating BIM into educational curriculum for the new generation of AEC professionals. Thus, information technology era has no space for the 'wait and see' syndrome that has been historical characteristics of the education sector in Nigeria.

LITERATURE REVIEW

Nigerian Construction Industry (NCI)

Nigeria is commonly referred to as the giant of Africa; this is due to its size, population, human and material resources and the economic growth potentials at its disposal (Zulu, 2009). In the same vein, the Nigerian Construction Industry (NCI) can also be referred to as giant within its continental neighbourhood because of the volume of construction projects and numerous services delivery offered to its clients (Kolo and Ibrahim, 2010). Tunji-Olayeni et al. (2014) noted that NCI is very vibrant and one of the largest in Africa. The industry is made up of 78% indigenous firms and 22% foreign firms. The indigenous firms are largely made of small and medium scale (SMs) firms. However, due to the sizes of these firms, the NCI has been challenged to improving its performance, due to large problems in terms of cost over runs, time over runs, poor quality of work, low productivity, and lack of best practises including poor team work of professionals (Tunji-Olayeni et al., 2014). Also, poor project implementation, poor planning and budgetary provision, project over invoicing, poor service delivery, abandoned non-functional facilities, building collapsed and poor satisfaction among the clients (Kolo and Ibrahim 2010) are the hitches pulling the NCI down. In another study, it was determined that globalization has also significantly affected the NCI, with evident threats and opportunities which industry players should as a matter of urgency recognize and adequately respond to, for the survival of the industry at this age (Mbamali and Okotie, 2012).

BIM as a Process of Change

Building Information Modelling (BIM) is also called n-D Modelling or Virtual Prototyping Technology. It is a revolutionary developmental phenomenal that is fast reshaping the

construction industry. BIM is both a technology and a process. The technology component of BIM makes the project appreciable for stakeholders to visualize what is to be built in a simulated environment to identifying any potential design, construction or operational issues; while the process component allows collaboration and encourages integration of the speciality roles of all stakeholders on a project. (Azhar, et al.: 2012). In another argument, BIM is a technology that revolves round three base components; people, process and digital technology. The inter-relationship of these elements make up a system called building information modelling. This is a very important reason why using BIM eliminates lone working for all stakeholders in the industry (Kiviniemi, 2013). BIM can therefore, be said to be a methodology for managing building design and project data in digital format throughout a building's lifecycle (Succar, 2009) and it is considered as paradigm shift within the industry.

BIM global developmental trends

BIM has rapidly spread around the world. Many countries around the world have expressed great interest towards implementing BIM within the construction industry but each country has its own arrangements and different levels of progression (Bataw, 2013). Below are some of the countries that have adopted BIM and how they fare within the new paradigm.

BIM in United Kingdom (UK)

In 1997, the construction industry in the UK was perceived as under-achieving in terms of meeting its own needs and those of its clients. It was at this instance that the government set up a task force under the chairperson of John Egan to advise on the ways to improving the efficiency and quality delivery of construction. It was contained in Egan report (1998) that manufacturers should make interchangeable component parts, investing in performance tools by Building Research Establishment (BRE) and standardization of construction industry which is hoped will lead to improving performance that would speed up construction and lowered capital cost (Murray and Langford, 2003; Egan, 1998). Also, consideration was given to an alternative building delivery pack, that was BIM, with full awareness of its benefits in controlling cost, time and quality and the advantages it could offer to everyone involved in the construction industry, including clients, designers, contractors, suppliers and facilities managers. With the assurance gained on BIM; in May 2011 the government finally announced the adoption of BIM technologies, processes and collaborative behaviours into all stages of the life-cycle of public projects worth more than £5 million by 2016 (Bataw, 2013). In addition, KOUIDER and PATERSON (2013) reported that the principle objectives behind the legislation of adopting BIM for all government projects above £5m as from 2016 include:

i. Achieving 20% savings on the overall cost of projects
ii. Building a reliable and effective data sets for the efficient management of assets using COBie (Construction Operations Building Information Exchange)
iii. Carbon reduction to meet international and local targets
iv. Improving competitiveness in the construction industry (KOUIDER and PATERSON, 2013)

BIM in the United States of America (USA)

The adoption of BIM in the public sector started in USA as far back as 2006, when the US General Services Administration (GSA) issued a BIM-guideline for the integration of BIM within the US AEC sector in general and Public Building Service (PBS) in particular. Also, the following year; 2007, marked the start of the mandatory usage of BIM by all planners while applying for GSA's funding schemes. This was based on the reorganization of benefits that the public sector stands to gain. Consequently, there emerged a success story as approved

by American Institute of Architects (2010) that 60% of US architects are using BIM holistically. (Bataw, 2013)

BIM in Australia

In Australia, it was identified that various problems facing AEC industry could be extinguished through the implementation of BIM as industry operational language. This gave rise to the development of 'National BIM Initiative Blueprint' which was developed by 'BuildingSmart', meant to promoting the education and adoption of BIM at higher education level. Also the blueprint was to facilitate Australia government's adoption of full collaborative BIM for all government building projects procurement coming year 2016. This follows the same line of BIM development in UK, US and other government world over (Kriengsak et al., 2013). Besides, Gu and London (2010b) revealed that limited understanding of industry needs and technical requirements pose a major factor hindering the advancement and adoption of BIM related technologies within the Australian AEC industry. Aksamija and Ali (2008) studied and identified "inadequate training and education" as a major hindrance to the adoption of BIM in the Australian AEC industry which is consistent with that being faced globally.

The development and the adoption of BIM in Malaysia

Malaysia has always been at the forefront of imbibing new technology and always wants to be at the same level with the developed nation of the world. This is evident in the government's approach to any new paradigm that is perceived to have the potential of aiding economic progress and serve the citizenry better. This competition is also entrenched in their early recognition that a trained, skilled and well-educated workforce with ICT-driven knowledge-based society will undoubtedly fuel high economic performance and sustainable economic growth in Malaysia (Awang, 2004). This has given more energy to government agencies, professional bodies, individual practices organization and education sectors to be involved in the BIM awareness campaign.

METHODOLOGY

The study employed a case study research design, where countries that have adopted BIM for project delivery are reviewed and lessons are derived. Also, interview survey of practitioners in the industry both in the academic and in business practices was carried out. Fifteen professionals were interviewed across major specialty in the industry, such as architecture, engineering, quantity surveyors and others. The findings revealed that the problems militating against the industry can only be arrested with full adoption of BIM. It is also noted that full BIM adoption is not obtainable without the educational institutions featuring prominently.

FINDINGS AND DISCUSSIONS

Influence of BIM on the Construction Industry

Building Information Modelling adoption and understanding vary from country to country, discipline to discipline and from client to client; this then affects the level of adoption and usage among various building project teams. This has posed challenges to building information modelling adoption in construction industry (Gu and London, 2010a). Although, building information modelling is a collaborative work process, Ford et al. (1995) noted that despite the abundance and complexity of information in the construction industry, the non-corresponding management of the information is increasingly resulting to fragmentation among industry practitioners. It is also worthy of note that the construction industry has always been very slow in adopting strategies, methodologies and techniques. In another study, Macdonald (2011a) noted that the construction industry is vital to the economies of most developed countries, but studies have shown that despite this importance, productivity

has declined over the past 30 years and the industry is extremely inefficient compared to other industries. The construction industry has also been described as extremely fragmented and lacking integration. To this end, to improve this situation it is necessary to enhance communication among the different disciplines through BIM technology, which is, contributing to greater construction industry efficiencies and boosting collaboration among project delivery teams, reducing collisions and removing rework (Darius et al., 2013; Ford et al., 1995). This can only be achieved with full adoption of BIM throughout the project lifecycle.

In other words, efficient information-technological solutions are needed and these can only be supported by complete design information of a building consisting of several domain specific design BIMs; such as architectural, structural, HVAC and electrical, with building construction processes and overall building environmental management operations. Therefore, in this context, Building Information Modelling (BIM) is a platform for performing complex building performance analyses to ensure an optimized sustainable building design (Azhar et al., 2009; Gray et al., 2013) and to carry out some of the basic sustainable building task such as; Service life design, Environmental assessment, Energy consumption estimate, Maintenance manual, Optimization on building refurbishment and sustainable building rating. The benefits that the building industry stands to accrue from the adoption of building information modelling for project delivery can be appreciated in the Table 1.

Challenges of BIM adoption

Despite the fact that BIM is seen to be the way out of the challenges facing construction industry at this age, it is not without factors that are delimiting its efficacy and usability. A standard is a measure of quality and it guides the level of acceptance of a product; BIM is still a product without standards which allows an array of BIM software products that lack the ability to produce interoperable files; lack the strict BIM implementation standards and rules for certain project participants, and contract obligations and unified documentations to be adopted for BIM operations (Darius et al., 2013). These are problems affecting the collaborative working together of professionals as they use different software thereby reducing the benefits to be gained (Gray et al., 2013). Darius et al. (2013) further noted that the under-listed are some of the challenges delimiting the adoption of BIM:

i. lack of adequate knowledge and training
ii. high initial investment cost
iii. conservative approach of professionals
iv. Interoperability among disciplines
v. the fears of low success and big failures
vi. lack of organizational and professional qualification alignment
vii. Lack of standardization of BIM practice

These enumerated BIM challenges are very normal and these will challenge the construction industry to look for the solutions. From the survey, all respondents acknowledged the existence of these problems and believed that the problems can be solved with educating young generation; who are believed to be computer native than the computer immigrants of the present generation.

Benefits of BIM adoption

Despite the challenges militating against construction industry globally and the problems preventing the adoption of BIM, its adoption in some countries have attested to its competency in solving construction project problems throughout its lifecycle.

Table 1:- BIM Qualities and Usage across Project Delivery Phases

Phases	BIM Qualities	Use of BIM
Design / Conception Phases	Virtualization	Use for visualizations of a design, accurate and consistent 2D Drawings at any stage of the design; this enables easy production of design drawings (Eastman et al., 2011), (Rwamamara et al., 2010)
	Earlier Collaboration Of Multiple Design Disciplines	-Earlier collaboration of multiple design disciplines. This allows simultaneous work by multiple design disciplines, shortens design time, reduces errors and omission and also unveils design problems and possible improvement opportunities (Eastman et al., 2011), (Poerschke et al., 2010)
	Cost Extraction At The Design Stage	BIM enables accurate extraction of bill of quantities and spaces that can be used for cost estimation at early design stage. (Eastman et al., 2011), (Gray et al., 2013)
	Clash Detector	It is very useful in the design stage, single model with conglomeration of the interwoven components e.g. Pipes, electrical, beam structure can be united to detect any clashes. (Sacks and Barak, 2008; Sacks et al., 2004).
	Clash Resolution	Practical, as with this case study, BIM software will notify you of these clashes and adjustments can be made so that the error that have arisen will not become a problem during actual construction. (Sacks and Barak, 2008; Sacks et al., 2004)
Construction Phase	Work Schedules	It also enables automated material take-offs, cost estimation and construction schedules. (Azhar et al., 2009)
	Construction Management	BIM also can be used as source of information for analysis of the building solutions as well as to store the results of analysis; in addition, it can be used to represent the entire lifecycle (LC) of buildings including the processes of construction and facility operation (Häkkinen and Kiviniemi, 2008)
	Construction Delivery Time	BIM can influence time management with a 7% reduction in time for project completion. Issa and Suermann (2009) also share the same opinion that BIM helps to deliver projects on time.
	Cost	Another cost effective evidence was a US study from 2009, with two thirds of over 1,000 BIM users attested to positive return on investment (ROI) (Young et al., 2009).
Operation Phase	Project Management	Easy evaluation of design, construction and management of project before the actual project implementation. Ellis (2006).
	Positive Return On Investment	BIM enables the investors to monitor the profitability of their investments before actually embarking on such projects. (Young et al., 2009)
	Sustainable Design	BIM facilitates complex processes of sustainable design such as daylighting and solar access, it also enables automated material take-off, cost estimation and construction schedules, all these from a single integrated building model. (Azhar et al., 2009)
	Data Management	BIM is an excellent tool for data management, that facilitates easy and fast access to information in a single centralized database through the 3D model (Meadati and Irizarry, 2010).
	BIM As A Learning Tool	Meadati and Irizarry (2011) submitted that due to the characteristics inherent in BIM, it is a better option as a learning tool. Some of BIM characteristics are: reducing accessibility time to data information and easy visual correlation with real world.

The phases of construction of any project must be respected for such to be a success. The NCI is therefore challenged to adopt BIM at all phases of project life to earn these benefits.

i. *Conception / Design phase:* - the problems of working in solitary of project team members, wasting time due to reworking at the design stage, unresolved design conflict at the project inception, cost and time overrun and virtualization and space appreciation problems; are problems bedeviling the NCI. However, with adoption of BIM through education and training of the up-coming generation, the problems will be solved as evidenced from the experiences of some countries around the world.

ii. *Construction phase:* - most construction problems at this phase emanated from the conception/design phase. This is because a lot of unresolved design conflicts are

passed over to this phase, such as; members of the same project team not communicating, construction sequence, work schedules, construction management plans, construction delivery time, and actual project estimates not planned or known. But upon the full integration of BIM education and training into academic institutions with a clear curriculum plan in Nigerian higher institutions, these challenges will be non-existence as the graduates produced will be BIM competent graduates with adequate knowledge.

iii. *Operation phase:* - the problem in this phase is also deferred from the previous phases. This entails the overall management of resources, time, capital, land, authorities and other logistics throughout the lifecycle of the project. BIM education and training is all-encompassing; as adequate management of construction project in NCI through the whole lifecycle of projects can be handled with utmost benefits and adequate returns on investment to the nation.

Education Response to BIM

Traditionally, academic institutions are found to be slow in adopting changes especially if they are pressured by a continuous flux of new technologies. In the university, curricular change takes longer time, thus serving as impediment to building environmental academic disciplines to match the speed at which the AEC industry is advancing in this arena. In addition, there tends to be reluctance on the part of these institutions in the adoption of digital and computational approaches (Sharag-Eldin and N., 2010). Sharag-Eldin and N. (2010) further noted that academic exercises tend to challenge technology with new needs, applications, and possibilities. This tends to delimit full integration of information technologies into academic curricular, which is a problem that affects both the practitioners and the academic, causing them to miss opportunities for developing the industry as a whole. Also, the success factor perceived of the BIM and the envisaged potentials, the embracement and the adoption of these opportunities have remain low due to lack of education and training (Becerik-Gerber et al., 2011).

CONCLUSION

BIM is very likely to be the construction industry standard in the nearest future, thus, the teaching and training of this technology in higher institutions of learning is inevitable (Kelly, 2010). However the growth of BIM globally is without limits while more breakthroughs of its usage are still unfolding. Therefore, for maximum benefit to be achieved now and for making solid foundation for the upcoming generations, an unrelenting effort in producing skilled and qualified work force to the construction industry is unavoidable.

Thus, taking clues from the successes in the UK, the US, Australia, and Malaysia, where BIM adoption and its integration into higher education is vigorously being pursued; and for NCI to follow suite, will enable achieving maximum BIM benefits at all levels, thereby checking the problems of NCI. This cue will also facilitate the adoption of international practices with education as the foundation.

Therefore, as a prospect to the industry, this research and some recent studies submit that BIM is full of potentials that will significantly change and improve performance and documentation in the Nigerian Construction Industry (NCI). This prospect will also invariably reduce inefficiencies, enhancing productivity, and increasing collaboration and communication (Goedert and Meadati, 2008), with the intent that BIM will achieve decreased project costs, increased productivity and quality, and reduced project delivery time (Azhar et al., 2008).

ABSTRACT

Compressed Stabilized Interlocking Earth Block (CSEIB) is fast gaining recognition among construction professionals in Nigeria, and this can be attributed to its enormous benefits. Despite this increasing popularity, its usage is still low. It is in view of this that this research was carried out to identify and assess the drivers and barriers of CSIEB for building construction in Nigeria. A questionnaire survey and semi-structured interview were conducted with a group of 67 professionals in the construction Industry (Architects, Builders, Engineers and Quantity Surveyors). While the questionnaire assessed the opinion of professionals on the drivers and barriers of CSIEB, the purpose of the interview was to get first hand information from the professionals on the challenges faced during the use of CSIEB for building construction. Data collected were analyzed using Relative Importance Index. Findings revealed that the major drivers of the CSIEB for building construction are the aesthetic nature, low cost of raw material, suitability of material and reduction in cost of finishes and maintenance. High cost of machine, lack of trained machine operator and skilled personnel to handle production process and low acceptability among most social group were some of the identified barriers. This study recommends that the use of CSIEB should be encouraged among stakeholders due to its enormous benefits, while tariff on import duties should be reduced by the government thus, minimizing the high cost of importing machines. Appropriate training of personnel to handle the machines and production process through organized skill workshop should be encouraged, and proper sensitization of the public as to the benefits and reliability of earth construction should be carried out by the professionals in the Nigerian construction industry.

INTRODUCTION

The construction industry today is faced with the day to day challenges of trying to keep up with the speed of technological advancement and the rising taste of the end users. In commissioning a building project, a client will expect to obtain a building that satisfies his needs as to form and quality, of which he can take possession at the agreed time and for which he will pay optimum price (Aghimien and Oke, 2015). Thus, it is the duty of the construction expert to develop new methods of construction that will meet the demands of the end users in terms of quality, sustainability and affordable cost. Bankole-Ojo, (2008) stated that the human taste and needs have gone beyond just having a structure as a shelter, but has gotten to a level of concern for durability, flexibility, functionality, short construction processes, cost effectiveness, aesthetics and in most cases comfortability.

Ghosh (2002) stated that in most developed countries, it has been noticed that the conventional technologies used for construction of buildings are inefficient and resource wasteful due to huge amount of resources consumed. This was corroborated by Adedeji (2005) who stated that the enormous waste associated with conventional masonry works facilitated the search and subsequent development of more rapid and less workmanship dependent building methods and materials. One of such development is the use of Compressed Stabilized Interlocking Earth Block (CSIEB).

CSIEB is made from laterite, stabilized with cement (in most cases) and compressed in an interlocking block making machine. According to Adedeji and Fasakin (2008) when used for construction, it has unparallel advantages such as shorter period of construction, lesser gang

Aghimien, O. D.; Makonjuola, A. S. & Adegbembo, F. T. (2016). Drivers and Barriers of Compressed Stabilized Interlocking Earth Blocks for Building Construction in Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 206-214

of labour and reduced cost of construction. Despite these advantages, its usage in construction of building is low when compared to the conventional sandcrete blocks. This is partly due to the ignorance of the people towards the advantageous use of this material for building construction (Adewole, 2008). This research therefore assessed the various drivers and barriers of CSIEB in building construction in Nigeria with a view of providing a more suitable, cost effective and faster method of construction. To achieve this, the drivers of CSIEB in building construction and barriers were assessed and possible solutions to reducing the barriers and possibly increasing the drivers were proposed.

LITERATURE REVIEW

Building Materials

Comfortability has been a major priority for man since the time of creation, and to achieve this lot of developments have been carried out over the centuries (Olaleye and Sangodina 2001). In achieving a comfortable environment, the choice of material is critical. Hence the complete life span of the material, environmental impact, cost, social requirements such as: thermal comfort; good mechanical properties; aesthetic characteristics, and an ability to construct quickly must be greatly considered (Adedeji and Fa 2012). Abeysundara, Babel and Gheewala (2009) observed that the combination of all environmental, economic and social factors can give a clear description of a material, and helps in a decision making process regarding the selection of the materials suitable for buildings.

Earth for Building Construction

Earth as a building material has been in use for thousands of years all over the world and according to Olotuah (2002) it is the indigenous material for building construction in Nigeria. Pollock (1999) opined that earth as a building material has been in used since the Ubaid Period in ancient Mesopotamia (5000 – 4000 B.C.) and ancient monumental structures which are still objects of tourist attraction such as ancient temples, the pyramids, the Great wall of China and even the walls of Benin city which was the worlds' largest man-made earth structure (Wesler, 1998) were all built with earth. Adam and Agib (2001) observed that earth still continued to enjoy patronage as a building material but with varying degrees of improvement in techniques as a result of improved technologies. Many different techniques have been developed in using earth as a construction material and these methods vary according to the local climate and environment as well as local traditions and customs.

Alagbe (2011) also observed that earth building technique was popular in Nigeria until the influx of cement blocks into the country immediately after independence. Most pre-independence houses were built of earth building techniques of mud wall or sun-dried bricks. The houses served their purpose of providing adequate shelter for the inhabitants and they were also durable to the extent that some of the buildings dated between 50 and 100 years.

Production and Features of CSIEB

In production of CSIEB soil is gotten from at least 1m below the top soil. The soil must be free of dirt in other to achieve a fine finish product. This dirt free soil is achieved with the use of sieve. The clay content of the soil must be low enough not to require reduction with sharp sand and high enough to make the blocks easy to handle. The soil is mixed with cement in predetermined ratios by hand or in a pan mixer and water added at an average proportion, making sure that the mixture is not watery. The mixture is loaded into the block making machine in which it is hydraulically compressed. It takes an approximate 15-20 seconds per block, after which the compressed block is then stacked and left to cure (Hydraform, 2004).

CSIEB is moulded by pressing along its length from the ends. It is also a solid block, slightly short, wide and thick in size (225x225x112mm). It has a Bed underneath and a Ridge at the

top. The recessed under surface of the block is referred to as the bed while the raised top surface of the block is called the Ridge. The ridge of one interlocking block is designed to key in to the bed of another, thereby providing a perfect lock in masonry (Hydraform, 2004; Bansal, 2010). Kintingu (2009) observed that the stability of the wall built from the CSIEB is not provided by the locking mechanism but by the width and weight of the block. CSIEB has proven to be suitable for the construction of load bearing walls, framed structures, boundaries etc. and this is because of its strength and stability (Bansal, 2010).

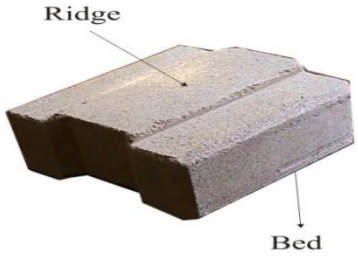

Figure 1: Full scale dry-stack block unit
Source: Adapted from Bansal (2010)

Use of CSIEB for Building Construction

The use of CSIEB for building construction follows the principle of dry stacking. In dry stacking construction, the interlocking blocks are laid without mortar thereby leading to considerable savings in cost associated with mortar. This method of construction according to Uzegbo and Ngowi (2003) has existed in Africa for thousands of year. Pave and Uzoegbo (2010) observed that ancient dry-stack masonry consisted of robust construction and the huge structural elements which were both material and time consuming construction process. At the time, attention shifted from dry-stack construction to research on new materials and applying new methods of construction. Adewole (2008) stated that these research activities that ultimately led to the development of the interlocking block technique, which is gaining popularity in Thailand, as well as Malaysia and the Philippines. Olusanya (2001) stated that the first documented usage of the interlocking masonry construction in Nigeria was that of a 60-unit housing estate experimented in 1991 at the University of Lagos, Lagos. Since then interlocking masonry has gradually gained recognition within the country, especially with the introduction of the Hydraform system of building, the use of CSIEB is increasing like the clinic, hostel and staff quarters in Elizarde University, Ilara-mokin, Ondo state, the Electronic Testing Centre in Federal University of Technology, Akure, and the construction of a caring heart mega school, Famese, Isokan, Akure, Ondo state.

Drivers of CSIEB in Building Construction

Deboucha and Hashim (2011) observed that although the stabilized earth blocks have been an area of interest for researchers in the past, its potential as a commercial construction material and the ability to fulfill several functions such as structural integrity, thermal transmittance and durability, makes the material an excellent walling material when compared to other masonry materials used in construction today and this has brought about the resurgence of renewed research interest in recent years.

The major drivers to the use of CSIEB for masonry construction include: shorter period of operation, lesser gang of labour, reduced cost of construction, aesthetic nature of the system, low cost of raw material, suitability of the system, reduction in cost of finishes and maintenance, time saving during construction, availability of materials, adaptability of blocks to tropical climate, better quality construction, less wastage, versatility as all other elements such as doors, windows and slabs used in the conventional system can be used with it, and

genuine eco-friendliness (Adewole,2008; Adedeji and Fa 2012; Taiwo and Adeboye 2013; Bansal, 2010).

Barriers of CSIEB in Building Construction

Despite the immense benefits of CSIEB for construction of sustainable homes, the level of usage is still low when compared to the popular conventional sandcrete blocks. This according to Wazir, Kadai and Biu (2014) is as a result of problems related to production which includes: delays in the production process, absence of quality control, lack of skilled machine operators, lack of trained personnel handling production; and those related to the construction, which includes: absence of trained masons for wall construction, high cost of block construction and slow rate of construction. Alagbe (2011) and Ng'ang'a, (2013) further identified some barriers to the use of laterite as a major material in building construction today. These includes: reduced durability of structures built with earth if not regularly maintained and properly protected, particularly in areas affected by medium to high rainfall; low resistance to abrasion and impact if not sufficiently reinforced or protected and; low acceptability amongst most social groups as it is considered by many to be a second-class and cheap material, hence it is meant for the poor.

METHODOLOGY

The aim of this paper is to identify the drivers and barriers of the use of CSIEB for building construction in Nigeria. In achieving this, a survey design was used. This involved the use of questionnaire and interview. A total of 60 questionnaires were distributed to respondents in Lagos and Ondo state, while 10 professionals who have been involved in the use of CSIEB for building construction in these two states were interviewed in other to ascertain the challenges faced during the course of the projects. Out of the 60 questionnaires distributed, 57 were returned and were found fit for analysis. Relative Importance Index (RII) was used to analyze the drivers and barriers of CSIEB for building construction while Content Analysis was used to analyze the information gotten from the interview.

RII according to Megha and Rajivis (2013) is written as:

$$RII = \frac{\sum W}{A * N}$$

Where, W is the weighting given to each factor by the respondents (ranging from 1 to 5), A is the highest weight, and N is the total number of respondents.

FINDINGS AND DISCUSSIONS

General information of respondents

Respondents profile showed that Quantity surveyors and Engineers formed the bulk of the respondents sampled with 28.1% while Architects and Builders form 24.6% and 19.3% of the total population. 29.8% of the respondents have between 0 to 5years working experience, 35.1% of respondents have between 6 to10 years working experience while 24.6%, 7% and 3.5% have between 11 to 15, 16 to 20 and 21 to 30 years of experience respectively. Since a total of 70.2% of the respondents have between 6 to 30 years working experience, it therefore implies that the result gotten from the respondents can be relied upon as answers were given based on experience. Also 89.5% of the respondents are aware of CSIEB for building construction, while 10.5% are not. This high awareness rate can be attributed to the vast years of experience of the respondents in the construction field. 50.9% of the respondents have been involved 1 to 10 construction projects where CSIEBs were used, while 38.6% have not. This 38% respondent includes those that have not heard of the material and method of construction before and those that have but have not actually been involved in its usage.

Drivers of CSIEB for building construction in Nigeria

Table 1 below shows the driver of CSIEB in building construction in Nigeria. Result shows that low cost of raw material and suitability of system and reduction in cost of finishes and maintenance as they are the top four major drivers with a RII of 0.800, 0.788, 0.776 and 0.770 respectively. Versatility of CSEIB was ranked last with a RII of 0.492.

Table 1: Drivers of CSIEB for building construction in Nigeria

Drivers	RII	Ranking
Aesthetic nature of the system	0.800	1
Low cost of material	0.788	2
Suitability of the construction system	0.776	3
Reduction in cost of finishes/maintenance	0.770	4
Time saving during construction	0.738	5
Availability of raw materials	0.734	6
Cost Effectiveness of the overall building system	0.724	7
Adaptability of CSIEB to tropical climate	0.722	8
Better quality construction	0.716	9
Lesser waste	0.704	10
Use of reduce Labour	0.674	11
Genuine eco-friendliness	0.642	12
Versatility of the CSIEB	0.492	13

Barriers of CSIEB for building construction in Nigeria

Table 2 below shows the barriers to the use of CSIEB for building construction in Nigeria. Result shows that the major barriers to the use of CSIEB are high cost of machine, lack of skilled machine operators, lack of trained personnel handling production and low acceptability amongst most social groups, as they are the top four major identified barriers with a RII of 0.919, 0.838, 0.819 and 0.808 respectively. Absence of quality control and Low resistance to abrasion and impact if not sufficiently were ranked last with a RII of 0.542 and 0.512 respectively.

Table 2: Barriers of CSIEB for building construction in Nigeria

Barriers	RII	Ranking
High cost of machine	0.919	1
Lack of skilled machine operators	0.838	2
Lack of trained personnel handling production	0.819	3
Low acceptability amongst most social groups	0.808	4
Delays in the production process	0.746	5
Absence of trained masons for wall construction	0.665	6
Slow rate of construction	0.627	7
Reduced durability of structures if not regularly maintained and properly protected	0.585	8
Absence of quality control	0.542	9
Low resistance to abrasion and impact if not sufficiently reinforced	0.512	10

Interview Findings

In other to get first-hand information on the challenges faced during the use of CSIEB for building construction, interview was conducted for those that have been involved in its usage. Quantity surveyors formed the bulk of the respondents with 40% while Architects, Engineers and Builders formed 20%, 30% and 10% respectively. 70% of respondents have between 6-10 years working experience while only 20% and 10% have 11 to 20 years and above 20 years of working experience respectively.

From the interview conducted, respondents outlined the following challenges faced during course of construction using CSIEB. This includes:

80% of the respondents stated high cost of acquiring the machine needed for the production of CSIEB as a major challenge faced in the decision to use CSIEB for construction.

Need for skilled machine operator trained in the handling of the machine is also a major challenge stated by 80% of the respondents. It was observed that only few trained machine operate are available and this usually leads to delay in the production process.

60% of the respondents stated that as a result of the technicality involved in the usage of CSIEB, not just any mason can lay the blocks hence leading to slow construction process.

Also 60% of the respondents stated that the opinion of people about earth construction is also an important factor, as it is generally believe that earth is a cheap and poor material for building construction.

Difficulty in determining the construction cost from the onset since interlocking stabilized earth blocks are not sold in the market was a challenge faced by 50% of the respondents. Unlike the conventional sandcrete blocks, the CSIEBs are not available in the market, hence the need to estimate the cost of hiring/purchasing the machine, materials and labour. This has proven to be a challenge for both the contractors and the clients, as approximate estimates are used and this in most cases leads to variation during the course of construction.

50% of the respondents stated that getting the required laterite type and quality from the proposed site was a major challenge, hence the need for a borrow pit elsewhere. This most times leads to increased cost and considerable time wastage.

40% of the respondents were of the opinion that the use of CSIEB for construction needs to be predetermined before the architectural design is done. Due to the irregularity in the length of buildings, the blocks would need to be cut to different irregular sizes on site, giving a non appealing look after construction. Also the irregular colour of blocks which is as a result of usage of laterite gotten from different pits, if not properly managed, could lead to a non-appealing finish. This might lead to the painting of these blocks leading to increase in cost.

Discussion of Findings

It was observed that the CSIEB is gaining popularity among professionals within the Nigeria building construction industry as 89.5% of the respondents are aware of it. The drivers and barriers to its usage in building construction are discussed below

Drivers of the CSIEB for Sustainable Building Construction in Nigeria

Findings corroborate Adedeji and Fasakin (2008) assertion that the high level of acceptability of the stabilized interlocking earth blocks is as a result of its cost effectiveness, adaptability to tropical climate, accessibility and suitability. While almost all the listed drivers showed considerable importance level, the aesthetic nature, low cost of raw material, suitability of the material for building construction and reduction in cost of finishes and maintenance have high relative importance in the use of the material for building construction in Nigeria, as they have a RII of 0.800, 0.788, 0.776 and 0.770 respectively. The versatility of CSIEB had a mean score RII of 0.492. This can increase with time if the material is used more often for building construction.

Barriers of the CSIEB for Sustainable Building Construction in Nigeria

Based on the responses from the questionnaires and interviews the problems associated with the use of CSIEB include:

High cost of acquiring the machine needed for the production of CSIEB and the need for skilled machine operator trained in the handling of the machine as they both have an RII of 0.919 and 0.838 respectively. This twin problem poses a big challenge during construction as observed by 80% of the professionals interviewed. This problem can be associated to the huge cost of buying and importing these interlocking block machines and also the lack of adequate skilled personnel that can handle the machines (Waziri et al, 2014).

The technicality involved in the usage of CSIEB and the lack of skilled personnel to handle the production with an RII of 0.0819 are also challenge identified by respondents during the course of using CSIEB. This can lead to slow production and construction process.

Low acceptability among most social group is another barrier to the use of CSIEB with an RII of 0.808. Finding revealed 60% of the professionals interviewed stated that the opinion of people about earth construction is also important factor militating against its use. It is generally believe that earth is a cheap material, hence it is meant for the poor (Ng'ang'a, 2013) but this can be address through proper sensitization of the public of the immense benefits of stabilized earth construction. Furthermore, several researches have been carried out on the strength of CSIEB and it has been proven that it is structurally suitable for any type of construction (Bansal, 2010; Chaibeddra and Kharchi, 2013).

Findings revealed that there is always difficulty in determining the construction cost from the onset since CSIEBs are not sold in the market unlike the conventional sandcrete blocks. Since the blocks are made on site, lot of 'guess work' are done during estimation which may lead to possible errors.

Absence of quality control ranked 9th with a RII of 0.542. This is contrary to waziri et al, (2014) research were absence of quality control on site which often leads to the production of poor quality blocks ranked highest. These two extreme views of respondents can be attributed to the capability of the organization handling the project in terms of quality control in construction.

Findings revealed that getting the required laterite type/quality from the proposed site is always difficult as observe by 50% of the professionals interviewed, hence the need for a borrow pit elsewhere. This can be attributed to the nature of soil in the proposed site as the nature of soil differs from one location to another. This is somewhat contrary to the general idea that materials can be gotten from anywhere as laterite earth is readily available (Adewole, 2008).

CONCLUSION AND RECOMMENDATION

Conclusively, the research has been able to determine the drivers and barriers to the use of CSIEB for building construction in Nigeria. The study showed that CSIEB is gaining recognition among construction professionals in Lagos and Ondo state, Nigeria. The study revealed that the major drivers of the CSIEB for building construction are the aesthetic nature, low cost of raw material, suitability of the material for building construction, reduction in cost of finishes and maintenance, time savings during construction, availability of raw materials and adaptability to tropical climate.

The study shows that while the benefits of using CSIEB are enormous, certain challenges might affect its adoption if not properly checked. These include; the high cost of machine, lack of trained machine operator and skilled personnel to handle production process, low acceptability among most social group as they have the opinion of the earth construction as being too cheap and structurally unfit for construction, difficulty in getting right material on proposed site leading to the need for a borrowed pit, difficulty in determining the cost of

construction from the onset, and a non-appealing look resulting from cutting of blocks and different types of laterite used.

The study therefore recommends that the use of CSIEB should be encouraged among stakeholders as a material for building construction due to its enormous benefits, while tariff on import duties should be reduced by the government, thus, minimizing the high cost of importing machines. Appropriate training of personnel to handle the machines and production process through skill workshops should be carried out in order to increase the number of available machine operators hence increasing the speed of production and construction. This training can also serve as a means of providing employment for members within the community. Proper sensitization of the public as to the benefits and reliability of earth construction should be carried out by the professionals in the Nigerian construction industry through workshops.

Managing Wastes on Construction Sites in Akure, Ondo State

Ganiyu, S.A.[1*]; Ogunmakinde, O.E.[1] & Oladokun, S.D.[1]

Department of Architecture, Federal University of Technology, Akure, Ondo State, Nigeria.

ABSTRACT

This paper is aimed at providing an insight into the management of wastes on construction sites in Ondo State, Nigeria with a focus on Akure, the state capital. Nigeria being a developing country is experiencing an increase in the rate of construction projects in almost all the states of the country. As a result of the construction activities, huge wastes are generated on the construction sites with little or no proper waste management methods put in place. Effective waste management on construction sites is therefore an important factor in construction management. This study reviews construction waste materials, type of wastes and the method of collecting wastes on construction sites. It also discusses the method of sorting wastes and the various means of waste disposal. Data for the study were collected through a structured questionnaire administered to site architects, project managers, quantity surveyors, contractors and masons on construction sites. Mean Item Score and Percentile were used to analyze returned questionnaires. The findings revealed that, most wastes are generated during construction as a result of broken or shredded materials. It also revealed that, inexperience on the part of the masons is the major cause of material wastage on construction sites and that most construction sites in Akure depends on Ondo State Waste Management Authority for the removal of wastes on sites. This study in conclusion suggests efficient technical training for the masons and the revitalization of technical colleges in Ondo State and Nigeria as a whole. This study then makes a succinct recommendation on the need to minimize wastes and proper disposal of the wastes generated on construction sites.

Keywords: Construction, Wastes, Management, Construction sites, Akure

INTRODUCTION

The management of waste is an essential aspect of sustainable building construction. Managing waste means eliminating waste where possible; minimizing waste where feasible; and reusing materials which might otherwise become waste (Napier, 2012). Construction waste is generally defined as by-products generated from construction, renovation and demolition workplaces or sites of building and civil engineering works. Construction waste issues have become more a part of the focus on a project due to cost and environmental awareness (Dajadian and Koch, 2014). Construction project costs increase significantly due to the amount of waste generated which also have negative impact on the environment by consuming landfills, and natural unrecoverable resources. Bossink and Brouwers, (1996) identified design, procurement, materials handling, operation, residual, and other as the six main causes of waste. Over production, poor handling, incorrect storage, incorrect ordering, design change, manufacturing defects and rework are factors that contribute in material waste. Other factors that contribute in a way or another in generating construction wastes are lack of training and poor craftsmanship. In general, a very high level of waste is assumed to exist in construction. Although, it is difficult to systematically measure all wastes in construction, but studies from various countries have confirmed that waste represents a relatively large percentage of production costs (Sagoe, 2011).

Construction activities are on the increase in most developing countries as most of these nations are striving to provide shelter for its citizenry. Developing nations normally want provision of more essential infrastructural facilities which includes major building projects, road construction, bridge construction etc. The construction industry in Nigeria is fast growing with the involvement of the Government at all levels, Public Private Partnership,

Ganiyu, S. A.; Ogunmakinde, O.E. & Oladokun, S. D. (2016). Managing Wastes on Construction Sites in Akure, Ondo State. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 215-223

International Organizations and individuals in various construction activities ranging from buildings to roads and bridge constructions. The construction industry generates large quantities of waste and contributes to the problems of environmental degradation in Nigerian cities due to ineffective waste management systems. This has inevitably led to the generation of waste at different stages of projects (Wahab and Lawal, 2011). Studies have shown that, not all materials procured for construction or renovation projects in Nigeria are used during the construction process. The left-overs are either sold to interested buyers or left as wastes that may not be accounted for by the contractor.

Waste management is a major challenge in many cities in Nigeria. The nature of this challenge is in effective management, ability to reduce, re-use and recycle wastes generated. Concerted efforts are being made by the Government at all levels through the establishment of Waste Management Agencies and Private Support Partnership (PSP) to curtail it. This is evident in Lagos state where the state waste management authority (LAWMA) collaborates with private partners to manage wastes generated. Studies however, show that improper disposal of waste has resulted in high rate of morbidity and mortality in a developing society such as Nigeria (Oluwaleye, 2012). Waste therefore affects success of construction projects significantly. More specifically, it has major impact on construction cost, construction time, productivity and sustainability of the project.

This study reviews the management of wastes on construction sites in Akure, the capital city of Ondo State, Nigeria with a view to identifying the causes, effects and the material that generates most wastes. This is done by investigating the stage at which most wastes are generated and the sources of waste as well as the waste management methods adopted on the construction sites. The study is justified in the sense that, it will support and enrich existing few data on construction and demolition wastes in Nigeria. It will serve as a reference material for professionals in the construction industry in Akure and Nigeria as a whole. This study is also an eye opener for all stakeholders in the Nigerian construction industry on the need to employ an effective waste management methods which will in turn reduce cost and ensure prompt project delivery. This paper is divided into five (5) sections. The first section being the introduction which is followed by literature review. The literature review is important as it identifies and acknowledge previous studies on construction wastes. It is followed by a description of the study area and the methodology adopted for the study. Section four gives a detailed analysis of the data collected and also discusses the results and findings. The fifth section contains the conclusion and concise recommendations.

LITERATURE REVIEW

The Building Research Establishment (1981 cited in Ekanayake and Ofori 2004) define construction waste as “any materials apart from earth materials, which needed to be transported elsewhere from the construction site itself other than the intended specific purpose of the project due to damage, excess or non-use or which cannot be used due to noncompliance with the specification, or which is a by-product of the construction process”.Mohanty and Deshmukh (1999), state that “any non-value adding activity carried out in any work system at any time can be defined as waste”. Also, Formoso et al. (1999 Cited in Yahya and Boussabaine 2006) define waste as “any losses produced by activities that generate direct or indirect costs but do not add any value to the product from the point of view of the client”. All the definitions cited indicates that, construction wastes are materials that becomes useless during and after the completion of the construction projects. Evidence from previous research shows the classification of wastes to include their sources, physical state, material composition and the level of risk associated with waste substances. Such

classification of waste provides a basis for the development of appropriate waste management practice.

The source classification of waste is based on the fact that, waste emanates from different sectors of society such as residential, commercial and industrial sources. A study conducted in Asia by World Bank (1999) identified residential, commercial, industrial, municipal services, construction and demolition, processing and agricultural as the source sources of waste. In the *Stakeholders' Guide: Sustainable Waste Management*, the UK Environment Council (2000 cited by Sagoe 2011) also employed source classification to identify the major sources of waste as municipal sources, commerce and industry, agricultural sources, demolition and construction activities, dredged spoils, sewage sludge and mining and quarrying operations. Waste from razed building and other structure are classified as demolition waste while waste from the construction, remodeling, and repairing of residential, commercial, and industrial buildings and similar structures are classified as construction waste. These wastes may include dirt, stones, concrete, bricks, plaster, lumber, shingles, and plumbing, heating, and electrical parts.

Stokoe et al. (1999) reported that around 1994/1995, construction and demolition waste took up about 65% of Hong Kong's landfill space. Ferguson et al. (1995), also reported that, over 50% of the waste in a typical United Kingdom landfill could be construction waste. According Serpell and Labra (2003), out of the 3.5 million tons of construction and demolition waste generated in Chile, only 10% is placed in authorized and controlled landfill sites. In Brazil construction industry, the level of waste at construction sites is 20 – 30% of the total weight of materials on site (Bossink and Brouwers, 1996). According to UK Statistics on Waste, UK generated 200.0 million tonnes of total waste in 2012. Based on the Nomenclature of Economic Activities, 50 per cent of this waste was generated by Construction. Commercial & Industrial activities generated almost a quarter (24 per cent), with households responsible for a further 14 per cent.

Wahab and Lawal (2011) grouped the construction activities which produce wastage into off-site and on-site operational activities. According to them, off-site activities include prefabrication, project design (architectural, structural, mechanical and electrical design), manufacturing and transporting of materials and components while on-site construction activities relate to construction of a physical facility which consists of the substructure and superstructure of the building. Their study indicated that, some degrees of waste materials are inevitable in the construction process. Neo and Koh (1995) also grouped the wastes produced at construction sites into physical and non-physical wastes. The physical wastes are mainly from broken concrete, bricks, metals, packaging waste, etc. Whereas the non-physical wastes are cost overruns and time delays in construction projects. Wastage may also lead to delays that cause costly idle time for other resources. Most loss of materials occurs as a result of the decision of the site management. Decision taken at the initial stage (design stage) of any project, either by the manufacturer or supplier of materials is capable of increasing waste level (Wahab and Lawal, 2011).

Solid waste management has emerged as one of the greatest challenges facing state and local government environmental protection agencies in Nigeria. The volume of solid waste generated continues to increase at a faster rate than the ability of the agencies to improve on the financial and technical resources needed to parallel this growth. According to Ogwueleka (2009), solid waste management in Nigeria is characterized by inefficient collection methods, insufficient coverage of the collection system and improper disposal of solid waste. The study revealed that, Nigeria has solid waste management problems that are different from those

found in industrialized countries in areas of composition, density, political, and economic framework, waste amount, access to waste for collection, awareness and attitude.

STUDY AREA

The study area utilized for this paper is Akure, the capital city of Ondo State, Southwest, Nigeria. Akure is a traditional Nigeria city and like other traditional Yoruba towns in the country, it existed long before the advent of British colonial rule. Akure has a population of 360,268 (National Population Census, 2006). Using 2% yearly increase, it is expected that by 2015 it would rise to 430, 553 and 475,365 by the year 2020. It is located approximately 700 kilometres South West of Abuja, the Federal Capital of Nigeria and about 350 kilometres to Lagos the former capital of Nigeria. It lies on longitude 5^0 $18^/$ East of the Greenwich Meridian and Latitude 7^0 $17^/$ North of the Equator. Akure is a medium- sized urban centre and became the provincial headquarter of Ondo province in 1939. The rapidity of the city's development within the last twenty-five years stemmed from the political status of the town which was initially a provisional headquarter and later a state capital thus serving as the seat of both the local (Akure South and Akure North) and State Governments since 1976. Akure has been classified as a Millennium Development City.

RESEARCH METHODOLOGY

Data for this study were collected through a structure questionnaire which was administered to construction professionals and contractors that were directly involved at design and construction activities in Akure. Out of the Two hundred (200) copies of questionnaire administered, 153 were returned and found useful for this research which represents a response rate of 76.5%. The research instruments used for this study are the 300Level Architecture students of the Federal University of Technology, Akure. Data for the major causes of waste on construction sites and building materials that generate wastes were derived from the literatures and used for the study.

A list of 8 factors that contributes to waste on site were preliminarily identified through extensive literature review. This was followed by a questionnaire survey to collect the relative importance of the factors. The responses to the items on the questionnaire were obtained on a 5-point scale ranging from 1 to 5. "Strongly Agree" responses were scored 5, "Agree" were scored 4 and "indifferent" were scored 3, "Disagree" were scored 2 while "Strongly disagree"

were scored 1. Tobe able to rank the factors perceived by the respondents to impact the various aspects of the study, it was necessary to highlight the relative importance of the factors (Kangwa and Olubodun, 2003). Therefore, Relative Significance Index, RSI (also known as Index of Relative Importance, IRI or Relative Importance Index, RII) was used for ranking the factors.

Bakhary (2005) gave an equation that could be useful for determining relative Importance Index (RSI) in prevalence data as:

$$RSI = \frac{\Sigma \mu}{A * N}$$

Where μ is the weighting given to each factor by respondents;
A is the highest weight (i.e. 5 in this case);
N is the total number of respondents.

For this research, the RSI was computed using the formula below:

$$RSI = \frac{5a + 4b + 3c + 2d + 1e}{JN}$$

Where a = number of respondents who responded "Strongly agree".
b = number of respondents who responded "Agree".
c = number of respondents who responded "Indifferent".
d = number of respondents who responded "Disagree".
e = number of respondents who responded "Strongly disagree".
N = sample size = 153.
J = number of response categories = 5.

FINDINGS AND DISCUSSION

Table 1 shows that 68.6% of the respondents are males while 31.4% are females. Some 38.56% of the respondents possess 1 to 5 years of experience in design and construction activities; the period of the experience of the remainder were; 6 to 10years 11.11%; 11 to 15years 5.88%; 16 to 20 years 7.20%; 21 to 25 20.26% and above 20 years 16.99%.

Table 1: Respondents' Characteristics

RESPONDENTS' CHARACTERISTICS		
Gender	**Frequency**	**Percentage**
Male	105	68.6
Female	48	31.4
Total	**153**	**100**
Years of Experience		
1-5	59	38.56
6-10	17	11.11
11-15	9	5.88
16-20	11	7.20
21-25	31	20.26
Above 20	26	16.99
Total	**153**	**100**

Table 2 reveals the stages of construction where most wastes are generated. 17 of the respondents indicated that 11.11% of wastes are generated during the pre-construction stage while about 106 of the respondents showed that 69.28% of wastes are generated during the construction stage. 30 of the respondents were of the opinion that 19.61% of wastes are generated during post-construction stage. Some 86.24% of the respondents agreed that most wastes generated on construction sites are from building materials while 13.76% indicated that it is from human waste or wastes from the labourers. A further investigation into the sources of wastes on construction sites in Akure revealed that, 39.87% are from broken or

shredded materials, 13.07% from off-cuts, 21.57% from packaging and bagging of materials and 25.49% are from excess materials brought to site.

Table 3 presents the material that generates most wastes construction sites according to the findings of the survey. It shows that, majority of the respondents agreed that wood (RSI = 0.492, Rank = 1) contributes the largest wastes on their sites. This is contrary to previous findings by Chu (2004), Ameh and Itodo (2013) and several other researchers whose studies identified mortar as being the material that generates most wastes on site.

Table 2: Types and sources of construction wastes

STAGE OF CONSTRUCTION WHERE WASTES ARE GENERATED		
Stage	**Frequency**	**Percentage**
Pre-construction	17	11.11
During construction	106	69.28
Post construction	30	19.61
Total	**153**	**100**
TYPES OF WASTES GENERATED		
Type	**Frequency**	**Percentage**
Building material	132	86.24
Human waste/labour	21	13.76
Total	**153**	**100**
SOURCES OF WASTE ON SITE		
Source	Frequency	Percentage
Broken materials	61	39.87
Off cut	20	13.07
Packaging/bagging of materials	33	21.57
Excess material	39	25.49
Total	**153**	**100**

Table 3: Construction material that generate most wastes

Materials	**SA**	**A**	**N**	**D**	**SD**	**R.S.I**	**Rank**
Roofing material	0	3	16	53	81	0.322876	10
Wood	8	19	37	61	28	0.49281	1
Tiles	3	15	39	52	44	0.444444	3
Sandcrete block	0	29	42	49	33	0.487582	2
Concrete	5	17	41	34	56	0.444444	3
Glass	0	3	11	36	103	0.287582	11
Paint	0	2	27	41	83	0.332026	9
PVC	0	4	27	56	66	0.359477	7
Asbestos	0	9	21	70	53	0.381699	6
Metal	4	12	16	38	83	0.359477	7
Rubbles	6	19	29	43	56	0.437908	5

The first five materials (Wood, Sandcrete blocks, Tiles, Concrete and Rubbles) contributes the largest wastes on construction sites in Akure with wood being the largest. This finding agrees with the study conducted in the United States between 2009 and 2010 where the percentage material wastage indicates wood 30%, concrete 5%, gravels, aggregate and fines, 20%, dry wall 3%, Asphalt roofing 5%, ferrous and non-ferrous metals, 9%, plastic 1%, cardboard and paper 3% and disposal as refuse 5% (Napier, 2012). The result of a study conducted in Hong Kong by Tam et al (2007) also identified the following percentage wastage; concrete 8.99%, reinforcement 7.7%, formwork, 20%, block/brick 8.9%, and tiles 15.58%.

Table 4: Causes of construction wastes

Causes	**SA**	**A**	**N**	**D**	**SD**	**R.S.I**	**Rank**
Poor design	43	57	31	20	2	0.755556	5
Inexperience labour	63	57	24	9	0	0.827451	1
Poor site practice/organization	26	73	42	12	0	0.747712	6
Over estimation	46	50	35	22	0	0.756863	4

Faulty design	30	52	46	18	7	0.704575	8
Use of non-professional	43	71	26	8	5	0.781699	2
Wrong construction methods	44	54	42	12	1	0.76732	3
Site constraints	37	54	46	9	7	0.737255	7

Table 4 reveals the major causes of wastes on construction sites in Akure. It shows that, most wastes are generated on the sites as a result of inexperience labour (RSI = 0.827), this is followed by use of non-professionals (RSI = 0.781). Wrong construction methods (RSI = 0.767) occupies the third position, it is closely followed by over estimation. Poor design (RSI = 0.7550), poor site organisation (RSI = 0.747) and site constraints (RSI = 0.737) occupies fifth, sixth and seventh position respectively while faulty design (RSI = 0.704) is the last on the list.

The means of collection and disposal of wastes generated on construction sites in Akure as practiced by the respondents are presented in table 5. It shows that, 45.10% of the respondents use big waste bins for collecting wastes, 41.83% uses waste pits which are dug on the sites and will be covered up after the completion of the project, while 20% of the respondents litter the sites by throwing wastes around. A further enquiry on how the wastes collected are disposed revealed that, 43.80% of the respondents dispose the wastes by burning, as back fills and some other ways. 50.98% uses the Ondo State Waste Management Board vehicles which are provided by the government for easy collection of wastes in and around Ondo State. 5.22% uses private companies for the disposal of the wastes generated on sites.

Table 5: Methods of collection and disposal of construction wastes

METHODS OF COLLECTION AND DISPOSAL OF CONSTRUCTION WASTE		
Means of collection	**Frequency**	**Percentage**
Waste bin	69	45.10
Waste pit	64	41.83
Littering	20	13.07
Total	153	100
Method of disposal	**Frequency**	**Percentage**
Self-disposal	67	43.80
Government owned	78	50.98
Private company	8	5.22
Total	153	100

The respondents were asked to identify the effects of poor waste management on construction sites. Their responses were presented in table 6. Some 39.22% were of the opinion that, it brings about material wastage which could leads to extra cost of construction. 3.33% said it causes pollution while 27.45% indicated that, it could lead to injury.

Table 6: Effects of poor construction waste management

Effect	**Frequency**	**Percentage**
Injury	42	27.45
Pollution	51	33.33
Material wastage	60	39.22
Total	153	100

Based on the above findings, it has become expedient to include waste management in building contracts as this could assist in its effective management. All stakeholders in the building construction industry have specific roles to play if construction waste is to be managed effectively on construction sites. Table 7 shows action required to be taken by some identified stakeholders.

Table 7: Actions required

S/N	**Actions**	**Stakeholder**

1.	Good site practice	All stakeholders on construction sites
2.	Appropriate building design	Architects
3.	Technical Training	Labourers/Masons
4.	New policy and enforcement of existing policies	Government
5.	Appropriate material estimation	Quantity Surveyors

CONCLUSION

This study has reviewed the management of wastes on construction sites in Akure, Ondo State, Nigeria using a well-structured questionnaire. The answers provided by the respondents were scrutinized carefully and the following can be summed up as conclusion:

i. Most wastes are generated during the construction stage.
ii. Building materials (86.24%) constitute the largest wastes on construction sites in Akure.
iii. The source of wastes on construction is from broken materials.
iv. Wood constitutes the largest waste on construction sites in Akure.
v. Majority of the respondents said inexperience labour is the major cause of construction wastes in Akure.
vi. The method of waste collection in Akure is by dumping the wastes in waste bins provided on the sites.
vii. The method of waste disposal is through the Ondo State Waste Management board.
viii. The main effect of poor construction waste management in Akure as revealed by the study is material wastage.

It is based on these findings that we conclude that, there is need for efficient technical training for the masons and the urgent resuscitation of technical colleges where such training can be undertaken. Finally, this piece of research is a result of survey conducted so far on managing wastes on construction sites in Akure, Ondo State. Further research could benefit from focusing on the characterization of construction wastes and the effective construction waste management methods.

Effects of Climate Change on Spatial Structures in South-western Nigeria

Olajuyigbe, A.[1*]; Enisan, G.[2] & Popoola, O.

[1, 2 &3]Department of Urban and Regional Planning, Federal University of Technology, Akure, Ondo State, Nigeria.
[*]aeolajuyigbe@futa.edu.ng

ABSTRACT

The built environment or structural aspects of cities, streets, buildings, and infrastructure systems contribute significantly to the emission of greenhouse gases, hence, the amplification of its effect on climate changes. Current planning strategies for future urban development often target issues such as housing, transport, water, and infrastructure; but very few strategies comprehensively consider the urban climate and its interaction with the built environment as well as the resultant effects. For the purpose of this research, the study areas are Ikeja, in Lagos State and Akure in Ondo State, rapidly growing urban centres with an annual growth rate of between 3.4 - 5 per cent. The methodology employed in this study involves the categorization of respondents according to required data and the dominant use. Samples were taken using the simple random sampling technique. Maps, tables and charts were used in presenting the data collected. This study exposes the fact that the study areas currently experiences a modified urban climate, as a result of gross development, with the research demonstrating that urban areas are often warmer than surrounding rural landscapes. This is due to the emission of greenhouse gases and industrial wastes generated from commercial activities and industries. This paper concludes by emphasizing the need for governance network in mitigating climate change impact on land use planning and development. This will promotes sustainable urban development with reduced effect on the urban climate of Nigeria.

Keywords: Urban Development, Climate Change, Environment, Spatial Structure, Climatic Impact

INTRODUCTION

Climate change has been one of the most engaging environmental subjects of debate in recent times. Indeed, the environmental problems associated with the potential impact of expected climate change may prove to be among the major environmental problems facing many countries. In Nigeria, it has been realized that serious environmental problems are likely to arise in association with the anticipated global warming resulting from emissions of greenhouse gases into the atmosphere. These problems in one way or the other affect location and planning of features and economic activities in Nigeria (Odjugo, 2010). The urban planning system is a key tool for adaptation in the face of changing climate. The quality of the planning system and its operation constitute an important dimension in institutional vulnerability (Campbell, 2006).

The changing climate is a challenge for both current and future generations. Climate change is increasingly threatening human lives, infrastructure, economic and social activities (Rodolfo and Siringan, 2006). Climate variability and future climate change impacts will increase the vulnerability of societies around the world. Especially in developing countries, the impacts will be severe, but also those living in high risk areas in developed countries could be greatly affected (Stern, 2006). Many sectors are important elements in responding to the challenges and potential opportunities afforded by a changing climate. Due to its role in regulating the development and use of land, spatial planning is particularly significant (Blanco and Alberti, 2009; Davondi, Crawford and Mehmood, 2009).

Human activities have modified the environment for thousands of years. Significant population increase, migration, and accelerated socio-economic activities have intensified

Olajuyigbe, A.; Enisan, G. & Popoola, O. (2016). Effects of Climate Change on Spatial Structures in South-western Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 224-231

these environmental changes over the last several centuries. The climate impacts of these changes have been found in local, regional, and global trends in modern atmospheric temperature records and other relevant climatic indicators. An important human influence on atmospheric temperature trends is extensive land use/land cover change (LULCC) and its climate forcing. Studies using both modelled and observed data have documented these impacts. Thus, it is essential that we detect LULCCs accurately, at appropriate scales, and in a timely manner to better understand their impacts on climate and provide improved prediction of future climate.

The primary focus of this research is to provide a policy documents for decision-makers and stakeholders regarding the implications of climate change on the efficiency of spatial structure and the impacts at the local level of the various adaptation options using Ikeja and Akure in Southwestern Nigeria as case studies. This was done through the assessment of the present state of land use development in the study areas and examination of the socio-economic patterns in both cities. There was also identification of factors responsible for the land use development in the area, assessment of situation of climatic components in the area and finally, investigation of the effects of climate change on spatial structure in the study area.

MATERIALS AND METHOD

Data for this research work was obtained through several methods, which include qualitative research method, direct conversation, and personal research among others. The qualitative research method involves interviews that are semi-structured in nature in which one or more areas will be explored through a number of questions. The flexibility of a qualitative research method makes it suitable for interviews in this paper.

of the research made use of the primary and secondary sources. The instrument used in collecting data includes the use of a structured questionnaire to collect information from the target population. Other instruments of data collection for this research were telephone interview and observation of situation on site. The questionnaires asked questions related to the socio-economic, infrastructure, land use information and climate ratings of the area were articulated and administered amongst the sampled population. In all, 350 questionnaires were administered in both States. 200 Questionnaires were administered in Ikeja, while 150 questionnaires were administered in Akure. The variation in the numbers is because of differences in population of the two cities. 300 (86%) questionnaires were for households, 32 (10%) questionnaires for specialized professionals, and 18 (6%) questionnaires for government establishments. The mode of questionnaire distribution and the various inputs of the respondents are summarized in the Table 1.

DISCUSSION OF FINDINGS

Planning for future urban growth and development amidst threats from climatic conditions is a difficult task for urban planners. Given the present state of land use development in the study area and the combined threat of global warming and the climate, strategies need to be developed to incorporate initiatives that can marry a change in climate with the need for land use planning of Southwestern Nigeria. Planning professionals need to incorporate climate change scenarios into both short-term planning decisions and longer term strategic regional planning decisions, using a more integrated approach than is currently adopted in modern day planning strategies.

Ratings of Climatic Components Affecting Land Use Development in South Western Nigeria

The assessment of climatic factors affecting land use development in the areas of study is limited to the below four basic climatic components namely; temperature, rainfall, precipitation and wind. Among all the climatic factors that constitute threat to spatial planning in the study area, rainfall seems to be the most prominent due to the damage caused.

Table 1: Categorization of Questionnaires Administered

Respondents	No of Questionnaires Administered	Percentage (%)	Remarks
Households (Major respondents and inhabitants in the study area)	300 (Lagos, 165; Akure, 135)	86	They provided information based on their perception of the research variables (climate change and land use development). In addition, they provide information on the socio-economic characteristics of the people in the study area.
Specialized Professionals (Comprise of professionals involved in climate studies and trends of land use development)	32 (Lagos, 20; Akure, 12)	8	They provided information based on their expertise and experiences in the study of trends of climatic changes and land use planning and development in Ikeja and Akure
Government Establishments (Ministry of Planning and Environment in Lagos and Ondo State)	18 (Lagos, 15; Akure, 3)	6	They provided information regarding development matters, land use development, government activities on climate and development etc.
Total	350 (Lagos, 200; Akure, 150)	100	Satisfactory

Table 2: Climatic Components that Affects Land Use Development in the Study Area

Climatic Factors	Responses	Percentage (%)
Temperature	76	25.3
Rainfall	169	56.3
Precipitation	32	10.7
Wind	23	7.7
Total	300	100.0

Source: Field Survey, 2015

The rate at which rainfall as a factor that affects land use development was put at 56%. The factor that is seen to be close in its impact on land use planning is temperature with a 25% rating followed by precipitation 11% and the wind 8%. Some of the respondents who spoke further believed that their opinion of rainfall as the major climatic component affecting land use development in both cities were connected with the recent rise in amount of rainfall experienced in the whole of region.

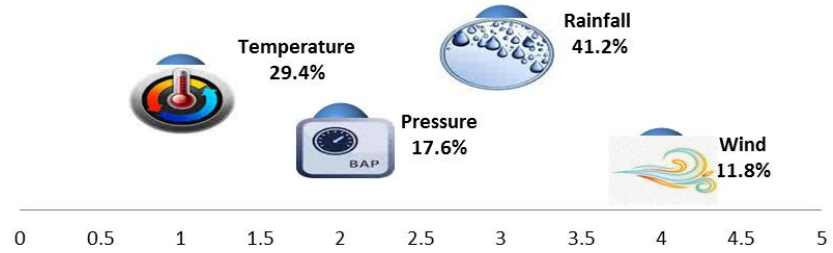

Figure 1: Impact of Climatic Change on Spatial Structure in the Area
Source: Field Survey, 2015

The Professionals in the study of climate changes in the environment both from NIMET and from the climate change department at the ministry of environment, in both states asserted that in the south west, the overriding climatic component that has a major impact on land use development and planning is the rainfall putting it at 41.2%. They then confirmed this fact with analysis of climatic components as observed by institutions working on climate data, which shows that amount of rainfall in the study area, has been on the increase. This will amount to 1,960 mm total annual amount of rainnfall. It was also gathered during the research that the main constraint to land use development in Southwestern Nigeria is the amount of rainfall. The other climatic factors that can hinder land use planning and development are temperature (29.4%) which is due to grossly urban heat island, general warming from heat caused by industrial activities etc. Others are pressure (17.6%) and wind-like actions (11.8%).

Climate Ratings in the Study Area

Generally, the climate rating as seen by both professionals and household respondents were similar as both believed that the climatic condition achievable in the study area was good. Of the 300 respondents who were asked to rate the climatic condition of the area, 171 people (57%) responded with a fair report believing that the overall climatic condition is fair enough. 90 respondents (30%) reported that climate rating is generally good while 39 respondents representing 13% believed that the climate condition is poor.

Effects of Climate Change on Land Use Planning in the Study Area

Climate Change Effects on Land Use Development

The investigation of the effect of climate change on land use planning in the study area is informed based on the results of analysis of data collected from households, private professionals and government institutions. As earlier discussed, the impact of rainfall as a major climatic component that affects land use planning is again manifested in the study area. Respondents believed that an effect of climate change on land use development is the increase for rainfall experienced in the study area, which has limited construction activities because of the lengthy rainfall periods. 85 households, which represented 28.3%, believed that the results of the rainfall i.e. flooding has more impact on the development of land uses in the study areas. These respondents claimed that almost every part of the study area is liable to flooding and hence any development around such vicinity is risky.

Table 4: Effects Caused by Changes in Climatic Conditions in the Study Area

Effects of Climate Change	Responses	Percent (%)
Others Effects	85	28.3
Increased Rainfall	102	34.0
Inconsistent Seasonal Changes	6	2.0
Increased Temperature	17	5.7
Flooding	84	28.0
Rise in Sea Level	6	2.0
Total	300	100.0

Source: Field Survey, 2015

In addition, some other 28% respondents believed that other effects that cannot be seen explained or easily measured but are a result of changes in climatic interplay, which is caused by anthropogenic action of man. It was also observed that the present climatic condition in the study area is not the best and hence it affects the overall health condition of inhabitants. This resulted in poor industrial outputs, and unbalanced mental well-being. Other climate change effects on land use development are in the aspect of increase in temperature, which affects building life and causes cracks. Inconsistent seasonal changes, which hamper development planning and rise in sea level also increases flooding in areas that are close to water bodies. From the perspective of the professional and climate researchers, the overriding

effect of changes in climate on land use planning and development are in various forms. However, the ones that are discussed here are those ones peculiar to the study area.

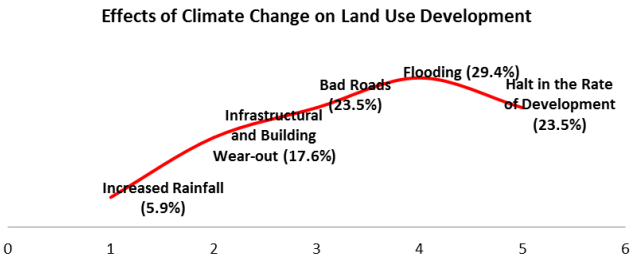

Figure 2: Effects of Climate Change on Land Use as seen by Private Professionals
Source: Field Survey, 2015

Contrary to the response from households that increased rainfall is the major effect of climate change on land use planning, professionals believed that increase in rainfall is only an action that can be manage and curtailed. However when it is not well managed, it affects land use planning in form of flooding. Hence, professionals concluded that rise in sea level and increase in rainfall contributes to flooding which makes it the overriding effect of climate change on land use development in the study area. Other associative effects caused by climate changes are seen on the impact it has on transportation network, infrastructural and building wear-out and total halt in the rate of development.

The respondents believed that flooding and inadequate drainages brings about bad roads in the study area thereby causing traffic congestion, which then hinders economic activities and other socio-economic spheres of the populace. In addition, the in-ability to define season's i.e. inconsistent seasonal differentials has been traced to be a major threat to development and has the potential of totally halting the steady rate of land use development in the study area. Infrastructure and buildings wear-out easily due to flooding, increased rainfall, temperature and other effects.

Climate Change Effects on Land Use

With respect to the discussed effects of climate change on land use development, land uses that are grossly affected by these changes are mostly commercial developments (29%), transportation land use (24%), industrial development (24%) and residential developments (23%). Commercial developments are been affected in terms of reduction in patronages recorded by commercial actors in the area as well as other economic activities.

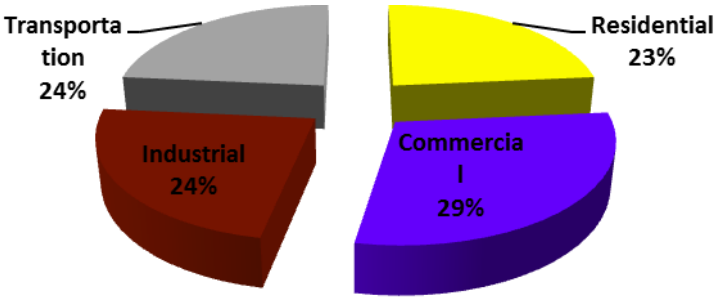

Figure 3: Land Uses Affected by Climate Changes
Source: Field Survey, 2015

Figure 4: Traffic Congestion along Ijare Road, Akure due to heavy rainfall that resulted in Erosion
Source: Field Survey, 2015

Property value has been diminished in some areas due to inaccessibility and lack of good roads. Since building wears out easily, residential development has also been reduced to just shelter other than housing as the available houses are not in the best living condition. Transportation is a means to every other land uses and hence contributes greatly to economic, social and other activities. However, the result of effects caused by climate change has reduced the potency of transportation network in the area to serve its main purpose of easy access. In view of this, industrial developments too have been affected in the right proportion as service vehicles finds it uneasy to access industrial zone, either when bringing raw materials or when distributing finished products.

Figure 5: Flooding and Corrosion Effects on Residential Property at Isolo Quarters, Akure

RECOMMENDATIONS AND CONCLUSION

Uncertainties in climate change and impacts projections are a characteristic feature that poses a challenge for anticipatory adaptation for any country. The key to adaptation to climate change with respect to land use planning and development in most instances is competent, capable, accountable urban governments that understand how to incorporate adaptation measures into most aspects of their work and departments. Many needed measures may seem to be quite minor adjustments to current practices – for instance in adjusting building codes, land sub-division regulations, land-use management and infrastructure standards - but the sum of all the minor adjustments over time can build greater resilience without high costs. The recommended interventions needed to adapt to climate change threats as it applies to land use planning and development includes the development of an information based system on current conditions. This should seek as much detail as possible; drilling down to include "small disasters" (disasters that do not get included in international disaster databases) as well as serve as data-bank for private individual who seek detailed information concerned with climatic conditions and land use of Ikeja. Initiation of risk/vulnerability assessments for the city with as much geographic detail as possible This needs to link hazard maps with details of what is currently located within the hazardous zones – including identifying population groups or settlements at risk and activities that may pose particular risks. They are needed for

climate change network governance/ government policies. This understanding must be modified with view on the demands of effective adaptation and mitigation governance.

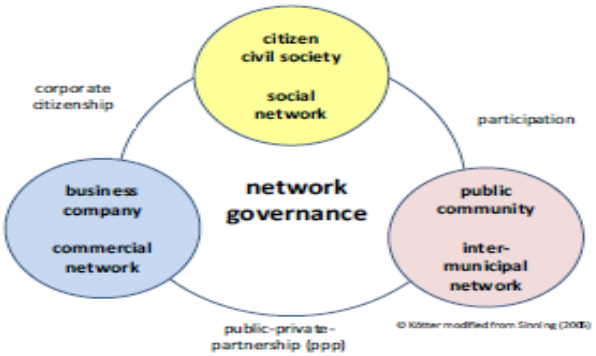

Figure 6: Network Governance and Stakeholder Participation on Climate Change
Source: Friesecke etal, 2012

In conclusion, the effects of climatic changes on land use development are enormous. Experts assume that rise in global temperature and sea levels will intensify climate change-related risks, such as floods, droughts, landslides, and extreme climate events (Friesecke, 2012). In order to be prepared for these disasters in the future, interdisciplinary and precautionary measures concerning land management are needed. In particular, urban planning with respect to the development of urban settlements plays an important role in disasters and risk management. Ordinarily, city and municipal governments have the main responsibilities for planning, implementing and managing most of the measures that can diminish risks (and the high vulnerabilities of sections of the population) from the direct and indirect impacts of climate change – through provision of infrastructure and services, disaster preparedness and the planning and regulatory framework. It is important to understand the scale and scope of local government involvement in urban centres, if their role in adaptation to climate change is to be understood. Urban governments typically have a range of roles that can include financing, Engineering/Public works, Social/community/safety services and Development planning and development control. In view of this, there is a need for governance network in mitigating climate change impact on land use planning and development. In addition, it is not just enough for development to take place in our cities there must be policies put in place to ensure that the concept of sustainable development is been adhered to when developments are arising.

ABSTRACT

The demand for innovative teaching approach for the development of entrepreneurial spirit among the graduating students is a critical issue in the Nigeria's Higher Learning Institutions (HLIs). Especially, now that both the government and general public request HLIs to produce graduates that can create jobs rather than job seekers in the labour market. Therefore, this article employed Ajzen's theory of planned behaviour to assess the impact of Arch-entrepreneurial Design Project (ArchDeP) teaching method on the architecture students' business know-how, value creation competence and intention to be self-employed. Quantitative approach with ex-post research design employed for the study. Statistical Package for Social Science (SPSS) and Structural Equation Modelling (SEM) tools of analyses were used to analyse the data collected from 150 students and to test the research hypotheses proposed. The research findings indicated a significant impact of the ArchDeP teaching approach on the students' self-employment intention. Hence, students' attitudes toward business know-how and perceived value creation mediate the relationship between exogenous and endogenous variables. In fact, the new market-oriented design project scheme has created an entrepreneurial cutting-edge for the students and for future jobs creation. More practical initiatives such as extended entrepreneurship teaching in the core architecture courses and across the program years of training recommended. Specifically, ArchDeP teaching model could provide the innovation required for the advancement of future entrepreneurial-architects.

Keywords: Architecture, Arch-entrepreneurship Education, value creation and Self-employment

INTRODUCTION

Entrepreneurship is connoted as a stimulant for the economic growth, wealth and jobs creation in Nigeria and other developing nations (Arogundade, 2011; Gafar et al., 2012). At the same time, entrepreneurship teaching in the HLIs has been deemed as one of the agents of change (Mars, 2013) to impact entrepreneurial capacities and self-employment intention on the potential future embryonic entrepreneurs (Okolie et al., 2014; Gafar et al., 2014). Currently, the graduates' unemployment has been a critical issue in Nigeria (Maina, 2014; Agboola, 2014). More so, the number of graduates entering into the labour market increase every year (Afolabi & Ehinomen, 2015). On this account, it is crystal-clear that more graduates will not be successful in getting employment. Given this, Nigerian HLIs need to inculcate more entrepreneurial spirit among the students. Particularly, now that employment opportunity for the architecture graduates is becoming more competitive (Mimarlik, 2013; Gafar et al., 2012). However, several scholars stated that effective entrepreneurship teaching in the HLIs is an indispensable channel for developing dynamic graduating students (Fayolle & Gailly, 2015). In fact, entrepreneurship education is denoted as the panacea to the graduates' unemployment dilemma in Nigeria (Oladele et al., 2011; Gbagolo & Eze, 2014).

Nevertheless, demand for the innovative pedagogical approaches for the inculcation of entrepreneurial spirit on the students of Higher Learning Institutions (HLIs) is critical in the academic circles. In this regard, the research aimed to assess the impact of the newly introduced teaching approach: Arch-entrepreneurial Design Project (ArchDeP) on the

Gafar, M.; Kasim, R. & Ahmed, M. D. (2016). Impact of Integrative Arch-entrepreneurial Design Project on the Students' Business know-how, Value Creation and Self-employment Intention. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 232-246

architecture students' entrepreneurial capacities and self-employment intention. ArchDeP is an integrational model to infuse entrepreneurship concept into the architectural design course. The essence of this teaching model is to inspire business creativity and foster enterprise innovation. Hence, to provide the necessary business-oriented skills, competence and capacities lacked to compete in the competitive labour market, locally and globally upon graduation.

The research applied a quantitative research approach and ex-post self-administered questionnaire instrumentation used to collect data from 150 architecture students. Statistical Package for Social Science (SPSS) and Structural Equation Modeling (SEM) tools of analyses were used to analyse the data collected and for the test of seven research hypotheses empirically.

This study advocates the reinforcement of the architectural curriculum content with the entrepreneurial know-how and the capacities imperative to inculcate entrepreneurial concept in the architectural project design process that could foster unlimited employment opportunity. The subsequent sections briefly discuss graduates' unemployment in Nigeria, the need for more entrepreneurship approach in the architecture education while the last section provides implications for future research.

REVIEW OF LITERATURE

Nigeria as a nation could be rated as the richest country in Africa based on her bountiful petroleum and solid minerals resources as well as enormous population capacity. Inharmoniously, Nigeria as a rich nation is a fallacy that is characterised by huge realistic unemployment among the students of HLIs. In fact, over 40 million Nigeria youth are unemployed, and Nigeria is classified as one of the countries prone to a socio-political, economic crisis as a result of increase poverty echelon (Salami, 2011). In fact, graduates of Higher Learning Institutions (HLIs) make up a larger percentage of the youth unemployment and some remain unemployed for over five years after graduation (Awogbenle & Iwuamadi, 2010).

In addition, Innocent (2014) stated that not less than 1.8 million graduating students are entering the labour market yearly. Apart from the current economic uncertainty as a result of the crash of the oil revenue, other possible reasons for the graduates' unemployment are the mismatch between the knowledge acquired by graduates and labour market skills demand (Gbagolo & Eze, 2014). This is further aggravated by graduates lacking entrepreneurial capacity such as critical thinking, creative skills and competence that are crucial in the current job market (Afolabi & Ehinomen, 2015).

In this regard, Nigerian government have established certain economic policies and several national agencies to advance employment opportunities for the youth. Recently, Youth Enterprise with Innovation in Nigeria (YOU-WIN) and Subsidy Reinvestment and Empowerment Programme (SURE-P) established. Also, compulsory entrepreneurship education was introduced across all the HLIs' curriculum structure as a way to develop more entrepreneurial consciousness among the graduating students, particularly, to shrink the unemployment problem. Conversely, Agboola (2014) and Afolabi and Ehinomen (2015) claimed that deficiency in the HLIs' curricula and use of ineffective pedagogical approach are the key factors responsible for the inability to provide the students with the appropriate skills and competence required to be job creators rather than being the job seekers. The critical challenge is how to improve the educational entrepreneurship ecosystem (Innocent, 2014; Salami, 2011). Particularly, to develop integrative course content and creative pedagogical

approach that could promote entrepreneurial reorientation and self-employment as a viable career substitute for the Nigerian HLIs students (Gafar et al., 2014).

Research's Theoretical Framework

In the literature, the concept of entrepreneurship education is ever revolving around opportunity discovery, formation and innovation of business ventures, and risk taking proficiency in conjunction to self-employment. The teaching development for the inculcation of the entrepreneurial skills and competence among the HLIs' students is defined as entrepreneurship education. Till date, scholars have stressed the merit of entrepreneurial activities as self-discovery that serves as a pathfinder for self-realisation and self-reliance (Gafar et al., 2012). Galloway (2006) stated that nations' economic growths are the valuable rewards for entrepreneurial success. In summary, Jones, et al. (2012) reaffirmed the important of entrepreneurship teaching for the graduating students as one of the fundamental channels for professional success in the current competitive economy.

The scholars' ideological stand on the subject of entrepreneurship education has always been a lasting debate in the HLIs. However, the dispute on the teachability of entrepreneurship in the HLIs is put to past (Fayolle, 2007). Even though, some commentators argued that renowned entrepreneur such as Bill Gates quit HLIs to seek for entrepreneurship experience in the world outside university environment. The fact remains that for an individual to become an entrepreneur he/she must have undertaken a learning process and such process is an education that could be formal or informal.

In the same perspective, Garavan & O'Cinneide (1994b) argued that "learning" entrepreneurship either from successful entrepreneurial family members, past work experience or through a proper education both would obviously add to the probability of entrepreneurial success. He advocated that "entrepreneurs are often made, not born" and believed that education of entrepreneurship can be taught, and the knowledge can impact on the potential future entrepreneurs in the HLIs. He further stressed that the teaching responsibility does not rest completely on the academic environment. Therefore, society has its role in providing an enabling environment and right atmosphere for the development of entrepreneurship ecosystem.

However, Hytti and O'Gorman (2004) suggest different ways to offer entrepreneurship education that should be based on the program's objectives. They noted that if the program's objective is to increase understanding of entrepreneurship, then the appropriate channels to fulfill this objective is to provide information through public channels such as media, seminars, or lectures. And that if the objective is to equip students with entrepreneurial skills then the best way is to provide education and training that would enable students to have a direct contact with the entrepreneurial process. Lastly, they noted that if the program's objective is to prepare students to act as entrepreneurs after graduation then most effective approach is to facilitate a practical experiment by caring out entrepreneurship in an environment close to a real-life situation such as role playing and teamwork projects.

Edwards et al. (2009) reported that it is a challenging task for the entrepreneurship educators to introduce entrepreneurship idea into the non-business disciplines. The question is, how and where do we start? Assuming entrepreneurship education as a new product of the University and academician as natural marketers, market research on the motivation of potential candidates (mainly technical and engineering students) on entrepreneurship curricula could provide us with better insights on their interest and awareness on the subject. In a discipline of marketing, individual acceptance of the new product is a result adoption process, which started with awareness and interest before reaching the adoption stage. In other words, it is pertinent to start with the understanding of needs and wants of the students which in many

cases is reflected in their knowledge, interest and acceptance of the new product idea – in this case, entrepreneurship course.

Hynes' (1996) study outlined the structural clarification to the challenge of introducing entrepreneurship ideas into the technical education. Hynes' entrepreneurship education framework outlined that entrepreneurship teaching must start with the students as input before the educators focusing on the course content; teaching approach and; assessment method as a process that ought to output/develop potential future entrepreneurs. Also, outputs should be measured based on a tangible and intangible parameters as listed in Table 1.0.

In sum, the majority of universities have long been known to encourage entrepreneurialism. About 93 percent of American professors in one research survey believe that entrepreneurship can be taught (Matlay & Carey, 2006). Survey of 15 "leading entrepreneurship educators" stated that their main objectives of entrepreneurship education are to teach students about the process involved in starting and running a new business (Fayolle, 2015). More so, the current Nigerian competitive economy demand entrepreneurship education's objective that focused on teaching for entrepreneurial inculcation, particularly, on the non-business disciplines in the HLIs.

For the purpose of this research, theory of entrepreneurial intention is applied to assess the perception of architecture students toward the impact of ArchDeP on their business know-how; perceived value creation and self-employment intention. The justification is that entrepreneurship intention theory has been tested and validated by renowned scholars to assess entrepreneurship education program (Fayolle et al., 2006; Kolvereid et al., 2011; Linan, 2008). More so, past researches have showed the capacity of intention as a predictor for an individual's desirability to be self-employed which equally has the capability to evaluate entrepreneurship education programs' impact.

Formulation of Research's Hypotheses

In the 21st century, entrepreneurship education has become a subject of upmost interest in the HLIs worldwide. The concept of entrepreneurial capacity is an amalgamation of individual's knowledge/skills, attitudes and perceived behaviour control that predicts his/her entrepreneurial intention (Ajzen, 1991). Okolie (2014) also outlined entrepreneurial capacity as a collection of interrelated building block such as attitudes, behaviour and skills that connect to the individual disposition to act entrepreneurially which can be enhanced through an educational teaching approach. Notable studies have showed that entrepreneurship education does play a significant role in cultivating entrepreneurship know-how, particularly, entrepreneurial capacities and competence in business start-up and value creation among the graduating HLIs' students (Fayolle, 2007).

Conversely, Matlay (2008) and Fayolle et al. (2006) noted that it may not be possible to develop graduates' entrepreneurial reorientation absolutely through education only, but it does have significant influence on the students' entrepreneurial know-how in the capacities of entrepreneurial attitude, entrepreneurial business start-up and capacity/aptitude in entrepreneurial skills.

Subsequently, Pihie and Akmaliah (2009) stated that entrepreneurship education plays a critical role in identifying and shaping entrepreneurial traits. In the same light, other studies have pointed out that entrepreneurship education, especially education that provides technological training is crucial to promote the development of entrepreneurs. To inculcate new product/project innovation skills on the architecture students is vital in an increasingly challenging Nigerian economic downturn.

Souitaris et al. (2007) claimed that students who major in related technical disciplines have greater interest to become entrepreneurs. In fact, those students have more confident in attitude toward business, venture creation and self-employment intention upon graduation.

More so, past entrepreneurship empirical studies have applied Ajzen's entrepreneurial intention models to assess entrepreneurship education program and appropriateness of the model has been validated. Reviewed literature support the existence of a strong relationship between students' participation in entrepreneurship education and positive attitude toward business knowledge and self-employment intention (Kolvereid & Isaksen, 2006; Fayolle et al., 2006). Therefore:

H_1: Participation in integrated ArchDeP has a significant impact on the students' self-employment intention.
H_2: Participation in integrated ArchDeP has a significant impact on the students' attitude toward business know-how.
H_3: Students' attitude toward business know-how has a significant relationship with their self-employment intention.
H_4: Participation in integrated ArchDeP has a significant impact on the students' value creation.
H_5: Students' value creation has a significant relationship with their self-employment intention.

In addition, individuals' nature to react positively/negatively toward an incident is called attitude that is a behavioural intention's foremost determinant (Ajzen, 1991). As claimed in the Ajzen's model that the more optimistic individuals' attitude toward the behaviour, the more definite intention to perform that behaviour by individuals. In the same perspective, the Career Choice Theory underlined that individuals' judgment about a choice of career is determined by their perception of past experiences and most importantly the attitudes and close relatives' expectations of toward those careers. This implies that beliefs and experiences determine a person's attitudes toward a given career preference.

More so, a meta-analytical study conducted by Bae et al. (2014) showed that early participation in entrepreneurship education plays a significant role in the formation of positive attitudinal values toward entrepreneurial development and self-employment inclination. The study maintained that students of HLIs will develop a positive attitude towards self-employment intention if they partake in an effective entrepreneurship education program. As a matter of fact, Okolie et al. (2014) provided an empirical evident that holistic education for entrepreneurship does influence the development of entrepreneurial-related attitudes in business know-how and necessary skills for self-employment. This implies that attitudes will mediate the relationship between integrated architecture-entrepreneurship education (ArchDeP) and self-employment intentions, given that the theory of entrepreneurial intention predicts that individuals' attitude positively direct intention to entrepreneurship. By the above-given literature, the sixth research hypothesis formulated as:

H_6: Attitudes toward business know-how mediate the relationship between integrated ArchDeP and self-employment intention.

Consequently, perceived behaviour control denotes an individual's conviction that he/she can fruitfully achieve a goal. Several researchers have showed that individuals' high perceived behaviour control predict that they are confident in their capacity to act and achieve a venture creation (Ajzen, 1991). Also, education of entrepreneurship has been documented as a facilitator of value added knowledge on how to start-up and manage a new venture creation among the HLIs' graduates (Linan, 2008; Gbagolo & Eze, 2014). Likewise, it provides value

gained experience in business reality that cultivates positive attitudinal change towards entrepreneurial proclivity (Lackeus & Williams Middleton, 2015). Above and beyond, it is a value enhancer that strengthens students' perceived behaviour control (self-efficacy) and increases their desirability of self-employment as a viable career option.

According to Okolie (2010), exclusive academic qualification cannot guarantee job prospect, particularly, graduating architects need to be more entrepreneurially inclined in the current competitive larbour market to survive the economic turbulent. More so, architecture graduates need a job before they get their professional license to establish a firm. As a matter of fact, Gafar et al. (2012) stressed that pure technical knowledge is not enough for the graduates to compete in the larbour market. Therefore, architects need to be entrepreneurial to sustain their professional relevance and increase market share. He believed that there was need for "more entrepreneurship architectural education". And that education of this nature could provide consolidated business experience in architectural project "design, build and dispose" market analysis for graduating architects who intend to start their business ventures upon graduation.

Ajzen's (1991) theory of planned behaviour also asserted that perceived behaviour control provides the individuals' subjective norms require in determining their degree of willingness to start a business venture and become self-employed. As aforementioned, entrepreneurship education is a teaching process for self-discovery that serves as a pathfinder for self-realisation and self-reliance (Gafar et al., 2012). More so, students develop self-attributes through this teaching process that is both meditative and behavioural-action oriented. The pedagogical reflective teaching process is expected to enhance individuals' behaviour that in turn employed to understand their entrepreneurial value creation competence and how they will probability behave after graduation.

In the same perspective, Linan (2008) outlined entrepreneurial value creation capacities in the context of perceived skills and competence. They further stated that an effective entrepreneurship education programmes should enable students of HLIs to be more innovative, creative (skills) and increase their risk loving (attitude, perceived behaviour control and motivation) in business start-up. On the account of above-given literature and the meritorious expectation on the newly introduced entrepreneurship teaching in the architecture education, this research further set out to test hypothesis formulated as:

H_7: Perceived behaviour control in value creation competence mediates the relationship between integrated entrepreneurship education (ArchDeP) and self-employment intention.

Conclusively, this research hypothesizes that architecture students' participation in an integrated entrepreneurship education (ArchDeP) has a direct and indirect effect on their self-employment intentions. In general, the relationships are buttressed in the validated theory of Ajzen (1991). Therefore, the entire research constructs illustrated in Figure 1.0

Therefore, the proposed assessment framework is to assess integrated ArchDeP that would be empirically validated. Hence, the model is to provide ways for improving entrepreneurship teaching methodological approaches that could facilitate the development of future entrepreneurial architects among the Nigerian architecture graduating students.

RESREACH METHODOLOGY

The research employed a quantitative methodological approach to testing the set hypotheses. The new arch-entrepreneurial teaching concept – ArchDeP was introduced into the architectural design studio module with a purpose of inculcating skills and competence in business know-how, value creation and self-employment spirit on the architecture students.

Ex-post research design approach was employed for this study. Statistical Package for Social Science (SPSS) and Structural Equation Modelling (SEM) tools of analyses were used to analyse the data collected from 150 architecture students and to test the three research hypotheses empirically.

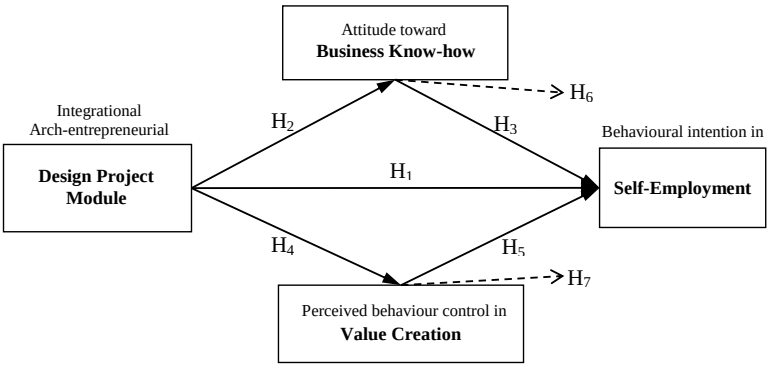

Figure 1.0: Hypothesised Research Framework for the Assessment of ArchDeP

Foremost, the architectural design studio (housing) module covered fifteen weeks within which the students carried out the learning process in and outside the university environment, specifically, in a team. The first two weeks focused on teaching the theoretical aspect of entrepreneurship principles. The topic of discussion covered idea development to venture creation in the context of architectural design and project development that focused on design, build and sell initiatives that are to create lifelong job creation prospect. Afterward, the students were divided into six (6) groups that consisted of twenty-five students as a team. In totality, 150 students of architecture participated in the design module.

After that, the remaining weeks focused on action-oriented entrepreneurial activities and architectural design planning. Every team were required to conduct a market analysis based on the module mentor's detailed design brief that promoted flexibility on the project design scope, type and site location. More so, the teams were expected to pass through all stages of creative thinking and problem-solving design schemes that focused on buyers/customers-oriented business approach from the project conceptualisation to actualisation and all for sustainable jobs prospects.

Consequently, the teams were taught and instructed to conduct a market analysis (feasibility and viability studies) on the potential buyers in a preferred location. The purpose was to establish their housing need, housing types' preference and retailing price range (purchasing power). The project's site selection was based on market analysis outcomes. The teams were then educated and directed to source for funds from the available commercial banks. The essence was to establish the pro and cons of project financing, determination of interest rate and repayment plans for the loans.

After the preliminary project's feasibility and viability studies, the teams then proceeded to the studio for the production of detailed architectural drawing plan with the approximate estimate of the project cost. The essence was to establish the selling price with the percentage profit margin. Also, the teams were requested to document their marketing strategies on how to package and sell the products. Finally, each group was demanded to present orally at the end of ArchDeP's program, and this was to advance the students' entrepreneurial spirit in communication, marketing and networking skills. In the end, the teams were assessed by examiners that comprise of module co-ordinator, entrepreneurial developers, bank managers and selected prospective buyers.

At the end of the examiners' assessment, every student was surveyed through a purposive sample technique because it focused on only the third-year students who have participated in the design module. To this end, an ex-post survey was used because EArDeP is a new studio teaching approach that was expected to strengthen students' entrepreneurial skills at the end of the module. More so, the students were expected to have detail understanding of the business-conscious design project initiatives after the scheme participation. The questionnaires were given to these particular groups of students through a self-administered method. As earlier mentioned, the purpose is to establish empirical answers to the predetermined research question, objective and to test the set hypotheses. However, the research's scale of measurement for each construct was adapted from past researchers' studies (Cheng et al., 2009; Linan, 2008; Gafar et al., 2015). The data collected were preliminarily screened with SPSS version 22. Structural analysis was performed with SEM version 22 because it is a second generation statistical tool that provides a robust and rigorous evaluation of a multivariate research assessment model (Guerrero et al., 2008; Awang, 2012).

RESEARCH FINDINGS AND DISCUSSIONS

The preliminary data analysis of the data collected was presented in Table 1.0. As earlier mentioned, of the 150 questionnaires distributed, 100% responded rate was achieved as a result of self-administered process used. The descriptive analysis of the sample presented gender percentage distribution of male at 63.2 percent while female was 37.8 percent. The respondents' ethnicity was not given consideration because it is not relevant in the study. Hence, the research variables' (IEE, ABK, PVC and SEI) cumulative mean scores were within the range of 3.12 and 4.25 on a 5 - likert scale measurement (see Table 1.0). The research indicated that architecture students have developed reasonable capabilities in business know-how, value creation and strong self-employment intention after participation in the new studio teaching approach (ArchDeP) that was market-oriented design project scheme for entrepreneurial cutting-edge and future jobs creation.

In addition, the reliability and normality examination of the data collected were satisfactory with the cronbach alpha ranging from 0.855 to 0.928 according to Pallant (2011). Hence, the normality test presented skewness and kurtosis values within the acceptable limit of -1 to +1 (Awang, 2012) that indicated a normal distribution data. Hence, the principal component factor analysis for entire research constructs' items were examined and result presented strong factor loading that were above 0.5. Table 1.3 showed that the research variables' items of measurement were satisfactory and acceptable as KMO and Bartlett's test presented good measure of sampling adequacy value of 0.931 and significant (Awang, 2012).

Awang (2014) emphasised that it is vital to examine/check the discriminant validity of the entire research constructs before the removal of the constructs' redundant items. Also, Hair et al. (2011) supported that correlation between the exogenous variables (discriminant validity) between in the research assessment model should not exceed 0.85. The result of the examination showed that hypothesised constructs' discriminant validity is adequate and acceptable since the correlation coefficient between the three exogenous and endogenous constructs are all within the permissible value lower than 0.85 (See Figure 1.1).

After the unidimensionality, reliability and validity of the research constructs were ascertained, the next stage of analysis modelled the entire constructs into a single structural equation model and used Analysis of Moment Structure (AMOS) since the multi-collinearity problem is absent among the research variables. However, the model was used to analyse the multidirectional relationships within the entire research constructs. Figure 1.2 presented the final structural measurement model that provided the analysis of the causal effects (impacts) for the multiple constructs in the research assessment model.

First and foremost, the fitness indexes for the structural model that reflect how fit is the hypothesized model with the data at hand was observed. The result of the SEM analysis was satisfactory within the established acceptable level of Goodness of fitness indexes as presented in Table 1.4 (Awang, 2014 and Hair et al., 2011).

AMOS gives two types of text output that are the standardized regression weights and regression weights. For the purpose of this research the standardized regression was used which indicated the estimate of beta coefficient that measures the impact of the main constructs/exogenous variable (integrated ArchDep) on the two mediating variables (Attitude to Business Know-how – ABK) and (Perceived Value Creation-PVC) as well as endogenous variable (Self-Employment Intention –SEI).

The SEM analysis's result presented in Figure 1.5 showed the standardized regression coefficient of the relationship between IEE (ArchDeP) and ABK is 0.42, factor loading for the entire items, for instance, item IEE1 is 0.74 with its R2 equal 0.55. The correlation coefficient of the relationship between ABK and SEI is 0.36. Also, the correlation coefficient of the relationship between IEE (ArchDeP) and PVC is 0.60 while between PVC and SEI is 0.14 respectively. In summary, the measure of quantity and magnitude of the relationship between the entire research constructs (standardized estimates and P-values) were presented in Table 1.5. The result showed that relationship between new IEE teaching approach (ArchDeP) and the two mediating variable (ABK and PVC) and SEI have the beta coefficient of 0.417, 0.297 and 0.602 respectively and IEE, ABK as well as PVC all have significant positive impact on the dependent variable (SEI).

For the H1, the p-value is less than 0.001. Thus, the correlation co-efficient for IEE in the prediction of ABK is significant at the 0.001 level, and this implies that impact of integrated ArchDeP teaching approach on architecture students' attitude toward business know-how is significant. For the H2, the p-value is less than 0.001, correlation co-efficient for IEE in the prediction of PVC is also significant at the 0.001 level that also implies that impact of integrated ArchDeP teaching approach on architecture students' perceived venture value creation capacity is significant. For other H3 and H4, the p-values are also less than 0.001, correlation co-efficient for ABK and PVC in the prediction of SEI are both significant.

Even though, the correlation co-efficient for IEE in the prediction of SEI is significant at 0.05 level because the p-value is less than 0.05. On this account, hypotheses H1 to H5 are supported. The next section dwells on the procedure used to analyse the mediating effect of the ABK and PVC variables in the hypothesised model. To test mediation effect in a structural equation modelling, the fundamental condition that must be met is that there must be an existence of a significant relationship between exogenous, mediator and endogenous variables (Awang, 2012; Hair et al., 2011). In this regard, the SEM's outcome indicated positive significant between the entire research's constructs as presented above in Table 1.4.

In the Figure 1.2, the computations for the test of mediators (ABK and PVC) showed as indirect effects. The first indirect path (IEE to ABK and ABK to SEI) equals 0.151 (0.42 X 0.36) and the second indirect path (IEE to PVC and PVC to SEI) equals 0.084 (0.60 X 0.14). The result showed ABK and PVC are mediating the relationship between IEE and SEI. The type of mediation here is called a partial mediation since the direct effect of IEE on IEE is still significant after ABK and PVC entered the model, even though, the direct effect is still greater than the two indirect effects (0.30 > 0.151 and 0.084) respectively as recommended by Awang (2014) and Hair et al. (2011).

By implication, the research finding showed that the new integrated ArchDep teaching approach has a strong significant impact on the architecture students' attitude to business

know-how, perceived behaviour control in venture value creation and strong intention to be self-employed after graduation. The possible assumption for this result may be that the following components: basic concept of firm start-up and management, skills of design presentation as marketing and cost control and monitoring as financial and strategic management principles are part of the basic rudiment core course of professional practices. This could have positively influenced the perception of architecture students' attitude in business knowledge and perceived value creation that subsequently impacts their self-employment intention.

Subsequently, the research finding support the past empirical outcomes of Fayolle (2015) and Linan (2008) who reported that there is significant relationship between students' participation in entrepreneurship education and positive attitude toward business knowledge and self-employment intention (Kolvereid & Isaksen, 2006; Fayolle et al., 2006). In fact, Souitaris et al. (2007) supported that student who majors in related technical disciplines has greater interest to become entrepreneurs. And, such students developed more confident in attitude toward business know-how, venture value creation and self-employment intention upon graduation. In summary, this research has revalidated Ajzen's (1991) theory of planned behaviour (entrepreneurship's intention model) for the assessment entrepreneurship education program. In the same perspective, Linan (2008) and Okolie (2014) stressed that perceived competence in skills of creativity and idea development to venture creation are the motivational component for business start-up. More so, an effective entrepreneurship education programmes should enable students of HLIs to be more innovative, creative (skills) and increase their business's risk loving (attitude, perceived behaviour control and motivation) in business start-up.

Based on the mediation effects' computation and the result of the hypotheses tested in Table 1.4, both indicated that architecture students' attitude toward business know-how and perceived value creation do mediate the relationship between integrated entrepreneurship education (IEE) and their self-employment intention.

Finally, the research's findings showed that the new teaching method (ArchDeP) had equipped architecture students with the business knowledge and venture value creation's skills that seem to have served as value enhancer and awake their motivation, knowledge-ability and intention toward entrepreneurship. Also, application of a holistic action-based pedagogy to teach architectural design studio seem to be more liable in generating positive outcomes that could prepare the graduating students against the challenges of larbour market employment competitiveness. Hence, the novelty of this pedagogical approach is that it accommodate the traditional studio module and integrated entrepreneurship concept into the architectural design that enrich architecture students' critical thinking and problem-solving initiatives in the context of business opportunity and employment creation.

CONCLUSION

The new arch-entrepreneurship pedagogical approach has a tremendous potential to rebrand and assist the architecture graduating students in the current competitive job market. As a matter of fact, evident from the reviewed literatures have shown that exclusive conformist technical knowledge of architecture is not enough to guarantee the students for employment and job creation prospect in the current knowledge-based economy. More so, external economic forces are changing the university's curriculum structure and expectation from the architecture graduates is huge. The competition to fit within the professional practice after graduation is exigent. In Nigeria today, the reality is that employment landscape of the architecture graduates is fast shifting ahead of the university's mainstream curriculum structure as result of the economic and political uncertainty, allied professionals and quacks

encroachment and technological revolution of the contemporary age. Therefore, a conformist approach to the architecture training could inhibit the development of flexibility and diversity required in the profession for the competitive modern-age economic landscape.

In this era, the professional practice of architecture need to be more entrepreneurially inclined rather than depending on the architectural design service that has less job prospect in the contemporary mass housing era.

Perception of Residents on Impact of Proximity of Religious Camps on Residential Properties in Nigeria

Adeniran, Y. Olusegun & Bamidele M. Ogunleye

Department of Estate Management, School of Environmental Technology, Federal University of Technology Akure

ABSTRACT

This study investigates the impact of religious camps developments on residential property with peculiar reference to selected areas along Lagos/Ibadan Expressway with a view to guiding property investors on the viability of residential property development between the year 2005 - 2014.The perception of the respondents on the proximity of religious camps on their properties were also investigated. A structured questionnaire was administered on the seven hundred and twenty (720) sampled respondents for the study. Data collected were analyzed using descriptive statistics in form of weighted mean score, moving average and regression analysis. The data collected on residential property developments in the study area revealed that most of the investors prefer to build tenement buildings as it provides more accommodation that can house many populations. The findings revealed that religious camp site development brings about increase in population, haphazard development and employment. This study recommended that government should stimulate the development of more residential properties around the religious sites assist in the provision of more infrastructural facilities to these neighbourhoods in order to cater for the population increase and areas in close proximity to religious camp sites should be strictly monitored to ensure that town planning laws and building codes are adhered to in order to curtail haphazard developments of buildings.

Keywords: Development, Religious Camps, Residential Properties

INTRODUCTION

There has been a controversy as to whether the externalities exhibited by religious centres are positive (amenities) or negative (nuisance or disamenities) in several societies (Do, Wilbur and Short, 1994); this was corroborated by Babawale and Adewumi (2011) that external factors can have either positive or negative effects on property rental value. Carroll, Clauretie and Jensen (1996) asserted further that there is usually the belief that neighbourhood religious camp, particularly the large ones, impact negatively on the values of properties in close proximity. Thus, externalities constituting a nuisance would adversely affect values of properties within close range in proportion to the distance from it. In the developed countries effective zoning regulation has curtailed indiscriminate location of religious property (Carroll *et al*, 1996). However, in developing nations like Nigeria, several religious centres are often sited arbitrarily which in turn affect property values either positively or negatively.

Recently, there is increase in number of religious camps in many parts of Nigeria, among which is the Lagos/Ibadan expressway. Siting of these camps is done without recourse to incompatibility in use and negative spill-over effects emanating to adjoining properties from religious camp development. Recai, Evert and Smith (2007) pointed out that there has been concern over property market impacts from nearby nonconforming land use. Nelson (2003) also affirmed that nauseating noise level in an area can contribute to violence and so disturb valuable activities as well as having adverse effects on health and in turn reduce efficiency and quality of life. Religious centres in Nigeria are prone to unrivalled enthusiasm, excitement, loud singing, clapping, and bell ringing, drumming which in some cases are with loud speakers mounted on roof tops. Religious centres on service days and other special

Adeniran, Y. O. & Ogunleye, M. B. (2016). Perception of Residents on Impact of Proximity of Religious Camps on Residential Properties in Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 247-254

events are faced with traffic congestion, `attendant parking problems, pollution from automobile exhaust; and sometimes robbery attack within the vicinity. This may negatively affect the ability of nearby residents to use and enjoy their property and as well create obnoxious public perception which may reduce the marketability and, therefore, the value of properties. Consequently, this study became imperative to examine the perception of residents on the influence of the proximity of religious camps on residential property in Nigeria. However, the study concentrated on religious camps along Lagos/Ibadan expressway. The restriction to the study area was informed by the increasing emergence rate of religious camps along the express way.

LITERATURE REVIEW

There is a growing recognition that property development, use and management should be evaluated against criteria that embody sustainability measures. That is, genuine sustainability evaluations should balance social, cultural and economic performance measures with environmental protection (Body, 2005). In this regard, location of churches within residential neighborhoods has been an issue of concern and controversy in several societies. The question remains whether the externalities exhibited by churches are positive (amenities) or negative (nuisance or disamenities). Existing empirical studies are inconclusive and anecdotal evidences are mixed. The notion of "externalities" is a useful concept developed in welfare economics. In real estate parlance, the notion of externalities states that external factors to a property can have either positive or negative effects on its value (Do et al., 1994; Appraisal Institute, 2008).

Due to its physical immobility, real estate tends to be affected by externalities more strongly than most other economic goods, services, or commodities. Religious camp site development attracts population to its location which in turn led to the demand for accommodation which thus makes the demand for residential land use to be on the increase (Appraisal Institute, 2008). The use to which the land can be put thus confers either owner occupied or rental values which bring about profitability of investment.

The demand for property is affected by changes in population, planning and development schemes, legislation, and availability of good road networks (Olayiwola, Adeleye and Oduwaye, 2006). Residential properties development can take diverse forms and those that are in proximity to religious camp site are not an exemption. The various types of residential properties development that are prevalent in close proximity to religious camps developments are: block of flats, tenement buildings, bungalows, mansion, detached and semi-detached properties.

According to U.S. Religious Landscape (2008), religion is the belief in the existence of a God or gods and the activities that are connected with the worship of them. It is the fundamental force through which man relates with the Supreme Being. Religion, in many respects, is a growing industry and so its importance, both social and economic, cannot be over-emphasized. One particularly successful manifestation of this growth is the religious camps. Religious camps have played a major role and have had a significant economic impact on the nearby communities. The revitalization and redevelopment of the communities which surround the religious camps have continued to improve the standard of living for many citizens living around their locations.

Religious facility is the centre for worshipping and socializing, and regarded as a symbol of morality. The provision of schools and other convenient facilities may be highly attractive for the community. In addition, churches and mosques that provide child-care centres and kindergartens have a positive externality on property value (Ooi 2004). Different

denominations of religious centres have also produced mixed externalities on housing value (Carroll *et al*, 1996). However, while neighbourhood qualities may appear to be a positive benefit to property values, they can also be detrimental. Des Rosiers (2002) submitted that seemingly negative neighbourhood qualities could also be a benefit to property values, while we might assume that neighbourhood religious centre would enhance a sense of community, and therefore, have a positive influence on property values. It is pertinent to note that, religious camps are on the increase in Nigeria, many of these camps are gradually turning to towns and sooner than expected, cities. Over the years, many of these religious camps have been generating externalities that are positively or negatively affecting the property rental values within their immediate environments and the society at large. This study is also a contribution to the volume of literature on religious camps in Nigeria as it investigates the perception of the influence of proximity of religious camp developments along Lagos/Ibadan Expressway on residential property.

While the tremendous positive benefits of religious centers may greatly outweigh the adverse effect on property rental values to the property owners, larger churches can cause impacts similar to commercial uses if they operate throughout the week and into the night. The presence of these religious camps may create a favourable or an adverse public perception which can increase or reduce the marketability and, therefore, the value of properties in the neighbourhood of the religious camps (Boyle and Katherine 2001). Chalmers and Scott (1993) pointed out that an adverse public perception regarding a property with some type of environmental defects and crime may exact a penalty on the marketability of the property and hence its value.

In certain situations, the pattern of real estate development for an entire area may be traced to a single, dominant land use (Bouvier *et al*, 2000). For instance, the location of the religious camps may possibly motivate all manner of commercial activities; warehouses, hotels, restaurants and the like - that may be desirable in terms of their effects on nearby property rental value. Thus, proximity to a religious centre has a significant impact on surrounding housing rental values. Furthermore, both the religious camp and supporting commercial real estate development generate demand for road and highway improvements to accommodate the increased vehicular traffic load that may further affect housing prices (Flynn, MacGregor, Hunsperger, Mertz, Johnson, 2004).

Weber, Bhatta, and Merriman (2007) attributed the majority of property value appreciation to demand increases created by a growing amenity base. According to Carroll *et al* (1996), real property values decrease, at a decreasing rate, as distance from neighbourhood church increases. On the contrary, Danderson (2003), pointed out that the traffic and tourist caused by religious centres cause property to lose their value. Though, religious centres by themselves do not detract neighbourhood property values, but the large size and the elaborate nature of temples is the detriment.

Do *et al* (1994), Simons and Saginor (2006) identified religious center as source of externalities and confirmed that externality-induced changes can have either a negative or positive effect on prices. Religious centers exhibit some of the same characteristics found by other externality studies to produce measurable effects on nearby residential property values. Positive externalities arising from land include neighbourhood schools (Cloffelter, 1975) and greenbelts (Correll, Lillydahl, and Singell 1978). Carroll *et al*., (1996) pointed out that some religious centres create positive externalities to nearby property values.

In Nigeria, Iroham, and Oloyode (2010) studied location of worship centres and its effect on

residential property values, a case of Living Faith Church, Ota,the findings from the study revealed that the location of religious centres had significant positive impacts on the residential rental values. The study however compared only mean of residential property values before and after the siting of the churches(see also Iroham, C.O., Oloyede, S.A. and Oluwunmi, A.O. (2011), Babawale and Adewumi (2011) conducted research on the impact of neighbourhood churches on housing prices on selected areas in Lagos metropolis, using hedonic model. The study however, based its empirical study only on rented apartments and as well on churches located within residential neighbourhood. The study revealed that there were positive as well as negative effects of churches on their immediate environments, particularly the study area. Therefore, considering the dearth of the previous studies in Nigeria, the emerging siting of camps and the uniqueness of this subject, there is the need for further studies.

THE STUDY AREA

Lagos/Ibadan expressway is one of the major controlled-access highways in the northern part of Lagos city as it serves as inter-state highways to Oyo and Ogun States respectively. About 20% of the length of the expressway falls within Lagos State, 60% falls within Ogun state and the remaining 20% falls into the Oyo state territorial boundary (Society Business and Economic News, 2012). Prior to the construction of the Lagos/Ibadan expressway, the Lagos/Sagamu/Ijebu-Ode old dual carriage-way was the only route used as entry point to Ibadan and some other South Western States of Nigeria. In order to reduce recurrent accidents and other hardships which were on high prevalence along that road, and given the importance of Lagos as the then capital of Nigeria, the new expressway was constructed.

The origin of religious camps along Lagos/Ibadan expressway dated back to 1983, when the Redeemed Christian Church of God (RCCG) began the construction of her permanent camp site located at kilometer 46 along the expressway. Before this time, many pentecostal churches made use of various mountains and hills tops as their prayer camps and these places were not easily accessible by many of their members. RCCG decided to site her camp along Lagos/Ibadan expressway in order to make it easily accessible to their members. Few years later, many other religious camps like Mountain of Fire and Miracle Ministry (prayer city), Deeper Life Christian Ministry Camp, Nasrul Lahi-il Fathi Society of Nigeria (NASFAT) Camp, just to mention a few, sprang up along the expressway, thereby bringing several socio-economic developments into the study area which have great effects on property rental values. The location map of the study area is as shown in Figure 1.

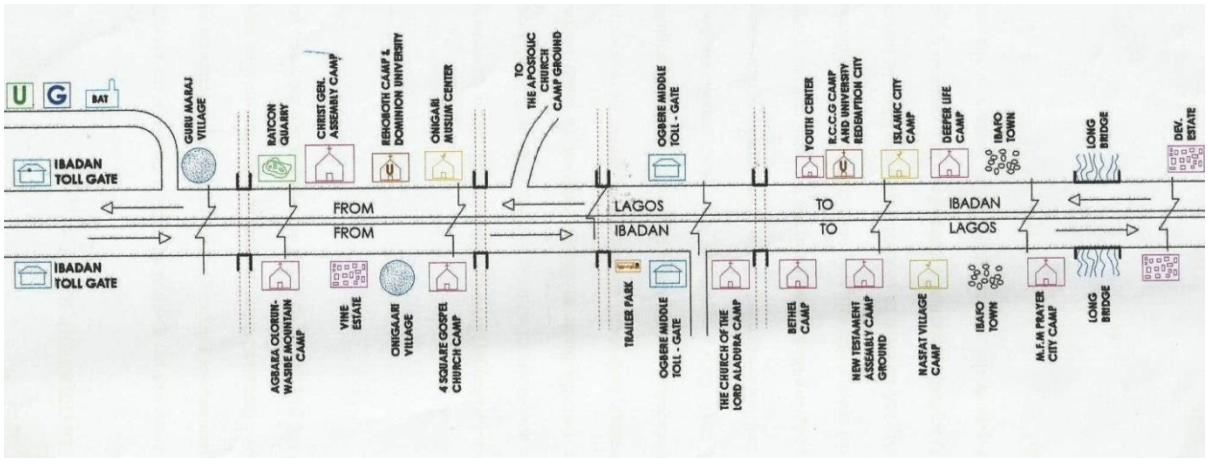

Figure 1: Locational map showing religious camps developments and other landmarks along Lagos Ibadan Expressway

RESEARCH METHODS

The target population comprises of residents and residential properties around the religious camps in the selected areas. The study relied on the primary data and the secondary data collected. Primary data were obtained through the administration of questionnaires on the residents of the study areas. It was administered on the residents of the areas under study for the purpose of obtaining information on housing types the perception of the residents on proximity of religious camps on their properties The secondary data were obtained from the records of; Directorate of Land Information Systems in the Lands Bureau, Abeokuta (who allocates and manages Ogun State Government properties), Ogun State Property and Investment Company (OPIC), Gateway City and Ogun State Urban and Regional Planning Board, Abeokuta (OSURPB).

The number of houses in the study areas was obtained from the Directorate of Land Information Systems in the Lands Bureau, Abeokuta (who allocates and manages Ogun State Government properties); and OSURPB, Abeokuta, who are in charge of Building Plan approval. There were 10,000 houses in Ibafo, Mowe, OPIC Estate at the Isheri/Berger axis end of Lagos State; while in Shagamu interchange there were 4,000 houses based on the approved building plan (OSURPB, 2012).

Kothari (2004) formula was adopted in determining the sample size of the residents in the study area as it made provision for the control of sampling error, specify margins of error for the items that were regarded as vital to the survey and would make the calculation of the sample size for the study areas easier.

Using Kothari (2004), the Formula for estimating Sample Size is given as:

$$n = \frac{Z^2.p.q.N}{e^2(N-1)+Z^2.p.q} \qquad \text{----------} \quad \text{(i)}$$

where,

n = sample size
z = value of standard deviation at a confidence level taken from table of normal curve at variants (z) for 95% confidence, which is 1.96
p = sample proportion **(q=1-p)** which in this study is taken as 50% (0.5)
N = number of the residents in the selected areas in selected locations which is 1km radius to the religious camps (Ibafo, Mowe, OPIC Estate in Isheri/Berger axis end of Lagos state) (10,000) and Shagamu interchange axis towards oyo state equals (4,000).
e = error margin estimated at 5% (0.05)

The estimated sample size, gives 369.9837 (approximately 370) for Ibafo, Mowe, OPIC Estate in Isheri/Berger axis end of Lagos state out of the total frame of 10,000 and 350.4781 (approximately 350) for Shagamu interchange out of the total frame of 4,000. Random sampling technique was used to solicit information from respondents for the study. Data analysis was carried out using weighted mean score. The 5- point scale was employed since it allows the respondents an option when they are not sure of their response with 5, 4, 3, 2 and 1 denoting "Very Important", "Important", "Neutral", "Less Important" and "Not Important" respectively.

Weighted Mean Score (WMS) is determined using equation (1).

$$WMS = \frac{5n_5 + 4n_4 + 3n_3 + 2n_2 + n_1}{n_5 + n_4 + n_3 + n_2 + n_1} \qquad \text{----------} \quad (1)$$

Where n_5 = number of responses for "Very Important", n_4 = number of responses for "Important", n_3 = number of responses for "Neutral", n_2 = number of responses for "Less Important", n_1 = number of responses for "Not Important".

RESULTS

Table 1: Types of Residential Buildings in the Study Area

Building Type	Ibafo Freq (%)	Mowe Freq (%)	Isheri Freq (%)	Shagamu Freq (%)
Block of flats	23(21.50)	28(23.93)	24(16.44)	112(32.0)
Tenement	41(38.32)	44(37.61)	40(27.40)	80(22.86)
Detached	18 (16.82)	14(11.97)	22(15.07)	51(14.6)
Semi detached	15 (14.02)	19(16.24)	32(21.92)	56(16.0)
Duplex	10 (9.35)	12(10.26)	28(19.17)	51(14.6)
Total	107(100.00)	117(100.00)	146(100.00)	350(100.00)

Source: computed from field survey, 2014

Table 1 revealed that tenement building was the most popular building type in Ibafo (38.32%), Mowe (37.61%) and Isheri (27.40%) except in Shagamu where block of flats (32.0%) was the highest while duplex was the least popular building type in all the study areas.

The analysis showed that most of the investors prefer to develop tenement buildings due to the nature of accommodation it provides, that is, can house many populations and thus solve the problem of housing need in the area which is in close proximity to religious.

The factors which influence the resident's perception include noise pollution, air pollution, traffic congestion, crime, tourist attraction, population increase, and promotion of moral value, generation of employment, security, and decline in property value, increase in property value, attraction of infrastructural facilities, haphazard development and attraction of manufacturing industries.

Table 2: Perception of the Respondents on the influence of the Proximity of Religious camps Developments

S/No	Factors	Mean Score	Rank
1	Haphazard development	4.695	2nd
2	Air pollution	4.108	6th
3	Attraction of industries	4.390	4th
4	Crime	2.113	10th
5	Noise pollution	3.099	8th
6	Population increase	4.823	1st
7	Promotion of moral value	2.958	9th
8	Generation of employment	4.413	3rd
9	Decline in property value	0.892	12th
10	Increase in property values	4.695	2nd
11	Traffic congestion	4.038	7th
12	Tourist attraction	1.080	11th
13	Attraction of infrastructural facilities	4.132	5th

Source: computed from field survey, 2014

Table 2 presents the perception of the residents on the proximity of the religious camps to their properties. The weighted mean score employed assigned 5 to "Very important", 4 to "Important", 3 to "Undecided", 2 to "Not important" and 1 to "Not Very Important" in order to obtain the mean value and rank the perception in order of its significance.

The table suggest that the siting of religious camps brings about population increase to its surrounding environment as it ranks 1st with a mean value of 4.823 while haphazard developments and increase in property values ranked 2nd with a mean value of 4.695 respectively. The general belief of the people that properties in close proximity to religious

camp sites will lack employment opportunities and attraction of industries was put to play. The perception of the residents shows that these factors ranked 4th and 5th with a mean value of 4.413 and 4.390 respectively.

CONCLUSION AND RECOMMENDATIONS

The study examines the perception of the residents about the influence of proximity of religious camps to their properties and reveals that tenement building was the most popular building type in the study area while the proximity of religious camps to the respondents' residential property increases population and causes haphazard development . Another factor affecting the residents close to the religious camps is high traffic congestion experienced around the community whenever there is religious activity in the camps.

The rental values of the residential properties in the proximity of the religious camps are on the increase as a result of more demand for housing around the camps. The proximity of religious camps to the residents was also observed to attract haphazard developments, which invariably results in generation of urban kiosk. Based on this findings, the study recommends that property developments in close proximity to religious camp sites should be strictly monitored to ensure that town planning laws and building codes are adhered to in order to curtail haphazard developments of buildings. Government should encourage the development of more residential properties around the religious sites in order to cater for the population increase.

Government should also assist in the provision of more infrastructural facilities to these neighbourhoods.

Assessment of Factors Influencing Building Maintenance in Public Housing Estates: A Case Study of Ijaiye Medium Housing Estate, Agege, Lagos

Ogunleye, M. B.[1] & Ajani, U. Y.[2]

Department of Estate Management, School of Environmental Technology, Federal University of Technology Akure
**ogunleyedelem@yahoo.com*

ABSTRACT

The study assessed factors affecting building maintenance in public housing estates in Lagos State using Ijaiye Medium housing estate as a case study with a view to developing a strategy for effective residential building maintenance to enhance the sustainability of existing housing stock. The sampled population was the residents of the estate. A simple random sampling of 2 Units of 3 bedroom flats per block were considered for the study. The data was collected through the administration of a total of One Hundred and Sixty-Three (163) structured questionnaires administered on the occupants of which a total of 120 (74%) were retrieved and used for analysis. The data collected was analyzed using descriptive statistical tools such as frequencies and weighted mean scores. The research revealed that majority of the respondents representing 61.67% opined to the fair level of management and maintenance of properties in the estate. There is also a collaborative effort of the government agency and the residents association for the maintenance of the estate services and infrastructures while the corrective method of maintenance strategy was used for the management and maintenance of the estate. The research made necessary recommendations and concluded that building maintenance management should be encouraged as it ensures that building facilities retain their structural, functional and aesthetic integrities throughout their lifespan, reduce unnecessary expenditures to facilitate the sustainability of the buildings and other infrastructure.

INTRODUCTION

The importance of housing to man cannot be overemphasized. According to Oyenuga (2006) housing comprises immediate accommodation, environment and facilities like roads, water, electricity and a host of other facilities that make living comfortable to the habitants. Leong (2009) also affirmed that housing is a major factor impacting on the health, safety, socio-economic and political life of the occupants; it impacts all aspect of human endeavour. Thus, the state of housing and its environment is an indicator of the level of development and condition of the citizens. Despite the pivotal roles of housing in the socio-economic development of a nation and the life of its citizenry, majority of the public housing are in deplorable condition and state of disrepair, due to long period of neglected maintenance of the available facilities; lack of maintenance culture; availability of funds; inadequate maintenance plans and strategies amongst other factors.

Maintenance of residential buildings is one major factor of housing ills in many cities of the world which needs urgent attention and cure. This problem seems pronounced most especially in developing countries, Nigeria inclusive where very little emphasis is laid on building maintenance functions and management; consequently, maintenance of the existing housing stock in habitable condition still remains a great problem to be solved in Nigeria (Olagunju, 2012). Maintenance management in the public sector in Nigeria has suffered from lack of funds for a considerable time. Maintenance of the built environment has great impacts on the whole nation and the condition of the surroundings in which we live and learn, is a

Ogunleye, M. B. & Ajani, U. Y. (2016). Assessment of Factors Influencing Building Maintenance in Public Housing Estates: A Case Study of Ijaiye Medium Housing Estate, Agege, Lagos. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 255-265

reflection of the nation's well-being. Maintainability of building has been identified as one of the key areas in which the built industry must achieve significant improvement (Nayantharas de Silva, Mohammed, Florence and George, 2004).

According to Iyagba and Adenuga, (2003) it is impossible to produce buildings which are maintenance free, but maintenance work can be minimized by good design and proper workmanship carried out by skilled experts or competent craftsmen using suitable codes of installation, requisite building materials and methods. Buildings are required to provide a conducive and safe environment for various human activities. The extent to which buildings provide the required environment for the required activity is a measure of the functionality of the building (Oladapo, 2005).

The standard of building maintenance has an important influence on the quality of the built environment. Several authors such as Olagunju (2012); Sunday, Oladele and Frank (2012); Waziri and Vanduhe,(2013); Ogunmakinde, Akinola and Shyanbola (2013) among others maintained that there are several factors influencing building maintenance. Also, poor maintenance culture of the residents and low aesthetic quality of neighbourhood centres, constitute problems that need to be solved to enhance residential buildings sustainability (Olagunju, 2012). In other words, for any meaningful approach to sustain maintainability of the existing housing stock in Nigeria like any other country there is the need to identify and assess the factors that influence maintenance of public residential buildings.

In addition, the Maintenance management sector in public section in Nigeria has suffered from lack of funds and negligence for a period of time (Owolabi, Amusan, Gani, Tunji-Olayeni, Peter and Omu, 2014). Existing building in Nigeria lack adequate maintenance attention and are in very poor and deplorable conditions of structural and decorative disrepair (Adenuga, Odunsami and Faremi, 2007). The main purpose of maintenance of facilities in a property is essentially to retain its values for investment, aesthetic, safety and durability with a view to ensuring that the property is continually in good condition for habitation to the satisfaction of the owner(s)/users and communal prestige (Brennan, 2000). According to Olatubara and Fatoye (2006), public residential estates, when compared with existing private housing estates, are known to be lacking in basic infrastructural facilities and services and the respective maintenances that are meant to enhance the livability of such estates. However, despite the various strategies adopted by the state government for maintenance of the Estate since its creation, poor maintenance culture is manifesting in various degrees in the estate; hence requiring adequate building maintenance to ensure the sustainability of the estate and ensure the properties therein are kept in a good and tenantable condition.

Odediran, Opatunji and Eghnure (2012) stated that the ability of a building to provide the required environment for a particular activity is a measure of its functionality. Therefore as the components of a building begins to deteriorate, it becomes necessary to take measures to ensure that the desired characteristics of that facility which provides safety and convenience are retained. Maintenance programme in Nigeria according to Ahmed (2000) and Kunya, Achuenu and Kolawole (2007) has not received much attention in the past as the emphasis is on the development of new properties. This is also in line with the statement of Odediran et al. (2012) who observed that there is apparent lack of maintenance culture in Nigeria, and that emphasis is placed on the construction of new buildings for public sector and neglecting the aspect of maintenance which commences immediately the builder leaves the site. This is also corroborated by Olagunju (2012) who opined that there is lack of maintenance set up in Nigeria that can sustain the current inadequate housing provision in the country.

Adejimi (2005) attributed the array of abandoned and epileptically functioning facilities in Nigeria due to poor or lack of maintenance. This therefore presents the need for studying the

various factors affecting residential building maintenance with the view to proffering relevant solutions. Hence, this study becomes imperative.

LITERATURE REVIEW

Maintenance Practice in Nigeria

Building maintenance is an important programme for the sustainability of infrastructural development. It plays an important role among other activities in the building operations (Zulkarnain et al., 2011). Maintenance according to BS 3811(1984) is the combination of all technical and associated actions intended to retain an item or restore it to a state in which it can perform its required function. Also, according to Musa (2002) maintenance denotes all actions carried-out on a building after completion to preserve it in its initial state, starting from the defects liability period of the building to its disposal. With appropriate maintenance, the building's economic life is prolonged. However, Musa (2002) took a look into some public buildings around and it reveals array of abandoned and epileptically functioning facilities. The malfunctioning of the facilities in most public buildings is a consequence of inadequate maintenance and/or poor management of the facilities. Adejimi (1998) posits that theories and hypotheses are postulated and propounded daily, but maintenance problems still remain adamantly unyielding and so unsolved and this is why there is a serious need to look at the problem from another perspective. Adejimi (1998) opined that maintenance issues can be resolved together by professionals at the project inception and planning (project conception, design, and construction to completion) stages through preventive rather than corrective or emergency approach.

The public Maintenance management sector in Nigeria has suffered from lack of funds for a period of time while the requirements for good practice in maintenance of building stock have been established over a considerable period, the achievements of good practice is by no means universal. Maintenance of the built environment impacts on the whole nation. The conditions of surrounding in which we live and learn, is a reflection of the nation's well-being ''Maintainability of building has been identified as one of the key areas in which the construction industry must achieve significant improvements".

Factors Affecting Building Maintenance

Previous studies revealed the effects of numerous factors affecting residential building maintenance. Assaf (1996) opined that design and construction faults that affect maintenance of buildings are defects in civil design, defects in architectural design, defects due to consultants firm's administration and staff, defects due to construction drawings, defects due to construction inspections, defects due to construction, defects due to contractual administration, defects of construction materials, defects due to construction equipment, defects arising from specifications and design defects in maintenance practicability and adequacy. Adejimi (2005) asserted that to a large extent, building maintenance problems can be attributed to problems originating from poor design. Adejimi (2005) further stated that the design process could be optimised to achieve adequate planning in choosing the right materials, good workmanship, plants and equipment and labour in order to reduce maintenance problem.

Adejimi (2005) in his study identified twelve relevant factors affecting the maintenance strength of buildings as design resolution, structural strength, specified material strength, maintenance manual, safety measures, skill maintenance personnel, maintenance plants, environmental factors, usage factors, quality control factors and post construction prevention strength. Kiong and Akasah (2012) analyse the maintenance factors for IBS precast structural system in Malaysia in order to produce a better quality of the IBS precast building. They identify design aspect as an important factor of the building quality. Zulkarnain et al. (2011)

reviewed the critical success factor in building maintenance management practice for University sector under four perspectives; customer (customer satisfaction, service quality, customer complaint, reaction to customer needs), internal processes (service excellence, technology capability, customer employee, competence, process efficiency, e.t.c.), financial perspective (management expectations, financial growth, cost reduction, productivity improvement, e.t.c.) and learning and growth perspective (technology leadership, continuous service improvement, upgrading staff competence, e.t.c.). They concluded that critical success factor can help in providing a successful competitive performance for the university sector in the area of maintenance management. Olagunju (2012) identified factors that influence the level of maintenance of residential building standard. In the study eight factors were identified to be significant to physical condition of building in Niger State, Nigeria. The variables are structural components condition, roof components, toilet facilities, discharge of waste water component, exterior wall condition, condition of walkway within the building premises, electrical wire and switches conditions, interior walls surface condition.

STUDY AREA

Lagos State Development and Property Corporation (L.S.D.P.C.)Estate, Ijaiye Medium Housing Estate, Agege, Lagos was built over 20 years ago, in the year 1986-1987 during Governor Muda-Shiru administration to accommodate the civil servants and curb the housing problems in the estate. The estate was sold out to citizen on mortgage in 1989 with but the Lagos State Development and Property Corporation still plays major role in its management and maintenance. The estate was designed as a storey building with 4 flats on a block, it is a 3bedroom flat with a spacious kitchen, 2 toilets and a bathroom. The estate constitutes 80 blocks distributed into seven zones with 13 blocks in a zone and 320units. Most residents of this estate are Lagos state's civil servants, entrepreneurs and professionals.

RESEARCH METHODS

The population of this study comprises the occupants of Lagos State Development and Property Corporation Medium housing estate, Ijaiye, Agege, Lagos. There are eighty three (83) housing units in the estate comprising of eighty (80) units of 4nos 3 bedroom flats in each block and a three 3nos bungalow. Thus, the sample frame for the entire residential properties is three hundred and twenty three (323).

Simple Random Sampling was adopted in selecting the occupants of the estate based on the 2 questionnaire/block ratio been set for the sample size. The sample size in respect of the study was therefore 2 units from the 4nos 3 bedroom flat in each block thus, 160nos of 3bedroom flat and 3nos of bungalows in the estate was therefore considered as the sample size. Structured questionnaires were administered on the occupants of the estate to elicit information on the factors affecting building maintenance in public estates. Descriptive statistics was employed to analyze the data.

Questionnaires were sent out to each of the occupants of the estate, thus a total of One Hundred and Sixty-Three (163) questionnaires were sent out to the occupants of which a total of 120 were completed and retrieved which was then used for the analysis.

DATA ANALYSIS AND DISCUSSIONS

The study examined the gender and employment status of the respondents as it is seen to be crucial in the knowledge of basic housing studies that make for good urban living. Table 1 and 2 shows the gender and employment status of the respondents'. The distribution shows that 68.33% are males while 31.67% are females which show a high number of males residing in the estates. The gender distribution relative to the occupation of the respondents

reveals that 4.17% of the respondents are unemployed, 49.17% are Civil Servants, 30.00% are Self-Employed, while 8.33% work in private firms and are retired personnel's respectively. These shows that majority of the respondents are those that work, have the requisite knowledge of the study area and hence their opinion can be adequately relied on.

Table 1: Respondents gender distribution

Gender	**Frequency**	**Percent**
Male	82	68.33
Female	38	31.67
Total	***120***	***100.0***

Source: field survey, 2014

Table 2: Employment status of the Respondents

Employment Status	Frequency	Percent
Unemployed	5	4.17
Civil Servants	59	49.17
Self Employed	36	30.00
Private Company	10	8.33
Retired Personnel	10	8.33
Others	-	-
Total	*120*	*100.0*

Source: field survey, 2014

Table 3: Respondents opinion on the level of management and maintenance of public services and infrastructures in the estate

Level of Management	Frequency	Percent
Poor	30	25.00
Fair	74	61.67
Good	7	5.83
Very Good	9	7.5
Total	*120*	*100.0*

Source: field survey, 2014

The respondent's opinion on the level of management and maintenance of the Public Services and Infrastructures in the estate was presented in table 3. As shown the occupants opined that the level of management and maintenance is fair with a percentage of 61.67% while those who consider it as poor represents 25.0%. 5.83% consider the level of management as good while 7.5% considers the level of management as very good.

Table 4: Respondents opinion on the adoption of any maintenance strategy in the maintenance of the infrastructures and services in the estate

Adoption of Maintenance Strategy	Frequency	Percent
Yes	44	36.67
No	76	63.33
Total	*120*	*100.0*

Source: field survey, 2014

Table 3, shows that the respondents opined that there is no maintenance strategy adopted for the management and maintenance of the infrastructures in the estate with a majority of the population representing 63.33% agreeing to the fact while 36.67% believe that the some maintenance strategies are been adopted in the management and maintenance of the infrastructures and services in the estate.

Table 5: Respondents opinion on the group that embarks on the maintenance of the infrastructures and services in the estate

Group	Frequency	Percent
Government Agency Only	10	8.33
Residents Association	32	26.67
Government agency and Residents association	78	65.0
Total	*120*	*100.0*

Source: field survey, 2014

Table 5 assesses the body majorly responsible for the maintenance of the infrastructures and amenities in the estate. The result shows majority of the occupants, agreed to the combination of the efforts of the government agency and the residents association for the maintenance of the estate services and infrastructures with the highest percentage of 65%.

Table 6: Respondents opinion as regarding the maintenance strategy adopted in the management and maintenance of the estates services and infrastructures

Maintenance Strategy	Frequency	Percent
No maintenance strategy	7	5.83
Preventive	23	19.17
Corrective	69	57.5
Condition Based	21	17.5
Total	*120*	*100.0*

Source: field survey, 2014

Table 6 analyses the maintenance strategy employed in the maintenance of the estates infrastructures and services. The research revealed that majority of the respondents opined that the corrective method was used with the highest percentage of 57.5%, this is closely followed by the preventive maintenance type with a percentage of 19.17%.

Table 7: Residents Opinion as regards satisfaction on the basic elements in the estate

Satisfaction	Mean	Rank
Satisfaction with structural components	4.6387	1
Satisfaction with dwelling features	4.6023	2
Total neighbourhood facilities and environment	3.9678	3
Total management services	3.6564	4
Overall housing satisfaction	3.3456	5

Source: field survey, 2014

The relative levels of satisfaction with the elements in the estate was also analysed and presented in Table 7. The Table 7 listed the different levels of satisfaction and ranked it on the level of importance and significance. The various opinions and reasons have being ranked to provide better meaning and interpretation to the work. The research revealed that Satisfaction with structural components is the major satisfaction derived by the occupants which is ranked as 1, followed by Satisfaction with dwelling features and Total neighbourhood facilities and environment which have been ranked 2nd and 3rd respectively.

Where VIS-Very Insatisfied IS- Insatisfied UD-Undecided S-Satisfied and VS-Very Satisfied

Table 8 and 9 analyses the respondent's opinion on the level of satisfaction and the condition of the infrastructures and facilities in the estate and the building elements in the estate. The various opinions have been analyzed and ranked for better meaning and interpretation to the work. From table 7, the research revealed that majority of the respondents are very satisfied with the level of security, sewage disposal and water supply. They also opine to the fairly good state of security, telecommunication infrastructure and water supply. Tables 8 on the other hand revealed that majority of the respondents are satisfied with building components such as service appliance and level of sanitation. The condition of the building components also reveals a fair state of sanitation and structural element.

Table 9: Table showing the State and Condition of the building Element and The Users Level of Satisfaction with the Building Elements

	Condition of the Building Elements					Level Of Satisfaction with The Building Elements

Source: field survey, 2014

Table 10 analyses the respondents' opinion on the factors affecting building maintenance in public estates. The various factors were assessed, presented with weighted mean score and ranked for better meaning and interpretation to the research. From the table, the most significant factors are maintenance culture, availability of fund and low concern to future maintenance with mean scores of 4.4250, 4.2167 and 4.1333 and have been ranked 1st, 2nd and 3rd respectively. The least considered factors are ignorance about the basic properties of building materials and components; inadequate knowledge of the importance of maintenance work and use of new materials and components in building which have been ranked 18th, 19th and 20th respectively.

Table 10: Respondents Opinion on the Factors affecting Building Maintenance in Public Estates

Factors affecting Building Maintenance in Public Estates	Mean	Std. Deviation	Rank
Maintenance Culture	4.4250	1.10509	1st
Availability of fund for maintenance of the building	4.2167	1.07049	2nd
low concern to future maintenance	4.1333	1.05267	3rd
Use of substandard of materials and building components	4.1000	.92944	4th
Design affecting Resolution	4.0500	1.01128	5th
inadequate building maintenance standard and policy	3.9500	.96013	6th
clients attitude to maintenance	3.9083	.93482	7th
availability of skilled maintenance personnel	3.9000	.92944	8th
poor management of maintenance group	3.8500	.89490	9th
Workmanship during construction and maintenance	3.7417	.97443	10th
behaviour and attitude of occupants	3.6833	1.06102	11th

CONCLUSION AND RECOMMENDATIONS

The importance of building maintenance in achieving and ensuring sustainability cannot be over-emphasized. It is evident that in Nigeria both public and private sector buildings face neglect due to lack of maintenance and as a result they are subjected to rapid deterioration. The study revealed lack of preventive maintenance for public residential buildings and this presents threats to the functional, structural and aesthetic conditions of such buildings. The research also assessed the condition and users satisfaction relative to the condition of the building elements and the infrastructures provided in the estate and revealed that majority of the respondents are satisfied with the structural components and dwelling features which invariably requires adequate building maintenance to avoid deterioration and total obsolescence. The research therefore made the following recommendations;

i. The government should formulate appropriate policies and strategies and make funds available for planning and development in order to set minimum maintenance standards for buildings in the estate. This may be through repair/remedial works and renovations such as; Minor repair works, Major repair works.
ii. Educate the residents on the need for residential buildings and buildings' premises maintenance and the implications for failure to maintain buildings and building's premises through radio and television announcement and discussions. In addition,

strategic placement of posters and effective distribution of hand bills can also be employed for the enlightenment campaign.

iii. The Nigerian Institution of Estate Surveyors and Valuers and other allied professionals in the construction industry should make appropriate recommendations and guidance notes to aid appropriate maintenance of properties in the country and ensure sustainability.

iv. Preventive maintenance of buildings should be encouraged in order to avoid building failure before the designed life of such buildings.

v. Building designs should be resolved to suite owners' requirements to avoid conversions during occupancy. As unresolved buildings are frequently converted to suit other uses through which the building face failures.

vi. Clients of residential building quarters should ensure that specified materials are used during construction and thereafter make funds available for periodic and corrective maintenance.

vii. Qualified and experienced personnel should be engaged in the construction and maintenance of public buildings.

ABSTRACT

Rainwater harvesting (RWH) is the process in which rain is captured, channeled, stored, and used as an alternative or supplementary water source. This study assessed a rainwater harvesting system (RWHS) in a non-residential building at Federal University of Technology, Akure using a triple bottom line approach of sustainability. In assessing the RWHS, data were collected using quantitative data collection methods: a detailed survey questionnaire, physiochemical/ microbiological assessment of water quality, and a cost-benefit analysis. The survey result showed that 66% of respondents would be open to using untreated rainwater for toilet flushing while 82% of the respondent agreed to using treated rainwater generally. The increase in agreed percentage is related to the fear of health risk in untreated rainwater. However, on the issue of choice, only 12% of the respondents agreed to using rainwater fed toilet when borehole water toilet is not functioning. The physiochemical/microbiological assessments of rainwater suggest that it poses a low risk to public health. Also the cost-benefit analysis shows that the project is viable with cost-benefit ratio of eleven and return on investment of one year. Consistently, water was available for use in the toilet throughout the implementation of the project, relieving the stress of staff and students of the department from going to wells and boreholes to fetch water. This research has demonstrated that rainwater harvesting system is an effective intervention for the perennial water shortage and sanitation problems.

Keywords: Rainwater Harvesting, Reliability, Rainfall, Water Quality, Cost-benefit Analysis

INTRODUCTION

Rainwater harvesting (RWH) is the process in which rain falling on an impervious surface, is captured, channelled, stored, treated if necessary and used as an alternative or supplementary water source, for a variety of water requirements. RWH can be particularly be useful in areas where surface and groundwater sources are hard to exploit (Fewkes, 2006).

Rainwater harvesting systems (RWHS) is not a new system and it has successfully been tested for higher crop productivity in smallholder farming of the semi-arid world by several researchers and developmental organizations as potential measures of supplemental moisture/water supply (Botha et al. (2003), Gicheru et al. (2003), Biamah and Nhlabathi (2003) and Chilimba and Kabambe (2003)). Also with regards to domestic uses, rainwater has successfully be implemented in residential buildings (Coombes et al. (2003), Rahman et al. (2012 & 2014), Domènech and Saurí (2010), Shittu et al., 2012; Hamid and Nordin, 2011; Lade et al., 2013) showing a significant impact on the total water consumption.

Sustainability of a RWHS signifies that the existent harvesting, use and consumption of natural water resources can be continued in to the future for optimal livelihood generation. One of the typical questions raised by sustainable assessment is how well sustainability can be measured (Waheed et al. 2009). According to Pachpute et al 2009, sustainability can be based on three important attributes of RWH system: (i) reliable water supply and production potential (ii) effectiveness of water use and (iii) minimal negative impacts on natural resources (Pachpute et al., 2009). The certainty of income generation is also an added advantage to the sustainability of RWHS.

Olanrewaju O. O. and Ilemobade A. A. (2016). Assessing The Sustainability Of A Rainwater Harvesting System In An Academic Building Using A Triple Bottom Line Approach. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 266-275

Assessing the sustainability of a RWHS has been a major challenge as many researchers has used several methods in assessing the sustainability of rainwater system. For gardening/irrigation, Woltersdorf (2010) assessed the sustainability of Rainwater Harvesting Systems used for Gardening by evaluating ecologic, economic and social implications. Pachpute et al. (2009) undertook a sustainability assessment of storage type of rainwater harvesting systems in Makanya catchment of rural Tanzania by assessing the reliable water supply potential and effectiveness of water use by crops.

With regards to domestic use, Ghisi et al. (2009) evaluated the financial viability of a rainwater harvesting system. Rahman et al. (2012) examined the water savings potential, reliability of water supply, financial benefits, and the adequacy of the current government rebate for a RWHS implemented within a stand-alone house at ten different locations in Greater Sydney, Australia. Rahman et al., (2014) also accessed the sustainability of Rainwater Harvesting System in terms of Water Quality. The author ensures the sustainability of it system through assessing several water-quality parameters of collected rainwater with respect to allowable limits. Hamid and Nordin (2011) studied the reliability of installing a RWHS by studying the reliability of water supply and production potential at a male residential colleges in Universiti Teknologi MARA (UiTM) Malaysia. The study concluded that the installation of RWHS could result in a 90% water supply reliability for the college. The economic appeal of the RWHS was also studied and this resulted in an annual savings of RM 10460 from the campus' water bill.

With respect to the above literature, none of the previous researchers have been able to combine the 3E (i.e. Environment, Equity, and Economics) of Triple bottom approach to assess a RWHS. In view of the above, this study present the evaluation of the RWHS using the triple bottom line approach of sustainability i.e. consideration of the social, economic and health/technical aspects of RWH.

SUSTAINABILITY AND TRIPLE BOTTOM APPROACH

Sustainable development was first described by the Brundtland Commission in 1987 as "development that meets the needs of the present without compromising the ability of future generations to meet their own needs" (WCED 1987). Since the Brundtland Commission, many alternative definitions of sustainability have been proposed and diverse interpretations of the concept made. However, the meaning of sustainability is subject of intense debate among environmental and resource economists and a concept difficult to define in a way that it is meaningful and sufficiently practical to allow it to be operationalized (Pope et al. 2004).
Sustainability Assessment is a new and evolving concept, which is being increasingly viewed as an important tool to aid in the shift towards sustainability (Pope et al. 2004). In literature, sustainability assessment is generally viewed as a tool in the 'family' of impact assessment processes, closely related to Environmental Impact Assessment and Strategic Environmental Assessment (Pope et al. 2004). Sustainability Assessment is often described as "a process by which the implications of an initiative on sustainability are evaluated, where the initiative can be a proposed or existing policy, plan, program, and project, piece of legislation, or a current practice or activity." (Pope et al., 2004). Assessing sustainability firstly requires a well-defined concept of sustainability (Pearce et al. 1996). Many concepts of sustainability are based upon the 'three-pillar'or 'triple bottom line' (TBL) concept, which is often conceptualized as three intersecting circles representing the environment, society and the economy (Figure 6) (Jörissen et al. 1999, Pope et al. 2004). It is assumed that the state of sustainability can be defined by environmental, social, and economic objectives and criteria are developed under these categories. (Pope et al. 2004, Waheed et al. 2009).

Figure 6: Three pillars of social, environmental and economic sustainability (Triple bottom line) (Wikipedia, sustainability http://en.wikipedia.org/wiki/Sustainability)

Triple-Bottom-Line Sustainability is based around the concept of the *"3 E's:" Environment, Equity*, and *Economics* (alternately, the *"3 P's:" Planet, People,* and *Profits*) as interrelated in their ultimate success or failure. Being a good steward of the environment by leaving it in a better condition than you found it is certainly a key goal of sustainability and sustainability planning. It is demonstrated, however, that an individual's concern for environmental stewardship increases as his or her prosperity increases.

The triple-bottom-line approach acknowledges the three pillars of sustainability—environmental stewardship, improved social equity, and increased economic development—as equal in their impact on allowing current generations to meet their needs while protecting the ability of future generations to do the same. Furthermore, it recognizes and capitalizes on the fact the three pillars of sustainability can be leveraged against one another to increase the positive outcomes of each beyond what would be possible if each pillar were addressed separately.

STUDY AREA

This project was carried out at the Department of Agricultural and Environmental Engineering (DAEE) workshop, Federal University of Technology Akure (FUTA), Nigeria. FUTA is located in Akure, the capital of Ondo State, South-Western, Nigeria and lies within Latitude: 7.25 °N and Longitude: 5.20 °E. Akure had a population of over 500,000 people in 2006 (Balogun et al., 2011). Akure's MAP is about 2,105mm and rainfall occurs between March and November (Encarta, 2014).

The Federal University of Technology, Akure, Nigeria (FUTA) was chosen as the study area due to the desperate need for water for toilet flushing within the university academic environment and the potential RWH holds as a viable source. There is currently no municipal water supply to the campus and the campus relies heavily on boreholes which are non-perennial.

METHODOLOGY

Assessing Sustainability of RWH System

The technical feasibility was addressed by assessing the rainfall potential and the storage reliability (Appendix 1A &B). For social feasibility (and thus, assessment), a questionnaire was developed to test for the sustainability of the project in order to ensure that the community was fully engaged at every stage of the project implementation and this included identifying their most serious water-related problems and potential solutions.

It is expected that after one or two years of implementing the RWHS, a follow-up questionnaire will be developed and administered to beneficiaries of the RWHS in order to assess the RWHS. The developed questionnaire in this study was an adapted version of the questionnaire used in Olanrewaju (2013) and obtained data on the demographic

characteristics of the respondents, practice of RWH, perceptions of rainwater quality and willingness to use the rainwater for toilet flushing. The questionnaire also solicited respondents' perceptions to using treated rainwater for toilet flushing prior to the RWHS being implemented and was administered to students registered at the Federal University of Technology Akure.

In relation to perceptions regarding using rainwater to flush toilets, the questionnaire employed the factors influencing perceptions published by Po et al. (2004) i.e. (i) Disgust or the "Yuck" factor; (ii) perceptions of risk associated with using treated rainwater; (iii) the specific uses of treated rainwater; (iv) the sources of rainwater to be treated; (v) the issue of choice; (vi) trust and knowledge; (vii) attitudes towards the environment; (viii) environmental justice issues; (ix) the cost of treated rainwater; and (x) socio-demographic factors.

The first section of the questionnaire solicits socio-demographic data such as age and status at university. The succeeding section has a number of statements requiring respondents to select the option that is most applicable to them using the 5-point scale provided i.e. *Strongly agree*, *Agree*, *Neutral*, *Disagree*, and *Strongly disagree*. The third section is open-ended and requests respondents to provide reasons (personal, cultural, religious or otherwise) why they may not use treated rainwater for toilet/flushing, and also to make whatever comments they wish to make. Table 1 provides additional details regarding the administration of questionnaires.

Table 1: Additional details regarding the administration of questionnaires

Year of administration	When administered	Respondents	Number of respondents
2013	Prior to the implementation of the RWHS	Students registered at the Federal University of Technology Akure.	50

The questionnaire was administered to 50 respondents based on the relative small number of student using the workshop facility (< 1000 students). Informed consent was obtained from each respondent before administering the questionnaire. The completed questionnaires were screened for completeness, coded and entered into the Statistical Package for Social Science (SPSS) version 16.0.

For rainwater quality assessment, samples were collected before and after pre-treatment (i.e through filter). Rainwater samples were collected in triplicate using guidelines of the American Public Health Association (APHA, 1985) and National Standard of Drinking Water Quality (NSDWQ) (2007). Water was collected aseptically in autoclaved 25 cl plastic. Samples were transported in black plastic bags containing ice to the laboratory within 2 hours of sampling, kept in a refrigerator at 4°C and examined within 16 hours of collection. Samples were analyzed using standardized bacteriological methods for water quality analysis (Cheesebrough, 1987) to determine the degree of contamination. All samples were analysed for total bacterial count and E. coli. The microbiological quality was assessed by most probable number (MPN) method (Fawole and Oso, 2001). Total coliforms were indicative of environmental contamination (from bird faeces, dead leaves, etc) and E. coli indicative of human faecal contamination (Abott et al., 2012).

RWHS cost varies considerably depending on location, materials used and RWHS capacity. The catchment area cost depends on the layout, topography, and elevation of the catchment areas with respect to the area allocated to the storage tank. The cost for the conveyance system (gutters and down pipes) also vary, based on the configuration or physical layout of the RWHS. Typically, the most expensive component in the RWHS is the storage tank. The

economic cost incorporates construction cost and operation and maintenance cost. Construction cost comprises the cost of equipment, materials and construction. Operation and maintenance cost includes the cost of filter replacement, maintenance and salaries. The *environmental cost* was not included in this analysis because of the low risk of rain water to human health.

The *economic benefit* of RWH is the money saved from not using potable water supplied via a centralised municipal system. Based on the current price of water in the city of Akure, 20 litres of water costs ₦10 (Ten naira). Benefit to Cost ratio (R_o) was calculated using equation (1).

$R_o = B_o / C_o$ .....*(1)*

C_o represents *economic cost* and B_o represents *economic benefit*. The annual discount rate employed was 10% over the 10-year RWHS design life. If $R_o > 1$, then the project is economically feasible.

Net present value (NPV) calculations discount future costs and benefits to a present value using a discount rate. A positive NPV indicates a net benefit. When evaluating different schemes, those with higher NPV values are more favourable. NPV is computed using

$$NPV = \sum_{t=1}^{T} \frac{C_t}{(1+r)^t} - C_0 \quad \text{.....(2)}$$

equation *(2)*

Where r is the discount rate, C_t is the net cash flow and T is the design life of the system.
Payback period, which is the time taken to gain a financial return equal to the original investment, is determined using equation (3):
Payback period = investment required/net annual cash inflow .....(3)

RESULTS AND DISCUSSIONS

Technical Feasibility

Due to the maximum rainfall experienced in April, there was a large volume of rainwater stored (82.76) over the 12 months. There were deficits recorded in December, January, and July 2013 with values of -24.00, -22.70, and -15.90 respectively (See appendix). Water demand for September and October were comparably much lower due to the school holidays. Maximum storage of 395.07m^3 occurred in June 2014.

Social and economic feasibility

Social feasibility

Of the 50 respondents, 66% of the respondents agreed that they will be open to using rainwater fed toilet, 20% of the respondents were neutral while 14% disagreed to be open to using rainwater fed toilet (Table 2).

Table 2. Willingness to use rainwater for toilet flushing

	Frequency	%	Cumulative %
Agree	33	66.0	66.0
Neutral	10	20.0	86.0
Disagree	7	14.0	100.0

Use of treated rainwater for toilet flushing

Of the 50 respondents, 82% were comfortable using treated rainwater for toilet flushing, 16% were neutral while 2% were not comfortable using treated rainwater for toilet flushing. In comparison to the results shown in Table 2, Table 3 shows a higher percentage of respondents agreeing to use rainwater water basically because of treatment.

Table 6 Willingness to use treated rainwater for toilet flushing

	Frequency	%	Cumulative %
Agree	41	82.0	82.0
Neutral	8	16.0	98.0
Disagree	1	2.0	100.0

The issue of choice

Twelve percent of 49 respondents will only use rainwater fed toilets if normal water fed toilets are occupied, 28% were indifferent while 58% will not use rainwater fed toilets even when potable water fed toilets are occupied (Table 4).

Table 4. Respondents reaction to if they will only use rainwater fed toilets when normal water fed toilets are occupied

	Frequency	%	Cumulative %
Agree	6	12.0	12.2
Neutral	15	30.0	40.8
Disagree	29	58.0	100.0

Perception of health risks associated with rainwater

Rainwater is generally believed to be safe to use for non-ingested purposes. Out of the 50 respondents, 28% were concerned about using toilets that flush with rainwater, 20% were neutral and 52% were not concerned about using toilets that flush with rainwater (Table 5).

Table 5. Respondents concern about their health when using rain fed toilets

	Frequency	%	Cumulative %
Agree	14	28.0	28.0
Neutral	10	20.0	48.0
Disagree	26	52.0	100.0

Economic feasibility

The Economic feasibility was assessed using the cost benefit analysis. Table 14 presents Net Present Value (NPV) for the RWHS over a 10 year design period. The Economic cost was calculated based on capital and recurrent costs for the RWHS over a 10-year design with the assumption of 5% increase annually. While the economic benefit of the rainwater system was calculated based on an annual increase of 5% per annum. This assumption was based on survey and the rate of increase in price of water in Nigeria. The result over a ten-year period as shown in Table 6 indicated that the cost/ benefit ratio of 11 while the net present value of the resultant income stream over a ten-year period is ₦1.2m. From the result, it can be deduced that implementing rainwater harvesting project for toilet flushing is economically viable under a 10-year period with return of investment of 1 year based on the payback period.

Environmental feasibility and health

Physiochemical and microbiological rainwater quality results (before and after filtration) are presented in Table 7. The filtrate temperature reduces from 24^0C to 23^0C from the tank to filtration outlet. The filter achieved the following: turbidity reduced from 0.45 NTU to 0.12 NTU; total suspended solids reduced from 0.12mg/l to 0.06 mg/l; hardness reduced from 180 mg/l to100mg/l and total dissolved solids reduced from 23mg/l to 16mg/l.

PH of the water sample increased from 3.50 to 4.50, this is as result of decrease in the temperature from the tank and the filtration outlet. This is also based on *Le Châtelier's Principle*, which states that as the temperature increases in pure water, the pH reduces and so vice-versa. Also the conductivity reduces from 36.33 (us/cm) to 25.88 (us/cm). Total alkalinity values reduces from 492 ($MgCaCO_3$/l) in the tank to 376 ($MgCaCO_3$/l) after filtration. Nitrate and phosphate were not detected in water sample. The chloride value was within the range 248.15mg/l before and 174.41mg/l after treatment. The low BOD and COD were minimal with a percentage reduction of 16.84% and 16.61% respectively.

Coliforms and E.coli were not detected in the stored rainwater samples in both the filtered and the unfiltered samples. The total heterotrophic bacterial (THB) counts ranged from 14.40 (cfu/ml) $x10^3$) in the stored water and 12.35 (cfu/ml) $x10^3$) after filtration, showing a percentage reduction of 14.24% as a result of the filtration process. The microbiology analysis of rainwater suggests that it poses a low risk to public health.

Table 6 Cost-benefit analysis of the rainwater harvesting system

	Year 1	Year 2	Year 3	Year 4	Year 5	Year 6	Year 7	Year 8	Year 9	Year 10	Total
Economic cost	140,520	500	500	500	500	15,500	500	500	500	500	160,020
Economic benefit	144,000	151,200	158,760	166,698	175,033	183,785	192,974	202,622	212,754	223,391	1,811,217

Chemical Oxygen Demand (COD) (mg/l)	35.35	29.48	16.61
THB (cfu/ml) × 10^3	14.40	12.35	14.24
Coliform (MPN/100ml)	0.00	0.00	0.00
E.coli (MPN/100ml)	0.00	0.00	0.00

THB = Total Heterotrophic
cfu = Colony Forming Unit/ml
MPN = Most Probable Number
NG = No Growth

CONCLUSION

This study has demonstrated that the use of harvested rainwater is an effective intervention for perennial water shortages and that it can be used to solve the problem of unnecessary inconveniences of water and sanitation problems in any environment with scarce water resources. RWHS complements other water sources and utility systems, thus relieving pressure on limited water supplies and has offered several advantages over some other interventions such as greywater reuse such as a high degree of design flexibility, ease of installation, high levels of reliability and a supply of water at a quality consistently good enough for most non-potable applications. Rainwater collected from the building's roof that has undergone basic treatment processes (primarily coarse filtration) poses low risk to public health when used for purposes such as toilet flushing, laundry washing and garden irrigation. Therefore, advocacy for the adoption of a RWHS will lead to drastic reduction in water-shortage/water related diseases and improve standard of living of the people.

The perception survey carried out showed that over 60% of the respondents were willing to use rainwater for toilet flushing. Users' willingness and acceptability of treated rainwater for toilet flushing has clearly proven RWH to be a success, as respondents have clearly shown their desire for the project. As clearly stated in the survey by the respondents, their major problem is lack of water. The toilet facilities are also not clean enough and with their responses as shown above, it is obvious that they are willing to take part in this project. Also, due to favourable responses from the respondents about the positive impact it can bring to the environment, it is believed that this project would be a success whenever it may be embarked on as it would give the environment a new source of water. Respondents have indicated that they are comfortable using treated rainwater for toilet flushing. They have also shown their willingness to use treated rainwater originating from the rainwater harvesting system. From the results, it can be deduced that implementing rainwater harvesting project for toilet flushing is economically viable under a 10-year period, with the resultant income stream over a ten-year period as ₦1.2m and a payback period of 1 year. The analysis reported in this paper revealed that Akure has a considerable rainfall potential. It also suggests that embarking on the design and construction of more rainwater fed toilets will go a long way in improving the toilet situation in the university premises and it will provide a good return on investment.

ABSTRACT

This study investigated the compressive strength characteristics of laterized palm kernel shell concrete with a view to establishing its suitability as an alternative Building material to the conventional ones. It examined the effect of varying water cement- ratios, palm kernel shell contents and laterite contents on the compressive strength of laterized palm kernel shell concrete. The percentage replacement of laterite as substitute in fine aggregates and percentage replacement of palm kernel shell as substitute in coarse aggregate were varied in the increment of (0%, 10%, 20% and 30%) respectively. The water-cement ratios (w/c) of (0.55 and 0.6), mix ratios of (1:1½:3 and 1:2:4) was used. A total of 576 cubes were cast and cured in water for (7, 21 and 28 days) respectively. The Laterized Palm Kernel Shell (LPKS) Concrete cubes of sizes 100 x 100 x 100mm were crushed using manual compression testing machine. The test results showed that the compressive strength of laterized Palm Kernel Shell Concrete decreases significantly with increase in water-cement ratio, increase in laterite content and increase in palm kernel shell content respectively. It was also discovered that during curing, the compressive strength of laterized Palm Kernel Shell Concrete increased from 7-28 days. This study concluded that laterized palm kernel shell concrete may perform better if up to30% laterite content and 30%PKS is use for mix ratio 1: 1½:3 at w/c ratio 0.55,up to 20% of laterite and 20% PKS for 0.6w/c. For mix 1:2:4 at both mix ratios and w/c ratios, up to 10% laterite and 20%PKS is adequate.

Keywords: Palm kernel Shell, Laterite, Concrete, Compressive strength

INTRODUCTION

The construction industry relies heavily on conventional materials such as cement, granite and sand for the production of concrete. The high and increasing cost of these materials has greatly hindered the development of shelter and other infrastructural facilities in the developing countries. As a result of shortage of building materials and with the advent of soil-cement as a material for the provision of cheap houses especially in the under-developed and developing countries of the world, a lot of investigations are now being made to determine the usefulness of cheap and locally available materials such as lateritic soils (Lasisi *et al.* 1990). Laterite is a soil formed by decaying rocks weathered by tropical heat and centuries of heavy rain. They are readily available in large quantities all over the tropical regions of the world, particularly in Nigeria. Lack of adequate information about its structural behavior in service coupled with lack of accepted standards regarding their performance characteristics when stabilized with some other materials may explain why the material has not been fully and confidently accepted for construction (Osunade, 2002).

The growing concern of resource depletion and global pollution has challenged many Researchers to seek and develop new materials relying on renewable resources. These include the use of by-products and waste materials in building construction (Teo *et al.* 2006). As stated by Olanipekun *et al.* (2006), one of the suggestions for cutting down conventional building material costs has been the sourcing, development and use of alternative, non-conventional local construction materials including the possibility of using some agricultural wastes and residues as constructional materials. Such wastes are palm kernel shell, coconut shell etcetera. One significant problem in the processing of palm oil is the large amount of

Popoola, O. C.; Obaju, N. B. & Alake, O. (2016). Compressive Strength Characteristics of Laterized Palm Kernel Shell Concrete. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 276-284

waste produced and this is one of the main contributors to the nation's pollution problem. At the mills, when the fresh fruit bunches is processed and oil extraction takes place, solid residues and liquid wastes are generated. These by-products include empty fruit bunches, fibre, shell and effluent (Nuhu-koko, 1990).

Palm kernel shell is not a common material in the construction industry, but with the quest for sourcing and developing alternative, non-conventional local construction materials, limited research work has been carried out on the use of PKS as aggregate in light and dense concrete for structural and non-structural purposes. Palm kernel shells are used mostly as aggregates in concrete (Olanipekun *et al,* 2006; Alengaram *et al,* 2010; Olutoge, 2010) and asphalt concrete (Ndoke, 2006).

Attempts have equally been made by various researchers to reduce the cost of its constituents and hence total construction cost by investigating and ascertaining the usefulness of materials which could be classified as agricultural or industrial waste such as palm kernel shells, coconut shells, corn cob ash, fly ash, rice husk ash etc that have being continuously generated. The reuse of this waste product will help to save our environs from environmental pollution and severe ecological (green) problem. Due to this reality, an alternative source for the potential replacement of fine aggregates in concrete has gained good attention. As a result, reasonable studies have been conducted to find the suitability of laterite replacement for sand in conventional concrete and the use of Palm kernel shell to replace granite. Sand is a well-known building material and has occupied a very important place in construction work but it is more expensive than laterite because the former is more difficult to collect from rivers than the latter which can easily be dug from pits.

Concrete is the most widely use construction materials worldwide. This is due to its versatility, strength, durability, easy to make to any forms and shapes. These characteristics are the major factors that universally make concrete a material of choice in housing, development and other construction activities (Dadu, 2011).Concrete is constructional material that has been important in the past, is one useful today and is confidently forecast to be indispensable in the future. When compared with other material used in construction industry, concrete is one of the materials that consume high quantity of natural resources. The factors that influence the compressive strength of concrete are; Quality of materials, grading of the aggregates, water, water-cement ratio, cement content and age of the concrete (Mamman and Abdulsalam, 2011).

At least about 80% of the volume of ordinary concrete is occupied by aggregates. This shows that sourcing alternative aggregates will conserve our aggregates deposit from 1 to 80% concrete production. As aggregates are cheaper than cement it is more economical to use it as much as possible in concrete than cement. Neville (1997), stated that aggregates contribute to the volume stability and durability of concrete. In an attempt to achieve environmental sustainability, a lot of effort was made by different researchers toward substituting aggregates with other suitable materials. Hence the need for this study.

Laterized Palm Kernel Shell Concrete

Laterized concrete as described by Olusola *et al.,* (2005) is concrete in which laterite fines are used partially or wholly to replace the conventional sand". In this light, it can be said that laterized palm kernel shell (LPKS) concrete is concrete in which laterite fines and palm kernel shells are used partially or wholly to replace the conventional sand and granites respectively. Also studies by (Olusola *et al,* 2004 and Ayangade *et al,* 2004) have established the suitability of palm kernel shells as floor finish aggregates and also that the introduction of granite dust in the coarse aggregate up to 30% maximum gave a maximum compressive strength. Likewise, Obadje (2011) investigated into aspects of the durability of *Kernelrazzo*

in terms of its fire resistance, abrasion resistance and impact resistance and had established its suitability. Despite all these researches, the compressive strength characteristics of concrete when both sharp sand and granites are partially or fully replaced with laterites and palm kernel shells respectively is scarce in literature. Hence the need for this study.

Experimentation

Material Sampling

The basic components of the materials used were Palm Kernel Shell (PKS), Ordinary Portland Cement (OPC), Sand and Water. The PKS was obtained from Iwoye village along Iwo-Ibadan express road, Osun State. The Cement was Ordinary Portland Cement (OPC) whose properties are believed to conform to the requirements of BS EN197-1 (2000).The Sand and the granite used was obtained in Ede town, and the range of size of the sand used are those that passed through 5mm BS Sieve. Portable water that is free from organic matter of any kind was used for mixing.

Experimental procedure

Preparing the test sample

The various test specimens were prepared at the department of Building, Federal Polytechnic Ede, Osun State. This stage involves mixing the constituents of the LPKS using certain parameters such as mix ratios(1:1½:3,1:2:4), determined percentage of PKS Content(0%,10%,20% and 30%), and granite content, determined percentage of laterite content(0%,10%,20% and 30%), and sand. The whole mixture was thoroughly mixed before water was sprinkle. The required quantity of sharp sand, laterite, palm kernel shells,and granite was measured and spread on the concrete platform. The required quantity of cement per each mix ratio was first thoroughly mixed with laterite and sharp sand before mixing with the palm kernel shells in their right proportion. The required quantity of water was measured and poured into the mixture in stages for adequate mixing and to enhance effectiveness of the binding. The component was thoroughly and adequately mixed to prevent segregation and bleeding until uniform, homogenous and consistent mix was obtained.

Placing

The mixture immediately was poured into wooden moulds of 100x100x100mm size to avoid setting before placement. The mould used was oiled before filling with the mix. This was done to enhance easy de-moulding and smooth surface finishes. The mixture was placed in two layers in the mould and then tampered using a 20mm tampering rod. This was done to ensure adequate compaction to avoid honeycombing. After the top layer had been compacted, the surface of the LPKS concrete cube was finished and leveled with the top of the mould by means of a trowel. This was labeled for easy identification after some minutes. The LPKS concrete cubes was left in the moulds for 24 hours and kept in a place free from vibrations or exposure to direct sunlight or other sources of heat. The specimens was de-moulded after 24hours and cured. The mixing and sampling of the concrete was done in accordance with BS 1881: Part 125: 1986. However, maximum care was taken into consideration to ensure the stability of the moulds on the platform when filling and tampering. Clean sheet of polythene was laid under the moulds to avoid the outflow of the water from the mix.

Curing of test specimen

The concrete cubes were stripped the second day (after 24hours of casting) and were placed in curing tanks filled with water. The cubes were cured for 7, 21 and 28days.respectively.

Determination of the compressive strength

The compressive strength were done by crushing Concrete cubes of sizes 100mm x 100mm x 100mm on a 1000kN capacity ELE Compression machine. Soft boards of 10mm thickness were used as packing materials between the blocks and the platens of the machine. The cubes

were well centered under the compression machine before the load was applied. The test was done for 7, 21 and 28days

Tests results and discussion

Effect of w/c ratio on the compressive strength of laterized Palm kernel shell concrete

The figures below shows the variation of the compressive strength of the Laterized Palm Kernel Shell Concrete with water cement ratio of two mixes investigated. For the two mix ratios 1:1½ :3 and 1:2:4 and at all levels of Palm Kernel Shell and Laterite content, the compressive strength of Laterized Palm Kernel Shell decrease with an increase in water cement ratio.

Effect of mix ratio on the compressive strength of laterized palm kernel shell concrete

The figures below shows the variation of the compressive strength of the Laterized Palm Kernel Shell with two water cement ratios 0.55 and 0.60 at all levels of palm kernel shell and laterite content, the compressive strength of laterized palm kernel shell decrease with an increase in mix ratio.

Effect of percentage replacement level of palm kernel shell content on the compressive strength of laterized Palm kernel shell concrete

For water-cement ratios of 0.55 and 0.60 and at 0% to 30% Palm kernel shell level, the higher the water cement ratio the lower the compressive strength. However the compressive strength decreases with an increase in Palm kernel shell concrete

Effect of percentage replacement of laterite on the compressive strength of laterized palm kernel concrete

The compressive strength increase as the percentage of laterite decrease for both mix ratios, at both water/cement ratio 0.55 and 0.6. The richer the mix, the higher the compressive strength, the higher value of compressive strength was recorded at lower water cement ratio.

Discussion of the result

a. Mix ratio 1: 1½:3 and 0.55w/c ratio
   All the values satisfy the requirement
b. Mix ratio 1: 1½:3 and 0.6w/c ratio. The percentage written below is satisfactory for PKS content and laterite
   0% laterite – up to 30% PKS
   10%laterite – up to 30% PKS
   20%laterite – up to 20% PKS
   30%laterite – up to 10% PKS
c. Mix ratio 1:2:4 and 0.55w/c ratio
   0% laterite – up to 30% PKS
   10%laterite –up to 20% PKS
   20%laterite – up to 10% PKS
   30%laterite – The result is less than the requirement
d. Mix ratio 1:2:4 and 0.6w/c ratio
   0%laterite –up to 30% PKS
   10%laterite –up to 20% PKS
   20%laterite –Result less than the requirement
   30%laterite –Result less than the requirement

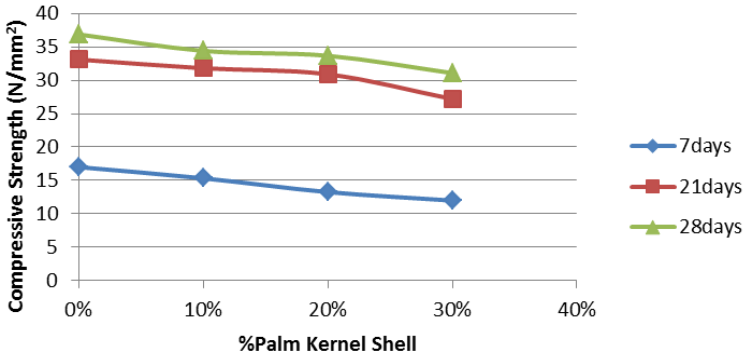

Figure 1: Compressive strength of Laterized Palm Kernel Shell concrete containing 0% laterite , 0.55 w/c ratio and mix ratio 1: 1½:3

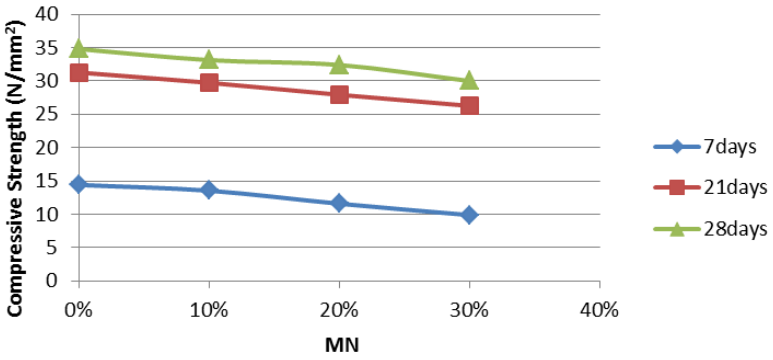

Figure 2: Compressive strength of Laterized Palm Kernel Shell concrete containing 10% laterite, 0.55 w/c ratio and mix ratio 1: 1½:3

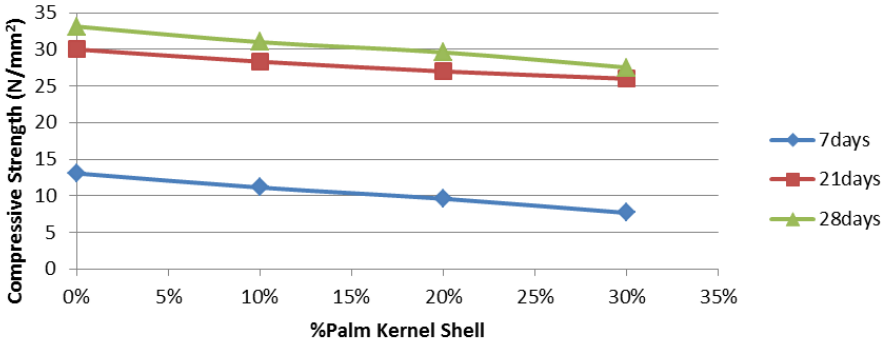

Figure 3: Compressive strength of Laterized Palm Kernel Shell concrete containing 20% laterite , 0.55 w/c ratio and mix ratio 1: 1½:3

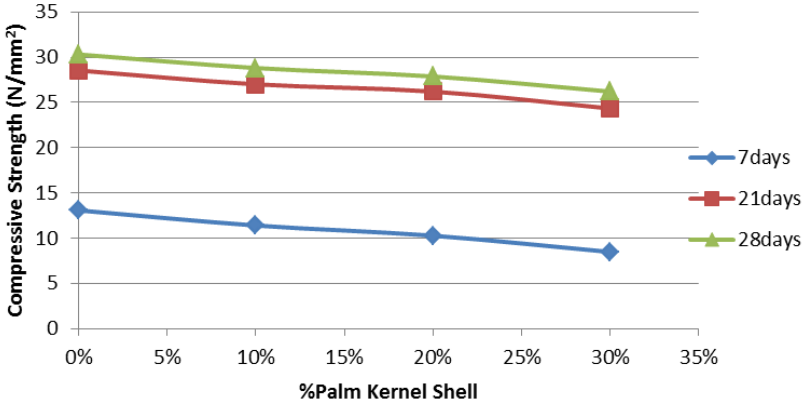

Figure 4: Compressive strength of Laterized Palm Kernel Shell concrete containing 30% laterite , 0.55 w/c ratio and mix ratio 1: 1½:3

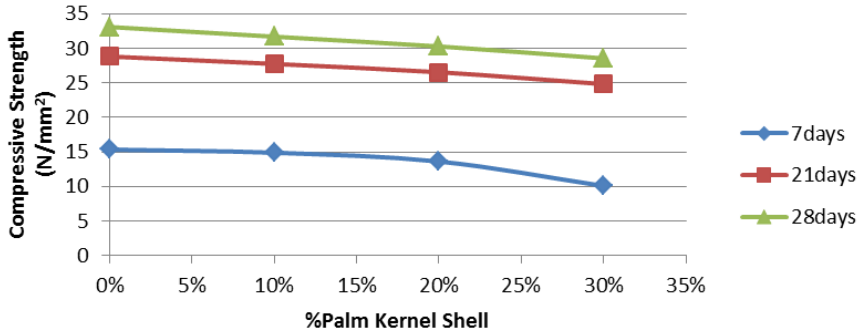

Figure 5: Compressive strength of Laterized Palm Kernel Shell concrete containing 0% laterite, 0.6 w/c ratio and mix ratio 1: 1½:3

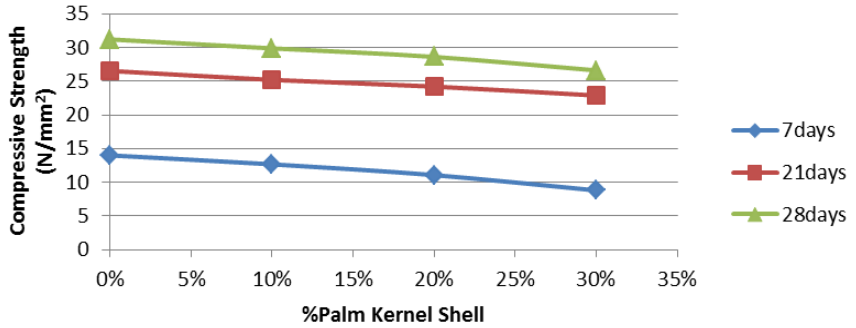

Figure 6: Compressive strength of Laterized Palm Kernel Shell concrete containing 10% laterite , 0.6w/c ratio and mix ratio 1: 1½:3

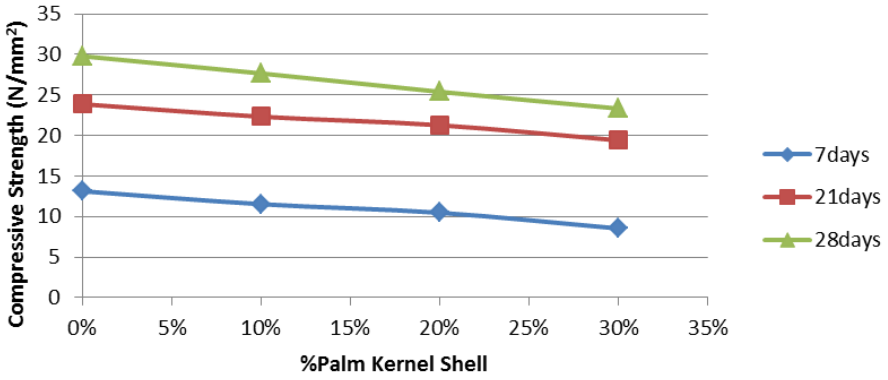

Figure 7: Compressive strength of Laterized Palm Kernel Shell concrete containing 20% laterite, 0.6 w/c ratio and mix ratio 1: 1½:3

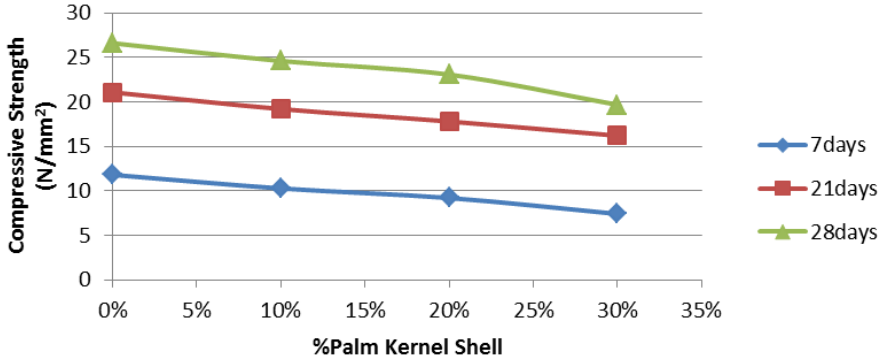

Figure 8: Compressive strength of Laterized Palm Kernel Shell concrete containing 30% laterite, 0.6 w/c ratio and mix ratio 1: 1½:3

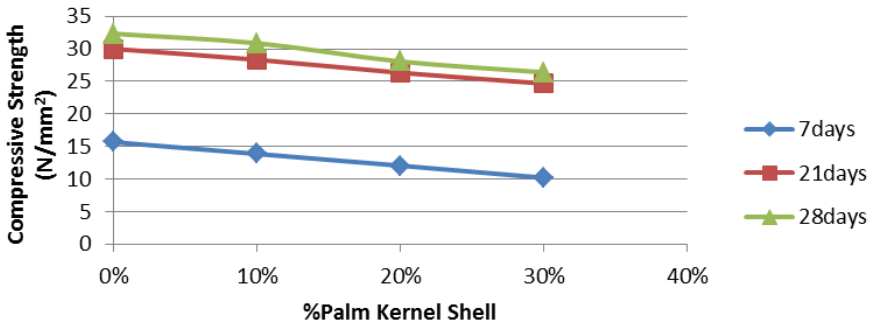

Figure 9: Compressive strength of Laterized Palm Kernel Shell concrete containing 0% laterite, 0.55 w/c ratio and mix ratio 1:2:4

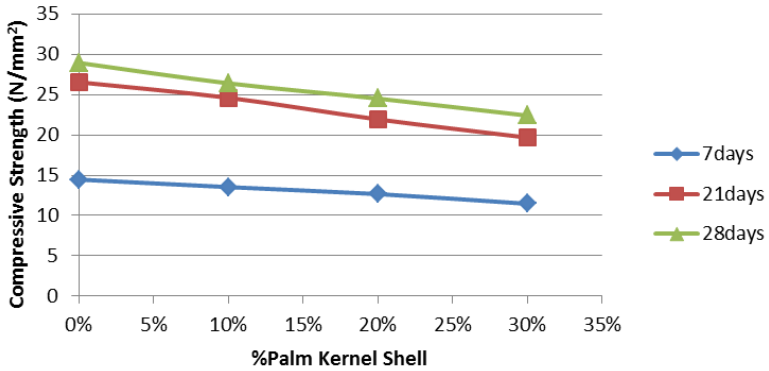

Figure 10: Compressive strength of Laterized Palm Kernel Shell concrete containing 10% laterite, 0.55 w/c ratio and mix ratio 1:2:4

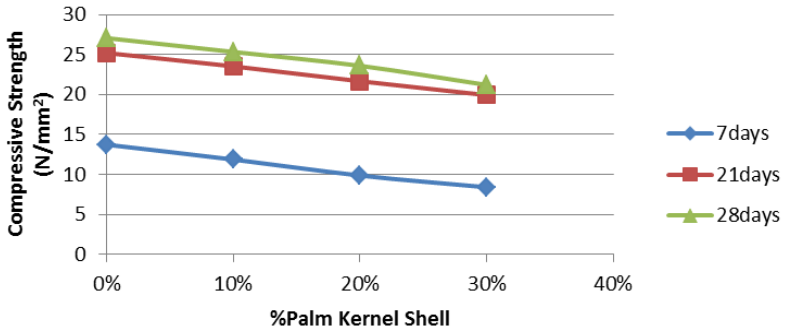

Figure 11: Compressive strength of Laterized Palm Kernel Shell concrete containing 20% laterite, 0.55 w/c ratio and mix ratio 1:2:4

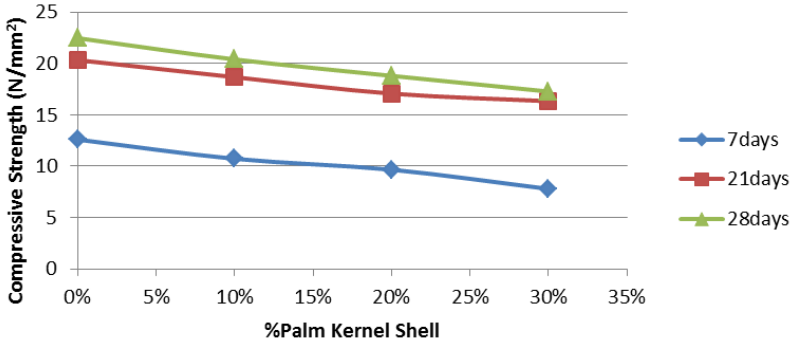

Figure 12: Compressive strength of Laterized Palm Kernel Shell concrete containing 30% laterite, 0.55 w/c ratio and mix ratio 1:2:4

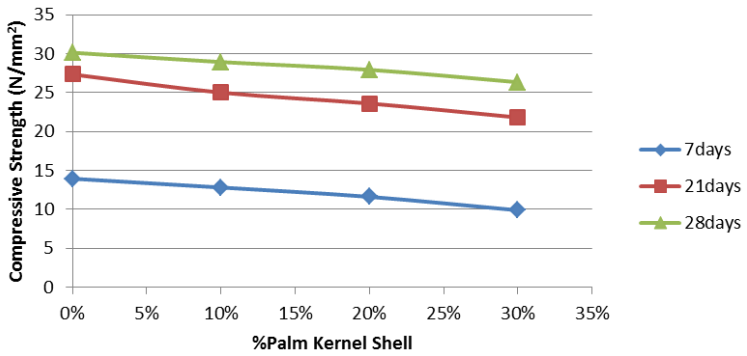

Figure 13: Compressive strength of Laterized Palm Kernel Shell concrete containing 0% laterite, 0.6 w/c ratio and mix ratio 1:2:4

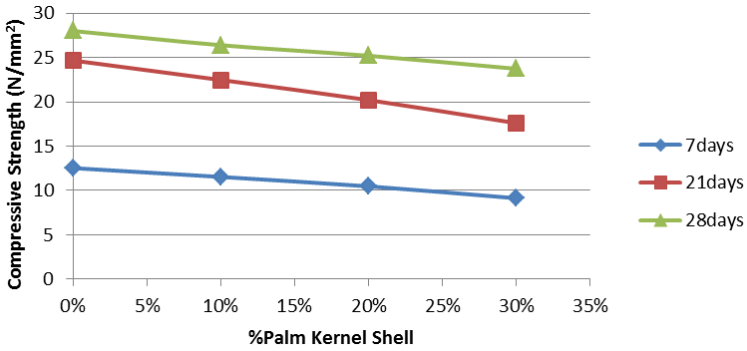

Figure 14: Compressive strength of Laterized Palm Kernel Shell concrete containing 10% laterite, 0.6 w/c ratio and mix ratio 1:2:4

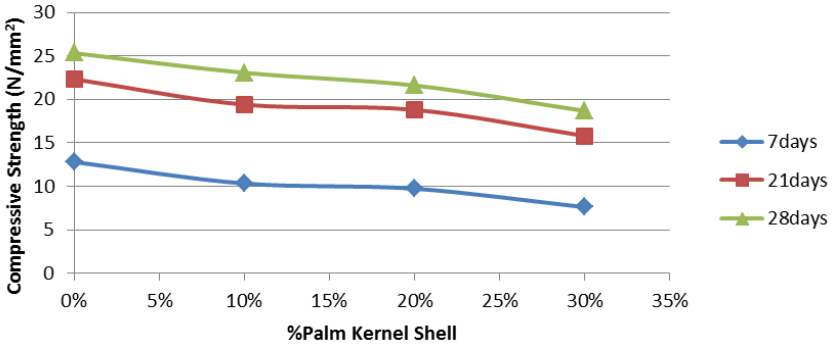

Figure 15: Compressive strength of Laterized Palm Kernel Shell concrete containing 20% laterite, 0.6 w/c ratio and mix ratio 1:2:4

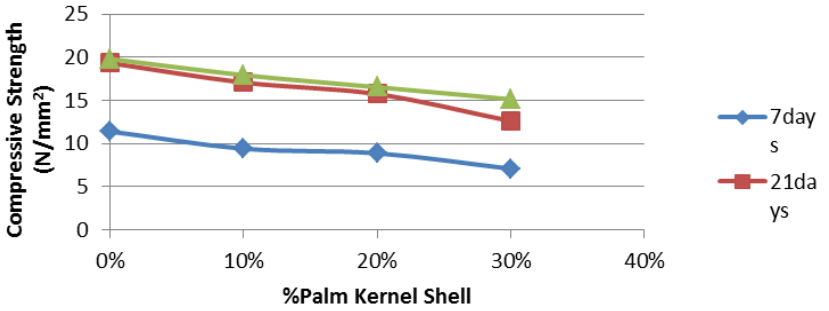

Figure 16: Compressive strength of Laterized Palm Kernel Shell concrete containing 30% laterite, 0.6 w/c ratio and mix ratio 1:2:4

CONCLUSION AND RECOMMENDATION

The following can be ascertained from the results of the study:

i. The compressive strength of mix rato 1: 1½s:3 is higher than for mix ratio 1:2:4

ii. The higher the cement ratio the lower the strength of the concrete. As the percentage of PKS content and percentage content of laterite increase the compressive strength decrease
iii. At 0%Laterite content for both the mix ratios and w/c ratio the strength of the concrete meet the required standard
iv. Up to 30% laterite content and 30%PKS for mix ratio 1: 1½:3 and 0.55w/c ratio c the concrete satisfy the minimum requirement of concrete
v. Up to 20% laterite content and 20% PKS for mix ratio 1: 1½:3 and 0.6w/c ratio satisfy the required strength of concrete
vi. Up to 10%laterite content and 20%PKS is satisfactory for mix ratio 1:2:4 and w/c ratios 0.55 and 0.6

Housing Habitability in Informal Settlements of Akure, Nigeria

Adetunji, O. S.[1*] & Ayoola, H. A.[2]

[1&2]Department of Architecture, Federal University of Technology, Akure
[*]osadetunji@futa.edu.ng

ABSTRACT

The informal private sector is at the fore-front in provision of housing in Nigeria. The combination of high rate of population increase, acute shortage of housing, uncoordinated attempts by governments and private sector to provide housing has resulted in the spread of informal settlements in the fringes of many urban centres in Nigeria. Also, informal settlements are characterized by regular exposure to spatial, social, economic and environmental exclusion. The purpose of this study is to examine the impacts of the characteristics of informal housing on housing habitability in selected suburbs of Akure. The objectives of this study are to evaluate the impacts of informal housing characteristics on housing habitability, assess level of habitability of houses in the selected informal settlement and suggest means of relevant upgrading needed to improve habitability in the informal housing. The study adopts a cross-sectional study since it is based primarily on interviews, documents, physical observations and administration of Housing Habitability Standard Checks (HHSC) questionnaires within a limited time frame. Twenty (20) questionnaires each were administered on residents in each of the Six (6) selected communities amounting to One hundred and twenty (120) HHSCQs. This paper shed more light on the initiatives deployed by dwellers to adapt informal housing to their changing needs and circumstances. The paper argues that there is great need for improving the livelihood and habitability of informal housing by integrating informal housing into the broader urban fabric to overcome spatial, social and economic exclusion. Therefore, this paper suggests that enabling policies and planning are to be implemented, physical infrastructural, health, socio-economic and environmental improvement in view to improving livelihood and habitability of informal housing.

Keywords: Housing, Housing Habitability, Neighbourhood quality, Housing infrastructure, Informal Settlement, Neighbourhood wellbeing

INTRODUCTION

Housing is a basic human need in all societies and fundamental right of every individual regardless of age, sex, economic status, race or religion (Adebayo and Iweka, 2013). Housing can be regarded as habitable when physical safety is guaranteed as well as adequate space, protection from cold, damp, heat, rain, wind and other threat to health and structural hazards (UN-Habitat, 2015). Unlike developing countries, habitable housing is more accessible to all categories of people including the poor and the needy in advanced countries as a result of subsidies from the government. Although, various studies here shown that the problem of housing is universal, it is however more critical in less developed countries (Ogundahunsi and Adejuwon, 2014).

Informal settlement describes a wide range of low-income settlements in poor human living condition. Nebutola (2004) described informal housing as one that is characterized with inadequate access to safe water, inadequate access to sanitation and other infrastructure; poor structural quality, overcrowding and insecure tenure status. Housing is described as informal when it does not conform to the laws and regulatory frameworks set up in the environment in which it occurs (UN-Habitat, 2015). This condition not only exemplifies the variety of manifestations of poverty, inadequate infrastructure and poor housing quality but demonstrate type and level of housing the inhabitants can afford. Housing conditions play major role in individual health status, as a wide variety of housing features have been reported to influence the physical, social, economic and the mental well-being of occupants (Ihuah, 2015). This precarious situation is prevalent in many urban centres in Nigeria like Akure which has resulted into various categories of societal vices and crimes.

Adetunji, O. S. & Ayoola, H. A. (2016). Housing Habitability in Informal Settlements of Akure, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 285-295

However, the importance of informal settlements needs to be understood from the perspective of people living there. Mohit and Nazyddah (2009) reveals that informal settlements is an asset in the city because of the locational and competitive advantages that inhabitants derived in continued stay in informal settlements. Informal settlements thus serve a critical function as 'holding places' where people can access the urban environment at extremely low financial cost and piece together various livelihood strategies there (Misselhorn, 2008). Some might remain permanently and even ultimately gain access to formal housing, whilst others might reside temporarily for specific purposes which, once fulfilled, result in them moving elsewhere in the city or returning from whence they came. Other advantages derivable from continued stay in informal settlements are provision of access to the city at unrivalled low cost, limited public administration and low cost accommodation (Mohit and Nazyddah, 2009).

In view of this, the paper attempt to assess the level of habitability to inhabitants of selected informal settlements in Akure and discuss innovative mechanisms and strategies for improving habitability to compliment the actual financial income of low income people in selected informal settlements in Akure. Assumption of this study is that inhabitants of informal settlements will be able to realise full benefits thereby enjoying better housing and sanitary environment.

Informal Settlements

Informal settlements (also known as non-formal cities, squatter settlements, or shantytowns) appear in city centres and on their peripheries. They result both from traditional squatting and pirate urbanism. These communities differ dramatically in size, character, age, and level of political and social organization. Living in informal settlements often poses significant risks on health, education and well-being. Access to health and other services may be limited; overcrowding can contribute to stress, violence and increased problems of drugs and other social problems. As a result of the high cost of housing, lack of good financing schemes, the increasing population is forced to live in substandard housing and unhealthy conditions giving rise to informal settlements (Olotuah and Adesiji, 2005). Informal settlements in Nigeria are increasing and posing serious problems to their own personal life and health. Slums and squatters are experiencing a massive change in the housing quality as they retain in the settlements that are characterized by numerous problems such as overpopulation, inadequate basic amenities, non-conventional housing and so on (Fadare and Olawuni, 2008).

According to UN-Habitat (2005) listed the followings as the main features of substandard housing and environment: Overcrowding; "being defined as having more than two people per bedroom", flooding and inadequate drainage of storm water, poor access, for vehicle/inadequate roads, presence of litter and illegal piles of solid waste, inadequate disposal of residential waste water, inadequate open spaces for other land uses, lack of space for open air living between housings, unreliable electricity supply, sanitary problems, inadequate solid waste collection system, poor quality of drinking water, inadequate disposal of human excreta, acute environment, pollution and nuisance from solid waste, air and noise.

Statement of the Problem

The challenge of informal settlement is obviously a complex one and there are thus a wide range of issues and contributing factors, many of which overlap. However, misconceptions about informal settlements abound due to many policy makers having limited or no direct experience and understanding of the functionality of informal settlements. Misselhorn (2008) reveals that one factor leading to formation of informal settlements serves as critical holding place where people have initial access point to incoming immigrants and those moving from other parts of the city to experience urban environment. However, this study assesses

standards of housing habitation in selected informal housing in view to determine their level of habitability.

The Concept of Housing Habitability

Housing habitability is the outcome of the interaction between a territory and the uses made of it by its inhabitants, based on housing choices, conditioned by community characters, biophysical conditions of the context, rules and organisational system (Aigbavboa, 2013). Considering "man" who is the occupant of the house for instance, some of his socio-economic characteristics such as marital status, family size, income level and others need to be examined. In addition, the culture of the group to which the occupants belong should be given adequate attention.

In order to evaluate housing habitability, there are several research approaches that can be adopted, all based on "users reaction". Various models such as Onibokun 'Habitability' Model, Integrated Conceptual Model and Housing Adjustment Model were used to explain housing habitability focuses on the resident, socio-physical environment and satisfaction. These housing is more than shelter and looks at the interaction of four main subsystem; tenant (man), shelter/dwelling, environment and institutional management which interact actively to produce the level of satisfaction and the level of satisfaction in turn determines the level of housing needs in a given place (Ihuah 2015).

However , Ogundahunsi and Adejuwon (2014) reveals that what constitute habitability varies according to the ambient circumstance and as such the habitability of a housing at a particular point in time can only be defined meaningfully in the relative terms or sense rather than to the absolute sense.

Elements of Housing Habitability

The need to appreciate the relevance of a habitable housing therefore, requires an understanding of the concept of housing habitability. Informal housing is believed to be an element of urban decay described by lack of housing and services (Misselhorn, 2008). But, Adeleye, Azeez and Yusuff, (2014) stated that getting a definition of quality depends not only on the dwellers and their desires, but also on the product being considered. In essence, habitability is a product of subjective judgment which arises from the overall assessment of the housing as a produt itself. In assessing the habitability of housing, various studies have identified some criteria as relevant elements for habitability evaluation in residential development. Among such is The National Affordable Homes Agency (2008) who acknowledged structure and materials, access, space and security, interior air quality, water supply, sanitary facilities, thermal environment, illumination and electricity, food preparation and refuse disposal, sanitary condition and fire safety as elements of housing habitability.

Fig. 1 Elements of Housing habitability

METHODOLOGY

The study focuses on Akure, the capital city of Ondo State since 1976. The city lies within Latitude 7º15'N and 7º28'N North of the Equator and Longitudes 5º6'E and 5º21'E East of the Greenwich Meridian. The city is witnessing rapid rate of urbanization characterised by high influx of people into the city from towns and villages in the state. This resulted into attendant land use problem, inadequate housing and excessive stress on the available infrastructure in the city. The city also, witnessed immense and uncoordinated growth in size built-up areas, inadequate assess to basic services, substandard housing and unhealthy living condition.

Six (6) informal settlements were randomly selected as sampling size namely: Ipinsa, Owena, Irese, Iju, Itaogbolu and Igoba. The study adopts a cross-sectional study since it is based primarily on interviews, documents, physical observations and administration of Housing Habitability Standard Checks questionnaires (HHSCQ) conducted within a limited time frame. Twenty (20) questionnaires each were administered on residents in each of the Six (6) selected communities amounting to One hundred and twenty (120) HHSCQs. The questionnaires covers Structure and material, Access, Space and security, Interior air quality, Water supply, Sanitary facilities, Thermal environment, Illumination and electricity, Food preparation and refuse disposal, Sanitary condition and Fire safety as the ten (10) standards embedded in Habitability Standard Checklist (HSC)

FINDINGS AND DISCUSSION

Structure and Material

The condition of structure and materials of housing within the study area (see Table 1) is not conducive for safe habitation due to poor quality materials used in the construction of the houses and dilapidated state of the building components. Buildings constructed with traditional mud bricks has an average life span of 50 years (Adeleye, Azeez and Yusuff, 2014) but within the study, 63.5% of houses surveyed are aged above 50 years, 15.6% only have 10 years more to the average years of 50 while 20.9% of the surveyed housing were built within the last 10 years. Owoeye (2013) affirmed that housing habitability depreciates along with the age of the buildings. Therefore, very few of the houses surveyed can be regarded relatively habitable for man. Also, 20.2% rated the external condition of the walls suitable for habitation while 43.4% rated the interior wall condition also unsuitable for habitation. 82.4% of the sampled housing made use of Galvanized Zinc roofing material while 17.6% used Corrugated Fibre board materials. Table 1 shows the level of materials and technology used within the study area.

Access

Table 2 reveals that 90% of the surveyed houses have a type of vehicular access and 10% has no access for vehicles. This shows that the dwellers of houses without vehicular access are having difficulties in moving heavy loads in and out of their residences. Also, the dusty vehicular access available to 36.7% predominantly from Iju and Itaogbolu shows that air quality available for residents within the communities is poor. Majority of the houses surveyed do not have well defined pedestrian access and parking space, therefore many of the houses with either tarred or surface-dressed vehicular access are not equipped with parking space. 55.8% of the dwellers considered their building setbacks inadequate. This situation is consequential of poor habitability condition of the houses.

Table 1 Structure and materials for housing

Variable	Frequency	Percentage
Material used for construction		
a. Walls		
- Clay blocks	45	37.5

Age of buildings		
a. 50 years and above	22	18.3
b. 40 – 49 years	36	30.0
c. 30 – 39 years	13	10.8
d. 20 – 29 years	33	27.5
e. Below 20 years	16	13.3
Total	**120**	**100.0**

Space and Security

Table 3 suggests that 55.8% of the rooms within the study area is congested. The room space that was designed for between 2 – 3 users is occupied by 4 and more users. The situation poses greater threat to the security of life and property of the dwellers. The level of insecurity is aggravated by the absence of necessary building and site security measures. 81.8%, 72.5% and 30.8% respectively are not equipped with vehicular and pedestrian gate, perimeter fence

and burglary-proof frames while 17.5% neither has a security feature. These situations resulted into 72.5% indicating that they have experienced robbery within the last one year.

Table 2 Access to buildings

Interior Air Quality

As shown in Table 4, over 72% respondents are dissatisfied with the quality of air available within their house. 84.2% reveals that their houses are not offering adequate protection against noise emanating from external sources such as automobiles and neighbours. As a result of this, external factors such as hazy weather, dusty road quality and inadequate green landscape are responsible for the poor air quality experienced by the dwellers.

Table 4 Interior air quality in housing

a. Available	19	15.8
b. Not available	101	84.2
Total	**120**	**100.0**

Water Supply

Water supply is regarded as a proxy indicator for weather the sources of water available for the dwellers of housing within the study area is safe. Within the study area, 43.4% and 12.5% rely on open well and water vendors respectively while 29.2% made use of water from borehole and public tap (see Table 5). World Health Organisation (2006) classified open well, stream and water vendors as unimproved sources of water. This connotes that majority of the dwellers of the study area are not having access to safe water for use within the houses. Also, the quality of water available for uses is poor with 73.3% reported that the water they use is cloudy and 68.3% uses water with foul smell. In view of this, 95% had to make use of water treatments such as boiling, water guard, alum, chlorine and water filter.

f. Let it stand and settle	21	17.5
g. No treatment	6	5.0

Sanitary Facilities and Condition

20.0% (24) of respondents made use of flush/pour toilets in their homes, and another 29.2% (35) and 15.0% (18) made use of slab and non-slab pit latrines respectively. 18.3% (22) of respondents also, used bucket/hanging toilets while 17.5% (21) used bush or toilet facilities in near-by house. 61.7% (74) of respondents share toilet facilities with other people and 38.3% (46) made use of their toilets alone. Also, 25.8% (31) of respondents within the study area revealed that children stools are disposed in toilets/latrines, 14.2% (17) disposed children stools into drains. A sanitation facility is considered adequate if it hygienically separates human excreta from human contact. In view of this, the types of technology that are likely to meet this criterion are flush to pipe sewer system and pit latrine with slab (The National Affordable Homes Agency, 2008). Therefore, about half (59) of respondents make use of safe and hygienic toilets and children stools are disposed poorly. This connotes there is great likelihood of faecal contamination within the study area.

Table 6 Sanitary facilities and condition in housing

Variable	Frequency	Percentage
Type of toilet facility		
a. Flush to septic system	24	20.0
b. Pit latrine with slab	35	29.2
c. Pit latrine without slab	18	15.0
d. Bucket/Hanging toilet	22	18.3

Disposal of Children stools		
a. Child use toilet/latrine	31	25.8
b. Put/rinsed into toilet	22	18.3
c. Put/rinsed into drain/ditch	17	14.2
d. Thrown into garbage	26	21.7
e. Buried	17	14.2
f. Left in the open	7	5.8
Total	**120**	**100.0**

Food Preparation and Refuse Disposal

With respect to food preparation and refuse disposal, location of kitchen and availability of store were assessed across the study area. Table 8 revealed that 70.8% (85) of respondents has their kitchen located indoor while 29.2% (35) have kitchen located outside the building. Also, kitchen store is available for 39.2% (47) and not available for 60.8% (73). Concerning waste disposal, 19.2% (23) disposed their waste beside the road, 26.7% (32) gave waste to waste collectors while 22.5% (27) burn their waste. The result in Table 8 depicts that most of the indoor kitchens are not equipped with store. This will result into preparing food under in an environment not hygienic.

Thermal Environment, Illumination and Electricity

Table 7 revealed that 37.5% (45) of respondents feel cold, 8.3% (16) feel hot, 30.0% (36) and 24.1% (29) feel cool and warm. 55.8% (67) rely public power supply only, 37.5% (45) are using generator or solar power to augment for the shortage supply of public power while 6.7% (8) have no access to power supply. Public power is available for 34.2% (41) of respondents within 1 – 6 hours daily while 36.7% (44) have public supply of power for 19 to 24 hours. Also, 59.1% (71) of respondents revealed that the quality of the light is bad while

40.9% (49) have good quality light. In view of this, respondents were generally satisfied with the thermal environment due the 54.1% of respondents feel cool and warm. This connotes that the houses offers satisfying thermal environment to the dwellers. Table 7 revealed that minimum 18-hour power supply is regarded adequate for improved habitability Also, larger population of dwellers within the study area are experiencing inadequate power supply.

Fire Safety

The result of the study (see Table 9) showed that 62.5% (75) has no fire equipment install within their house while 37.5% (45) have fire extinguisher, hose reel or fire alarm install within the house. Also, 60.8% (73) of respondents have emergency exit while 69.2% (83) stored inflammable materials such as petrol within their house and 39.2% (47) have their houses located close to filling station. The implications of these are that one-third of the houses within the study area are not safe for habitation in emergency period and many of the houses are poorly located due to closeness to filling station. Also, many of the dwellers are engaged in the act of storing flammable materials within the house.

a. Near to filling station	47	39.2
b. Far to filling station	73	60.8
Total	**120**	**100.0**

CONCLUSION

Amidst other findings of the study is that there is relationship between level of housing habitability derivable and the satisfactions of the dwellers. The level of housing habitability in the selected informal settlements is not yet beyond remedy. A timely action will definitely forestalls further deterioration of habitability in these areas. A lot of intervention programmes should be put in place to improve the elements of habitability in these areas. Firstly, the governments at all levels should make well informed and targeted policies that are geared towards improving living condition within the areas. Such policies will involve building codes and Settlement development controls to help in planning pattern of developments of the informal settlements.

Also, upgrading of the informal settlements should be considered to improve living condition in the existing informal settlements. The upgrade should be done in the preferred approach informed by the dwellers and should minimize or eliminate relocation. Given that informal settlements afford people spatial access in respect of a range of key issues and given that most are better located relative to prospective relocations destinations, all efforts should be made to maximise densities in the upgrading process by whatever means possible (e.g. reduced level of internal services, more dense housing typologies). In most instances residents will prefer to remain in-situ, even with some compromises such as higher densities, than to be relocated to bigger houses with larger sites which have a distinct locational disadvantage.

ABSTRACT

Climate change, a major challenge globally can have social, economic and environmental impact on the global and/or local climate. In buildings, the increase in external temperature will affect the performance of the building fabric and also energy demand for cooling in a tropical climate like Nigeria. The materials used in the construction of the building fabric will therefore have an impact on the internal environment thus influencing the need for cooling and energy demand. Using secondary data, it is highlighted that incorporating thermal simulation in the design stage of buildings can help mitigate the impact and also adapt buildings in Nigeria to predicted future climate change. It establishes that thermal simulation of a building at design stage through modelling predicts how the building will perform in future, thus allowing the designer to incorporate strategies that will aid the mitigation of and adaptation to climate change. As a result, it is recommended that designers in Nigeria should incorporate thermal simulation in designing to future-proof buildings.

Keywords: Adaptation, Building fabric, Climate change, Energy demand, Mitigation, Nigeria, Thermal simulation

INTRODUCTION

Climate change is causing a change in weather patterns, thus a change on the impact of a local climate of buildings in terms of how the building fabric which is a barrier between the indoor and outdoor environment will perform to help provide a comfortable indoor environment for its inhabitants (Biliyok, 2010). As a result, it is important that in designing buildings, the future impact of climate change and how the building will perform is explored in order to predict the thermal performance of the building fabric and also the energy demand for cooling and/or heating as the case may be. This will enable the designer to test and adopt measures which will aid in future-proofing the building against identified impacts of climate change.

A number of works have been carried out globally using thermal simulation by researchers to test the impact of climate change on buildings taking into consideration mainly the building fabric and energy demand of occupants. Unfortunately, little or nothing has been done on predicting the impact of climate change on the building fabric and energy demand of buildings in Nigeria using thermal simulation.

This study therefore aims to highlight the importance of thermal simulation in adapting buildings to climate change and also in mitigating the contribution of buildings in Nigeria to climate change using existing works which show the importance of thermal simulation in future-proofing buildings globally.

LITERATURE REVIEW

Climate Change in Nigeria

Climate change is a gradual process that is anticipated to become increasingly noticeable over the next 50 - 100 years. In recent years, climate change has become a very important

Shamang, K. J. & Makarfi, U. (2016). Importance of Incorporating Thermal Simulation in Designing Buildings to Mitigate and Adapt to Climate Change in Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 296-303

issue globally as predicted future climate is anticipated to have an adverse effect on man and his environment (Biliyok, 2010). 'Climate change and weather are intertwined and it is the statistics of changes in weather over time that identifies climate change' (Solomon et al, 2007). The term climate change usually refers to changes that have occurred since the early 1900s as a result of natural and human factors (UK Climate Impact Program, 2008). Greenhouse gases, released into the atmosphere as a result of human activities, allow the Sun's rays to reach the Earth's surface but impede the heat they create from escaping back into space and absorb energy that is radiated from the Earth's surface. The Sun's rays which reaches Earth and the absorption of energy as a result of greenhouse gases causes the warming of the atmosphere, thereby increases temperatures globally – 'global warming' (UK Climate Impact Program, 2008). It has been argued that extreme events that currently have return frequencies of 1 in 100years could have return frequencies of 1 in 5 or 1 in 10 years by prevailing climate change conditions (Ezeabasili and Okonkwo, 2013). As the climate changes, the probabilities of certain types of weather events are affected.

In Nigeria, climate change will bring about extreme climate conditions such as high wind, heavy rainfall, heat and cold which can result in wide-ranging scenarios such as tropical storms, floods, landslides, droughts and sea-level rise (BNRCC, 2015). Extremes of heat tend to occur more often, although their frequency and intensity change as climate changes. Other anticipated consequences of climate change for Nigerian cities include fewer periods of extreme cold; increased frequency of air and water pollution, rising and changes in the timing, frequency and severity of urban flooding associated with it (Ezeabasili & Okonkwo, 2013).

Thermal simulation

'Modeling can help designers to ensure good internal conditions can be achieved under all foreseeable operating conditions' (CIBSE, 1998); through the prediction and analysis of the thermal performance of a building which affects the thermal comfort of building occupants. To better understand the thermal performance of a building, thermal simulation can be used (Biliyok, 2010). A number of thermal simulation computer based tools exist that may be used to predict the performance of buildings and to calculate energy use. These tools are created based on a mathematical model, 'constructed to represent each possible energy flow path and their interactions' (Clarke, 2001). Thermal simulation of a building through modeling provides an important tool for analysing not only the performance of the building envelope but also passive and active systems for heating and cooling used to attain occupant comfort (CIBSE, 1998). The external weather and climate where the building is located is important and should be considered in thermal modeling because it is responsible for the solar heat gain, incoming ventilation air temperature, and conductive and convective heat exchanges through the building envelope (Belcher et al, 2005).

The thermal performance of a building can be analysed as a steady state or as a dynamic state. The steady state assumes that the temperature outside is constant, the temperature inside is constant and hence the heat loss is constant. It, however, does not show how much energy the building is likely to consume during a year or how comfortable the occupants are likely to be as it does not incorporate the fluctuating outside temperature and activities within the building which affect heat loss/gain in its calculation. The dynamic state on the other hand takes into account the fluctuating outside temperature, the building thermal mass, and fluctuating heat loss/gain from the building including activities within the building. It also considers how much energy the building is likely to

consume during a year and how comfortable the occupants are likely to be. But to quantify these interactions the dynamic state requires weather data to carry out thermal simulation (Clarke, 2001). Weather data is an essential variable required in thermal building simulation that is unique and depending on the location of the building (Biliyok, 2010). Thus, in future-proofing buildings to the impact of climate change, it is recommended that dynamic state thermal simulation is used.

The use of thermal simulation in the design of buildings

It is evident that a changing climate and its implications will need to be reflected in future building design and refurbishment in form, material choice, thermal mass and building services; thus, at the planning stage building performance assessment can deliver valuable information on the viability of a design approach (Jentsch et al, 2008). Thermal simulation can be used to test designs where measures are put in place for thermal comfort to see if the measures are adequate for the predicted future climate change. This can be done by using weather data for the predicted climate change to run simulation.

There are a range of simulation programs available which use the dynamic state technique. (Crawley et al, 2005) described the capabilities of different simulation programs in their study which analyses what the different programs can do. This analysis can help building designers interested in answering specific questions select the appropriate simulation program. Dynamic state thermal simulation is identified as the appropriate simulation method that can be used to check thermal performance and energy demand of a building in present and future climates; based on the weather file used to run simulation.

In carrying out thermal simulation using the dynamic state technique, weather data including the fluctuating external temperature of the area where the particular building in question is located, the materials used in constructing the building fabric and activities within the building that affect heat loss/gain which in turn affect the energy consumption of the building over a period of a year are required. Results from such thermal simulation will therefore highlight how a particular building will perform in terms of the energy demand and the building fabric thermal performance for specific weather files. Thus where the weather files for present and future climatic condition is used, the behaviour of such a building at the time the building is designed and constructed and in future when the climate changes can be obtained. This can help the designer in choosing materials for the building fabric which are appropriate for present and future climate.

The thermal performance of a building depends on a large number of factors. Including:

i. Design variables (geometrical dimensions of building elements such as walls, roof and windows, orientation, shading devices)
ii. Material properties (such as density, specific heat, thermal conductivity, transmissivity)
iii. Weather data (such as solar radiation, ambient temperature, wind speed, humidity)
iv. A building's usage data (such as internal gains due to occupants, lighting and equipment, air exchanges).

Various factors which affect the heat balance of a building are presented in Fig. 2.1. The influence of these factors on the performance of a building can be studied using different techniques for estimating the thermal performance of buildings. Dynamic state thermal simulation technique takes into consideration these factors as against steady state. Dynamic thermal simulation can estimate the thermal performance and energy demand of different designs of a building for a given environmental condition (Clark, 2001).

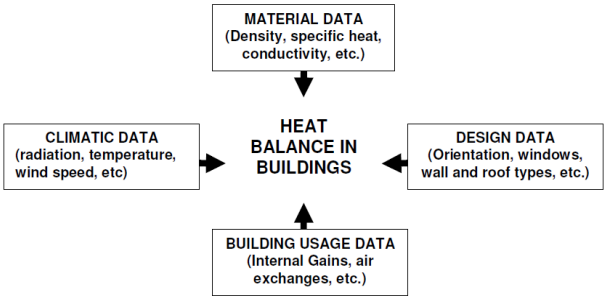

Figure 2.1 Thermal Simulation flow paths of a building (Source: mnre.gov.in/solar-energy/ch4.pdf)

Correct site orientation of buildings for thermal efficiency must pay attention to: solar radiation and resultant heat load; direction and force of the wind; the topography of the site. In a tropical climate like Nigeria, protection from the sun is always necessary as the intensity, duration and the angle of incidence of solar radiation to a particular surface are the main determinant necessary for comfort. Thus where suitable sun shading devices are provided; they minimise the heat load and consequently reduce air conditioning, provide cooler indoor environment, ensure greater thermal comfort of the occupants and increase productive efforts (Oni and Akingbohungbe, 2013). These design measures can be tested to identify one which is suitable for present and future climatic condition using thermal simulation.

FINDINGS AND DISCUSSIONS

The Impact of Climate Change on a Building Fabric

The external fabric of a building is the first line of defence against climate parameters which include; temperature, wind, humidity, solar radiation, precipitation and atmospheric conditions (Gaterell et al, 2005). As the change in climate has a direct effect on the weather conditions of an area, buildings that are provided to create shelter for people against the external weather will have to be able to withstand the change in weather patterns to perform their primary function.

The main effects of wind on a building are those of force, heat loss and rain penetration. The direction of the wind on a building affects both the structural design and the thermal design (McMullan, 2007), showing that changes in wind speed and/or direction as a result of climate change may affect the structural and thermal performance of buildings. Solar effects on a building have to do with the sun position in the sky and the angle made with the building surfaces; the quantity of radiant energy received upon the ground or other surfaces; and obstructions and reflections caused by clouds, landscape features and other buildings. For any position of the sun, the angle that the solar radiation makes with the wall or roof of a building can be predicted by geometry. This angle of incidence has a large effect as intensity is at a maximum when the radiation strikes a surface at right angle (McMullan, 2007). These can be analysed using thermal simulation.

The most important consequence of climate change on the built environment concerns the impact of higher temperatures on the thermal performance of buildings which does not only pose a risk of illness and mortality to building occupants but may increase the need for cooling (Gaterell et al, 2005). A major impact of this consequence will be a greater risk of overheating in free-running naturally ventilated buildings, especially those which are mostly free-running; making them particularly vulnerable to the impacts of extreme high temperatures (Hacker et al, 2008).

Indoor temperatures are closely related to external temperature as heat flows easily from the hot exterior to the interior through conduction, convection and radiation between the external environment and the building fabric (Biliyok, 2010). Thus when external temperatures are high, internal temperatures become high, this encourages the adoption of measures such as mechanical cooling to attain thermal comfort for occupants.

The Impact of Climate Change on the Energy Demand of a Building

Operational energy is the most energy consumed by buildings in use and includes energy used for heating, cooling, lighting, ventilation and other activities. Operational energy use is complex and depends on the location, design and construction of a building, the specification of heating and cooling systems and their controls, the efficiency of appliances and the life style of the occupants (Yohanis et al, 2008). Energy use is a consequence of the services provided to occupants to obtain an acceptable indoor environment for human activities in a building. Space conditioning (heating and cooling), lighting and ventilation are the three main energy related building services that affect energy use in buildings (Omer, 2008). In a climate like Nigeria, energy demand of buildings may include the aforementioned except heating, with cooling where used taking the bulk.

Higher external temperatures, one of the consequences of climate change in Nigeria, will increase the demand for electricity, which is the dominant source of energy for air conditioning. An increase in air conditioning in order to keep buildings at comfortable indoor temperatures when external temperatures are high will therefore be experienced as a result of climate change. This will in turn bring about an increase in CO_2 (a greenhouse gas) emissions due to the increase in energy demand for cooling.

Mitigating Climate Change Using Thermal Simulation in Designing Buildings

The rate at which climate change will occur in future depends on how much greenhouse gas emissions grow and how sensitive the climate system is to these emissions (The Hadley Centre, 2005). The atmospheric content of the climate system therefore contributes to the characterisation of the climate and changes that occur (Solomon et al, 2007). The role of greenhouse gases on global warming was further validated in 2007 by the Intergovernmental Panel on Climate Change (IPCC), the world's most authoritative body on climate change. The IPCC concluded that most of the observed increase in global average temperatures since the mid-20th century is very likely due to the observed increase in anthropogenic (man-made) greenhouse gas concentrations (UK Climate Impact Program, 2008).

Therefore mitigating the human factor will have to involve the reduction of greenhouse gases such as carbon dioxide which has been identified as a major contributor to global warming as shown in Figure 2.3.

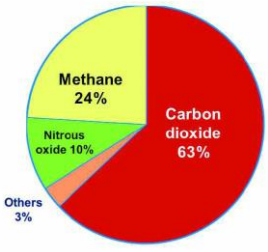

Figure 2.2 Percentage of Greenhouse gases that contribute to global warming (Source: Hadley Centre, 2005)

Mitigation means that measures must be taken to reduce rate and magnitude of climate change caused by human activities. According to IPCC, the mitigation options includes

reduction in burning of fossil fuels and reduction of greenhouse gases and soot from the energy sector; reduction in burning of deforestation ;increase in reforestation and afforestation; modification of agricultural practices to reduce emissions of greenhouse gases and build up soil carbon (Olaniyi et el, 2013).

Since mitigation includes reduction in burning fossil fuels and greenhouse gases emission from the energy sector and energy is used in the construction and operation of buildings, it is necessary to employ measures which encourage the reduction of energy from the building sector. This is important because it is estimated that at present, buildings contribute as much as one third of total global annual greenhouse gas emissions, primarily through the use of fossil fuel during their operational phase and consumes up to 40% of all energy. This includes energy used in the production and transportation of materials to building construction sites, as well as the energy used to operate buildings. Given the massive growth in new construction in economies in transition, and the inefficiencies of existing building stock worldwide, if nothing is done, greenhouse gas emissions from buildings will more than double in the next few years (Oni and Akingbohungbe, 2013). Buildings can contribute in mitigating climate change by the reduction of the energy and demand on resources associated with construction and operation of buildings. This can be achieved where thermally efficient building materials are used in construction to reduce or eliminate the need for mechanical cooling in a climate like Nigeria where external temperatures are expected to become higher as a result of climate change.

Thermal simulation can be used to check how efficient measures taken to address a good design for thermal comfort in the Nigerian climate which should take into consideration; the orientation of the building with due regard to solar incidence angle, direction and force of wind and the topography of the site; cross ventilation within the habitable rooms; solar control and appropriate shading techniques; use of appropriate properties of materials like heat storage and insulation; appropriate and correct use of vegetation and air humidification or evaporative cooling (Oni and Akingbohungbe, 2013). Using thermal simulation enables the designer to choose the best option for the present and also the future climate when changes occur. This will help in mitigating climate change as it will encourage the use of thermally efficient materials and reduce or eliminate the need for energy for cooling thereby reducing the burning of fossil fuels and the emission of greenhouse gases which contribute in bringing about climate change.

Adapting Buildings to Climate Change Using Thermal Simulation in Designing

Adaptation to climate change includes responses that may be used to reduce vulnerability of buildings (Solomon et al, 2007). The study of buildings and the understanding of the effects of weather patterns in existing climates can help buildings to cope with extreme conditions caused by climate change (Ezeabasili & Okonkwo, 2013). Thermal simulation is a tool which can be used to undertake such study. Adaptive strategies in building design involve incorporating flexibility into the design to allow for predicted climate change. It is important that in designing buildings research of localized risk of climate change is undertaken to prepare buildings for predicted hazards as identified by (BNRCC, 2015).

The considerations for a good design for thermal comfort in Nigeria as incorporated into a design need to be analysed under predicted future climate to assess if measures taken can provide sufficient protection against climate change impacts anticipated for the lifetime of the building to reduce the vulnerability of the building to such changes. The internal temperature in buildings will be higher leading to overheating as heat is transferred from the external to the internal environment; thus reducing heat gain from solar radiation is

therefore considered a priority in adapting buildings in Nigeria to climate change. Again, these can be analysed using thermal simulation to select the best possible option which can reduce or eliminate the vulnerability of the building and its occupant to the impact of high temperatures which can be detrimental to the health of the building occupants.

CONCLUSION

The treat of climate change on the environment is imminent. As a result, every possible avenue to reduce or curb this treat is important. The construction and operation of buildings have been identified as contributors to climate change; buildings are also at risk as a result of climate change. It is therefore paramount that measures are taken to help reduce and/or eliminate the contribution of buildings to climate change (mitigation) and also reduce and/or eliminate the impact of climate change on buildings (adaptation).

This work has identified how buildings contribute to climate change and also some of the impacts of climate change on buildings. It has highlighted that using thermal simulation in the early stage of the design of buildings; the designer can test how the building may perform in future as the climate changes using predicted future climate weather data. Results gotten by running simulations can inform a designer's choice of a design that consumes minimum energy at present and future climate. This also aids the designer's use of adequate design variables and building materials that will make it possible for the building fabric to adapt with the change in climate. The designer is also able to predict and reduce the future energy demand of the building; enabling the incorporation of measures which will reduce such energy loads, thus mitigating the contribution of the building to climate change. Thermal calculations also help to select appropriate retrofits for existing buildings from the viewpoint of energy conservation. Thus, by integrating the simulation of thermal performance of a building with its architectural design, one can achieve an energy efficient building that can adapt to climate change.

Further work need to be undertaken to identify and test the thermal simulation tools that can be used by designers in Nigeria.

ABSTRACT

Over the years, professionals in the built environment have increased their concern about environmental protection in order to achieve a more sustainable built environment. In line with this, an architect is required to help achieve a sustainable environment through reasonable incorporation of sustainable principles into the design of buildings, evaluate and reduce their environmental impacts by understanding the life cycle performance of their proposed buildings. Life cycle assessment evaluates the environmental impacts of building components and materials. This study reviewed related published literatures to give an insight into life cycle assessment of buildings and its relevance to sustainable architecture with a view of incorporating it into architectural practice in Nigeria. This paper noted that adequate building performance assessment throughout the building process enhance health, safety, quality of life and sustainable environment. This paper finally highlights effective strategies which when adopted would improve the architects' decision making in achieving sustainable built environment.

Keywords: Architectural practice, built environment, life cycle assessment, sustainable architecture, sustainable building

Introduction

Architecture is concerned with the ways in which the built environment is planned, designed, used, furnished, landscaped and maintained (United Nations Educational, Scientific and Cultural Organization/International Union of Architects, 2011) . Architects are saddled with the responsibilities of preserving, improving and creating a high quality built environment (Chansomsak and Vale, 2009). According to Odebiyi, Subramania and Braimoh (2010), the building sector consumes more than one third of the world's energy and resources. This affects the built environment and is one of man's major contributions to the depletion of the natural resources and a major cause of environmental issues such as pollution, solid waste generation and global warming (Ashraf, 2011). The architects' responsibility, is not only the health and safety of end users of their products, but also extends to the effect of their creations on the environment; hence this informed the adoption of sustainable architecture that describes energy and environmentally conscious approach to the design of the built environment. A sustainable building is an outcome of a design that focuses on increasing the efficiency of resource use, energy, water, and materials-while reducing building impacts on human health and the environment during the life-cycle of building (Frej, 2005; Sirija, 2013).

Architects henceforth need to improve their knowledge about strategies for sustainable design. The knowledge of life cycle assessment (LCA) of buildings allows the architect to carefully consider building materials or components with the greatest environmental impacts, hence this improves the architect decisions as he thinks broadly about picking the right material or component, optimizing and selecting the most preferred one. Tsanova and Galabov (2013) identified Life Cycle Assessment (LCA) as one of the most functional assessment tools which considers the building along with its materials and components, from their extraction, manufacture and transport, to their use, reuse, recycling and disposal. It reinforces the architects' decisions and provides answers to numerous questions that arise during the design and construction of a green building (Bayer, Gamble, Gentry and Joshi,

Oladokun, O. S. & Odekunle, O. O. (2016). Integrating Life Cycle Assessment into Architectural Practice in Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 304-310

2010). Life Cycle Assessment (LCA) provides design guidance or feedback on how well a given design decision is working.

Furthermore, the importance of considering the life cycle impact of a building has been recognised as a way to increase profitability and engender sustainability (Finnegan, Ashall, Brady, Brennan, Dunne, Gammon, King, Turley, 2013). This study therefore looks into incorporating life cycle assessment technique/tool into Nigerian architectural practice to enhance delivery of building projects with good quality and minimal environmental impact for more sustainable environment.

LITERATURE REVIEW

Sustainability in Architecture

According to Ray-Jones (2000) sustainable architecture is a thoughtful and well-considered use of the energy systems to make a building more conducive for human use and comfort without generating pollutants or borrowing earth's resources meant for future generations. The use of environmentally conscious approaches and guidelines in building design and planning of the built environment has become expedient in order to achieve sustainability as the effect of climate change has become a serious problem facing humanity across the globe (Smith, 2010).

The architect plays a vital role in the quest of creating a climate resilient environment using design actions and guidelines. Kim (1998) and Haines(2010), noted that "careful selection of environmentally sustainable building materials is the easiest way for architects to begin incorporating sustainable design principles in building. Kim(1998), identified life-cycle design as one of the three principles of sustainable architecture which depict a process where the impact of building processes on the environment are analyzed, before during and after building. Moreover, architects must not only be concerned with the appearance of buildings but also be familiar with how they work, by increasing their understanding of the environmental performance of buildings, materials, systems and construction.

Life Cycle Assessment

LCA is a tool for measuring the environmental performance of products over their life cycle, from "cradle" (where the raw materials are extracted) to "grave" (where the product is finally disposed-off) and allows focusing effort to resolve them (Schenck, 2005). It is applied methodologically to build a quantitative inventory of environmental burdens or releases, evaluate their potential impacts, and consider alternatives to interpret the results or improve environmental performance (Fava, 2005). The use of LCA for buildings requires a set of guiding principles, which are based on each building design, performances of its components and on the environmental profile of the building components during production, service life and end of life (Campioli and Lavagna, 2007). Life Cycle Assessment (LCA) allows architects and other building professionals to understand energy use and other environmental impacts associated with all life cycle phases of the building. Khasreen, Banfill,and Menzies (2007), suggested that LCA should be part of the design process as a decision making support tool, to be used by the designers of the building in parallel with other aspects like cost, and functional requirements to achieve the optimum performance of the building.

As stated in ISO 14.040, LCA is composed of four different phases, which are:

i. **Goal and Scope definition:** This phase defines the preliminary concern of the LCA study in terms of its objectives, scope and depth of the assessment to be performed. The phase includes the definition and assessment of the products and materials, the determination of the functional unit and the depth of assessment. In addition the

phase deals with identifying the types of analysis, impact categories to be evaluated, the methodologies of impact assessment and data requirements.

ii. **Inventory Analysis:** This phase involves data collection and calculation that is quantifying of all materials, energy and emissions are considered as inputs and outputs from the studied system during its life cycle. In this step, the energy and raw materials used and the emissions to environment are quantified for each step in the process, then combined in the process flow chart and relates back to the functional unit. Thus, products and processes can be compared and evaluated using Life Cycle Inventory (LCI) results. The quality of life-cycle assessment is directly related to the quality of inventory data, its correctness and its concordance with the goal of the study.

iii. **Impact Assessment:** In this phase, inputs and outputs are related to actual (or assumed) impacts based on a series of environmental indicators, such as global warming potential, human toxicity, and resource depletion to makes the results of an LCA easier to communicate and comprehend. In other words, data from the inventory analysis is attributed to appropriate impact category defined in the goal and scope of the LCA .Categories are generally divided among three broad topics of resource use, human health, and ecological consequences.

iv. **Interpretation:** The purpose of this is to analyze results obtained at the inventory and/or impact assessment steps, and includes conclusions and recommendations on the findings of the preceding phases of the LCA or LCI study. LCA results are reported in the most informative way possible, and the need and opportunities to reduce the impact of the product(s) or service(s) on the environment are systematically evaluated. LCA can be an iterative process; therefore, the interpretation of the LCA can lead to changes in the proposed design, which then leads back to inventory analysis in the process.

Khasreen et al, (2007) identified two levels at which LCA can be applied to building: whole process of building, and building material and component combination (BMCC). In this case it is very important to recognize the component impact equivalent according to the functional unit of the building. The most important aspect of LCA is the energy consumed by a building, which are "Operational" and 'Embodied energy' (Tsanova and Galabov, 2013). Operational energy is the projected energy use within a building as it operates over a typical meteorological year while embodied energy comes from the materials manufacturing and construction phases of the building project. The most commonly studied impacts when LCAs were applied to whole building were global warming, acidification, eutrophication, and ozone depletion, which are present in most studies (Khasreen et al, 2007). The ATHENA® Impact Estimator, ATHENA® EcoCalculator, BEES®, EIO-LCA are the Four commonly used LCA tools in the U.S. EQUER, LCAid™ Eco-Quantun,LISA, Envest, LCAit, PEMS, TEAM™, Umberto, SIB LCA, Boustea, SimaPro , GaBi are used in other countries (Bayer, Gamble, Gentry and Joshi, 2010).

LCA and Architectural Practice

LCA is an attractive tool used in enhancing sustainability in architecture which supports evaluation of environmental performance, green labeling, compare the environmental implications of different materials or components, select environmentally preferable materials or components, and identifies cost-effective green materials and products. When carrying out a building design, it will assist the project team to establish environmental goals for the design and ensures that the goals are met through decisions made by the project team. Adoption of LCA in architectural practice of a firm could give the firm an edge over others and increase the market value of the firm (Bayer, Gamble, Gentry and Joshi, 2010). Although

the LCA method may reduce total resource use, it is cost and time intensive and also has problems regarding interpretation of results (Malmqvist et al., 2011). In addition, lack of data inventory and benchmarks established by government authorities because of little standardization within the building sector that can be used for comparisons are also limitations to the use of LCA. However, investment in LCA may be viewed as accumulative as it provides information that adds to the overall body of knowledge and reduces the need for additional testing. Nevertheless these studies are very important for advancing sustainable development.

Implementation Strategies for LCA in Architectural Practice

Integrative Design Approach

During the design process, stakeholders of the project combine their respective strengths and technical expertise to produce buildings with long life spans. In order to successfully undertake a LCA, it is essential to promote an integrative design process as it gives opportunity for stakeholders to discuss, brainstorm, test (via LCA tools), and refine their design ideas . Each of the stakeholder occupies distinct and essential roles. For example, the Architects have the opportunity to take ownership of material sustainability and, more importantly, high-level building design while Structural Engineers are responsible for producing structural systems that are optimized in terms of design and material. General contractors ensure that optimized designs are brought into fruition, while minimizing impacts and emissions from the construction process. In particular, the architect and structural engineer for the project should communicate closely to deliver sustainability on the system level.

Building Design phases

The potentials of optimizing a project is higher in early phases, therefore improvement of the building's sustainability performance must begin in the design stage (Rahim, Muzaffar, Mohd Yusoff, Zainon and Wang, 2014). Most of the building's material, energy, and environmental loadings are likely to be committed during the design phase, therefore the earlier LCA is brought into the building process, the greater its potential benefit to the project.

Design stage I - phase 1 (Commitment)

During this stage, it is essential to appoint other consultants with good knowledge of LCA as this will help to define the environmental goals of a project. Challenges, opportunities and project cost implications emanating from the brief and site analysis could serve as basis for conducting LCA. Conducting the LCA of the whole-building in this phase can also assist the project team with high-level decisions regarding the building footprint, structural systems, and assembly types. LCA encourages project teams to think about the intended lifespan of the building and the system durability necessary to support this. LCA can help the project team to quantify these relative impacts and, ultimately, choose the system that better aligns with the project goals.

Phase II (Concept Design)

This phase focus on the technical and functional characteristics of proposed project, estimated cost in relation to budget and considers inputs of other consultant and specialists. Hence it is essential to evaluate several systems alternatives to meet the defined environmental goal of the project. LCA can help project teams optimize structural systems to use less material by selecting the most environmental friendly option from among those available. LCA can also guide decision making regarding building assemblies, by considering both the type and quantity of material involved. LCA encourages project teams to refine their design in light of environmental impacts, bringing considerations of modular construction

and prefabrication into the discussion. Energy conservation measures can be assessed for their environmental burdens and an informed decision can be facilitated by the use of LCA.

Design Stage 2 Phase III (coordinated detailed design)

At this phase, the project team is ready to select specific products to be used on the project site, including lighting, heating, ventilation and air conditioning systems, and material finishes. LCA can help evaluate the life-long impacts of these components and compares the pros and cons of different products of a particular component selected. The design team can then consider the best product that meets the environmental goal of the project.

Table 1: Application of LCA in scope of Standard Architectural Services

Design stage I		Design stage II
Phase 1 (commitment)	Phase 2 (concept design)	Phase 3 (coordinated detailed design
i. Procedure to meet his clients requirement	**i. The technical and functional characteristics of proposed projects**	**i. Detailed site plan and location of all site structures**
ii. Constraints and challenges in meeting his requirements	**ii. The estimated cost in relation to budget**	**ii. Graphically define the construction of the building**
iii. The need for the appointment of other consultants	iii. The anticipate project programme	**iii. Spatially coordinated the design by other consultants and specialists**
iv. Selections of procurement method	iv. **The inputs of other consultant and specialists**.	**iv. Review the design with relevant authorities**
v. Challenges, opportunities and project cost implications emanating from the site analysis		v. Submit project for planning approvals

(Activities in "**bold**" indicate those where input from and LCA is clearly relevant.)

Source: NIA/ARCON conditions of engagement, charges and consultancy agreement for professional architecture and project manager services

The establishment of attractive remuneration will lead the path of integration of LCA in building design and promote its use by architects. The new conditions of engagement which is the approved document for remunerating the architect based on hourly rate should be enforced so that the architect will not only base their charges on the cost of the building but also assessing its life cycle impact on the environment.

RECOMMENDATIONS

Fundamental Research

Significant collaborative research is needed to establish detailed, comprehensive and robust data to support environmental impact and sustainability assessments of buildings. The building research and standards of the Nigerian Institute of Architects' should undertake fundamental research into typical buildings with various levels of environmental friendliness; however, it could provide useful indicators or benchmarks of the sensitivity of various technical strategies to the overall performance of the building. There is a need to produce accurate local datasets with the possibility to convert their results to an internationally comparable form. The research institutes should keep informing architects about current developments in sustainability. Policy or legislation that will encourage prospective clients to use sustainable design tools need to be enacted by encouraging standardization of building components in Nigeria in line with the global trend as canvassed by the International Standard Organization (ISO) to promote environmental impact reduction. The professional bodies should also examine incorporation of energy tools into the building code.

Education and Training

A designed frame work for incorporating LCA teaching into schools of architecture to further enhance Sustainability Education should be developed. This will avail architecture students the knowledge and skills required to apply sustainability concern into their everyday practice to enable them estimates the embodied and operational energy of buildings in various regional and size categories, based on data from both real and idealized structures.

Architects training through the Continuing Professional Development Program (CPDP) of the Nigeria Institute of Architects (NIA) could serve as a platform for discussions and collaboration for the exchange of ideas and information promotion of sustainable building practices.

Conclusion

The stake holders within the built environment are to ensure that quality buildings have low environmental impact on the environment with the aim of meeting the need of the present users and also be assets to be future generation. The institute and statutory body guiding the practice of architecture in Nigeria have embraced auspicious targets for combating climate change potentials of buildings via its architect colloquium and Archi-built programs clamouring for sustainable built environment. In view of this, keeping up with trends, technologies, challenges, and policies requires the acquisition of knowledge. This study has reviewed LCA and outlined strategies for it implementation into architectural practice in Nigeria. Despite the limitations to the use of LCA; cost, time intensive, lack of data and bench marks, it is a potential tool to make a strong contribution to the goal of sustainable development. The study identified integrative design approach and incorporation of LCA into scope of standard architectural practice in Nigeria as strategies for implementing LCA. The study further recommends that fundamental research should be undertaken by building research and standards of Nigerian Institute of Architects to provide useful indicators or benchmarks. Training of architects and integration LCA into curriculum of architectural schools are also important to incorporating LCA.

ABSTRACT

The availability of healthcare facilities in a nation contributes to the wellbeing of the citizens and in turn translates to economic development of the nation. Therefore, it is imperative to ensure that healthcare projects are successfully completed according to plan and within the scope of design. To this end, an evaluation of the Critical Success Factors (CSFs) for delivering healthcare projects successfully, using Ondo State, Nigeria as the study area is investigated in this study. The construction industry professionals practicing in the study area that have been directly or indirectly involved in healthcare projects delivery were sampled with the use of questionnaire survey. The data obtained from the questionnaire survey were analyzed using mean score ranking, thereafter, the results were presented in tables. It is evident that project managers' leadership skills, site managers' management skills and collaboration/cooperation between project participants are the three most important CSFs that influence the successful delivery of healthcare projects in Ondo State. These findings provide an insight into healthcare project delivery CSFs that will serve as a guide to construction industry professionals currently engaged or will be involved in the future construction of healthcare facilities.

Keywords: Critical success factors, healthcare projects, construction industry professionals, Ondo State, Nigeria

INTRODUCTION

Project construction involves different parties as well as different inputs. In most project construction, all the project team members determine the three common project targets of quality, cost and time but there has not been a universal measure of project success (Chan et al., 2005). The dynamic nature of the construction environment which is characterized with some level of uncertainties (Walker, 2015) has led to numerous efforts into examining the factors that ensure the success of a construction project. However, managing healthcare projects requires special attention due to its peculiar nature (Chan et al., 2003). Studies on the management of healthcare projects have rarely been conducted in this part of the world, especially in Nigeria. Most of the previous studies were based on the situation in some developed nations. While Leonard (2004) looked into the Critical Success Factors (CSFs) relating to healthcare's adoption of new technology in general, Chan (2003) gave an assessment of the CSFs in delivering healthcare projects in Hong Kong.

Healthcare projects are specialized buildings equipped with up-to-date mechanical and electrical equipment in which medical care is been provided to the public (Chan et al., 2003). According to Lam et al. (1997a), the characteristics of a healthcare project include complexity of design, multiple end-users, many participants, requires state-of-the-art technology and tight time schedule and budgets. The outbreak of diseases in Nigeria (WHO Ebola Response Team, 2014), of which Ondo state is not exempted echoes the need for an efficient healthcare service that can only be delivered in a modern healthcare building. Since the economic development of a nation is hinged on improved health conditions of the citizens (Suhrcke et al., 2006), it is therefore, expedient to investigate the CSFs that will ensure

Oladinrin, O. T.; Oke, A. E.; Abidoye, B. R. & Koleowo, A. N. (2016). Assessment of the Critical Success Factors for Healthcare Project Delivery in Ondo State, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 311-318

successful completion of healthcare projects in Ondo state due to significant development in health system by the current administration.

LITERATURE REVIEW

Increased advancement in technology has created a dynamic construction environment, making construction projects much more complex and difficult. Similar scenario affects the delivery of healthcare projects (Chan, 2000). This is because hospitals provide different specialized but necessary facilities and services for people in a society (Chan and Chan, 1999). In providing an efficient and effective medical care and operation to the public, hospitals are highly serviced with up-to-date medical equipment, electrical and mechanical installation. Such projects require extraordinary considerations of special functions, medical techniques being employed and the social and economic conditions prevailing at the time (Lam et al., 1997a; Chan et al., 2003). Hence, it is imperative to study the challenges involved in construction projects delivery which may also affect healthcare projects as shown in Table 1.

Table 1: *Challenges involved in healthcare project*

Factors	Source
Lack of up-to-date technology	Chan et al. (2003)
Limited incorporation of new technique	Lam et al. (1997a)
Highly complicated building services	Chan et al. (2003); Chinowsky et al. (2009)
High risk of project delay	Kolhatkar and Dutta (2014)
Frequent changes were demanded by multi-head clients	Lam et al. (1997b)
Insufficient cooperation between various project participants	Wilkins and Smith (1996)
Tight time schedule	Chan et al. (2003)
High level of rework required for achieving the specification	Lam et al. (1997b)
Facing great pressure by general public and client	Chan et al. (2003)
Large number of claims involved	Gibb (1995)
Difficulty in dealing with large number of professionals	Chan et al. (2003)
Inadequate exchange of knowledge and skills between parties	Lam et al. (1997b)
Exposure to litigation	Chinowsky et al. (2009)
Productivity of workmen is comparatively low	Chan et al. (2004)

The concept and definition of project success remains ambiguous to many construction professionals, however, the study of project success and CSFs provides a course for understanding and thereby improving the effectiveness of construction projects (Babu, 2015). The need to identify CSFs is particularly acute in the provision of major healthcare projects due to their complexity, long design and construction periods, ongoing developments in healthcare planning and technology, and a need for a highly accountable approach to procurement by health authorities (Chan et al., 2003). A comprehensive literature review about CSFs for construction project delivery was conducted as presented in Table 2.

RESEARCH METHODOLOGY

The present study adopted the survey research approach to gain insight into the CSFs that influence the successful completion of healthcare projects in Nigeria. Easterbrook et al. (2008) posited that when data is collected from a study population in a study area, quantitative research approach is most appropriate in order to focus on the established factors from a larger spectrum. Hence, quantitative approach was adopted to elicit data from the targeted respondents in the study area.

The systematic literature review conducted revealed a total of 14 factors that pose as challenges to healthcare project delivery. At the same time, 20 CSFs that influence healthcare project delivery were retrieved from literature review. These factors were used to design a questionnaire that was administered on construction industry professionals that have been involved in healthcare project delivery in the study area. The questionnaire was divided into three sections. The first section contained questions that pertain to the professionals' demographic characteristics. In the other two sections, the challenging factors and CSFs were presented, respectively and the professionals were asked to rank the importance of each factor

based on a five point Likert-scale on a scale of 1-5, representing highly insignificant - high significant, respectively.

Table 2: *Critical success factors for construction project delivery*

Factors	Source
Leadership skill for project manager	Müller and Turner (2007); Fisher (2011)
Management skill of site managers	Pant and Baroudi (2008)
Collaboration of project participants	Larson (1997); Suprapto et al. (2015)
Supervision of workmen	Oloyede et al. (2010)
Nature of project	Turner (2006)
Planning effort	Hamilton and Gibson Jr (1996)
Location of Project	Cheng and Li (2004)
Technological advancement	Babu (2015); Chan et al. (2003)
Political condition	Abraham and Chinowsky (2003)
Suitability of equipment	Ng et al. (2009)
Tendering method	Tiong (1996)
Quality, health and safety program	Datta (2003)
Size of project	Babu (2015)
Site conditions	Akintoye et al. (2000)
Timely payment to sub-contractors	Ng and Tang (2010)
Procurement method	Chan et al. (2003); Oladirin et al. (2013)
Construction Method adopted	Chan and Chan (2004)
Complexity of project	Baccarini (1996)
Client's erratic changes	Kaliba et al. (2009)
Formal dispute resolution process	Fenn et al. (1997)

The respondent of this study are built environment professionals who include architects, engineers, quantity surveyors and builders practicing in the study area. They were contacted to establish their willingness to participate in the survey. Eventually, 60 professionals were sampled. At the end of the data collection exercise that lasted for 3 months, 55 questionnaires were retrieved and valid for statistical analysis. This represent a response rate of 92% which is satisfactory considering what is obtainable in construction industry studies (Oyedele, 2013).

In order to establish the Relative Importance (RI) of the various factors under consideration, the Mean Score (MS) of each factor was estimated. This approach is not uncommon in related studies (for instance, Chan et al., 2005; Gudienė et al., 2013). The MS was calculated using the formula presents in Equation (1).

$$\mathrm{MS} = \frac{5n_5 + \ 4n_4 + \ 3n_3 + \ 2n_2 + \ 1n_1}{N} \tag{1}$$

Where n is the score given by the respondent based on the five-point scale of 1 to 5 and N is the number of professionals that ranked a factor.

This study focuses on Akure, the state capital of Ondo state, Nigeria. The political influence the city gained in 1976 when it was made a state capital (Fadairo, 2013) can be attributed to the rapid urbanization being experienced in the city (Tofowomo, 2008), which has made it one of the fastest growing state capitals in Nigeria (Ogunleye and Kayode, 2013). The economic richness of the city in terms of the availability of numerous mineral resources which include crude oil, the development of Olokola Deep Sea Port and also the construction of OK Free Trade Zone (Ogunleye and Kayode, 2013) has made Akure to become an emerging metropolis in Nigeria. The recent developments in the health sector under the current administration in the state make it an area that is worth studying.

The characteristics of the respondents of this study in terms of their professional background (Figure 1) shows that most (45.50%) of the professionals are quantity surveyors and about 23.60% are architects. Engineers represent 21.80% of the respondent, while 9.1% of the professionals are builders. The respondents have acquired varying years of cognitive industry experience. However, about a total of 67.30% of the respondents possess industry experience

of above five years, although majority of this portion fall within 6-15 years of experience. This information implies that the professionals are well experienced and their length of experience is noteworthy for this study. This is substantiated with the impressive Cronbach's alpha value which is recorded in this study.

On the academic qualification (Figure 2), more than half (58.20%) of the professionals possess Bachelor of Science/Bachelor of Technology degrees, 20.00% of them have acquired a postgraduate degree in terms of Masters of Science or Masters of Technology degrees, probably in their fields or allied professions. However, a minuscule portion of them possess ordinary and Higher National Diploma degrees. In sum, about 78.20% of the respondents have at least a B.Sc./B.Tech. degree holder which makes it safe to suggest that the respondents are well educated and well informed about the latest developments in their chosen professions. Analyzing the number of projects they have handled in the course of their professionals career, majority (a total of 68.20%) of the respondents have had cognitive experience in between one and four projects. A proportion of 31.80% respondents have handled over four projects.

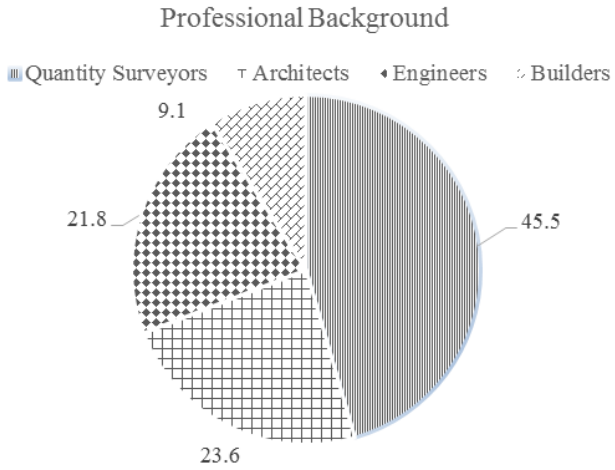

Figure 1: Professional background of the respondents

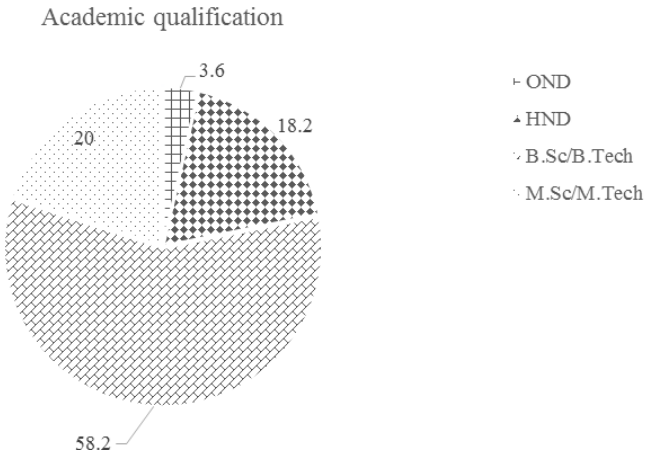

Figure 2: Academic qualification of the respondents

RESULTS AND DISCUSSION

In order to establish the internal consistency of the data collected, the Cronbach's alpha was estimated. This values ranges between 0 and 1. However, a Cronbach's values of 0.70 and above depicts a high internal consistent reliability (Hair et al., 2010). For this study, a

Cronbach's alpha value of 0.89 was recorded, this implies that a reliable internal consistency was achieved in this study. Thus meaningful inferences can be drawn from the analysis.

In order to establish the most significant factor(s), a threshold of 2.5 was adopted. This was informed by what is obtainable in literature, see for example Hsueh et al. (2009) and Le et al. (2014). To fully understand the CSFs that determine the successful completion of healthcare projects, insight into challenges that may affect such project is necessary. The information in Table 3 presents the ranking of the 14 factors that may pose as a challenge to healthcare projects as indicated by the respondent. All the 14 factors recorded a MS higher than the 2.5 threshold, which implies that they are all significant factors that can hinder the successful completion of healthcare projects. This is because the highest ranked factor (lack of cutting-edge technology) and the lowest ranked factor (low workmen productivity) recorded a MS of 4.04 and 2.98, respectively. However, in order of importance, lack of up-to-date technology, lack of adoption of new techniques, complicated building services, risk of project delay and frequent changes by clients are the five highly ranked factors with MS ranging between 3.49 and 4.04 that can militate against the successful completion of a healthcare project. The ranking of lack of up-to-date technology as the highest factors is consistent with literature, because Chan et al. (2003) argued that lack of up-to-date technology can impede the provision of efficient healthcare facility that will meet the needs of the people.

Table 3: *Ranking of the challenges involved in healthcare project*

Factors	Mean Score	Rank
Lack of up-to-date technology	4.04	1
Limited incorporation of new technique	3.80	2
Highly complicated building services	3.71	3
High risk of project delay	3.64	4
Frequent changes were demanded by multi-head clients	3.49	5
Insufficient cooperation between various project participants	3.45	6
Tight time schedule	3.42	7
High level of rework required for achieving the specification	3.42	7
Facing great pressure by general public and client	3.40	9
Large number of claims involved	3.35	10
Difficulty in dealing with large number of professionals	3.31	11
Inadequate exchange of knowledge and skills between parties	3.16	12
Exposure to litigation	3.09	13
Productivity of workmen is comparatively low	2.98	14

The RI in terms of the MS of the CSFs that determines the successful completion of healthcare projects in the study area are presented in Table 4. Considering the RI threshold of 2.5 established earlier, it is evident that all the 20 CSFs are significant determinants of healthcare projects delivery. They recorded a MS that range between 4.53 (Leadership skills for project manager) and 3.38 (design changes that occurs during construction). Some of the CSFs tied in ranking at the $4^{th}$and 8^{th} positions, which implies that same level of importance should be accorded to such CSFs during project construction. Be that as it may, the three most highly important CSFs are Leadership skill for project manager, Management skill of site managers and Collaboration of project participants, respectively.

A closer examination of these three CSFs shows that they are related project team personnel development and relationship. This suggests that in order to achieve a successful completion of a healthcare project, the project manager should ensure that experienced team members are recruited and they should possess a good teamwork spirit. This is in line with the position of Chan et al. (2003) that pointed out that the ability of a Project Manager to constitute a capable project team is essential for the successful completion of a healthcare project.

Table 4: *Ranking of the critical success factors for healthcare project delivery*

Factors	Mean Score	Rank
Leadership skill for project manager	4.53	1
Management skill of site managers	4.47	2
Collaboration of project participants	4.38	3
Supervision of workmen	4.36	4
Nature of project	4.36	4
Planning effort	4.36	4
Location of Project	4.29	5
Technological advancement	4.27	6
Political condition	4.25	7
Suitability of equipment	4.22	8
Tendering method	4.22	8
Quality, health and safety program	4.13	9
Size of project	4.09	10
Timely payment to sub-contractors	4.04	11
Procurement method	3.98	12
Construction Method adopted	3.96	13
Climate Condition	3.93	14
Complexity of project	3.85	15
Client's erratic changes	3.65	16
Formal dispute resolution process	3.53	17

CONCLUSION

Effort was made to assess the CSFs that determine the successful completion of healthcare projects in Ondo state, Nigeria. This was investigated in order to provide an insight into the CSFs of healthcare project, being that the health of the citizens usually have impact on the economy of a nation. Built environment professionals practicing in the study area and that have been involved in healthcare projects were sampled with the use of a questionnaire. A total of 20 CSFs were identified from the literature and they were included in the survey instrument used for the study. The professionals were asked to rank the CSFs in the order of their importance based on their opinion. Although all the CSFs were found to be significant, however, the top three highly significant CSFs can be categorized as human personnel and they are leadership skill for project manager, management skill of site managers and collaboration of project participants. This implies that when embarking on a healthcare project, the construction team should accord these factors utmost concentration as this will ensure successful delivery of such projects, within the stipulated time, estimated cost and with good quality.

This study may be limited in terms of its generalization to every part of Nigeria, being that it focused on Akure city. The inferences drawn from the data represents what is obtainable in the study area. However, due to the paucity of literature on this research topic both locally and internationally, this issue could be investigated in other cities in Nigeria and ultimately, researchers in other countries can replicate such study in order to present an international overview of the research topic.

Assessing Compliance with Noise Control Guidelines in the National Building Code for Residential Estates in Ondo and Ekiti States, Nigeria

Ganiyu, Sikiru Abiodun

Department of Architecture, Federal University of Technology Akure, Nigeria
**ganiyusikiru@gmail.com*

ABSTRACT

The National Building Code (NBC), launched in 2007, is a document meant to control all matters concerning the design and specification of any building or structure within Nigeria and to proffer lasting solution to the hazardous trends in the Nigerian building industry. Environmental noise pollution is one of the problems affecting the quality of life of people and negatively impacting on the built environment which the national building code is meant to address. This paper seeks to assess the level of compliance to provisions of the national building code in terms of noise control measures in residential estates. Two residential estates were chosen for study in the state capitals of the Ondo and Ekiti states. Data were collected through structured questionnaires administered on the residents of the estates and actual measurements of the noise level within the estate and physical survey of the estates. The data were analyzed using percentile and compared with the recommendations in the national building code. It was revealed that most of the buildings in the estates did not comply with the provisions of the code. This paper recommended that the code be domesticated in all the states and publicised among the residents compliance.

Keywords: Building, Estates, Noise, Pollution, Residential

INTRDUCTION

The residential estates are supposed to be haven of rest, providing serenity and quietness for residents after a noisy day at work. Unfortunately, they have been bedevilled with noise pollution. The built environment has recently become noisy due to rapid urbanisation. While most countries are making conscious efforts at addressing the menace of noise pollution through legislation in from of building codes and effective guidelines, Nigeria seems not to be doing enough in this direction.

A building code is a systematic statement or a body of rules that govern and constrain the design, construction, alteration, and repair of buildings (Farlex, 2011). The codes are meant to proffer lasting solutions to the hazardous trends in the building industry. These problems might have resulted from planlessness of the built environment, use of non-professionals, use of substandard materials, insufficient referenced design standard for professional and lack of adequate regulations and sanctions against offenders (Toluhi, 2009). The resulting effects of these problems include frequent building collapse, fire outbreaks, environmental pollution and other disasters.

The national building code which was launched in 2007 is meant to address the problems and the challenges facing the building industry in Nigeria when fully put to operation. This paper seeks to find out the level of awareness of the people about this document and the level of compliance to some of its provisions, especially the aspect that has to do with acoustics and noise control.

THE STUDY AREA

Ado-Ekiti and Akure are the state capitals of Ekiti and Ondo states respectively. The two towns were the major towns from the old Ondo state before the creation of Ekiti state on October 1, 1996. The selected estates from Ekiti and Ondo were Irewole Housing Estate and Ijapo Housing Estate respectively. While Ijapo Housing Estate is bounded by Oke-Ijebu road and Fiwasaye roads, Irewole Housing Estate is located along Ilawe road. The two housing

Ganiyu, S. A. (2016). Assessing Compliance with Noise Control Guidelines in the National Building Code for Residential Estates in Ondo and Ekiti States, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 319-325

estates were purposely designed and built with prototype buildings. These estates were purposefully chosen based on their ages to allow for good comparison. While Ijapo is the oldest, being the first housing estate in old Ondo State; Irewole Housing Estate is relatively a new estate allowing for good comparison.

The buildings in Ijapo ranges between 3 and 5-bedrooms bungalow while those of Irewole are essentially 3-bedrooms detached bungalows. There are six hundred (600) buildings in Ijapo estate, Akure and four hundred and twenty (420) buildings in Irewole estate, Ado-Ekiti.

THE NATIONAL BUILDING CODE

Introduction

The National Building Code is a document evolved to proffer lasting solution to the hazardous trends in the Nigeria building industry. The code was evolved by the collective effort of all the seven professionals in the building industry. It was launched into operation on 25th January, 2007 (Toluhi, 2009; Oresegun, 2010). The Code, which is meant to control all matters concerning the design and specification, construction, alteration, repair and demolition of any building or structure anywhere within Nigeria as local building regulations and bye-laws, has only been adopted by few states like Ondo State (Toluhi, 2014). The section 6 of the Code is titled 'Environmental Requirements' and is meant to 'govern the means of light, ventilation and sound transmission control required in all buildings intended for human occupancy'.

Sound Transmission Control

The sub-section 6.2.11 is dedicated to sound transmission control in residential buildings whose scope apply 'to all common interior walls, partitions and floor/ceiling assemblies between adjacent dwelling units or between a dwelling unit and adjacent public areas such as halls, corridors, stairs or service areas in all buildings of Use Group H'. The section considered both the air-borne noise and structure borne noise.

Airborne Noise

The Code required that walls, partitions and floor/ceiling assemblies separating dwelling units from each other or from public or service areas shall have a sound transmission class (STC) of not less than 45 for airborne noise when tested in accordance with ASTM E90. This requirement shall not apply to dwelling unit entrance doors, but such doors shall be tight-fitting to the frame and sill.

Structure borne Noise

The Code required floor/ceiling assemblies between dwelling units and between a dwelling unit and a public or service area within the structure to have an impact insulation class (IIC) rating of not less than 45 when tested in accordance with ASTM E492.

Acceptable Noise Level:

As preventive measure, the Code recommended the following daily maximum exposure to noise to avoid any hearing damage (National Building Code, 2007).

The Effect of Distance on Noise Level

The inverse square law of sound states that the intensity of sound in a free field is indirectly proportional to the square of the distance from the source. This infers a decrease in the intensity of sound the farther the observer is from the source. When sound spreads out from a point source in a free space the wave fronts are spherical and the sound pressure level will decrease 6 dB for each doubling of distance. However, When sound spreads out from a line source (such as a road with constant traffic or a pipe carrying fluid), the wave fronts are cylindrical and the sound pressure level will decrease 3 dB for each doubling of distance (Ogunsote, 2015).

Table 1: Recommended maximum daily exposure to noise.

Sound Pressure Level (dBA)	Maximum Exposure in any 24 Hours
85 or less	24 hours
87	16 hours
90	8 hours
93	4 hours
96	2 hours
99	1 hour
102	30 minutes
105	14 minutes
108	71/2 minutes
110	33/4 minutes

Acoustic Guidelines for Design of Residential Estates

The 1987 American Society of Heating, Refrigerating and Air-Conditioning Engineers (ASHRAE) guide suggests an NR 25 to 30 (30 to 35 dBA) as appropriate for residential and apartment dwellings. The EPA aircraft noise study (Gierke, 1973) indicates that a night time level of 30 dBA in a bedroom would produce no arousal effects. Their recommendation of a maximum exterior L_{dn} of 60 dB(A) was based, in part, on a maximum interior level of 35 dB(A) at night with closed windows. The same reasoning, when applied to the Levels Document recommendations of L_{dn} 55 dB(A), would yield a maximum night time level of 30 dB(A) with windows closed. It is important to note that most residential structures provide about 20–25 dB of exterior to interior noise reduction with windows closed and about 10–15 dB with windows open. Table 2 shows the summary of noise levels identified by Environmental Protection Agency (EPA) as requisite to protect public health and welfare of residential areas.

Table 2: Summary of Noise Levels Identified as Requisite to Protect Public Health and Welfare with an Adequate Margin of Safety (EPA Levels Document, 1974)

EFFECT	LEVEL	AREA
Hearing loss	$L_{eq(24)} < 70$ dBA	All areas
Outdoor activity interference and annoyance	$L_{dn} < 55$ dBA	Outdoors in residential areas and farms and other outdoor areas where people spend widely varying amounts of time and other places in which quiet is a basis for use.
	$L_{eq(24)} < 55$ dBA	Outdoor areas where people spend limited amounts of time, such as school yards, playgrounds, etc.
Indoor activity interference and annoyance	$L_{eq} < 45$ dBA	Indoor residential areas
	$L_{eq(24)} < 45$ dBA	Other indoor areas with human activities such as schools, etc.

Source: Marshall, 2006

Van Houten, according to Harris (1994), states that levels of plumbing related noise between 30 and 35 dB(A) in an adjacent unit can be "a source of concern and embarrassment." In multifamily residential developments, intrusive levels generated by activities in another unit are rarely a problem below 25 dB(A). At 30 dB(A) they are clearly noticeable and can be a source of annoyance, and above 35 dB(A) they frequently generate complaints.

People in their homes would have the lowest annoyance threshold. As a general guide, Szokolay (2008) recommended the following L_{10} (90th percentile) noise levels should not be exceeded inside any residential unit (Table 3).

Table 3: Emission limits of community noise in residences

	Day (dBA)	Night (dBA)
Country areas	40	30
Suburban areas	45	35
Inner city areas	50	35

Sound Level Meters

The sound level meter (Figure 1) is the fundamental acoustical instrument used for measuring sound. The instrumentation must comply with the specifications given in IEC 61672-1, which has two performance categories, classes 1 and 2. Both classes have the same design goals and differ only in the tolerance limits: class 1 for precision sound level meters, and class 2 for ordinary sound level meters (Maekawa, Rindel and Lord, 2011).

Figure 1: Sound Level Meter. (Extech Sound Meters and Sound Calibrators, 2009)

RESEARCH METHODOLODY

The research adopted a survey method of the study areas using a structured questionnaire which was administered on one out of every five buildings in Ijapo and one out of every ten buildings in Irewole. Eighty one (81) questionnaires were administered in Ijapo while forty (40) questionnaires were administered in Irewole out the six hundred (600) and four hundred and twenty (420) buildings respectively. The reason for the difference in the percentages of the questionnaires administered was that the buildings in Ijapo were more heterogeneous than those of the Irewole housing estate. The buildings in Irewole Housing Estates were essentially 3-bedroom detached bungalows. These represent approximately 15% and 10% coverage respectively. In additions to the questionnaire, the prevalent noise levels of the estates were measured using sound level meter in front of the buildings.

The variables examined include:

a. Type of building
b. Setback from road
c. Type of barrier/demarcation
d. Level of noise exposure
e. Awareness level about the building code.

DATA COLLECTION, ANALYSIS AND DISCUSSION

The data were collected and analysed as follow:

Type of Building

The buildings were classified as rooming, detached, semi-detached, duplex and multi-storey buildings. The number of detached buildings in Irewole Estate is thirty-eight (38) representing eighty-five percent (85%) as against the forty-seven (47) detached buildings in Ijapo which represented fifty-eight percent (58%). There is no rooming apartment in Irewole Estate and the number of semi-detached buildings was small compare to Ijapo Estate. There are no duplex and multi-storey buildings in Irewole Estate while Ijapo Estate has fifteen (15) and six (6) respectively (Table 4). The rooming apartment and the semi-detached buildings can be a source of noise and great disturbance to neighbours causing discomfort.

Table 4: Type of Building

Type of building	Ijapo Estate		Irewole Estate		Total	
	Frequency	%	Frequency	%	Frequency	%
Rooming	2	2.5	0	0	2	1.7
Detached	47	58	38	95	85	70.2
Semi-detached	11	13.6	2	5	13	10.7
Duplex	15	18.5	0	0	15	12.4
Multi-storey	6	7.4	0	0	6	5.0
Total	81	100	40	100	121	100

Setback from Road

The distance of the buildings from the road were measured to determine whether they meet up with the minimum setback of 6m specified in the building regulations in Nigeria. It was discovered that over forty percent (40%) of the buildings in the two estates have a setback that is lesser than the half of the minimum requirement of 6m. It is noteworthy that none of the buildings in Irewole Estate has a distance that exceeded 6m (Table 5).

Table 5: Distance from Road

Distance from road	Ijapo Estate		Irewole Estate	
	Frequency	%	Frequency	%
Below 3m	35	43.2	16	42.1
Between 3 – 6m	34	42.0	22	57.9
Between 6 – 9m	7	8.6	0	0
Above 9m	5	6.2	0	0
Total	81	100	40	100

Type of barrier/Demarcation

The kind of barrier used to reduce the effects of the noise, thereby enhancing acoustic comfort on the residents was also determined. It was interesting to know that nearly all the buildings in Ijapo were fenced with block wall (90.1%) while about forty percent (40%) of the buildings in Irewole have no fence at all thereby exposing them to serious acoustic discomfort arising from the vehicular noise from the road (Table 6).

Table 6: Type of Barrier/Demarcation

Type of Barrier	Ijapo Estate		Irewole Estate	
	Frequency	%	frequency	%
Block fence	73	90.1	20	50.0
Trees	1	1.2	0	0.0
Shrub	4	5.0	4	10.0
No Barrier	3	3.7	16	40.0
Total	81	100	40	100

Level of Exposure to Noise

The actual measurement of noise level within the estate was measured using Sound Level Meter at strategic locations along the major streets of the estates. The meter used has accuracy of ±1.4 dB; frequency range of 31.5 Hz – 8 KHz; auto range (30 dB – 130 dB); time weighting for both fast (125s) and slow (1s); resolution of 0.1 dB; and display update of 2 times/second. It was discovered that the average noise level on the street of Ijapo Estate on a typical weekend ranges between 77.5 dB (A) and 95.0 dB (A) depending on vehicular traffic and type of noise breaker/barrier. The noise level at Irewole Estate, however, ranges between 70.3 dB (A) and 90.5 dB(A). This clearly shows that the residents of Ijapo Estate are exposed to more noise than the residents of Irewole Estate. While the National Building Code specify maximum daily exposure of 85 dB(A), it was observed that the residents of these estates are often exposed to noise above the daily limit exposures set in the Code.

Awareness Level about the National Building Code

Virtually all the respondents claimed ignorance of the knowledge of the national building code. All the few respondents but one (1) from each of the estates who claimed to have heard about it confessed that they have never seen a copy of it, not to talk of reading it (Table 7).

Table 7: Awareness level about the National Building Code

Type of Barrier	Ijapo Estate			Irewole Estate		
	Yes	No	Total	Yes	No	Total
I have heard about it	3	78	81	5	35	40
I have seen it	1	80	81	1	39	40
I have read it	0	81	81	0	40	40

DISCUSSION OF FINDINGS

The type of buildings may contribute to level of noise in a residential estate. People who live in rooming apartments and semi-detarched buildings are most likely to be subjected to higher level of noise due to the number of occupants and their degree of proximity. This probably account for the higher level of noise recorded in Ijapo housing estate. It has been established in the literature that there is a strong relationship between distance or setback from source of noise and the level of noise recieved from the source. This shows that the farther away a recipents is the lower the level of noise exposure. Only 14.8% of the residents of Ijapo estate have their buildings farther than 6m while none of the buildings in Irewole estate enjoys such a luxury thereby exposing them to high level of noise from vehicular road. Over 90% of the buildings in Ijapo estate are protected with barriers in form of block fence, trees of shrubs but only 60% of the buildings in Irewole estate are protected by any form of barriers leaving 40% of the buildings exposed to external and unprotected.

While the average noise level along the street of Ijapo estate ranges between 77.5 dB(A) and 95.0 dB(A) on a typical weekend, that of Irewole estate ranges between 70.3 dB(A) and 90.5 dB(A). The recommeded emission limits of community noise in residential areas are between 50 – 55 dB(A) for the protection of public health and welfare. Though the National Building Code allows for a maximum daily noise exposure of 85 dB(A), it was observed that the average noise levels in these estate are often above this limit. It was observed that the reason for the high level of environmental noise pollution in Ijapo estate was as a result of large volume of vehicular traffic within the estate coupled with the fact that commercial taxis are also allowed into the estate, a situation which is not obtainable in Irewole estate in Ado-Ekiti. This situation is likely to expose the residents of Ijapo to higher noise level despite their barriers

RECOMMENDTIONS

Arising from the above, the following recommendations are hereby made:

i. Conscious efforts must be made to create awareness on the negative effects of noise pollution with a view to safeguard the health of the people.
ii. Efforts should be made to minimise the exposure of residents of the residential estates to high level of noise. This can be achieved by encouraging the erection of noise breakers/barriers in form of fence and/or shrubs.
iii. The minimum setback of 6m should be enforced by relevant government agency to reduce the level of exposure to noise.

CONCLUSION

It is apparent that the residents of these estates are often exposed to noise level above the limit specified in the national building code which was promulgated to proffer solution to the hazardous trends in the Nigeria building industry including environmental noise pollution.

However, the code, which was signed into law since 2007, has remained grossly under-utilised due to poor awareness. The level of compliance to the provisions of guidelines on noise control in residential environment in the code which has remained largely unknown to the people cannot but be low, even in government owned housing estates. The paper has therefore recommended aggressive awareness drive to sensitise people on the negative effects of noise pollution and call on the professionals in the building industry to insist on the provisions of the building code with a view to minimising the level of exposure of occupants of the residential environment to high level of noise pollution.

ABSTRACT

The concept of Sustainable design also called environmental design, environmentally sustainable design, environmentally conscious design, etc. is the philosophy of designing physical objects, the built environment, and services to comply with the principles of social, economic, and ecological sustainability. This research embraced quantitative data collection method by looking at sustainable architectural designs around the world with an aim to highlight practices which promote sustainable design that is about creating a better quality of life now, for future generations in architecture and construction industry in Nigeria. The main objectives of sustainable design are to reduce, or completely avoid depletion of critical resources like energy, water, and raw materials; prevent environmental degradation caused by facilities and infrastructure throughout their life cycle; and create built environments that are liveable, comfortable, safe, and productive. Principles and methods of sustainable design are discussed in this write-up. The paper recommends working with nature as the most efficient way to sustainable development through architecture in Nigeria.

Keywords: Sustainable Design, Sustainable materials, Sustainable Construction, Architecture and Sustainable Development

INTRODUCTION

We all want to improve the quality of life in Nigeria and this guidance highlights the important contribution which can be made to improve the design of new developments. It is important to create developments that are more cost effective to run, more secure, and that minimise their environmental impact and provide healthy living conditions, while respecting the area's rich heritage and distinctiveness.

This paper is intended to sensitize architects and contractors when undertaking new developments. Careful consideration of design and specification at an early stage can provide significant savings compared with an ad-hoc approach and proposers of development will benefit at the planning stage if they understand the principles of sustainable design prior commencing the design work.

The intention of sustainable design is to "eliminate negative environmental impact completely through skillful, sensitive design". According to McLennan (2004), the Philosophy of Sustainable Design Manifestations of sustainable design requires no non-renewable resources, impact the environment minimally, and connect people with the natural environment.

Beyond the "elimination of negative environmental impact", sustainable design must create projects that are meaningful innovations that can shift behaviour. A dynamic balance between economy and society, intended to generate long-term relationships between user and object/service and finally to be respectful and mindful of the environmental and social differences. The negative impacts of poor sustainable designs lead to poor construction industrial activities on the environment include destruction of natural habitats, demand for

Bello, M. M.; Auwalu, U. & Bello, B. B. (2016). Trends in Sustainable Design in Architecture. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 326-334

materials which leads to mining activities and consequently land destruction, air emissions/pollutants, health and safety harm, among others.

Design Process

The exact point in time when design professions' embrace of green principles changed from a desirable commodity to a fully integrated design expectation is probably lost in history. The difference between both designer and client expectations now versus the 1990s is striking. Green design transcends mere descriptions of the techniques that may be employed in shaping a more sustainable existence on Earth. It must also incorporate the principles, processes, and cycles of nature in a way that leads to a deeper understanding of what makes a design successful. Ideally, a book in the first decade of the third millennium that addresses green design should form the foundation for exploration and discovery of new and innovative ways to minimize ecological footprints. Now, and from now on, designers must strive for an end product that mutually benefits the client, the public, and the environment.

It is only through creating a better understanding of the natural world that new strategies can emerge to replace the entrenched design mind-sets that have relied on traditional schemes steeped in the exploitation of nature. Designs of much of the past four centuries have assumed an almost inexhaustible supply of resources. Almost everything we do in some way affects the health of the planet, from showering and brushing our teeth in the morning to well after we are finally tucked in at the end of the day, and the small clock on our nightstand continues to demand energy from the grid. One of the great misconceptions of scientists and non-scientists alike is that environmental consciousness is not dictated by sound science. To the contrary, everything that we do to the environment can be completely explained scientifically. The good news is that by applying the laws of science, we can shape our environment and provide the products demanded by society both predictably and sustainably. That is, strategic use of the principles of physical science informs our designs and engineering decisions.

Since the industrial revolution of the nineteenth century, architects and engineers have been key players (culprits?) in the war against nature. Single-minded exploitation and subjugation of nature was the norm during much of the twentieth century and persists as a mainstay of design. Technology has hastened the process. Notably, "man-made weather" (i.e., air conditioning) is now a universal expectation of building design in the West, following the invention of an

"Apparatus for treating air" patented by Willis Carrier in 1906. It is also entrenched in the desire for conformation of the International Style of Architecture, which spanned much of the twentieth century. Many of us follow the remnants of this style, still seeking one universal building, regardless of climate and place.

Actually, green thinking is not new at all. In fact, our new way of thinking resembles an understanding of and respect for nature found in antiquity, as evidenced by the designs of cliff-dwelling native peoples. Re-establishing the link between built form and the environment will require a more complete understanding of the science that underpins successful sustainable design strategies, and incorporating this knowledge as architects and engineers engaged in shaping our world along with the construction community charged with realizing a new vision.

The *law of unintended consequences* is ever ready to raise its ugly head in design. There are numerous examples of building design solutions touted as sustainable that fail to recognize and respond to the specifics of local climate. A building project that has applied sustainable principles with the mind-set that these principles are "universal" solutions will produce less

than optimal results, if not total failure. For example, a wind system is renewable but is not necessarily efficient. Incorporating wind turbines without first understanding local climate and the physics of wind-generated energy could lead to poor design solutions by placing turbines in an area that does not generate sufficient wind speeds throughout the year. The idea of a more "holistic" approach is required to arrive at complete, sustainable design strategies. The notion of life cycle in the design and construction community has too often been confined to a cost–benefit economic model of demonstrating the return on investment that can be expected over the life of a building.

STATEMENT OF THE PROBLEM

The specific problem of creating sustainable design in sustainable human habitats is visible in both rural and urban centres of developing countries. Olotuah (2009) averred that incremental design and construction has pervaded most urban centres in Nigeria. Many of such buildings are inhabited with the barest facilities in place. Although sustainability is fast assuming a global trend, the position of architecture in actualizing the sustainable design goals in developing countries is not encouraging. The concept of the necessity to protect the environment through architecture is not well understood by many intending developers or house-owners. Quacks, who claim to be architects most times, use corrupt means of getting architectural works done. Consequently, the environment is left unsafe and unsustainable for habitation. Furthermore, poverty seems to have clouded reasonable thoughts of what a habitable and sustainable house should be, and consequently, people find shanty and uncompleted dwellings habitable. It is obvious that the role of architecture in its theory, education and practice, in sustainable development cannot be over-emphasized.

Sustainable Design

Peakstoprairie (2005) describe a sustainable design as "the systematic consideration of a project's life cycle impact on environmental and energy resources". One of the key features is the need to minimise material and resource consumption and some strategies for achieving this, and consequently sustainable construction, include:

i. Ensuring land is safe for development
ii. Ensuring access to and protection of the natural environment
iii. Reducing negative impact on the local environment
iv. Conserving natural resources and reducing carbon emissions
v. Conserving economic and social well-being

The Push for Sustainable Design

There are now many factors encouraging designers and developers to adopt more sustainable design practices:

i. Growing awareness from shareholders, investors and the public has led to increased public reporting on social and environmental issues, with some developers now producing annual environmental, social or sustainability reports
ii. Socially responsible investment has placed pressure on government to integrate social and environmental considerations into their working practices, and to adopt environmental management systems, creating greater pressure from clients for buildings with reduced running costs and more attractive and healthy working environments for their staff
iii. Planning authorities around the world are setting increasingly high standards for sustainability, adopting a strong sustainability strategy for all developments will save time and money when sustainability is required on individual developments.
iv. The UK Government in conjunction with BRE released the Code for Sustainable Homes rating scheme in April 2007, it is expected that this will become a mandatory

requirement in a few years and Code Level 3 is already stipulated by the Housing Corporation and English Partnerships for developments built on their land

Sustainable Architecture

Sustainable architecture is the design of sustainable buildings. Sustainable architecture attempts to reduce the collective environmental impacts during the production of building components, during the construction process, as well as during the lifecycle of the building (heating, electricity use, carpet cleaning etc.) This design practice emphasizes efficiency of heating and cooling systems; alternative energy sources such as solar hot water, appropriate building siting, reused or recycled building materials; on-site power generation - solar technology, ground source heat pumps, wind power; rainwater harvesting for gardening, washing and aquifer recharge; and on-site waste management such as green roofs that filter and control storm water runoff. This requires close cooperation of the design team, the architects, the engineers, and the client at all project stages, from site selection, scheme formation, material selection and procurement, to project implementation. Ji and Plainiotis (2006)

Sustainable architects design with sustainable living in mind. Holm (2006) Sustainable vs green design is the challenge that designs not only reflect healthy processes and uses but are powered by renewable energies and site specific resources. A test for sustainable design is — can the design function for its intended use without fossil fuel — unplugged. This challenge suggests architects and planners design solutions that can function without pollution rather than just reducing pollution. As technology progresses in architecture and design theories and as examples are built and tested, architects will soon be able to create not only passive, null-emission buildings, but rather be able to integrate the entire power system into the building design.

An essential element of Sustainable Building Design is indoor environmental quality including air quality, illumination, thermal conditions, and acoustics. The integrated design of the indoor environment is essential and must be part of the integrated design of the entire structure.

Principles of Sustainable Design

While the practical application varies among disciplines, some common principles are as follows:

i. Low-impact materials: choose non-toxic, sustainably produced or recycled materials which require little energy to process
ii. Energy efficiency: use manufacturing processes and produce products which require less energy
iii. Emotionally durable design: reducing consumption and waste of resources by increasing the durability of relationships between people and products, through design
iv. Design for reuse and recycling: "Products, processes, and systems should be designed for performance in a commercial 'afterlife'. Anastas & Zimmerman (2003).
v. Design impact measures for total carbon footprint and life-cycle assessment for any resource used are increasingly required and available. Vallero & Brasier (2008), Sustainable Design.
vi. Sustainable design standards and project design guides are also increasingly available and are vigorously being developed by a wide array of private organizations and individuals. There is also a large body of new methods emerging from the rapid development of what has become known as 'sustainability science' promoted by a wide variety of educational and governmental institutions.

vii. Biomimicry: "redesigning industrial systems on biological lines ... enabling the constant reuse of materials in continuous closed cycles… Hawken, Lovins, & Hunter Lovins (1999). Natural Capitalism
viii. Renewability: materials should come from nearby (local or bioregional), sustainably managed renewable sources that can be composted when their usefulness has been exhausted.
ix. Robust eco-design: robust design principles are applied to the design of a pollution sources. Ben-Gal et al., (2007)

Sustainable planning

Urban planners that are interested in achieving sustainable development or sustainable cities use various design principles and techniques when designing cities and their infrastructure. These include Smart Growth theory, Transit-oriented development, sustainable urban infrastructure and New Urbanism. Smart Growth is an urban planning and transportation theory that concentrates growth in infill sites within the existing infrastructure of a city or town to avoid urban sprawl; and advocates compact, transit-oriented development, walkable, bicycle-friendly land use, including mixed-use development with a range of housing choices.

Sustainable landscape and garden design

Sustainable landscape architecture is a category of sustainable design and energy-efficient landscaping concerned with the planning and design of outdoor space. Plants and materials may be bought from local growers to reduce energy used in transportation. Design techniques include planting trees to shade buildings from the sun or protect them from wind, using local materials, and on-site composting and chipping not only to reduce green waste hauling but to increase organic matter and therefore carbon in the soil.

Samples of Sustainable Designs

The term sustainable is thrown about quite a bit these days, but there's more to it than adding some solar panels to the roof of an inefficient building and calling it a day. True sustainability is made up of many facets, from building materials to the use of renewable energy sources to design that strives for efficiency and harmony with the surrounding environment. Below are few selections of sustainable buildings with element of sustainable design criteria.

Waste

The Waste House is a sustainable construction project installed at the UK's University of Brighton. As its name suggests, the prototype home is built *almost* exclusively from discarded waste. Around 90 percent of the materials that went into making the Waste House derive from household and construction waste, including 20,000 toothbrushes, 4,000 DVD cases, 2,000 floppy discs, and 2,000 used carpet tiles, used to clad the home's facade. While nobody actually lives in it at present, the building is a remarkable achievement and proves the organizer's mantra that "there is no such thing as waste, just stuff in the wrong place."

S House

Vietnam's Vo Trong Nghia Architects has been tinkering away at the issue of providing practical, sustainable, and most importantly, cheap, homes. The result is the S House, a US$4,000 dwelling part-built using local, easily-obtained materials, including Palm leaf thatching and bamboo.

Fall House

San Francisco's Fougeron Architecture recently designed and built a particularly beautiful luxury house that's guaranteed to make the neighbours see green. Located on California's Big Sur coastline, the Fall House sports a copper facade that will weather and patina over time, as it comes into contact with the sea air. The copper is also designed to offer a degree of fire-

protection. In addition to its enviable looks and views, the two-story Fall House features energy-efficient windows and its open design naturally encourages stack ventilation, automatically opening windows help reduce the need for air-conditioning. A grey water recycling system is also installed.

ZEB Pilot House

The ZEB Pilot House, by international architecture outfit Snøhetta is a remarkable experimental home that makes an even more remarkable claim: thanks to incredible efficiency and ample solar panels, it's said to generate almost three times the amount of electricity it requires.

Pop-Up House

Whatever kind of home you live in, the chances are it took longer to build than the Pop-Up House, by French architecture firm Multipod, which was erected by a team of builders in just four days with no more tools than a screwdriver. The firm likens the construction process to building with Lego.

Tight house

Said to be the first certified Passive House in New York City, Tighthouse represents an impressive energy-efficient renovation of an existing row house that's over a hundred years old. Architectural design firm Fabrica718 added a new rear facade, an additional story, a roof terrace, and an art studio to the house. Sustainable technology installed includes two solar thermal panels for hot water needs, and solar PV panels, which reduce grid-based electricity requirements. As the home is almost air-tight, a highly-efficient heat recovery ventilation system (HRV) is always running to provide plenty of fresh air.

Blooming Bamboo

Like Vo Trong Nghia Architects, Vietnamese firm H&P Architects has also produced a prototype home that will eventually be mass-sold to Vietnamese people on a low income. However, this particular home is also flood-proof. The Blooming Bamboo house is placed on stilts and designed to withstand floods of up to 1.5 m (5 ft) in depth, though H&P Architects hopes to increase this to 3 m (10 ft).

Illawarra Flame

Students from Australia's University of Wollongong took a typical Australian "fibro house," and retrofitted it with enough sustainable technology to make the notoriously energy-hungry style of home into a net-zero houses. The Illawarra Flame house project involved a lengthy renovation process, including transforming a bedroom into a living space, and the installation of prefabricated pods which contain amenities including laundry room and bathroom.

Z6 House

The Z6 House in California is all about innovative and convenient sustainable design. In fact, the name itself is based on the philosophy of achieving zero levels across key areas: waste, energy, carbon emissions, water and ignorance. Essentially, the Z6 house is a combination of every sustainable method of construction, and the result is not only a zero waste home, but a stylish looking one too. The building makes heavy use of solar power and this is responsible for around 70% of its energy use. Through other luxuries such as solar powered water heaters and heated floorboards, the Z6 house makes the best of natural resources.

Z6 House

The Change Initiative

Located in Dubai, TCI is officially the most sustainable commercial building in the world to date. The building itself is a shop that provides sustainable solutions, so we certainly know that it practices what it preaches. While most of the materials used to create TCI is recyclable (including the water they use), the roof is equipped with solar panels and heat-reflective paint which provides 40% of the building's energy, and the outer structure has three times the insulation of your average building. The building's logo is a clever play on the 'on switch,' reinforcing the circuitous nature of sustainable living.

The Change Initiative
Source: www.bigprojectme.com

Pixel

Pixel was the most sustainable commercial building in the world before TCI knocked it from the top spot, so it's certainly worthy of note. Built in Australia, it was the first building to ever be granted a perfect Green Star score and set precedence for sustainable architecture in the country. Pixel itself is a small office building that makes use of several innovations for sustainability, including a sun shade system that lets natural light into the office whilst reducing glare and heat. The building even generates its own electricity through the use of wind turbines. It's also fair to say that the design is pretty striking; certainly one to be remembered.

The Experience of Building Research Establishment (BRE) Innovation Park, Watford, United Kingdom

Created in 2005, The Building Research Establishment (BRE) Innovation Park has some of the world's most sustainable buildings, landscape designs and many innovative low carbon products, materials and technology. It is an independent research-based consultancy, testing, certification and training organisation, offering expertise in every aspect of the built environment.

Recommendation

The adoption of urban design principles can contribute significantly to a safer environment. Development schemes could incorporate measures in their design, layout, siting and landscaping to minimise the risk of crime and maximise security. Blank walls and parts of buildings such as loading bays, which cannot contribute to passive surveillance, should not face onto public space but should be placed at the backs of blocks. The adoption of the 'perimeter block' layout can support these measures, comprising frontages where the public realm is readily overlooked from adjacent properties and the rear gardens are private

Secure areas which are difficult for third parties to access. The following issues should be considered when designing a safe development:

i. Opportunities to incorporate passive surveillance of streets, spaces, parking and servicing areas
ii. Strong demarcation between public and private space
iii. Public areas are well lit and landscaping does not obscure views into and out of the space
iv. Developments are constructed of vandal resistant materials, and that maintenance arrangements are in place
v. Installation of sprinkler systems and hard wire smoke alarms where feasible
vi. All Designs to be developed must have satisfied the principles of sustainable designs before been approved for development by the various approval bodies in the country
vii. More discussion on sustainable design, sustainable living, sustainable materials, sustainable construction etc. should be carried out in architecture schools, NIA/ARCON organised events; this will create more awareness on sustainable living in the built environment within country.
viii. Nigerian architectural education should be a conscious process which entails effort towards development of skills, knowledge, attitudes and information for the improvement of our architecture within our cultural realm.

CONCLUSION

For any progress to be made in entrenching sustainable Design through design and constructing buildings that are sustainable, we in turn are allowing the building's inhabitants to lead more sustainable lives. Building occupiers will experience lower fuel and water bills, healthier living conditions and draw comfort from the fact that they are helping to protect the environment. While responsible development can ensure that resources are protected and carbon emissions reduced over the lifetime of the building, occupiers can deliver further environmental benefits by choosing to live sustainable lifestyles. However, without the provision of appropriate facilities or information, these options can be restricted or even withdrawn altogether. We need buildings that can breathe naturally, not sick buildings. Let us now design with nature, an architecture deeply rooted in our culture and traditions. That is the architecture of our time.

Paul University, Awka, Anambra State
ben.nwankwo@yahoo.com

ABSTRACT

Communication is the process of sharing ideas, information and messages with others in a particular time and place. It includes writing, talking, as well s non-verbal communications (facial expression, body language or gestures), visual communications telephone calls, email, cable television or satellite broadcasts). In order to provide advanced and efficient way of communication, the GSM technology has emerged from a cell-based mobile system at Bell Laboratories in the early 1970s. It is a circuit-switched system that divides each 200 KHz channel into eight 25 KHz time-slot. This digital technology has evolved over the year. The impact is that the globe has been miniaturized into a mere village as never before. There are however its inherent challenges. These, notwithstanding, with time and much effort, more discoveries will be integrated into the GSM technology for much more communications. This research was designed to examine the origin, developments, benefits and challenges of the GSM with aim of improving the technology. The secondary sources of data collection were used in obtaining relevant data and information where a study of wireless communications including analog and digital system was carried out and special attention was given to GSM as a digital communication system which is the topic under review.

Keywords: GSM technology, cell-based, circuit-switched, digital technology and miniaturized

HISTORY OF GSM

Before the advent of the GSM networks, there were public mobile radio networks or cellular networks. Cellular mobile communications systems use a large number of low-power wireless transmitters to create cells which is the basic geographic service area of a wireless communications system. Variable power levels allow cells to be sized according to the region. They normally used analog technologies in which signals propagate through the medium as continuously varying electromagnetic waves. These technologies however vary from country to country and from manufacturer to manufacturer.

According to Adam (2011), the idea of the first cellular network was brainstormed in 1947. It was intended to be used for military purposes as a way of supplying troops with more advanced forms of communications. From 1947 till about 1979 several different forms of broadcasting technology emerged. The United States began to develop the AMPS (Advanced Mobile Phone Service) network, while European countries were developing their own forms of communication. However, when Europeans quickly realized the disadvantages of each country operating on their mobile network such as incompatibility of cell phone use from country to country within Europe, they came together to resolve the issue. Global System for Mobile Communications, originally "Groupe Spécial Mobile", is a standard developed by the European Telecommunications Standard Institute (ETSI) to describe protocols for second-generation (2G) digital cellular networks used by mobile phones. In 1982, work began to develop a European standard for digital telephony when the European Conference of Postal and Telecommunications Administrations (CEPT) created the Groupe Spécial Mobile committee and later provided a permanent technical support group based in Paris. Five years later in 1987, fifteen representatives from thirteen European countries signed a memorandum of understanding in Copenhagen, Denmark, to develop and deploy a common cellular

Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 335-347

telephone system across Europe and EU rules were passed to make GSM a mandatory standard eventually resulted in a unified open, standard-based network which was larger than that in the U.S.A.

In February 1987, Europe produced the very first agreed GSM technical specification. Ministers from the four big EU countries cemented their political support for GSM with the Bonn Declaration on Global Information Networks in May, 1987 and the GSM memorandum of understanding drew mobile operators from across Europe to pledge to invest in new GSM networks to an ambiguous common date. It got GSM up and running fast. France and Germany had earlier in 1984 signed a joint development agreement while Italy and UK joined them in 1986. The initial release of GSM was called GSM Phase I, and it is commonly referred to as the first generation. This release made provision for the basic voice, SMS and circuit switched Date (CSD) services. CSD allow a maximum data rate of 9.6kbs and was capable of fax transmission as well. Supplementary services at that point were very basic consisting of call forward and called barring capabilities. The second generation (GSM Phase 2) was released in 1995 and provided enhanced supplementary services, amongst which were Calling Line Identity (CLI), call waiting and multiparty services. Data services however remained limited to 9.6kbs. GSM Phase 2+ was an enhancement to GSM Phase 2 and was released two years later in 1997. Realizing the need for enhanced data service, Phase 2+ addressed this requirement by making provision for High Speed Circuit Switched Data (HSCSD) and General Packet Radio Services (GPRS). HSCSD and GPRS allowed maximum data rates of 48kbs and 177kbs respectively.

The world's first GSM call was made by the former Finnish Prime Minister, Harri Holkeri to Kaarina Suonio, and the Mayor of Tampere on July 1st, 1991 on a network built by Telenokia and Siemens and operated by Radiolinja. In 1992, the first short messaging service (s.m.s) or text message was sent and Vodafone UK and Telecom Finland signed the first international roaming agreement. In the same 1991, work began to expand the GSM standard from the initial 900MHz reserved spectrum band for GSM to the 1800MHz frequency band. Consequently, the first 1800MHz network became operational in the UK by 1993. In that same year, Telecom Australia was the first network operator to deploy a GSM network. As a result of this, the first practical hand-held GSM mobile phone became available. In 1995, facsimile (fax), data and s.m.s messaging services were launched commercially. Also, the first 1900MHz GSM network became operational in the US. This made the GSM subscribers worldwide to exceed 10 million. In the same year, the GSM Association was formed. In 1996, pre-paid GSM Subscriber Identification Module (s.i.m) cards were launched. In 1998, the global or worldwide GSM subscribers surpassed 100 million.

THE MILLENIUM ADVANCEMENTS

By 2000, the first commercial General Packet Radio Services (GPRS) were launched. Also, the first GPRS-compatible handsets became available for commercial purposes. However, in 2001, the first Universal Mobile Telecoms System (UMTS) Wideband Code Division Multiple Access (WCDMA) network was launched which is a 3G technology that is not part of GSM. Similarly, the global subscribers surpassed 500 million. In 2002, the first multimedia messaging service (m.m.s) was introduced and the first GSM network in the 800MHz frequency band became operational. In 2003, Enhanced Data rates for GSM Evolution (EDGE) services first became operational in a network. By 2004, the global GSM subscribers exceeded 1 billion. Also, by 2005, GSM networks provided more than 75% of the global cellular network market with 1.5 billion subscribers. In the same year, the first High-Speed Digital Packet Access (HSDPA)-capable network also became operational. In 2007, the first High-Speed Uplink Packet Access (HSUPA) network was launched. It will be noted

that High-Speed Packet Access (HSPA) and its up and downlinks versions are 3G technologies, not part of GSM. In 2008, worldwide GSM subscribers exceeded 3 billion. In 2010, the GSM Association estimated that technologies defined in the GSM standard serve about 80% of the global market, encompassing more than 5 billion people across more than 212 countries and territories, thus making GSM the most universal of the many standards for cellular networks.

It will be noted that GSM is a 2G standard that employs Time-Division Multiple- Access (TDMA) spectrum-sharing, issued by the European Telecommunications Standard Institute (ETSI). Also, the GSM standard does not include the 3G Universal Mobile Telecommunications Service (UMTS) Code Division Multiple Access (CDMA)-based technology or the 4G Long Term Evolution (LTE)-based technology issued by the 3rd Generation Partnership Project (3GPP). Following the ETSI's adoption of GSM standard in 1991, the GSM is now used in about 210 countries and has included both the CDMA and TDMA/FDMA radio spectra. Thus the GSM allows eight concurrent calls on same radio frequency. It operates on four special frequencies worldwide. However, some countries like Macau planned to phase out its 2G GSM networks by June, 2015, making it the first region to decommission a GSM network. Singapore intends to phase out 2G services by 2017.

The Structure of a GSM Network

The GSM is a cellular network. This means that the cell phones connect to it by searching for cells in the immediate vicinity. There are five different cell sizes in a GSM network; namely: macro, micro, pico, femto and umbrella cells. The coverage area of each cells varies according to the implementation environ.

i. Macro cells: These can be regarded as the cells where the base station antenna is installed on a mast or a building above average rooftop level.
ii. Micro cells: These are cells whose antenna height is under average rooftop level. They are usually used in urban areas.
iii. Pico cells: These are small cells whose coverage diameter is a few dozen meters. They are usually used indoors.
iv. Femto cells: These are cells designed for use in residential or small business environments. They connect to the service provider's network via a broadband Internet connection.
v. Umbrella cells: These are used to cover shadowed areas or regions of smaller cells. They fill in gaps in coverage between those cells.

Cell horizontal radius varies depending on antenna height, antenna gain and propagation conditions from a couple of hundred meters to several tens of kilometers. The longest distance the GSM specification supports practically is 35 KM or about 22 miles. There are also several implementations of the concept of an extended cell where the cell radius could be doubled or even more depending on the antenna system, the terrain type and the timing advance.

GSM also supports indoor coverage and may be achieved by the use of an indoor pico cell base station or an indoor repeater. These are usually deployed when significant call capacity is needed indoors such as in shopping centers or airports. However, this is not a prerequisite since indoor coverage is also provided by in-building penetration of the radio signals from any nearby cell.

GSM Architecture

A GSM network comprises of many functional units. The network can be broadly divided into:

i. The Mobile Station (MS)
ii. The Base Station Subsystem (BSS)

iii. The Network Switching Subsystem (NSS)
iv. The Operation Support Subsystem (OSS)

Given below is a simple pictorial view of the GSM architecture:

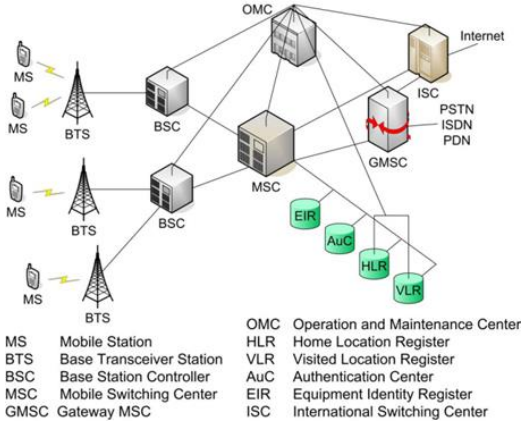

Figure 1: GSM Architecture

The additional components of the GSM architecture comprise of databases and messaging systems' functions:

i. Home Location Register (HLR)
ii. Visitor Location Register (VLR)
iii. Equipment Identity Register (EIR)
iv. Authentication Center (AuC)
v. SMS Serving Center (SMS SC)
vi. Gateway MSC (GMSC)
vii. Chargeback Center (CBC)
viii. Transcoder and Adaptation Unit (TRAU)

The following diagram shows the GSM network along with the added elements:

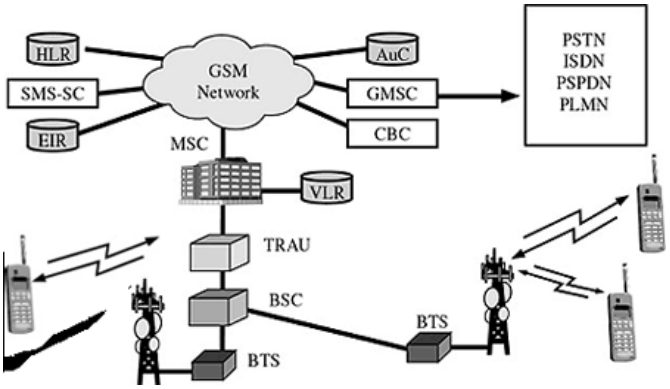

Figure 2: The GSM network along with the added elements

The MS and the BSS communicate across the Um interface. It is also known as the *air interface* or the *radio link*. The BSS communicates with the Network Service Switching (NSS) center across the *A* interface.

GSM User Services

GSM offers much more than just voice telephony. It offers three basic types of services:

i. Telephony services or teleservices
ii. Data services or bearer services
iii. Supplementary services

Teleservices

The abilities of a Bearer Service are used by a Teleservice to transport data. These

services are further transited in the following ways:

Voice calls
The most basic teleservice supported by GSM is telephony. This includes full-rate speech at 13 kbps and emergency calls, where the nearest emergency-service provider is notified by dialing three digits.

Videotext and Facsimile
Another group of teleservices includes Videotext access, Teletex transmission, Facsimile alternate speech and Facsimile Group 3, Automatic facsimile Group 3, etc.

Short text messages
Short Messaging Service (SMS) service is a text messaging service that allows sending and receiving text messages on your GSM mobile phone. In addition to simple text messages, other text data including news, sports, financial, language, and location-based data can also be transmitted.

Bearer services
Data services or Bearer Services are used through a GSM phone. to receive and send data is the essential building block leading to widespread mobile Internet access and mobile data transfer. GSM currently has a data transfer rate of 9.6k. New developments that will push up data transfer rates for GSM users are HSCSD (high speed circuit switched data) and GPRS (general packet radio service) are now available.

Supplementary services
Supplementary services are additional services that are provided in addition to teleservices and bearer services. These services include caller identification, call forwarding, call waiting, multi- party conversations, and barring of outgoing (international) calls, among others. A brief description of supplementary services is given here:

i. **Conferencing:** It allows a mobile subscriber to establish a multiparty conversation, i.e., a simultaneous conversation between three or more subscribers to setup a conference call. This service is only applicable to normal telephony.
ii. **Call Waiting:** This service notifies a mobile subscriber of an incoming call during a conversation. The subscriber can answer, reject, or ignore the incoming call.
iii. **Call Hold:** This service allows a subscriber to put an incoming call on hold and resume after awhile. The call hold service is applicable to normal telephony.
iv. **Call Forwarding:** Call Forwarding is used to divert calls from the original recipient to another number. It is normally set up by the subscriber himself. It can be used by the subscriber to divert calls from the Mobile Station when the subscriber is not available, and so to ensure that calls are not lost.
v. **Call Barring:** Call barring is useful to restrict certain types of outgoing calls such as ISD or stop incoming calls from undesired numbers. Call barring is a flexible service that enables the subscriber to conditionally bar calls.
vi. **Number Identification:** There are following supplementary services related to number identification:
vii. **Calling Line Identification Presentation:** This service displays the telephone number of the calling party on your screen.
viii. **Calling Line Identification Restriction:** A person not wishing their number to be presented to others subscribes to this service.
ix. **Connected Line Identification Presentation:** This service is provided to give the calling party the telephone number of the person to whom they are

connected. This service is useful in situations such as forwarding where the number connected is not the number dialed.

x. **Connected Line Identification Restriction:** There are times when the person called does not wish to have their numbers presented and so they would subscribe to this person. Normally, this overrides the presentation service.

xi. **Malicious Call Identification:** The malicious call identification service was provided to combat the spread of obscene or annoying calls. The victim should subscribe to this service and then they could cause known malicious calls to be identified in the GSM network, using a simple command.

xii. **Advice of Charge (AoC):** This service was designed to give the subscriber an indication of the cost of the services as they are used. Furthermore, those service providers who wish to offer rental services to subscribers without their own SIM can also utilize this service in a slightly different form. AoC for data calls is provided on the basis of time measurements.

xiii. **Closed User Groups (CUGs):** This service is meant for groups of subscribers who wish to call only each other and no one else.

xiv. **Unstructured Supplementary Services Data (USSD):** This service allows operator-defined individual services.

Benefits of GSM

i. It provides easier and efficient communication: Since this service is in most countries, it is quite easy to communicate anywhere in the world through roaming capabilities.

ii. Emergency Response: 112 is now a universal number among GSM networks. Other things being equal, no matter where a user is, he can call for help using this code.

iii. Universal Data Transfer: it allows for reliable and efficient data transfer. With the developments of many apps, sounds, pictures and graphics can be sent and shared.

iv. Better Sound: As a digital carrier, a GSM cell phone makes for clearer connections, as it can filter background noise, attenuations and distortions. This makes communications despite the distance.

v. Technological Growth: The universality of GSM has enhanced the growth of communications technology. This has lead to a reliable cell phone service and improved quality in both connection stability and ease.

vi. Greater Job provider: Being the highest employer of labour, the GDP is enhanced. The GSM also stands out with its range of services from health, education, research, economic, social and other human endeavours.

Some Challenges and Solutions to Gsm Security Issues

Recently, the mobile industry has experienced an extreme increment in number of its users. The GSM network with the greatest worldwide number of users succumbs to several security vulnerabilities. Although some of its security problems are addressed in its upper generations, there are still many operators using 2G systems. The GSM has experienced gradual improvements that leaded to several versions such as GSM1800, HSCSD (High Speed Circuit Switched Data), EDGE (Enhanced Data rates for GSM Evolution), and GPRS (General Packet Radio Service). The GSM improvements are continued to 3G systems such as UMTS. It is believed that the GSM has many inherent security flaws and some of its security flaws are addressed in the upper generations such as UMTS. However, many operators especially in the developing countries are still using the traditional GSM network that succumbs to several security flaws. This paper provides a brief and complete review of

the GSM security flaws, and some applicable solutions to improve the security of currently available GSM systems.

Security Architecture of the GSM

The security architecture of GSM was originally intended to provide security services such as anonymity, authentication, and confidentiality of user data and signaling information. The security goals of GSM are as follows:

i. Authentication of mobile users for the network
ii. Confidentiality of user data and signaling information
iii. Anonymity of subscriber's identity
iv. Using SIM (Subscriber Identity Module) as a security module

The Mobile Station (MS) consists of the Mobile Equipment (ME), and the SIM card. The SIM is a cryptographic smart card with the GSM specific applications loaded onto it. As a smart card, it has some inherent security functions specified to smart cards. Its operating system and chip hardware have several security attributes. SIM includes all the necessary information to access the subscriber's account. IMSI and Ki are stored on every SIM. IMSI is the International Mobile Subscriber Identity with at most 15 digits uniquely devoted to every mobile subscriber in the world. Ki (Individual subscriber authentication Key) is a random 128-bits number that is the root cryptographic key used for generating session keys, and authenticating the mobile users to the network. Ki is strictly protected and is stored on the subscriber's SIM, and AuC.

The SIM is itself protected by an optional Personal Identification Number (PIN). Each user is requested to enter the PIN unless this feature is deactivated by the user. After a number of invalid attempts that is usually 3 times, the SIM locks out the PIN, and the PUK (PIN UnlocK) is then requested. If the PUK is also incorrectly entered for a number of times that is usually 10 times, the SIM refuses local accesses to its privileged information and authentication functions, and makes itself useless. Authentication and confidentiality of user data are in deposit of the secrecy of IMSI and Ki. With disclosure of such numbers, anyone can impersonate a legitimate user. A3 and A8 algorithms are also implemented on every SIM. This means that each operator can determine and change such algorithms independent of other operators and hardware manufacturers.

Therefore, the authentication will work when a user is roaming on other countries or operators since the local network will query the HLR of the home network for the results and does not need to know the A3/A8 algorithm of the home network. A3 is mainly used for authenticating users to the network while A8 is used for generating the session key of encryption Kc. The network sends a random challenge to the user so that SIM produces Kc and SRES. After user authentication, the network can order the phone to start the encryption by using the generated session key Kc. The cryptographic algorithms are implemented on the hardware of mobile phones. The network can choose from up to 7 different encryption algorithms (or the mode of no ciphering) but it should choose an algorithm that is implemented on the phones. A class mark message has been earlier specified the phone's capabilities to the network.

Three algorithms are generally available: A5/1, A5/2, and A5/3. A5/1 and A5/2 are two stream ciphers originally defined by the GSM standards. A5/1 is stronger but it is subject to export control and can be used by those countries that are members of CEPT. A5/2 is deliberately weakened to be deployed by the other countries. The use of such algorithms is controlled by the GSM Memorandum of Understanding (MoU). A5/3 is a block cipher based

on the Kasumi algorithm that is defined by the 3GPP at 2002 and can be supported on dual-mode phones that are capable of working on both 2G and 3G systems.

The GSM authentication, session key generation, and encryption processes are depicted in Figure 3 below:

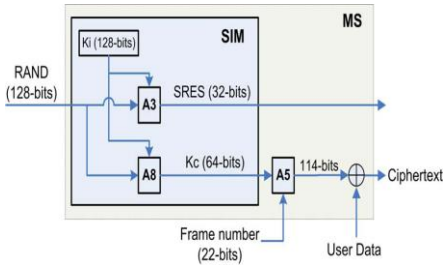

Figure 3: GSM authentication, session key generation and ciphering

The anonymity in the GSM is provided by replacing the use of IMSI with a 32-bit Temporarily Mobile Subscriber Identity (TMSI). TMSI is typically handled by the VLR and is valid in a particular Location Area (LA) and will be updated at least in every location update procedure. It is also stored on the subscriber's SIM and prevents an eavesdropper to track a particular subscriber.

Challenges to the GSM Security

The openness of wireless communications makes the communicating parties more vulnerable to the security threats. Although GSM tried to harden the interception by using several techniques such as frequency hopping, the real-time interception of the exchanged information is completely practical. Currently, there are commercial equipment capable of simultaneously intercepting several collocated subscribers. While GSM was intended to be a secure wireless system and considered the user authentication and over-the-air encryption, it is completely vulnerable to several attacks, each of them aiming a part of network. Hereunder, the most important security flaws of the GSM are briefly listed. Several practical scenarios can also be deployed to misuse such vulnerabilities that are neglected for the case of brevity.

i. *Unilateral authentication and vulnerability to the man-in-the-middle attack:* This is the network that authenticates users. The user does not authenticate network so the attacker can use a false BTS with the same mobile network code as the subscriber's legitimate network to impersonate himself and perform a man-in-the-middle attack. The attacker can then perform several scenarios to modify or fabricate the exchanged data. At the designing phase of the GSM protocols, this kind of attack seemed impractical due to costly required equipment. Currently, this kind of attack is completely applicable due to the decreased costs.

ii. *Flaws in implementation of A3/A8 algorithms:* Although the GSM architecture allows operator to choose any algorithm for A3 and A8, many operators used COMP128 (or COMP128-1) that was secretly developed by the GSM association. The structure of COMP128 was finally discovered by reverse engineering and some revealed documentations, and many security flaws were subsequently discovered. In addition to the fact that COMP128 makes revealing Ki possible especially when specific challenges are introduced, it deliberately sets ten rightmost bits of Kc equal to zero that makes the deployed cryptographic algorithms 1024 times weaker and more vulnerable, due to the decreased key space. Some GSM network operators tried another new algorithm for the A3/A8, called COMP128-2. COMP128-2 was also secretly designed and inherited the problem of decreased key space. Despite of such important problem, no other problems are reported so far. However, we can prospect

for new discovered vulnerabilities in the future as it is secretly designed. An improved version of COMP128-2, called COM128-3, is also proposed that generates 64 bits of session key and resolves the problem of decreased key space.

iii. *SIM card cloning:* Another important challenge is to derive the root key Ki from the subscriber's SIM. In April 1998, the Smartcard Developer Association (SDA) and the ISAAC research group could find an important vulnerability in the COMP128 algorithm that helped them to extract Ki in eight hours by sending many challenges to the SIM. Subsequently, some other schemes were proposed that were based on the chosen challenges and were capable of extracting Ki in fewer times. Ultimately, a side-channel attack, called partitioning attack, was proposed by the IBM researchers that makes attacker capable of extracting Ki if he could access the subscriber's SIM just for one minute [9]. The attacker can then clone the SIM and use it for his fraudulent purposes. The COMP128 algorithm needs large lookup tables that would leak some important information via the side channels when it is implemented on a small SIM.

iv. *Over-the-air cracking:* It is feasible to misuse the vulnerability of COMP128 for extracting the Ki of the target user without any physical access to the SIM. This can be accomplished by sending several challenges over the air to the SIM and analyzing the responses. However, this approach may take several hours. The attacker can also extract IMSI using an approach that will be explained later. After finding Ki and IMSI of the target subscriber, the attacker can clone the SIM and make and receive calls and other services such as SMS in the name of the victim subscriber. However, the attacker will encounter with a slight problem. The GSM network allows only one SIM to access to the network at any given time so if the attacker and the victim subscriber try to access from different locations, the network will realize existence of duplicated cards and disables the affected account.

v. *Flaws in cryptographic algorithms:* Both A5/1 and A5/2 algorithms were developed in secret. The output of A5/1 is the XOR of three LFSRs. An efficient attack to A5/1 that can be used for a real-time cryptanalysis on a PC includes two kinds of attacks. The former that requires the first two minutes of eavesdropped encrypted conversation is capable of extracting the ciphering key in about one second, while the latter just needs two seconds of encrypted conversation to extract the ciphering key in several minutes. A5/2 is the deliberately weakened variant of A5/1. An efficient attack to A5/2 requires less than one second of encrypted conversation to extract the ciphering key in less than one second on a PC.

vi. *Short range of protection:* The encryption is only accomplished over the airway path between MS and BTS. There is not any protection over other parts of network and the information is clearly sent over the fixed parts. This is a major exposure for the GSM, especially when the communication between BTS and BSC is performed over the wireless links that have potential vulnerabilities for interception. In some countries, the encryption facility of the air interface is not activated at all. There are also security problems on the GSM backbone. The deployed Signaling System no.7 (SS7) has also several security vulnerabilities. The messages in the current SS7 system is so that they can be modifies or even fabricated into the global SS7 system in an uncontrolled manner. SS7 incorporates very limited authentication procedures since it was originally designed for the closed telecommunication communities. The interconnection with Internet can also have its potential vulnerabilities. Additional vulnerabilities will be arisen when SS7 systems are interconnected using the Internet. Remote management of the GSM backbone elements that can be conducted by connecting them to the IP networks can also introduce additional vulnerabilities. If the

HLR and AuC are physically separated, it can be a new point of vulnerability since the authentication triplets may be obtained from AuC by masquerading as another system entity, e.g. a HLR. Unauthorized accesses to HLR, AuC, and MSC will also cause several problems.

vii. *Lack of user visibility:* The ciphering is controlled by the BTS. The user is not alerted when the ciphering mode is deactivated. A false BTS can also deactivate the ciphering mode and force MS to send data in an unencrypted manner.

viii. *Leaking the user anonymity:* Whenever a subscriber enters a location area for the first time or when the mapping table between the subscriber's TMSI and IMSI is lost, the network requests the subscriber to clearly declare the IMSI. This can be misused to fail the user's anonymity and can be accomplished by sending an IDENTITY REQUEST command from a false BTS to the MS of the target user to find the corresponding IMSI.

ix. *Vulnerability to the DoS attack:* A single attacker is capable of disabling an entire GSM cell via a Denial of Service (DoS) attack. The attacker can send the CHANNEL REQUEST message to the BSC for several times but he/she does not complete the protocol and requests another signaling channel. Since the number of signaling channels is limited, this leads to a DoS attack. It is feasible since the call setup protocol performs the resource allocations without adequate authentication. This attack is economical since it does not have any charge for the attacker. It can also be used for many practical situations such as terrorist attacks.

x. *Absence of integrity protection:* Although the GSM security architecture considers authentication and confidentiality, there is no provision for any integrity protection of information [2]. Therefore, the recipient cannot verify that a certain message was not tampered with.

xi. *Vulnerability to replay attacks:* The attacker can misuse the previously exchanged messages between the subscriber and network in order to perform the replay attacks.

xii. *Increased redundancy due to the coding preference:* The Forward Error Correcting (FEC) is performed prior to the ciphering so there is a redundancy that increases the security vulnerabilities of deployed cryptographic algorithms.

Security of Transport Channels

The GSM network has some transport channels: *Short Message Service* (SMS), *Unstructured Supplementary*

Service Data (USSD), *Wireless Application Protocol* (WAP), and the voice channel. There are also some newer services such as *Enhanced Messaging Service* (EMS) and *Multimedia Messaging Service* (MMS) that have been added in the GSM upgrades. The security flaws described in the previous section are commonly applicable to all the services and transport channels since they aim all the exchanged data and signaling information. However, in addition to such common flaws, some of GSM transport channels have some extra problems and vulnerabilities. The SMS messaging has some extra security vulnerabilities due to its store-and-forward attribute, and the problem of fake SMS that can be conducted via the Internet. When a user is roaming, the SMS content passes through different networks and perhaps the Internet that exposes it to various vulnerabilities and attacks. Another concern is arisen when an adversary gets access to the phone and reads the previous unprotected messages. The USSD that is a session-oriented technology is also vulnerable to attacks since the messages are not encrypted and secured on the GSM backbone. The WAP allows ME to connect to the Internet. The WAP Gateway that resides between MS and Web server in the WAP architecture and acts as an interpreter between the Internet protocols (HTTP, SSL/TLS, and UDP/TCP/IP) and the corresponding WAP protocols (WSP/WTP, WTLS, and WDP),

introduces an additional security flaw in some implementations that is referred to as the WAP gap. Other concerns are arisen from security problems of the Internet as a huge uncontrolled network that is in contradiction with assumptions of the GSM security architecture in which the core network is assumed as a secure and controlled environment. The web servers may also download and execute malicious applets at the client (ME) so the safety of applets and other downloaded programs is another concern.

Solutions to the GSM Security Flaws

The GSM specifications have been revolutionized since its inception. In 2002, several efforts were done to design new cryptographic algorithms for GSM, ECSD, GPRS, and EGPRS that can be implemented on dual-mode phones. Ultimately, A5/3 for GSM and ECSD/EDGE, GEA3 for GPRS, and f8 for UMTS were proposed, all of them having a similar structure.

The security mechanisms of the GPRS are similar to that of the GSM. However, instead of using A5 algorithm, GPRS uses the GPRS Encryption Algorithm (GEA) that currently has three versions: GEA1, GEA2 and GEA3. In the GPRS, the end terminal of encryption is moved towards a deeper point in the network, i.e. the SGSN. Although the encryption is performed at the physical layer of the GSM, it is accomplished at the Logical Link Control (LLL) layer of the GPRS. The UMTS, in addition to its new offered applications, has scrutinized the GSM security problems and has resolved most of them. The main reason of GSM security problems was due to the fact that its security was provided by obscurity so the UMTS algorithms were openly designed. Consequently, its algorithms are not encountered with serious problems. Although some theoretical attacks are proposed, they are not practically feasible with the current technology. However, there are also some other problems related to the deployed protocols.

Regardless of security improvements in the upper generation networks, it is necessary to provide solutions to improve the security of the currently available 2G systems. Hereunder, some practical solutions are proposed for this purpose. They are:

i. *Using secure algorithms for A3/A8 implementations:* This can thwart the dangerous SIM card cloning attack. This solution is profitable since the network operators can perform such improvement themselves and without any need to the software and hardware manufacturers or the GSM consortium. However, this solution requires providing and distributing new SIM cards and modifying the software of the HLR. Currently, both COMP128-2 and COMP128-3 algorithms thwart the SIM card cloning and over-the-air cracking of Ki. Since COMP128-3 enhances the effective key length of the session key to further 10 bits, it allows the deployed cryptographic algorithm to have its nominal security. Although it is soon to judge on the real security of COMP128-2 and COMP128-3, they have apparent advantages over the traditional COMP128-1 that its SIM cloning apparatus are available at very low prices.
ii. *Using secure ciphering algorithms:* Operators can use newer and more secure algorithms such as A5/3 provided that such improvements are allowed by the GSM consortium. The deployed cryptographic algorithms should be implemented on both BTS and mobile phones. Any change to the cryptographic algorithms requires agreement and cooperation of software and hardware manufacturers since they should perform the appropriate changes to their products. Since the cryptographic algorithms should be implemented on the cellular phones, the agreement of mobile phone manufacturers is also required. However, a lonely upgrading of the deployed cryptographic algorithms cannot be so useful. Even though the ciphering algorithms are replaced with the strongest ones, the attacker can simply impersonate the real

network and force MS to deactivate the ciphering mode so it is also necessary to modify the authentication protocols.

iii. *Securing the backbone traffic:* Encrypting the backbone traffic between the network components can prevent the attacker to eavesdrop or modify the transmitted data. Although this solution may be implemented without the blessings of GSM consortium, the co-operation of hardware manufacturers is still required.

iv. *End-to-end Security:* The best, easiest, and most profitable solution is to deploy the end-to-end security or security at the application layer. Most of GSM security vulnerabilities (except SIM cloning and DoS attacks) do not aim at ordinary people. Their targets are usually restricted to special groups. So it is reasonable and economical that such groups make their communications secure by the end-to-end security. Since the encryption and security establishment is performed at the end-entities, any change to the GSM hardware will not be required. In this way, even if the conversation is eavesdropped by the police or legal organizations, they cannot decrypt the transmitted data without having the true ciphering key, provided that a secure enough cryptographic algorithm is deployed. Therefore, in order to avoid illegal activities, it should be transparent to both GSM operator and service provider. It may also be necessary to find solutions for a legal interception or a key screw scheme. The end-to-end security establishment has a complete flexibility to the deployed algorithms so the appropriate upgrades can be easily accomplished when necessary. However, it may be a subject to export control. Generally, the end-to-end security can be provided in the cellular systems by following one or some of the following approaches:

    a. Exploiting the processing capabilities of mobile phone using the programming languages such as J2ME (Java 2 Mobile Edition): Supported by the most recent cellular phones and Personal Digital Assistants (PDA) with the improved processing capabilities.
    b. Exploiting the processing capabilities of the SIM using the SIM Application Toolkit (SAT): Not supported by all SIM cards; especial SIM cards are required; the processing resources are still limited; and operations may be so time-consuming.
    c. Exploiting the processing capabilities of an additional smart card, e.g. JavaCard: Not supported by the usual phones; requires costly dual slot cellular phones.
    d. Exploiting the processing capabilities of a portable PC (laptop) connected to the ME: suitable for security mechanisms with huge processing and memory requirements, e.g. real-time end-to-end secure voice communications over the GSM voice channel.
    e. Exploiting the processing capabilities of a crypto processor that is embedded in the ME: It should be accomplished by the mobile manufacturer; cannot be changed or manipulated by the user; and may be a subject to export control. The first four approaches have an inherent advantage due to their capability of being simply manipulated by the end-entities. However, choosing the most profitable approach regards to some parameters such as required memory and processing resources of the corresponding application. For example, if the voice is to be end-to-end encrypted over the data channel, it can even be implemented by a software application that is installed on an advanced cellular phone. On the other hand, for encryption over the voice channel that is hard to be tracked and so attractive for the terrorist and illegal activities, the fourth approach may be

suitable. The end-to-end security can be established by both symmetric and asymmetric encryption. The asymmetric encryption is usually too slow to be used for the real-time applications and may be used for the key establishment of a symmetric encryption algorithm. The public keys are usually jointed with the certificates. The private keys and the certificates can be securely stored on either SIM card, an additional smart card (for the dual slot phones), or a secure hardware on the phone. There are also some proposals for the Wireless Public Key Infrastructure (WPKI).

CONCLUSIONS

The GSM has become a tool for economic, political and social interactions among people of all profession, classes and status. This research effort was aimed at tracing the origin, developments, challenges and the solutions to the greatest communications technology the GSM has become. There is no gainsaying that this super tech is as large as the services and benefits it provides. Its technology has challenges in infrastructure, installation, commissioning, management and optimization. Since there is no end to research to research, this work was able to focus on the security of the network which aims at providing efficient, seamless, secure and effective services. Further areas of research can be on the hardware infrastructure. If the solutions are critically and judiciously implemented, it will enhance better quality service delivery from the operators and better value for money spent by the subscribers.

ABSTRACT

This study evaluates two different plastering materials for mud buildings. Mud stabilized with straw was used to cast two types of bricks of 450 mm by 225mm by 225 mm dimension using steel and wooden moulds. Six (6) samples of bricks were tested for strength, using the hydraulic compression machine. Bricks were used to construct eight (8) walls and finished with mortar and plaster rendering materials. The first four walls have mud mortar with plaster varied with mud and sandcrete for wood and steel moulded bricks respectively. The last four have sandcrete mortars, with variation in the brick type and plaster. The walls were observed for strength, crack and peel. Cracks on the walls were measured by the use of thread while the wall strengths test was done by the use of rebound hammer method. The results showed that walls constructed with steel moulded bricks, bounded with mud mortar and plastered with sandcrete gives the highest strength and the least amounts of cracks. Walls constructed with wooden moulded blocks using mud mortar and plaster tends to give the least amount of peel. Result shows that the older the bricks, the greater the failure load and hence the greater the compressive strength. Mud stabilized with grass and used engine oil gave the highest compressive strength of 1.123 N/mm2. The amount and type of stabilizers also affects the strength of bricks. This can be seen as in the bricks made of paste stabilized with grass alone and that stabilized with grass and used engine oil. Also the more compacted the mould is, the more the weight of the brick. This might be the reason while the steel moulded bricks were higher than those of wooden bricks at all ages.

Keywords: Cracks, Mortar, Mud bricks, Strength, Wall

INTRODUCTION

Mud as alternative building material

The meteoric and continuous rise in the cost of building materials possesses strong challenges to the construction industry (Abagale and Twumasi, 2013). This challenge led many researchers into finding alternative cheap materials of construction. This challenge was further emphasized in the Nigerian New National Housing Policy, where it was stated that the nation should gradually and systematically develop appropriate capabilities to reduce construction cost and achieve self sufficiency in the production of basic building materials and components from local resources at affordable cost (Olusola, et. al., 2006). Low cost shelter can maintain good health of vulnerable lives in many places (Vatandoost et. al., 2009). Locally building materials commonly used are organic materials such as timbers, stalks, wood, bamboo, grasses, rubber and bitumen and inorganic materials such as concrete, sandcrete, iron, steel, earth (mud), rock, stone and lime (Alabadan, 2006, Alabadan, et. al., 2012 and Fawale, et.al., 2016). One of the available alternative materials is the mud. It is primarily the most readily available materials around. Mud is used in its pure state and mixed with straw to make it more resistance to water effect because of its structural limitation. It has high thermal capacity. Mud is cheaper and readily available, resistant to fire, easy to work, using simple tools and skills and a good noise absorbent.

Challenges of using mud as a building materials

Mud is characterized by failure through cracking, under scouring and shrinkage, poor in durability and hence required frequent routine maintenance on the walls. Mud is generally available in all locations but varies in its quality and strength from one location to another hence the need for stabilization to increase its resistance to weather conditions. Stabilizers

Alabadan B. A.; Ajayi E. S. & Musa, Y. P. (2016). Evaluation of Different Plastering Materials for Mud Buildings. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 348-356

include grasses, fibres, bitumen, ashes, termite hills, vegetable oil, lime, Portland cement, electrolyte solution of sodium silicate salts and soil compaction (UNCHS, 1986 and Ahmed, 1987).

Mud buildings are generally more relevant to the modern building than it sometimes looks. They are easy and less costly to build and their waste can re-integrate with the soil. Their weakness to wind and water can be improved, and an appropriate finishing to these buildings will improve appearance, durability and comfort. There is the need to improve the strength, quality of the mud and the life expectancy of the mud buildings and thereby reduce the cost of maintenance carried out every year to keep the structure stable and in good condition (Abagale and Twumasi, 2013).

The most common finishes are plastering for inside surface of a wall and rendering for outside surface of a wall. Both applications serve identical purposes to provide resistance to moisture penetration, increase the fire resistance, sound and thermal insulation properties of the wall, give a more pleasant appearance and protect the structural wall from rain and sand storms (Banda, 1981; Ragsdale and Raynham 1972).

Problems associated with plastering and rendering of mud buildings include cracks, crazing or hair cracks, shelling and bond Failure. A plaster based on Parkia biglobosa husk extract is cheaper and has been used by the Kasena-Nankana people of Northern Ghana (Abagale and Twumasi, 2013). The objectives of this study are to evaluate different plastering materials on mud walls and to suggest ways on how to reduce these effects of failure on mud building wall.

METHODOLOGY

Mixing and casting of mud bricks

Clay soil was obtained from Federal Polytechnic Kaura-Namoda, Zamfara State, Nigeria. The mud paste was made by mixing the clay with water and treaded upon. Straw was added as stabilizers to the mud paste at different moisture contents. Mixing was done manually three different times. A little amount of straw spread on the surface of the mixture is remixed and left for a period of one to three week in which the mixture is remixed at interval of three to five days.

Wooden and steel moulds of 450 mm x 225 mm x 225 mm dimension were made and used for the casting of the bricks. The cast from the wooden mould batch had more moisture than that of the steel mould batch so that the consistency was good enough for the paste to come off easily from the wooden mould. To avoid sticking of mud to the wooden mould, a rag soaked with water was rubbed over the internal surface of the mould. In the case of steel mould, spent motor car engine oil was used to provide lubrication at the internal sides of the mould. The oil is also another form of stabilizer because it is derived from bituminous compounds.

To ensure workability the moisture content at each batch mixed was determined by weighing and oven drying. The consistency was also determined. After the first batch has been cast, the second mix was made while allowing the cast bricks to be strong enough to be moved, so that the second casting can be done. Each mixture was divided into two batches for the casting with the two moulds.

Consistency test

The apparatus consist of a cone shaped metal known as the cone penetrometer, in which a reading needle is attached to it. This is held by a clamp called the holder , the whole set is attached to a cubical container which houses the mud paste, by the aid of a long straight metal

which has the graduated scale on it. Mud paste was poured in the cubical container until full. The cone is released until its tip touches the surface of the paste. The position of the tip of the cone was noted on the graduated rule. It is then released fully to note the position on the graduated rule. The differences between the initial and final value is taken as the paste consistency (pc). The procedure is repeated for every batch of mud mix.

Moisture content determination

Mud paste samples were prepared in three containers and weighed in three replicates. Oven dried at a temperature of about 105^{o}C. The dried mud samples were removed and weighed to note the moisture loss. The moisture content is expressed as a percentage, as follows:

$$\% \text{ Moisture Content} = \frac{W_w - W_d}{W_d} \times 100 \qquad (1)$$

Where:

W_w = weight of wet soil

W_d = weight of dry soil

The procedure was repeated for each batch of mud paste and for mortars and plaster.

Brick testing

Two samples of bricks from each batch of the bricks and for each type of mould were used for compression strength test using the hydraulic compression test machine available in the Department of Civil Engineering, Federal Polytechnic Kaura-Namoda, Zamfara State, Nigeria. Each brick was first weighed and placed on a board of the size of the brick and another placed on top of the brick. It was then mounted on the machine and tested. The deflection of the indicator was observed. Lines of cracks appear on the brick surfaces which widens until a point of failure was reached when there was no more deflection. The failure load of each brick was noted and recorded.

Experiment design for different wall-plaster combination (2^3 Factorial)

The experiment was carried out in a way that the mortars and plaster were varied for each case. For the first row of walls, the first four walls have mud mortar with plaster varied with mud and sandcrete for wood and steel moulded bricks respectively. The last four has sandcrete mortars, with variation in the brick type and plaster. The arrangement of the walls and numbering according to the way they were constructed is shown in the Table 1 below:

Wall construction

Walls were constructed using the bricks from steel and wooden moulds. The walls were coated with two types of rendering materials. The walls were observed for changes due to environmental or weather conditions to note the extent of degradation and also tearing which could be on both sides of the walls.

Eight walls were constructed using the two types of brick and varying the plaster and mortar as shown in the 2^3 factorial experiments. For effective evaluation of the effect of these mortars and plaster, a replicate for each was also constructed with the same variation. The surface area was first cleaned, and the walls were constructed facing the direction of rainfall. Straight line was drawn using a tape, so that walls could be constructed along the line. The soil was excavated to about half the height of bricks. Mortar was laid as blinding and bricks arranged with the aid of spirit ray of bricks before the second course was laid. Each wall was made of 4 bricks for a course and 4 courses altogether. A total of sixteen walls using 256 bricks were constructed in two rows. Mud and sandcrete mortars were used for joining of bricks.

Table 1. Wall arrangement and numbering

Wall no	Code	Description of wall		
1	$A_{11}B_{11}C_{11}$	Wooden moulded bricks	+ mud mortar	+ mud plaster
2	$A_{22}B_{11}C_{11}$	Steel moulded bricks	+ mud mortar	+ mud plaster
3	$A_{11}B_{11}C_{22}$	Wooden moulded bricks	+ mud mortar	+ sandcrete plaster
4	$A_{22}B_{11}C_{22}$	Steel moulded bricks	+ mud mortar	+ sandcrete plaster
5	$A_{11}B_{22}C_{11}$	Wooden moulded bricks	+ sandcrete mortar	+ mud plaster
6	$A_{22}B_{22}C_{11}$	Steel moulded bricks	+ sandcrete mortar	+ mud plaster
7	$A_{11}B_{22}C_{22}$	Wooden moulded bricks	+ sandcrete mortar	+ sandcrete plaster
8	$A_{22}B_{22}C_{22}$	Steel moulded bricks	+ sandcrete mortar	+ sandcrete plaster
9	$A_{22}B_{22}C_{22}$	Steel moulded bricks	+ sandcrete mortar	+ sandcrete plaster
10	$A_{11}B_{22}C_{22}$	Wooden moulded bricks	+ sandcrete mortar	+ sandcrete plaster
11	$A_{22}B_{22}C_{11}$	Steel moulded bricks	+ sandcrete mortar	+ mud plaster
12	$A_{11}B_{22}C_{11}$	Wooden moulded bricks	+ sandcrete mortar	+ mud plaster
13	$A_{22}B_{11}C_{22}$	Steel moulded bricks	+ mud mortar	+ sandcrete plaster
14	$A_{22}B_{11}C_{22}$	Steel moulded bricks	+ mud mortar	+ sandcrete plaster
15	$A_{22}B_{11}C_{11}$	Steel moulded bricks	+ mud mortar	+ mud plaster
16	$A_{11}B_{11}C_{11}$	Wooden moulded bricks	+ mud mortar	+ mud plaster

Where: A_{11} = *Wooden moulded bricks* A_{22} = *Steel moulded bricks;*
B_{11} = *Mud mortar;* B_{22} = *Sandcrete mortar;*
C_{11} = *Mud plaster;* C_{22} = *Sandcrete plaster*

The wall no. 9 to 16 stand for the replicates of the wall no. 1 to 8

Plaster and mortar thickness

Two types of mortar and plaster were used: mud and sandcrete respectively. The thickness of the sandcrete plaster ranges between 10 to 13 mm while the mortar thickness for jointing ranges between 20 to 50 mm respectively, the initial mud plaster thicknesses were recorded as the walls were being washed off by rain. This was done to know the reduction in thickness of plaster as shown in Table 6.

Walls strengths test (use of rebound hammer Rh)

Rebound hammer is an instrument used in testing the strength of a building or wall. In case of this study, it is the index used in determining the strength variation between walls. Another index is the use of a mallet hammer. The rebound hammer is used to know the extent the walls can resist loosening their plaster due to rain and other environmental conditions. It also helps to determine the effect of cementing properties of plaster and the general strength of the walls. Each wall was divided into twelve grids. Readings were taken at specific points in each grid. The rebound hammer was pressed to project a rod-like structure from the inside of the hammer. It was pressed at the point whose reading was to be taken, until the entire length of rod has gone back into the hammer. This was accompanied by a sound; a button was pressed to hold the rod-like structure from projecting outside, so that the value can be read on a graduated scale attached to the hammer. Readings were taken at interval of one to two weeks for two months.

Measurement of cracks

Measurement of cracks was by the use of thread, whose tip is knotted to serve as a reference point and a 2m long tape. For each grid, the number of cracks was measured by placing the thread on the wall following the contours of the cracks to be measured. The length obtained is placed on the tape to read the value. The sum of individual crack in each grid, gives the total length for that particular grid. The procedure was repeated five times at intervals of one to two weeks. For each case, new cracks were noted and their lengths measured, while old ones were measured some of which increase in length and some remained the same.

Measurement of peel area

Mud plastered walls were observed for peels. The peels were mostly irregular in shape. A paper was placed on the peel to trace the shape of the peels. The figures obtained are sectioned to respective squares, rectangles and triangles of known dimension. The dimension were used to get the areas and hence, the total area of the peel.

RESULTS AND DISCUSSIONS

Moisture contents for mud, plaster, and mortars

Moisture contents of samples of mud paste used for casting of bricks and for the two types of brick cast, and moisture contents of plaster and mortars used for rendering and joining of bricks are given in Tables 2 below.

Table 2 Moisture Content of Mud Pastes

Brick type	Moisture Content (%)			Average Moisture Content (%)
	1	2	3	
Wooden molded bricks	28.13	27.47	28.49	28.04
Steel molded bricks	24.18	24.76	25.76	24.90
Mortar (Mud)	29.50	-	31.29	30.40
Mortar (Sandcrete)	30.10	-	30.70	30.40
Plasters	30.86	30.14	29.64	30.21

Table 2 shows that the moisture content of mortar is greater than that of plasters. Mortars are used for joining bricks which are dry, the moisture in mortars aid in effective joining, if moisture is less in mortars, bricks may not be fully joined. Moisture content of bricks cast with wooden mould was found to be 28.04 % while that of steel mould was about 24.90 %. The moisture content of the mortar for brick laying was found to be 30.40 %, while that of plaster for rendering was about 30.21 %.

Mud consistencies

The consistency of mud paste batches for the different casting periods and for the two types of bricks are presented in Table 3 below.

Table 3: Values of Consistometer test

S/N	Brick type	Description	Mud consistency (mm)		
			Straw Stabilizer		
			Initial value	Final value	difference
1.	A_{11}	Wooden moulded bricks	170 130	178	8
2.	B_{11}	Steel moulded bricks	140	133	3
3.	A_{22}	Wooden moulded bricks	110	142	2
4.	B_{22}	Steel moulded bricks	150	115	5
5.	A_{33}	Wooden moulded bricks	110	153	3
6.	B_{33}	Steel moulded bricks		114	4

The result in Table 3 shows that the consistency of mud paste decreases with a corresponding decrease in the moisture content. This can be observed in the consistency of the steel mould paste which appears to be less than that of the wooden mould paste, because the moisture level in the wooden mould paste is higher than that of the steel mould paste.

Compressive strength of cured bricks

The failure loads and compressive strength of bricks cast with wooden and steel mould for samples of bricks selected at different casting are given in Table 4 below. The result in Table 4 shows that the older the bricks, the greater the failure load and hence the greater the compressive strength. The amount and type of stabilizers also affects the strength of bricks. This can be seen as in the bricks made of paste stabilized with grass alone and that stabilized with grass and used engine oil. Also the more compacted the mould is, the more the weight of

the brick. This might be the reason while the steel moulded bricks were higher than those of wooden bricks at all ages.

Table 4 Failure Loads of Cured Bricks

Age (Days)	Brick Type	Weight of Block (kg)	Failure load, P (kN)	Area of Block, A (mm^2)	Stress= P/A (N/mm^2)
239	Wooden Moulded	37.45	105.0	100.833	1.041
239	Steel Moulded	39.21	115.0	102.383	1.123
198	Wooden Moulded	36.55	81.5	102.383	0.796
198	Steel Moulded	37.31	94.0	100.100	0.960
166	Wooden Moulded	36.20	40.0	100.100	0.399
166	Steel Moulded	37.41	91.0	100.133	0.909

Wall dimensions

Dimensions of walls for the mud and sandcrete plastered walls before the commencement of the test and grid dimensions for the sandcrete plastered walls are given as shown below in Table 5.

Table 5 Grid and Wall Dimensions for Mud and Sandcrete plastered Walls

Mud plastered wall dimension before commencement of test						**Sandcrete plastered wall dimension before commencement of test**					
Wall No	Width b(cm)	Height h(cm)	Length l(cm)	b + h (cm)	Grid length	Wall No	Width b(cm)	Height h(cm)	Length l(cm)	b + h (cm)	Grid length
1	23	88	192	111	49.50	3	25	84	198	109	36.33
2	23	89	200	112	50.00	4	22	89	200	110	37.45
5	23	89	190	112	41.20	7	23	90	190	113	37.66
6	23	89	194	112	46.33	8	23	89	193	112	37.33
11	24	89	191	113	48.33	9	23	90	191	113	38.33
12	23	90	190	113	48.00	10	23	92	192	115	38.43
15	23	93	190	116	48.00	13	23	92	194	115	38.33
16	23	93	194	116	48.00	14	23	92	194	115	48.33

The results in Table 5 show that the change in the dimension of bricks results in the variation of the walls dimensions. The mud plastered wall had higher grid length. This is as a result of mud paste not properly compacted during casting, inconsistency of the mixed constituents, the level of moisture content of mud paste and drying effect of casted bricks.

Plaster and mortar thickness of walls

The values of plaster and mortar thickness of both mud and sandcrete and for the sandcrete plastered walls is given in the Table 6 below:

Table 6 Plaster and mortar wall thickness

Mud			Sandcrete		
Wall No	Plasters thickness (mm)	Mortars Thickness (mm)	Wall No	Plasters thickness (mm)	Mortar thickness (mm)
1	10	15	3	20	20
2	20	20	4	20	30
5	30	20	7	20	20
6	20	25	8	30	25
11	20	30	9	20	30
12	20	25	10	20	15
15	20	30	13	10	20
16	10	25	14	20	25

The result shows that, there is a variation between the walls and thickness of plasters and mortars. This is as a result of the method of application of plasters and mortars, which is done by hand. It can be observed that the thicknesses varies between 10 mm and 30 mm for mud and sandcrete plastered walls and between 15 – 30 mm for mortars of both walls.

Rebound hammer test

Results of walls strength test using Rebound hammer at interval of two weeks in N/mm^2 are given in Table 7 below:

Table 7 Values of rebound hammer readings.

Total Rebound Hammer Readings (N/mm^2)							
Wall 1	Wall 2	Wall 3	Wall 4	Wall 5	Wall 6	Wall 7	Wall 8
0.92	0.86	0.68	0.58	0.74	0.60	0.55	0.38
0.89	0.99	0.85	0.43	0.61	0.72	0.73	0.67
0.61	0.64	0.71	0.19	0.50	0.50	0.46	0.60
0.74	0.81	0.53	0.38	0.40	0.63	0.79	0.11
0.97	1.04	0.49	0.64	0.35	0.43	0.72	0.21

The results shows that at specific points on each grid, the rebound hammers readings are not the same as a result of the inconsistency in the mixing of plaster because mixing is done by hand. The application of plaster is another reason for variations in readings taken. At some points plaster thicknesses is greater than other points. Looking at individual walls and their replicates the walls combinations of brick, mortar and plaster types greatly influences the strength of such walls. The type of stabilizers used also affects the walls strength. Walls constructed with mud stabilized with straw and used engine oil (bituminous compounds) tends to be stronger and durable than those constructed with mud stabilized with only straw. The walls constructed with steel moulded bricks, bounded with mud mortar and plastered with sandcrete gave the highest strength.

Cracks

The result of the total length of cracks which occurred in each wall recorded at interval of two weeks is given in Table 4.7 below.

Table 8 Total crack length for each wall

Total crack length (mm)							
Wall 1	Wall 2	Wall 3	Wall 4	Wall 5	Wall 6	Wall 7	Wall 8
-	-	-	-	-	-	-	-
1915	4745	3365	4680	8815	7875	4870	5355
5450	7890	5170	6695	5935	8395	5515	7075
6590	13155	6720	11205	10600	10255	15645	8340
7685	15170	7930	11405	11555	23860	19670	11085

The results in Table 8 shows that the amount and rate of cracks is due to the level of exposure of walls to ambient conditions and the most exposed walls to such conditions were wall 6 and 7. The type of brick, mortar and plaster used, affects the amount and rate of cracking. The consistency in the constituents of brick and mortar also affects the binding property of plaster on walls, hence the amount and rate of cracking. The highest amount of cracks was recorded in walls constructed with wooden moulded bricks, bounded with sandcrete mortar and plastered with sandcrete.

Peel area and reduction in mud plasters

The result of the peel area and reduction in mud plasters in each wall recorded at interval of two weeks are given in Table 9 below.

Table 9a Peel area and reduction in mud plasters

Peel Areas (mm^2)							
Wall 1	Wall 2	Wall 5	Wall 6	Wall 11	Wall 12	Wall 15	Wall 16
-	-	-	53590	-	77716	140530	89410
-	-	263069	209450	212250	173670	275680	238460
-	-	341060	365310	254790	508590	493970	275310

It was found that walls constructed with wooden moulded bricks binded with sandcrete mortar and plastered with mud have the highest amount of peel. Results shows that peels occur as a result of plaster not properly bound to the wall. This is due to the constant wetting and drying of walls which causes the swelling and shrinking of walls. When the plaster is not properly bound to the wall, it tends to peel off the wall. The tendency for mud plasters to stick to the wall depends on the consistency in the constituents of bricks, mortar and plasters used.

Table 9b Reduction in mud plasters thickness

Reduction in mud plasters thickness (cm)							
Wall 1	Wall 2	Wall 3	Wall 4	Wall 5	Wall 6	Wall 7	Wall 8
24	16	14	15	30	26	16	28
19	11	10	12	10	13	14	25
10	8	5	10	5	4	5	8

On the other hand, reduction in plaster thickness is as a result of constant washing of the surface of walls plastered with mud. The main weakness of mud lies on its low resistance to water as stated in the review of this study. The tendency of mud plasters to be washed depends on the stabilization, because stabilizers increase the resistance of mud plasters to weather conditions.

CONCLUSIONS

Mud paste with higher moisture contents results in high level of shrinkage upon drying of bricks. The age and type of bricks influences the failure load and the compressive strength of bricks from steel mould has higher value. Bricks compacted by hand tends not to be fully compacted, which results in reduction in block dimension and the compressive strength of bricks.

Walls constructed with steel moulded blocks, binded with mud mortar and plastered with sandcrete gives the highest strength. Walls constructed with steel moulded blocks, binded with mud plaster and plastered with sandcrete gives the least amounts of cracks. It was found that walls constructed with wooden moulded blocks, binded with wooden moulded blocks, binded with sandcrete mortar and plastered with mud has the highest amount of peel.

The Building Profession and the Challenges of Achieving Sustainable Buildings in Nigeria

Abiodun, Isaac

Executive Director, Units Environmental Sciences Ltd., 1 Kandi Close Wuse 2, Abuja, Nigeria
**iabiodun@yahoo.com*

ABSTRACT

The incessant building collapse happening across the country is a matter of concern to authorities, developers, users and professionals alike. Some buildings no longer reach their life expectancies. Some even collapse in the process of construction. In this sense, sustainable buildings seem to be at large in Nigeria. When a building collapses before the expiration of its lifespan or before being put into use, sustainability is even far from being attained. The effort of concerned stakeholders especially the professionals to formulate and see to the implementation of a standard National Building Code for all building projects in the country has not reached a conclusive point. The National Building code was approved by the Federal government in 2006, but it is yet to be put into practice. The lack of continuity, consistencies and commitment in policy implementation is identified as a major problem militating against the use of the building code. This paper adopts literature review to examine the incidents of building collapse and sustainability issues in the nation's environment, the contributing factors and proffered solutions to curb the undesirable situation. It evaluates applied theories of policy analysis to address the policy implementation problem of the building code, education, professional training and other relevant policy issues in the industry, encourages professionals in the industry to solve the problem in collaboration with the government using policy implementation networking.

Keywords: Building collapse, Sustainable building, builder, Building Code

INTRODUCTION

The quest by the construction industry professionals and other stakeholders to move towards sustainable buildings and green buildings is beclouded by the ugly incidences of building collapse across the country. Buildings are scarcely fulfilling their life span, while some even collapse in the process of construction. The attitude towards maintaining and upgrading the existing structures is not encouraging. It is also noticeable that some of the new structures that are springing up within the environment are of less value in terms of sustainability features and aesthetics. This state of things in towns and cities is rather worrisome and does not pose a good image of the industry. How can one talk about sustainable built environment or the Green Building when buildings die at 'infant' or as 'foetus' in the process of delivery before reaching matured age. The blame for this, cut across all participants, ranging from the professionals to the authorities and building owners and users. There has been an effort on the side of the professionals to instil in the government, the need for adoption of building code for standardization of building construction and practice in Nigeria. After much effort the National building code was approved but its implementation has not been enforced. The lackadaisical attitude towards policy implementation needs a critical redress. The paper in the following paragraphs highlights the trend of building collapse in the country, the likely causes and some measures needed to address the ugly situation.

UPDATES FROM THE INDUSTRY – THE PERFORMANCE

Sustainability Crises and Building Collapse

The news coming from the industry is not a palatable one. The industry is said to be 'underperforming and uncoordinated' with lack of discipline and operates in a seemingly 'lawless situation' which partially account for the incessant building collapse in the country.

Abiodun, I. (2016). The Building Profession and the Challenges of Achieving Sustainable Buildings in Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 357-367

Report has it that from 1994 to 2011, the reported cases of building collapse stand at about 114 with attendant 404 deaths, 136 various degrees of injuries and property losses worth billions of Naira (Jambol, 2012). The study conducted by Ebehikhalu and Dawam (2014) shows a recorded number of building collapse between 1974 and 2012 as 139 with 798 lives lost. It shows further that 54.17% of the reported cases of collapsed buildings are residential buildings (15.83% under construction), 10% for commercial buildings, 8.33% for educational buildings, 5% for religious buildings, 2.5% for hotels, 1.67% for courts, and 0.83% for hospitals. These figures do not take account of unreported cases and still not updated till date. It could be seen around the environment what seems like unplanned cities, abuse of the built environment, incessant building collapse, fire outbreak and the like which are majorly attributable to the lack of referenced design standards for professionals, use of quacks, lack of supervision, poor workmanship, use of substandard/untested materials, and the lack of maintenance culture, conversion of building use from its original purpose, excessive loading, faulty design, lack of compliance with building regulations and approved plans (Obiegbu, 2008; Mbamali and Okotie, 2012; Ebehikhalu and Dawam, 2014). These results indicate that sustainability of the built environment is undermined. In the situation that this generation is still struggling to cater for itself, it will not be out of place to admit that the present generation is already compromising the rights and expectations of the future generation to enjoy the environment. If the authorities and industry professionals are still struggling to address issues related to meeting the objectives of what can be termed first degree sustainability (safe structures), one wonders the state of their preparedness in achieving the second degree sustainability- the green building.

Theoretically the terms ‘Sustainability’ and ‘Sustainable Construction’ can be used interchangeably. Sustainable Construction is the set of processes by which industry delivers built assets that enhance quality of life, offer customer satisfaction, provide the potential to cater for user changes in the future, provide and support desirable natural and social environment, and maximise the efficient use of resources (Highway Agency, 2003). A building may fulfil its intended purpose and ‘die at old age’ or die an untimely death by way of collapse referred to as ‘total failure’, or it may be partial failure where the observed performance is less than the designed performance. In both cases sustainability is undermined. This is mostly attributed to human errors by way of design, build and the use (Jambol, 2012). Sustainable construction spans the entire project life cycle- design, procurement, construction, commissioning and use. It involves the use of environmentally friendly materials, energy efficiencies and waste management (Izam and Ameh 2012). Sustainability features need to be incorporated at different stages of the life – cycle of the construction facilities due to its network of interaction with people and environment, but unfortunately, and sad to note also, that infrastructure sustainability till date has proved elusive to the Nigeria public infrastructure and buildings (Abiodun, 2013). Having summarised the industry performance in terms of sustainability, it is imperative to proceed to examine the major causes so that suggestions can be proffered for appropriate remedial actions.

Update from the Industry – Causal Factors

Government Side

The picture painted by the industry commentators about government’s posture towards developing the industry is a bleak one. Since government has a larger share of the industry, its impact on the industry development and performance is great either by action or inaction. The construction industry is said to account for about 17% of GDP out of which building subsector is estimated to account for 12% per annum and 70% of the demand of the building industry is by the public sector. Abandoned projects are commonplace due to lack of fund,

political change where successive government fails to honour their predecessor's obligations, leadership problem, corruption and inconsistent policies. The posture of the past government towards housing and urban development and the lukewarm attitude towards encouraging the intervention of the Green Building Council of Nigeria (GBCN) to ensure sustainable development of the environment does not show any positive drive to set the industry on the path of achieving sustainable environment (Akindoyeni, 2012). Nigeria's development efforts over the years have been characterized by lack of continuity, consistencies and commitment (3Cs) to agreed policies, programmes and projects (Izam, 2012). The lack of referenced standard code for design and construction, occasioned by the non-passage of the building code into law to make it effective show government's characteristic lack of '3Cs' which undermines the industry's growth (Obiegbu, 2008; Akinsola and Fatokun, 2012; Izam, 2012). Although the National Building Code has been approved by the Federal Executive Council since 2006, it is yet to be given a legal backing and so it is yet to be accepted across board.

Other factor is the state of our tertiary education to respond in terms of improved curriculum to cope with emerging demand of the industry. This area too on the side of government is lacklustre.

Professional Side

One major setback in the industry practice is duty overlap and rivalry. Instead of the industry professionals to work collectively towards the development and growth of the industry, some prefer to take undue advantage over others by practising profession of others where they have not received requisite trainings. This has been argued extensively in the author's research work (Abiodun, 2012), particularly how the sister profession (the engineers) have taken over the profession of quantity surveying in civil and infrastructure works, known or unbeknownst to the authorities. Building profession suffers similar fate in the hands of other professions in the industry. In this regard, Akindoyeni (2012) lamented on the seemingly unending state of unhealthy rivalry in the industry. Due to the absence of enforcement of regulation and monitoring of the industry practice by the authorities, the industry 'limped along' where some 'greed –induced' rivalry has placed other profession in a position of advantage over others. In an ideal situation, members of the design team, on a building project, should be the architect, structure engineer, a builder, electrical engineer, mechanical engineer, quantity surveyor. If the functional coordination of spaces and the environment, structural stability, buidability potentials, green potentials and sustainability, health and safety potentials as well as cost limit assurances are faulty, it means the whole members of the team have not been given adequate chance to participate and contribute their respective skills. He puts it rather humorously this way "It is not only the lawyer or shoemaker who design and build that is unqualified" but when one professional in the industry performs functions of another professional, he is unqualified and as such a quack. This means that quacks are not just unskilled street guys. This situation is majorly caused by the lack of any legal instrument currently in operation that forces professionals to observe boundary limit of their respective practice without interfering in other's area of competence.

Other problem from the professional side is the lack of adequate coordination of the design and construction among the project team to resolve sustainability issues during the project lifecycle. In most cases no feedback mechanism are performed by the project team in respect of performance of the completed projects (See also Jambol, 2012).

Capacity building and continuous professional development individually and by the professional bodies to meet the emerging realities of the industry have not been addressed adequately. This is in the area of the use of new methodologies, environmental friendly materials, energy efficiencies, waste management and global best practices that gear towards

maintaining sustainable environment.

Having summarized the major problems, suggestions on the possible remedial courses of action are proffered in the following paragraphs.

Suggested Solutions – Government Side

Policy Formulation and Regulation

The converging views from the foregoing review in respect of causal factors to the sustainability challenge in the industry are that government is deficient in the area of policy formulation and implementation. Then, what is policy and how is it formulated and implemented? In discussing the theories of policy analysis, it is imperative to first highlight the precursor to policy process and agenda setting. Public policy is "a course of action of government or inaction in response to the public problems." It involves dealing with public problems to 'address conditions considered not acceptable which requires intervention'. It formally deals with policy goals and means of achieving them, including setting regulations for agencies that implement government programmes (Kraft and Furlong 2010). Public policies are one of the main means through which order is set in the societies and changes are introduced which modifies individual and collective behaviour' (Parag 2006). Policy process is conceived through three separate streams: Problem stream; Policy stream; and political stream. Firstly, there must be policy problems to be solved. These problems usually emanates from the feedback from the performance of an existing policy. There must be awareness of problems seeking government intervention which were possibly not seen as such in the previous regime. Secondly, there must be available policy solution to resolve the lingering problems. Thirdly, the political environment must be conducive to accommodate the intending policy change (Parsons 1995).

Applying this theory to the situation at hand, a need arises for the use of Building Code to standardise building planning, design and construction, with the objectives of addressing the dysfunction of the built environment such as building collapse, quackery, use of substandard products and so on (problem stream). Building code has been formulated already as a concrete policy solution to the problem (policy stream). Accepting and implementing the code within the industry to make it effective to solve the problem is still lingering (political stream). The stage of political stream is the most problematic in the Nigeria's system. It is rarely got done!

The National building code has been formulated, but passing it into law to regulate building practice is still begging for attention. Building Code is a collection of technical and legal requirements that guides the design, construction and maintenance of buildings. "It is the minimum acceptable standard used to regulate design and construction and maintenance of buildings for the purpose of protecting the health, safety, and general welfare of the building users" (Obiegbu, 2008). The code is to make the building safe, reduce deaths, injuries and property damage, preserves the environment, contribute to durability of buildings to maintain quality of life. Until 2006 when the building code was approved by the Federal Executive Council (FEC), Nigeria's building industry has operated without uniform regulation and guidelines for design, construction and maintenance of buildings leading to disorganization and deplorable state of affairs in the industry (Mbamali and Okotie, 2012). The building code needs to be implemented to serve its purpose and also integrate it into the various States' Physical Planning laws (see also Jambol 2012). As at 2012 only Lagos State has passed and implemented physical planning law that incorporates National building code. Ogun State is also implementing physical planning law but without using the national building code. Others are at various stages of the process, while some are yet to start the process at all (Akinsola and Fatokun, 2012). It is worrisome that the federal government is not taking a proactive

measure towards the implementation of the building code. This attitude can be termed a pure state of accountability insensitivity.

In addition to the code, there should be regulations that will demarcate practice limit and boundaries and provides minimum standards of practice of professionals in order to correct the anomalies in the system and to improve service delivery, thereby reducing incidence of building failure and ensuring sustainability of the environment. This could be achieved through the establishment of Construction Industry Development Board which will encourage genuine transformation of the construction industry in Nigeria (See Akindoyeni, 2012; Izam 2012).

Governance System and Sustainable Policy implementation

The lack of continuity consistencies and commitment in policy implementation identified by commentator's centres around deficient governance system (leadership problem). The lack of continuous and consistent policy implementation is rife in Nigeria. The failure of incumbent governments to honour the obligations of the past regime negates the notion of 'inheritance' in policy analysis. The policies of the past governments have impact on whatever the present policy decision will be. The inheritance from previous governments has great impact on the present government. In fact since problems are inherited from the past, a newly installed government needs to 'look back before it can look forward' (Rose, 1990). The commitment of past government must be accepted by the incoming government as legacy that is carried forward by institutional commitment grounded in laws. If government abides by this rule, projects of previous administration will not be abandoned to award new ones, probably for selfish or political interest.

The process of implementing a new policy whether in public or private domain involves effective change management strategies. Accepting new rules and culture of working in a system is always a process and not by happenstance. This is because it is not always easy to change the culture of an organization because change is always a source of 'shock' to the organization in the first instance (Burnes, 2009). However changes to the organization culture can be done by following an organized procedure. For example, using Cummings and Worley's six steps to culture change: Formulate a clear strategic vision; Display top-management commitment; Model culture change at the highest level; Modify the organization to support organization changes; Select and socialize newcomers and terminate deviants; and Develop ethical and legal sensitivity. Change management could also be done through Lewin's three-phase model of change. The first step is to 'Unfreeze' the status quo and establishing the need for change (policy formulation). The second step is to Change to a new state by using the available resources (policy implementation). The third step is to 'Refreeze' the change to make it sustainable by integrating the change into organizational/institutional processes (consistent and continuous monitoring for policy sustainability). Unless refreezing or what is called internalization is done, it is expected that the change will be 'short-lived' (Robins and Judge, 2008). Short-lived changes are ubiquitous in the nation's governance system.

Most organizational/institutional changes are accompanied by resistance from individuals or groups. People repel change because of the fear of losing something of value, but in any transition 'old things have to be done with and new things must begin to take place' (Bridges, 2003). Four most common reasons why people resist change are: fear of loss of something of value; lack of understanding of the change and its implications; a belief that the change is not appropriate or not needed in the organization; and a 'low tolerance for change' (Kotter and Schlesinger, 1979). The fear of ability to develop new skill and behaviour that will be required in the changed organization is another reason for resistance to change (Kotter and

Schlesinger, 1979). The builder needs to learn new skills to adapt the global best practices in the industry especially in the area of sustainable development.

The system of government must recognize these policy and change management theoretical framework and sincerely put system in place to make it work. Professionals on their own part must be willing to adapt to change by altering behavioural pattern to fit into the changed system and structure so that policy implementation can be sustained.

Education

Government need to take a closer look at the academic system by providing funds for research and development including staff remuneration to build capacity for indigenous professionals (Dlakwa, 1998). If the tertiary institutions will continue to maintain relevance in the market place, then they need to update their curriculum to serve the outside world. Marketization of higher education is characterized by a closer partnership with outside client. There is now a movement away from the 'traditional pedagogy and conventional curricular' to the one that is responsive to the employers' demand (El-Rufai, 2006). The clear inadequacies in the university curriculum covering the area of sustainable construction and also in the area of related professional training need to be reviewed (Izam and Ameh 2012). Moving to the professional side, what are the expectations, particularly from builders?

Suggested Solutions – Professional Side

The Role of a Builder

"A Builder (or Professional Builder) is an academically trained specialist and statutorily registered professional responsible for Building Production Management, Construction and Maintenance of Buildings for the use and protection of mankind and his assets" (http://www.niobuilding.org/builderrole.html; Adeniye 2008) . The core practice of a builder is building production management and it encompasses services relating to buildability and maintainability (Obiegbu, 2008). Two distinct areas of practice identified by NIOB for builders are Building Construction Companies and Consultancy Firms of Professional Builders. Nigerian Institute of Building (NIOB) is the professional association of the builders in Nigeria. NIOB was recognized through the promulgation of Decree 45 of 1989 (now known as the ACT CAP 40 of the Laws of the Federal Republic of Nigeria of 1990) (http://www.niobuilding.org/aboutus.html). NIOB functions are "To develop and promote an Institute that will be Nigeria's authority in Building Production Management, Building Construction, Building Maintenance Management, Building Surveying and investigation through continuous professional development, research and training for the benefit of all stakeholders such as the government, the clients, construction professionals, construction industry operators, the Nigerian public and international interest groups through effective information management and efficient propagation of the Institute's activities and appropriate interaction with relevant corporate organizations locally and international" (NIOB-http://www.niobuilding.org/missions.html).

From the description, it is clear who a builder is and his functions and that of the professional body-NIOB. In the author's view, the consultancy services role of the builder needs to be well developed and marketed to the public, because the fact on ground at the moment is that builders are still restricted to the traditional construction role. Among the builders themselves, some commentators when describing the role of builders, still restrict builders' role to physical building construction and not as part of design team (see Mbamali and Okotie, 2012). In order for the builder to be properly equipped to perform in both the design and construction team for sustainability issues to be addressed adequately, the key issues highlighted in the following paragraphs should be looked into.

Building Capacity to Cope with Emerging Responsibilities

Professional upgrade and improvement is constantly needed to meet the emerging realities of the industry (see also Mbamali and Okotie, 2012). A consultant must have 'the necessary experience, qualifications, skills and expertise to help with a task that an individual or company wants performed'. The question is; can the professional/consultant add something of value to the client (Cohen, 2009)? A builder must strive constantly to improve and update skills and professional competence to be able to fit adequately into the scheme of things. For instance a builder must be well versed in the letter and provisions of the building code to be well positioned to perform design, construction and maintenance functions. The importance and benefits of capacity upgrade is not farfetched in the emerging era of Public Private Partnership that is trending the infrastructure provision landscape globally. Now that the traditional role of government as a sole provider of these services is dwindling and giving way to private provision, the stage is set for all professionals to demonstrate their abilities to be relevant. No more 'free lunch'. The private sector that is business oriented is willing to pay only, for professional services duly rendered- added value. Government does not, and will no longer perform their traditional functions of rowing and steering. It will continue to only steer (regulate) the network of systems in the economy. In essence professional bodies should ensure adequate training and retraining for practising professionals about the new development in the industry to ensure sustainability of the built environment (See Olagunju, et al. 2013).

Marketing

A professional builder individually and NIOB as a body, need to embark on some sort of marketing to sell the practice to the consumers. "To build and maintain a viable professional firm, marketing must permeate every activity. The professional sells image, technology, knowledge and insight, competence, creativity, attitude, and even philosophical approach. Unlike other products, professional service cannot be separated from the delivery vehicle (professional). As professionals we should not create the impression that we are hungry to the client. No one wishes to do business with someone perceived to be needy, hungry or unsuccessful. The most successful professional avoid any appearance of needing the business" (Shenson 1994). Professional builders need to present to the client the value they are adding to his present state that he needs to pay for. NIOB and Council of Registered Builders in Nigeria (CORBON) need to do aggressive marketing to sensitize the stakeholders in the built environment of the need to accept the use of professional builders in preparing and using construction methodology as a planning tool in building production (Abdulhammeed et al., 2012).

Sorting out the Unhealthy Rivalry within the Construction Professionals

It is hoped that professionals in the industry will see themselves as colleagues who must work collectively to develop the industry and not as rivals. Otherwise, there will not be any moral justification to blame the government for the industry's peril when the industry professionals fail to put their own house in order. Working together will ensure role definition and agreement on the scope of services of each profession to avoid overlap and rivalry. Architect to design and supervise, QS to cost, engineers to design structures and services, builders to build, and estate surveyor and valuers to market and manage completed structure (Obudu 1998). The design team should through regulation, implement appropriate design quality management system while the construction team should through the builders, produce and implement the project quality plan as envisaged by the code (Izam, 2012). A contractor or a builder can be integrated in the planning and design team to help designer integrate design with technology that ensures efficient and sustainable building production. In this case a builder can prepare work methodology as a consultant to be used by the design team in the

design process (Abdulhameed et al. 2012). This affords the builder to be part of the client's team to prepare production management document or vet the one produced by the contractor. These documents include construction methodology, construction programme, project quality plan, project health and safety plan, early warning system, schedule and so on.

Table 1 Building Collapse Cause-Effect and Solution

Building Sustainability Crisis	**Causal Factors**	**Recommended Solution**	**Desired Sustainability Effects**
- Incessant Building Collapse - Loss of Properties - Deaths and Injuries - Fire Outbreaks - Undermining Sustainable Enviroment	*Government* - Lack of Adequate Planning in project execution - Leadership problem and Political Change - Inconsistent policy fomulation and implementation - Lukewarm attitutde towards urban development and green buildings - Non-implementation of Building Code - Tertiary Education not dynamic to address emerging Industry's demand *Industry's Professionals* - Inadequate design planning in project execution - No referenced design standard document - Use of untested /substandard materials - Faulty design - Duty overlap and unhealthy rivalry among professionals - Lack of laws that regulate and monitor boundaries of professional practice - Inadequate coordination of design and construction among project team to resolve sustainability issues - No feedback mechanism on the performance of completed projects - Inadequate capacity building by professionals to meet new industry's demand *Owners & Professionals* - Use of quacks by building developers - Lack of maintenance culture - Conversion of building use without approval - Non-compliance with building regulation and approved plans	*Government* - Promote capacity building in the area of policy formulation, analysis and implementation - Proper identification of policy analysis segments (Problem stream, policy stream and political stream) - Ensure consistent policy implementation across successive government regimes - Establish an effective change management mechanism - Academic curricula to addrress industry's requirements *Industry's Professionals* - Capacity building by way of training and retraining - NIOB and CORBON to coordinate and monitor building construction practice to eliminate quackery - Ensure the use of tested and standard materials for construction - Adequate participation of all construction professionals and stakeholders from design to construction and maintenance stages - Maintian high level of professionalism - Adequate marketing of building profession especially for incorporation in the design team - Professionals in the industry to encourage team work not unhealthy rivalry and to observe practice boundaries - All stakeholders to work together in a policy network to formulate and implement construction policies *Owners & Professionals* - Prospective building owners to be compelled to use qualified professionals - Ensure adequate routine and periodic maintenance - Buildings should be used for the purpose designed and constructed - Adhere strictly to approved building plans	- Elimination of Building Failures - Fit for Purpose Buildings - Sustainable buildings and Environment - Fuller realisation of Expected Economic Benefits from buildings - Eradicate Deaths and Injuries associated with building failures

Suggested Solutions- Joint Effort

Collaboration with Government in a Policy Network

Summing it up all, an effective and workable strategy is collaborative efforts of government and professionals to achieve the stability and the growth that the industry desires. The new synergy is embedded in the theoretical framework of Policy Network- different actors (government, private and interest groups) working together in policy formulation and implementation for good governance. A Policy network comprises different actors, such as government structures, organizations, labour and trade unions, academicians, researchers, professionals and social critics. Network governance is concerned with 'how other actors, such as civil society organizations, may play a role in taking decisions on matters of public concern' (Graham et al., 2003). Governance is broader than government by covering non-state actors, thereby blurring the boundaries between public, private and voluntary sectors for information and resources exchange. Networks are self-organizing and regulated by laws and not accountable to the state but are being steered by the state (Rhodes, 2000). Accountability in respect of network governance is not linear or one directional pointing towards one specific organization (say government), but must fit the policy and its network', as Rhodes puts it 'accountability disappears in the interstices of the webs of institutions' (Rhodes, 2000). In the network, all stakeholders (Network of professionals and interest groups, and government) are working together towards a common goal to achieve sustainable development of the environment. No more pointing accusing fingers, the entire network is accountable.

A system must be put in place to ensure adherence (by all stakeholders) to the minimum required standard – 'system of plan checks, site inspection, professional responsibilities and regulatory accountability' (Obiegbu 2008). Government can use its state police power to enforce regulation and also use trained and certified professional to ensure compliance. The three tiers of government in Nigeria should collaborate with building professionals including other industry professionals working synergistically to work out strategies and policies to enhance the operation of the industry (Dikko 2002; Mbamali and Okotie, 2012). This collaboration should ensure standardization of local construction methods, education, training, enforcement of building regulations and monitoring, because previous attempts in addressing building sustainability have achieved very little so far (Olagunju, et al., 2013). This new direction is hoped to bring about the much needed sustainable built environment and national development. In Table 1, the paper condensed the current effects of building collapse, factors responsible, recommendations to curb it and sustainability effects realisable upon proper implementation of the recommended solution.

CONCLUSION

The ubiquitous incidents of building collapse and the quest to attain sustainability have been discussed. Causes identified are the non-implementation of standardized building code for building design and construction, the use of quacks in design and construction, lack of clear define roles of professionals in the industry, rivalry among professionals, inadequate use of skills of professional builders and other relevant professionals, and lack of consistent policy implementation by government. The paper recommends immediate implementation of the national building code, more proactive and collective approach by the industry's professionals in a network structure with the government to address the situation. Improvement is required in the curriculum of higher education to meet with the current demand of the industry. Professional builders in collaboration with the professional bodies need to acquire new knowledge and skills to be able to adapt to emerging changes in the industry's practice and advancement in technology. The building industry's professionals and

government need to work together in a policy network to ensure sustainable policy implementation to promote healthy growth of the industry, thereby ensuring sustainability of the environment.

Economic Impacts of Energy Consumption and Supply in Office Buildings of Kaduna Metropolis, Nigeria

Salihu Murtala Muhammad[1*] & Ejeh Ekoja David[2]

Department of Architecture, Ahmadu Bello University, Zaria
[*]murtalasg@gmail.com

ABSTRACT

This study sought to present the findings of an energy audit exercise carried out on some selected office buildings in Kaduna metropolis. The investigation is aimed at assessing the cost implications associated with energy demand, supply and consumption pattern in the study area. Four office building facilities are purposefully sampled; where an energy audit exercise that involved questionnaire surveys, structured interviews and physical observation methods is conducted through collection of data from three-year bills of utility and back-up sources of electricity supply. Findings revealed that the major actor in energy consumption is the cooling demand with 53% of the total end use demand, followed by other electrical equipment and lighting demands with estimated values of 35% and 12% respectively. It was also discovered that, although the normalized electricity demand is within an adequate range, the cost of supply is not commensurate to the rate of consumption. A significant level of overdependence on the backup electricity supply systems due to inadequate supply from the national grid also contributed adversely to the Total Energy Consumption Cost (TECC) of running the facilities. This study expresses a primary assessment strategy that is necessary to pave way for pin pointing the areas in which energy consumption can be minimized in such a building typology.

Keywords: economy, energy consumption, energy cost, energy supply, office buildings

INTRODUCTION

In the building industry today, discourses that relate to energy consumption and provision have become the focal point of concern towards achieving the much desired sustainable development within the confluence of our natural environment. It has been established by numerous studies from many parts of the world, that energy consumption in the built environment exceeds that of all other sectors, including transportation (Haoyang, 2012; Brown, 2010; Perez-Lombard, Ortiz, and Pout, 2008). Researches have also shown that commercial buildings and office buildings in particular, accounts for a significant amount of energy consumption that cast a direct impact on their immediate settings (Mu'azu, 2012; Sadrzadehrafiei et al, 2012; US Energy Information Administration (EIA) 2014). Although in Nigeria residential buildings form the major building stock in our cities, office buildings tend to be the dominant buildings in the city's central business districts (energy commission of Nigeria (ECN) 2003). It is therefore consequently connected to the energy challenges in our localities, in term of provision and distribution. It has therefore become imperative that energy consumption and distribution in office buildings is streamlined so as to reduce the potential adverse impacts it inflicts upon its settings both economically and environmentally.

The rise in number, scale, standards and elaborate requirements associated with office buildings today, due to recent economic boom experienced across the world has subjected it to a constant and increasing state of intricate energy demand (Rai, 2004; Ochoa & Capeluto, 2009). It is a building typology that requires uninterrupted energy supply within its activity period, hence it is regarded to be amongst the major energy consuming building typologies anywhere (Mu'azu, 2012). In terms of energy consumption per meter square, office buildings consume about 70-300KWh/m2 to function effectively, which is 10-20 times higher than the

Salihu, M. M. & Ejeh, E. D. (2016). Economic Impacts of Energy Consumption and Supply in Office Buildings of Kaduna Metropolis, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 368-376

residential sector (Sadrzadehrafiei et al, 2012). This sort of energy requirement entails a great deal of effort to sustain building performance, a task that has been identified as a key area where significant progress towards meeting the global ambitions of energy efficiency can be made (Ausiello & Raimondo, 2014).

Studies geared towards assessing the pattern of energy use in office buildings have been carried out in the past across Nigeria by many researchers. In their stydies, Akambami (2010); Mu'azu, 2012; Batagarawa, Hamza & Dudek, 2012; and Umar, 2015; posited that, office buildings employ the use of about 40% - 60% of the total energy supplied by the National grid, out of which 40% - 65% is used for cooling. Lighting has been confirmed to take the least percentage with about 12% - 25%. However, with this magnitude of energy requirements, it was gathered that, the national grid does not supply adequate power across all sectors of the building economy (Oyedepo, 2013). This resorts to a large portion of the industry to rely on diesel and petrol generators as primary or back-up source of electricity, which can be expensive, polluting and a significant source of greenhouse gas emission (Energy Commission of Nigeria (ECN) 2015). The study is in line with the aspirations of the National Energy Master Plan (2014), which highlighted that, the driving force behind sustainable energy is to push industrialization of the country by 2030 at a rate of 11-13%.

Using methodologies that involved energy audit and subsequent disaggregation of energy use index as employed by previous researchers, the study aims to highlight the track record of energy consumption and supply patterns in various functions of office buildings in Kaduna metropolis. Subsequently, it is also geared towards presenting the estimated cost implication associated with such energy consumption and supply patterns. Selected as the study context, Kaduna is the largest city in North Western Nigeria (Butler, 2009). It is also one of its leading industrial cities that has a large number of commercial and corporate building stoke capable of casting significant impact on other energy demanding sectors of the city. Presence of such a large corporate stock in Kaduna's CBD could be attributed to the city's former status of being the capital of the federal republic of Nigeria for fifty years, from 1916 to 1966 (*Fletcher and Cruickshank, 1996).*

The study is however limited to carrying out an investigation on only the electricity supply and consumption aspects of the studied facilities, with focus on uncovering the cost implication involved. Although the economic impact of energy utilisation is expressed when placed side by side the total income generated in any commercial set-up (Yudelson, 2010; and Adnan & Riaz, 2008); the study encountered a major limitation in extracting such related information from the facility managers of the studied area. It is therefore limited to uncovering only the cost implication of energy consumption the facilities.

ENERGY CHALLENGES IN THE NIGERIAN ECONOMY

Energy requirement is essential for all operations in the building industry. Like in all other sectors, it serves as the pillar of wealth creation evident by being the nucleus of operations and engine of growth of Nigeria's economy (Ogundipe & Apata, 2014). Unfortunately; even though energy provision in either public or private sector is capital intensive anywhere, it has been found to be facing a more serious challenge in Nigeria (Oyedepo, (2013). Although a major oil producer and investor in the electricity sector, an estimate carried out by the World Factbook (2015), holds the country as low as 69th place in per capita electricity consumption globally; and the 210th in the list of world countries that exploit the use of electricity from other renewable sources.

Energy provision has been a discouraging factor for the Nigerian economy; a study carried out by Ibitoye and Adenikinju (2007) estimated that up to 60% of the population are

unconnected to the national grid, especially those in the remote areas. Political instability, mismanagement, limited funds, long period of return of investment and maintenance neglect are all factors that result in electricity generation deficit, brought about by poor utility performance, and weak transmission and distribution infrastructure (International Conference on African Development Issues (ICADI) 2015). Past studies have also exposed that; in Nigeria, cost of energy production enjoys a free fall nature of energy billing with no regular accountability for energy costs, where government budget has to step-in on settling the payment deficit incurred (Muazu, 2012). However, the resultant use of backup generation system for long hours of the day throughout the year, also consequently leads to cost of diesel and other fuels used in running the generating plants by building owners (Umar, 2015). This sort of endeavor has formed a major glitch to the development of the building industry and the economy in general; whether our economy is ready for developmental take-off should be based on its readiness to ensure adequate and regular power supply, which represents a crucial factor that supports economic growth in developing countries (Ogundipe & Apata, 2014).

Like in all commercial endeavors running an office building entails a lot of financial inferences. A study by Yudelson (2010), has shown that lower utility rates amount to an increase in net annual income which also is a yard stick for determining a building's value. Income generation as the key factor in commercial buildings has a direct bearing with a country's economy with regards to its net energy consumption; where it is believed that national income enhances energy consumption, and adequate supply of energy thus becomes central to the radical transformation of the nation's economy (Adnan & Riaz, 2008; & Energy Information Administration, 2010).

MATERIALS AND METHODS

To conduct the study, purposive sampling method was adopted in selecting four office buildings within Kaduna metropolis. the selection is made in a manner that it will represent different variety of office buildings based on variation in size (large and small), ranges in floor heights and total floor area (between single to ten storeys and 5000m^2 to 500m^2), track record of optimum utilization of the facility, types of ownership (private and public), and ease of access for data collection.

Data collection is carried out mainly through a walkthrough energy audit exercise in respect with regulations stipulated in DOE energy audit guidelines of 2011. Data collected is for three years for each facility. Self-administered questionnaire and structured interviews are also employed in the study. The method of assessing the collected data involves estimations of energy consumption, supply and subsequent cost of such supply. Calculations on the estimated end use demand were grouped into cooling, lighting and electrical appliance.

To conduct calculations and/or estimations in demand and supply of electrical energy on the case studies, various formulas were adopted from previous researches and adapted for the study. To calculate the estimated energy demand, Equations 1 and 2 as adopted by Oyedepo et el, (2015) are used progressively during the study. Total energy demand (TED) in kW is given by:

$$TED = \left(\frac{SW}{1000}\right) n \; x \; F_d \text{ (in kW)} \; \ldots\ldots\ldots \text{equation 1}$$

Where n is the number of appliances (cooling, lighting and other electrical appliances), SW is the system wattage and F_d is the demand factor. F_d is the assumed average percentage of available appliances used at a building's peak time. The demand factor is taken as 34%, this is because all appliances except for the exterior lighting are calculated based on the activity

period of the buildings, which is eight out of the twenty four hours of the day. To estimate the total energy consumption of all the appliances therefore; equation 2 as stated below is adopted, where h is the total hours used by the appliance during the year. To provide an estimate for all appliances, 2080 hours (8 hours of the day x 260 working days of the year) are used in all facilities.

$$TEC = \left(\frac{sw}{1000}\right) n\ x\ F_d \text{ (in kW) } \ldots\ldots\ldots.\text{equation 2}$$

To calculate the estimated electricity supply, a formula is adopted from Batagarawa (2013); where to find the average monthly utility supply, the monthly utility charges are divided by the utility rate per KWh, and for the backup system, the generator capacity (multiplied by 0.8 machine factor) is multiplied by its hours of daily operation against the number of working days in a month. Where Qu is the total electricity supplied from the utility supply and Qg is the total electricity supplied by the back-up power respectively.

$$Qt = Qu + Qg \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots..\text{equation 3}$$

The total energy consumption cost (TECC) is obtained by inputting the actual rate of unit electricity tariff on the estimated energy demand earlier determined; it is computed as adopted from Oyedepo et el, (2015) given as:

$$TECC = TEC\ x\ CUE \text{ (in NGN) } \ldots\ldots\ldots.\text{Equation 4}$$

Where TEC is the total energy consumption, and CUE is the current cost of a unit electricity in Nigerian tariff, which is 26.24NGN FOR commercial buildings.
To achieve the aim of this study, all subsequent calculations are geared towards uncovering the cost implication of providing energy for the operation of office buildings within context. Therefore, estimated cost of energy supply is carried out; after which the normalized cost of energy supply, and the total energy consumption cost is presented. This is to enable the provision of data that may help in any further related study involving related endeavors like bench marking and retrofitting exercises.

RESULTS AND DISCUSSION

The buildings selected were Northern Nigerian Development Company (NNDC), Bank of Industry Building, Investment House and Federal Inland Revenue Office (Katsina Road Branch). A walkthrough Inventory of selected buildings as illustrated in Table 1 shows that; the tallest amongst the buildings is the NNDC Building with eleven floors and 329 rooms. It is used in full capacity, and is a publically owned facility rented to individual occupants. The BOI main building is next in size with nine floors and 112 rooms, it is government owned and partly rented to individuals and also used in full capacity. Investment House has four floors and 68 rooms, it is owned by the Kaduna state government and rented to individuals as well. The smallest in representation is the FIRS building with two floors and 18 rooms, it is federal government owned and used in full capacity. The major energy consuming systems found are Lifts, HAVC systems, lighting appliances, and other office equipment like computers, printers, photocopiers, refrigerators, televisions and many other related appliances. Major electricity supply is via National Grid that alternates with backup systems throughout the activity period of 8 hours (8am-4pm). A wide range of generators are used in the facilities; the largest is a 625KVA was found in the NNDC and the smallest a 100KVA in the FIRS, as reported on Table 1.

All the buildings have a high track record of energy consumption as exposed by the records of both utility and backup bills collected. Three year utility bills and cost of diesel/maintenance of generators were also collected and presented on the table. For the NNDC Building, supply from the National Grid is to the tune of 10,125,000NGN/annum

while the back-up cost recorded is 3,074,000NGN/annum from a 625Kva generator. Utility billing rate for BOI Building is to the tune of 6,581,000NGN/annum, and 1,758,855NGN/annum from a 500Kva plant; while Investment House has a total annual electricity bill of 2,550,000NGN, and back up bill of 1,004,000NGN. The smallest building being the FIRS building has a utility bill of 910,000NGN, and back up bill of 1,201,000NGN.

Table 1 Walkthrough inventory of the four office buildings

Item	NNDC Building	BOI Building	Investment House	FIRS Building
Number of Floor	11,6,7&2(4 blocks)	9&1 (2 blocks)	4 & 1 (2 blocks)	2 &1 (2 blocks)
Num. of Rooms	329	112	68	18
Total Area	11312	3816	2653	528
Avg. utility Bill/annum (NGN)	10125000	6581000	2550000	910000
Avg. Backup Bill/Annum(NGN)	3074000	1758855	1004000	1201000
Utility Supply	National Grid	National Grid	National Grid	National Grid
Backup (Kva)	625	500	250	100

Disaggregation of Energy Demand

To determine the disaggregated end use demand, estimation was carried out for the four buildings based on three set of categories namely cooling, lighting and a group of other appliances. Equations 1 was used to calculate the total energy demand (TED), while Equation 2 was used to find the total energy consumption (TEC).

Table 2 expresses the disaggregation of energy demand across the four office facilities. Cooling takes the highest demand of about 53% of the total demand from a cumulative demand of 1,023,979.6kWh in NNDC, 597,580.80kWh in BOI, 398,387.20kWh in Investment House, and 46,686.00 kWh in FIRS. Office appliances used have 35% from a cumulative demand of 713,101.00kWh in NNDC, 388,909.44kWh in BOI, 200,759.84kWh in Investment House, and 54,878.68kWh in FIRS. Lighting being the least took 12%, from a cumulative demand of 247,144.64kWh in NNDC, 142,005.76kWh in BOI, 61,605.44kWh in Investment House, and 24,288.76kWh in FIRS. The disparity of such a difference in total end-use demand in term of percentages is expressed graphically in Figure 1.

Table 2 Disaggregation of energy demand across the four offices

	Cooling load (kWh)	lighting load (kWh)	Other appliances (kWh)	Total (kWh)
NNDC Building	1,023,979.60	247,144.64	713,101.00	1,984,225.24
BOI Building	597,580.80	142,005.76	388,909.44	1,128,496.00
Investment House	398,387.20	61,605.44	200,759.84	660,752.48
FIRS Building	46,686.00	24,288.76	54,878.68	125,853.44
Total	**2,066,633.60**	**475,044.60**	**1,357,648.96**	**3,899,327.16**

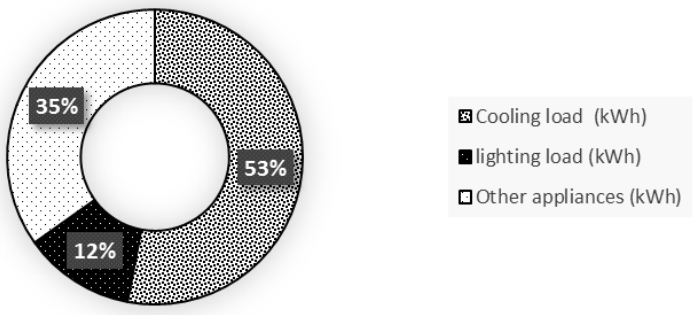

Figure 2: Percentage of total end-use demand across the four office facilities

Electricity consumption per meter square for each facility is also calculated in the normalization process. The disaggregated end-use and the averages per annum across all the studied facilities is determined by dividing each disaggregated end use demand to the total square meters of the facility given in KWh/m^2 . Table 3 shows that the BOI Building has the highest normalized annual demand of 296KWh/m^2, Investment House was calculated to be 249 KWh/m^2, FIRS Building has 239KWh/m^2 and the NNDC Building having the lowest value of 175KWh/m^2.

Table 3: Normalized energy demand (ND) for Cooling, lighting and other electrical Appliances

	Cooling Demand	**lighting Demand(kWh)**	**Appliances Demand**	**Avg. Annual Demand**
	ND (KWh/m^2)	ND (KWh/m^2)	ND (KWh/m^2)	ND (KWh/m^2)
NNDC Building	91	22	63	175
BOI Building	15	37	102	296
Investment House	150	23	76	249
FIRS Building	88	46	104	239
Total	486	128	345	824

Estimated Electricity Supply

The hours of distribution from both utility and backup is shown in Table 4. It shows that utility hours are in all cases more than the backup hours throughout the year. Investment House and NNDC building have the highest hours of 6.5 each, while B.O.I Building and FIRS Building have 6.0 hours each. The amount of Annual power supplied was found to be highest in the N.N.D.C Building and the B.O.I Buildings with 565,850.00KWh and 442,800.00KWh respectively. While FIRS Building has the lowest of 73,080.00KWh, followed by the Investment House with 217,180.00KWh.

Table 4: Estimated electricity supply from the utility and backup energy supply

	power supply (hrs)		**Avg Monthly Supply (Kwh)**		**Annual Power Supplied (KWh)**
	Utility	**Backup**	**Utility**	**Backup**	
NNDC Building	6.5	1.5	32,155.10	15,000.00	565,850.00
BOI Building	6	2	20,900.00	16,000.00	442,800.00
Investment House	6.5	2.5	8,098.32	10,000.0	217,180.00
FIRS Building	6	2	2,890.00	3,200.00	73,080.00

The normalized electricity supply is determined by placing the annual power supplied against the approximated area of the building, and is given in KWh/m^2. Table 5 below shows that; NDDC has the lowest supply of 50.02 KWh/m^2, BOI has a normalized value of 116.03 KWh/m^2, and Investment House has 81.86 KWh/m^2, while the highest recorded value is from the FIRS Building with 138.40 KWh/m^2.

Table 5: Normalized electricity supply per M^2 of each facility.

	Annual Power Supplied (KWh)	**Approximate Floor area**	**Estimated Normalized energy supply (kWh/m2)**
NNDC Building	565,850.00	11312	50.02
BOI Building	442,800.00	3816	116.03
Investment House	217,180.00	2653	81.86
FIRS Building	73,080.00	528	138.40

Cost of Electricity Supplied

To determine the actual cost of electricity paid for by the management, data is collected from the facility managers of the study areas. It is made up of emoluments from electricity supplied by the utility company and diesel generator supplies in the buildings. The actual

three year bills paid from the utility charges of the national grid, and the total cost of fuel and oils are generated and presented.

As gathered from the interview and physical observations, none of the facilities has employed the use of the prepaid meters supplied by the utility companies. The bills paid therefore are based on estimations from maximum demand metering or clamp meters supplied.

Table 5 shows that NNDC building has the highest rate of consumption of up to 13,199,000.00NGN per annum, BOI Building and Investment House have 8,339,855.00NGN and 3,554,000.00NGN respectively, while the FIRS Building has the lowest rate of 2,111,000.00NGN.

Table 5: monthly average, annual cost and Total annual cost of energy supply

Offices	Avg. Monthly Cost of Utility Supplied (NGN)	Total Cost of Utility/Annum (NGN)	Avg. Monthly Cost of Diesel For Backup (NGN)	Total Cost of Diesel/Annum (NGN)	Total Cost of Energy Consumed Per Annum (NGN)
NNDC Building	843,750.00	10,125,000.00	256,167.00	3,074,000.00	13,199,000.00
BOI Building	548,417.00	6,581,000.00	146,571.00	1,758,855.00	8,339,855.00
Investment House	212,500.00	2,550,000.00	83,667.00	1,004,000.00	3,554,000.00
FIRS Building	75,835.00	910,000.00	100,084.00	1,201,000.00	2,111,000.00

Total Energy Consumption Cost

To determine the total energy consumption cost (TECC); a task that exposes the difference between the costs of energy paid for and the actual energy consumed, equation four was used as stated in the methodology. Further calculations of normalized total energy consumption cost are also done in m^2 for each facility.

Table 6 shows the actual total energy consumption cost incurred in the facilities and the normalized range of TECC, given that the current cost of unit (CUE) is 26.24NGN as stated in the methodology.

An average of 40,927,337.87NGN was recorded from the four facilities. Where NNDC has an estimated value of 52,066,070.30NGN and a normalized TECC of 2,982.0 NGN/m^2. BOI has 29,611,735.04NGN with normalized cost of 5,027.4 NGN/m^2, while Investment House and FIRS have 17,338,145.08NGN and 3,302,394.27NGN respectively, with normalized values of 4,234.0NGN/m^2 and 4,234.0NGN/m^2.

Table 6: Total energy consumption cost, and the normalized cost per m^2

	TEC (kWh)/annum	TECC (NGN)/annum	ND (KWh/m2)	Normalized TECC (NGN/m^2)
NNDC Building	1,984,225.24	52,066,070.30	175	2,982.0
BOI Building	1,128,496.00	29,611,735.04	296	5,027.4
Investment House	660,752.48	17,338,145.08	249	4,234.0
FIRS Building	125,853.44	3,302,394.27	239	4,052.1
Total	3,899,327.16	102,318,344.68	959	16,295.4
average	974,831.79	40,927,337.87	240	4,073.9

CONCLUSION

Prompted by the need to conserve the limited energy resources available, the study focused on assessing the cost of energy supply and distribution in office buildings of Kaduna metropolis. The study confirmed that, cooling for thermal comfort for the interior takes the highest rate of energy demand in the buildings. It is responsible for about 53% of the energy use index, and therefore has that equal bearing on the resultant cost of energy consumption.

Other electrical appliances constitute 35%, while lighting has the least with 12% due to the presence of adequate natural lighting during the activity period.

It was observed that there is disparity between energy demand and supply in all facilities, where the estimated annual energy supply of 73,080.00 KWh to 565,850.00KWh as recorded, falls short of meeting up with the required annual demand that ranges from 125,853.44kWh to 1,984,225.24kWh in the buildings. This is why the cost of energy supply in the facilities is on the high side, due to insufficient supply from the national grid. This consequently led to alternative dependence on backup supply to cover up the supply deficit, making the cost of supply economically unsustainable. The normalized supply has also been found to be inadequate with a low estimated range of 138.40kWh as the highest record and 50.02kWh as the lowest.

Despite the high cost of energy consumption however, the study affirmed the claim highlighted from the literature that electricity supply experiences a free-fall billing against energy consumption in our buildings. The study confirmed that there is a huge gap between the total cost of electricity supplied from utility and back-up bills, which ranges from 2,111,000.00 NGN/annum to 13,199,000.00NGN/annum; and the total energy consumption cost, which ranges from 3,302,394.27NGN/annum to 52,066,070.30 NGN/annum. This proves that the energy consumed, though massive in term of quantity and cost is not commensurate to the due rates. The normalized energy demand was found to be within the stipulated range for office buildings as highlighted by the literature, and is between 175KWh/m^2 to 296KWh/m^2; while the normalized total energy consumption cost per annum ranges between 2,982NGN/m^2 in the largest building (NNDC), to 5,027NGN/m^2 in the smallest (FIRS)**.** This implies that energy consumption per square meter in the larger buildings is much lower than that of the smaller ones.

From the cost analysis carried out, the study posits that, high energy consumption rate indicates high cost of operation; a trend that can be reduced to a significant level in order to bring down the cost of operating buildings. The relevance of this study therefore is that, it may serve as a reference point in appreciating the magnitude and impact of cost of energy consumption in running corporate buildings. As a preface to further research, it may also serve as a useful information in pin pointing the basic areas in which retrofitting options are required in order to reap the economic and social benefits of running and maintaining office buildings in a sustainable manner.

ABSTRACT

This research was carried out to determine the effect of different brands of cement on the strength of pavers. Stone dust plus Cement A (4:1), stone dust plus Cement B (4:1), stone dust plus Cement C (4:1), stone dust plus Cement D (4:1), sharp sand plus Cement A, sharp sand plus Cement B (4:1), sharp sand plus Cement C (4:1), sharp sand plus Cement D (4:1), formed 8 treatment and were replicated five times. The pavers were analyzed for strength properties, compressive strength at the materials testing laboratory. The data collected was subjected to Analysis of Variance (ANOVA) and Duncan Multiple Range Test (DMRT) was used to separate treatment means. The result shows that Treatment C and Treatment G, were not significantly different with respect to compressive strength. Treatment B, produce the least value of (133KN), while Treatment C has the highest value (285KN) which agrees with the recommended standard of pavers of 150-300 Kilo Newton by the Standard Organization of Nigeria. Also, the cost of production of pavers produced with stone dust is costlier than pavers produced with sharp sand. Cement C, Cement A and Cement B are very neat and strong products. Cement D does not produce a well finished product.

Keywords: ANOVA, Cement, Compressive Strength, Sharp sand and Stone dust

INTRODUCTION

Landscape design is an act of designing, planning management of and or open space and arrangement of natural and man-made through application of cultural and scientific knowledge which concern resource conservation and stewardship to the end that result to environmental service as useful, healthy and enjoyable purpose. (Catriona, 2003). Interlocking concrete pavements are a special dry mix pre-cast of concrete commonly use in exterior landscaping pavement application. Paving stone are installed over a compacted stone sub-base and a leveling bed of sand. Concrete paving stones can be used for walk way, patios, pool decks, drive ways and airport of loading dicks. Instead of connecting the pavers by pouring grout between the joint as one would with tiles, sand particles are spread over the pavers and tamped down. The sand stabilizes the interlocking pavers, yet allows for some flexibility. This type of pavement will absorb stress such as small earth quakes, freezes and thaws, and slight ground erosion by flexing. Therefore, they do not easily creak, break or buckle like poured asphalt or poured concrete. Benefit of pavers than asphalt and poured concrete include high compressive strength, pleasant look, time saving, easy removal and replacing (Timothy, et al., 1997). The most vital aspect of landscape construction is the choice of appropriate materials that will satisfy the basic principles of modern landscaping in order to achieve a balance between safety, elegance and economy. (Adenihun, 2001).

Cement is any material that hardens and become strongly adhesive after applied in plastic form. The term cement is often used as a similar meaning to glue and adhesive. Cement is used for different reasons one is to hold sand and gravel together. It is also used to put different surfaces together made up of various materials, another use can be for coating surfaces to protect them from being damaged by some outside forces of nature or by chemical reasons. The hardening of cement is mostly caused by the hydration of tricalcium silicate, which from the watering substance becomes harden. This substance bind together, the

Yusuff, A. Q.; Adams, B. A.; Olatoke, T. I.; Emmanuel, I. B.; Adedeji, M. S. & Bankole, S. O. (2016). Statistical Investigation of Effects of Different Brands of Cement on the Strength of Pavers. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 377-385

particle of sand or stone, which are always include in a morter or concrete mixture into a hard mass (DCCM, 2006).

In Nigeria, production of cement with different trade names is increasing daily. There is availability of more than ten types of cement in the market. Cement is very essential in human's life as regard building, construction and other landscape materials. (Justrus, et al., 2005).

Over the years, paving stones have generated a lot of attention. Hence the demand for it has greatly increased. It is environmental friendly and its beautification also goes a long way in promoting its use. The occurrence or frequent collapse structure due to poor quality construction materials has stirred up the researchers concern on how to test for strength and durability of landscape materials. Therefore, there is need to determine the strength properties of various brands of cement available in the market in order to identify the best for producing pavers.

LITERATURE REVIEW

Road paving with tightly fitted stones resting on a flexible granular base dates back to the Roman Empire. Even, stones are still being used as paving materials the model version of this road techniques utilizes concrete blocks instead (Rada et. al., 1990). Paving stone was the traditional surface material in the Netherlands before the second world war.

British builders realized the importance of selecting clear stones for surfacing to make better roads. The selection of clean stones make road paving a bit costly until later on when concrete pavers would be manufactured. Most of these roads provided a means of fast transportation with the use of horse drawn carriages.

Paving are made from a very dry mix of gravel, sand, cement and color. Since there is very little water, the mixture is moved on conveyor belts and then funneled into the paver mould. Pavers are said to have zero slump, the more the slump the weaker the concrete is achieved in three ways. The amount of water, the amount of cement mix (the more cement the stronger), the amount and size of aggregate (the bigger the stronger).

Sharp sand is generally known as builders sand refer to sand that has a gritty texture. This sand is often mixed with concrete for a number of different constructions applications. Sharp sand can also be added to soil in order to create potting soil or to loosen clay soil. In most instances, this type of sand is made from ground quartz rocks. On occasion, clay and iron may be mixed with quartz in other to create sharper type of sand.

Landscapers and builders use this sharp sand as a base for laying pavement, mixing mortar, dressing lawns and smoothing floors. Sharp sand allows garden soil to drain with ease, which is not the case with fine sand.

Concrete block paving available in a constantly expanding variety of colors, shapes and textures and can be installed bonds and laying patterns (Interpave, 2003). Concrete pavers offer unique aesthetic benefits when compared to other forms of pavement in their ability to integrate and harmonize with both the built and natural environment (CMAA, 1999)

Paving stones offer numerous opportunities in residential and pedestrian areas by their light reflection, water absorption, noise generation features and are often used for traffic management (Interpave, 2003).

Maintenance cost can be kept low as it is possible to rehabilitate areas of concrete segmental pavement without leaving to purchase a new surface. Repair to underground utilities or local deformations in the base materials can be accessed by simply removing and replacing the

concrete pavers. Paving materials are not wasted and jackhammers or heavy equipment are not required (Ackerstone, 2003)

The uniquely flexible surface course of concrete block paving, with its characteristics interlock, prevents the block from moving in isolation and dissipates applied loads sideway and diagonally downwards through the sub-base to the foundations. Combined with the high compressive strengths of the blocks, this prove a working surface with remarkably high load bearing capacity (Interpave, 2003). Paving stones is extremely durable. It withstands severe frost attack and repeated freeze thaw cycle and can be used in harsh environments. It can be laid on airfield or highways where temperature falls below 30 degrees centigrade (Interpave, 2003).

There are two common methods of producing precast concrete: a) wet mix, b) dry mix. In wet mix fresh concrete is placed and compacted into moulds, stripping the moulds when adequate strength has been reached. However, in a dry mix, a semi dry cohesive concrete mix is placed in the mould, which is later, compacted and extruded (pushed out) from the mould, right after compaction. The units are then cured and stored. This latter process is commonly used in the manufacture of concrete masonry and paving units as it is most economic way of producing large volume of bricks, blocks and pavers (CMAP, 2002).

Portland cement is the binder used for the production of concrete blocks just like any other concrete product. In choosing a Portland cement for the manufacture of pavers, rate of strength gain and sensitivity to curing should be considered (CMAP, 2002).

The cement content to achieve the require strength level will depend on the type of cement, rate of strength gain, degree of compaction (CCI, 2001). The only accurate method of establishing the optimum cement content is through a series of trials, using the machine intended for production, in which cement content is varied and the physical properties monitored (CCI, 2001)

The optimum moisture content (OMC) for molding depends on the materials being used, quality of vibration, and moldng equipment. Generally, the coarser the particles are graded and greater the compactive effort, the lower will be the OMC. Using moisture content below OMC will hamper good compaction and may necessitate longer periods of compaction will reduce durability. Using too much water will result in a reduction of density and may cause units to stick in the mould and thus make extrusion difficult, or cause deformation of the unit after extrusion. It must be noted that certain pigments, because of their particle shape, can have a significant effect on OMC (CCI, 2001)

There are many design options available for interlocking pavers. Whether you choose a hexagonal, herringbone or diamond design, there is something to suit all individual taste. Interlocking pavers can create a casual or formal design depending on your style. They are also available in varieties of colors, shapes and sizes, with a thickness that depends on the type of application. The many shapes, patterns, and colors of interlocking concrete pavers allow for design creativity as well as declination of pavement areas, such as parking lanes, cross walks and inter sections. The beauty of the paver add value and visual appeal to any property. By adding flexibility not possible with rigid pavement paver can flow with existing landscaping to deliver beauty to any property.

Good surface and sub-surface drainage is essential for satisfactory pavement performance. Drainage needs to be considered during the design, specification and construction phases of a project. Adequate drainage of flexible and rigid paving systems is an extremely important design consideration for successful performance and durability.

There are three main operation for a successful installation of a concrete block pavement; preparation, detailing, and compaction. Workmanship is a critical factor which has a great impact on the performance of pavement proper preparation and compaction of the base is absolutely critical (BIA, 1993).

One element common to all paving assemblies is the soil or sub grade. Excavation of the sub grade to the proper elevation, removing deleterious materials, and the sub grade compaction are preparation or for the base or sub base (BIA, 1993). It may also be necessary to introduce drainage into sub grade to lower the water table and improve the bearing capacity of sub grade. The entire sub grade should be compacted to 90-95% maximum density (BIA, 1993).

Broken pavers can be easily replaced without patches. Ants and weeds can be prevented by using proper type of sand to fill in the joints between the pavers. Pavers can be repaired by lifting the affected area, re-grading and re-compacting the base and bedding sand and re-installing the same pavers. It is an in-expensive procedure that leaves no unslightly repair patches. Pavers are easy to maintain when properly sealed, an angular sweeping and occasionally rinsing are usually the most maintenance needed for stains, pressure washing with appropriate clearing solutions or a spot treatment with a brush, cleaner, water and some elbow grease will solve problem.

Curing can also be described as keeping the concrete moist and warm enough so that the hydration of cement can continue more elaborately, it can be described as a process of maintaining a satisfactory moisture content and favorable temperate in concrete during the period immediately following placement, so that hydration of cement may continue until the desired properties are developed to a sufficient degree to meet the requirement of service.

Curing is being given a place of increasing importance as the demand for high quality concrete increase. It has been recognized that the quality of concrete shows all round improvement with efficient uninterrupted curing. If curing is neglected in the early period of hydration, the quality of concrete will experience a sort of irreparable loss. An efficient compared to good and wholesome feeding given to a new born baby.

In dealing with the relationship between output and costs there are two situations. First, short run change which cover periods when it is only possible to adjust the variable factors being used and when there is at least one fixed factor. Secondly, long run changes which apply to period of time which are sufficiently long for all the factors to be varied. Increasing returns means that the ratio output, variable input is increasing and this should mean that average cost is falling. Similarly, diminishing return means that the ratio output, variable input is declining and we should expect average cost to be rising (Yusuff, 2004).

MATERIALS AND METHOD

The experiment was carried out at Federal college of Forestry Ibadan at the horticultural nursery, situated at 7.9^0N and 3.58^0W respectively with the annual rainfall of about 1300mm – 1500mm and an average relative humidity of about 80% - 85% (FRIN, 2013).

The materials used are: stone dust, sharp sand, cement, shovel, hand trowel, field book, water, moulds (didalo 5inch), brush, lubricant (diesel), weighing balance. The sharp sand was collected from Federal College of Forestry Ibadan and the cements sample use were purchased at Dugbe Market, Ibadan. All other materials used were gotten from Horticultural Garden, Federal College of Forestry, Ibadan.

Methods

Step 1: The moulds were cleaned and lubricated, with water and diesel.
Step 2: The amount of all aggregate used were measured.

Step 3: The materials were mixed thoroughly and equal amount of water was added to the aggregate.
Step 4: Each treatment were poured into the mould and vibrated manually.
Step 5: Each treatment were placed in an aeration surrounding.
Step 6: The treatment were de-molded after 48hours.

Table 1 Mixing ratio (Treatment Combination) for the production

Treatments	Stonedust	Sharpsand	Cement (A)	Cement (B)	Cement (C)	Cement (D)
A	4	-	1	-	-	-
B	4	-	-	1	-	-
C	4	-	-	-	1	-
D	4	-	-	-	-	1
E	-	4	1	-	-	-
F	-	4	-	1	-	-
G	-	4	-	-	1	-
H	-	4	-	-	-	1

Table 1 shows the different proportion of the materials being used for the experiment which form various treatments. The proportion goes thus, T_A constitutes four buckets of stone dust and one bucket of Cement (A), T_B consisted of four buckets of stone dust and one bucket of Cement (B), T_C consisted of four buckets of stone dust and one bucket of Cement (C), T_D consist of four buckets of stone dust and one bucket of Cement (D), T_E consist of four buckets of washed sharp sand and one bucket of Cement (A), T_F consist of four buckets of washed sharp sand and one bucket of Cement (B), T_G consist of four buckets of washed sharp sand and one bucket of Cement (C), T_H consist four buckets of washed sharp sand and one bucket of Cement (D). The weighed of cement used for each treatment was approximately 12.5kg. For even mixture and to prevent airspace within the pavers, the mixture is shaken thoroughly during casting operation. For each treatment, 8 pavers were produced.

DATA ANALYSIS

The data obtained was subjected to analysis of variance to determine the difference in the weight before and after curing. The experimental design used for their study is Completely Randomised Design (CRD) based on the fact that data are obtained from observational studies.

$X_{ij} = \mu + T_i + \varepsilon_{ij}$

Where X_{ij} is the value of the response variable in the jth trial for the ith factor level or treatment.

μ are parameters or the general means.
T_i Treatment effect
ε_{ij} are random error effect associated with the X_{ij} (experimental error).
i = 1, 2, ..., 8; j = 1,2, …, 6 (Lasisi, 2014).

Procedure for Pavers Compressive Strength Property

Testing of the quality of the materials were designed and performed to ensure adequate quality of construction research being executed. It involved laboratory test of each paving stone which was done at the materials testing laboratory, Ministry of Works and Transport, Oyo State Secretariat, Ibadan.

The comprehensive strength property in the laboratory was done after four days of immersion in water. The procedures are as follows:

Each replicate were separated according to their treatment. Each replicate were placed in between the flat plate one by one. The machine was switch on and the place pull up and pavers until it touches the metal plate at up and compressed the treatment until it get weaken and then the meter stopped reading.

The values of each treatment showed on the meter were recorded and the average was written down in KN/m^2.

Cost Analysis of the Production of Pavers

The cost of production was determined using the formula of economic theory cost of production:

Total cost of production = fixed cost + variable cost

RESULTS AND DISCUSSION

Table 5.1 Cost of production for each treatment (per 8 pavers)

Treatments	A	B	C	D	E	F	G	H
Cost of production	₦1060.4	₦1060.4	₦1060.4	₦1060.4	₦740.4	₦740.4	₦740.4	₦740.4

Table 5.1 shows the cost of producing 8pavers of each treatment. Values obtained ranges from ₦928.4 to ₦743.4k. the cost of producing paver with stone dust and each brands of cement is costly which is ₦928.4k per treatment. The pavers produced with sharp sand and each brands of cement process lesser cost of ₦743.4k compared to the one produced with stone dust. The difference in cost is a direct reflection of the cost of materials acquisition. Treatments with sharp sand and different brands of cement are less costly than that of stone dust. Considering the present government policy whose trust or focus is toward encouraging self-employment and beautification of environment at a reduced cost and utilization of readily available materials. This may justify the choice of Treatment E, F, G, H, as a better replacement of Treatment A, B, C, D.

Table 5.2 Percentage Damage during demoulding

Treatments	A	B	C	D	E	F	G	H
Percentage Damage	0%	0%	0%	10%	60%	0%	0%	30%

Table 5.2 shows that Treatments A, B, C, F, G recorded zero percentage or no damage T_E (60%) recorded high percentage of damage while T_H (30%) recorded the highest damage percentage sharp sand after demolding.after demolding. Cement (G) and Cement (B) does not damage when applied with stone dust and sharp sand after demolding.

Table 5.3 The Compressive strength (KN) of the pavers

Treatments	A	B	C	D	E	F	G	H
Comprehensive strength	260^a	133^c	285^a	200^b	165^{bc}	205^b	280^a	205^b

Mean of the same alphabet following in the same column are not significantly different from each other at 5% level of probability.

Table 5.3 shows the values of compressive strength of the pavers. Treatment C had the highest value of 285 (KN). Treatment H, D, F, was not significantly different from each other. Treatment B has the lowest value of 133 (KN). The result showed that Treatment C produce the best compressive strength, in terms of cement mixed with sharp sand and stone dust even at the same proportion.

Table 5.4 LSD result before curing

Treatments	A	B	C	D	E	F	G	H
Before curing	4.9^b	5.0^a	5.0^a	5.0^a	5.09^{ab}	5.05^{ab}	5.05^{ab}	4.93^{ab}

Mean of the same alphabet following in the same column are not significantly different from each other at 5% level of significant.

Table 5.4 shows the LSD value of pavers before curing. There is no significant different between treatment E, F, G Treatment E has the highest water absorption rate of 5.09 which agrees with Ajayi (2000), that sharp sand enhance water absorption in concrete constructed object due to its high porosity. The least water absorption is Treatment A with a value of 4.9.

Table 5.5 LSD result after curing

Treatments	A	B	C	D	E	F	G	H
Percentage Damage	5.10[a]	5.12[a]	5.24[a]	5.36[a]	5.21[a]	5.05[ab]	5.05[ab]	4.93[b]

Mean of the same alphabet following in the same column are not significantly different from each other at 5% level of significant.

Table 5.5 shows the LSD value after curing. Treatments A, B, C, E, were not significantly difference. Treatment D has the highest water absorption rate of 5.36. Treatment H has the least water absorption rate of 4.93.

CONCLUSION

The study revealed that it is highly feasible to produce pavers from sharp sand and Cement (C) at a much cheaper cost. It also shows that water absorption of pavers increases in sharp sand indicating characteristics of lasting longer. The paver produced wholly of sharp sand provides a good substitute to stone dust with each cement brands. The three variables (Cement, Stone dust, Sharp sand) used in pavers production has significant effect on the strength properties examined. Pavers produced wholly from sharp sand can satisfactory be used for both heavy and light traffic construction work. There is need to create awareness concerning the possibility of replacing stone dust with sharp sand in the production of pavers. However, the effect of difference in cement on the pavers is another important factor to be considered in other to avoid collapse building or construction damage. This will guide lay man who would have interest in beautification of his environment with durability and aesthetic purpose.

Therefore, we hereby recommend for the strength properties of the production of pavers that Treatment G should be used in paver production. Also, cement A, B, D, with sharp sand, are to be used in light traffic construction such as walk way and patios, and areas where humidity is low and less traffic.

ABSTRACT

Pavers are increasingly being used by corporate bodies and individuals for its function, ability and aesthetic values. The demands for those expensive landscaping materials are increasing steadily, hence the need to look for close alternative that will drastically reduce the cost of the production. Therefore, the cell means model was employed to compare the strength of pavers from Milicia excelsa and Gimelina arborea sawdust. Sawdust from Milicia excelsa and Gimelina arborea undertook the pre-treatment, treatment combination and making ratio. Pavers were tested for their weight and strength properties. After, the data were subjected to statistical analysis called SAS command file and the results show that; the mean weight indicates that T2 (stonedust + boiled Milicia excelsa sawdust + cement) and T5 (stonedust + cold Milicia excelsa sawdust + cement) had the highest comparative strength and mean value. There was significant difference between the treatment of compressive strength with stonedust + sawdust (Milicia excelsa) performing better than stonedust + (Gimelina arborea) sawdust. The stonedust + Milicia excelsa had the lowest percentage damage which is the good indicator in the production of paver. Milicia excelsa in any form (cold or boiled) can enhance water absorption in concrete object due to its high porosity. It was recommended that the water absorption of pavers containing sawdust was very low and the fact that sawdust produced pavers could withstand total immersion for 2 weeks in water and have low absorption rate which will be able to withstand environmental stress and reduce the cost of production.

Keywords: Cell Means Model, Gimelina arborea, Milicia excelsa, Pavers and Sawdust

INTRODUCTION

Hard landscaping or landscape design has become a major instructional field in the use of man solid substance to design the environment. Hard landscaping involves the use of pavers, kerbs etc. in designing the environment and other materials are asphalt, concrete, paving stone or brick gravel etc. The use of each material depends on the choice of individual as well as the function of the area of the landscaped (Hoskin, 2011).

Pavers or paving stones are flat slabs which are designed to be used outdoors. Paving is a stylist, low cost way to create feature or utility area in outdoor space. One classic use of pavers is in garden pathways, and pavers are also used for making or producing patios and other recreation areas, or to line pools, ponds, and water features, along with raised beds and other decorative landscaping features. There are wide varieties of colours, textures and formats available. Pavers are more versatile than other hard surfaces (Adenihun, 1994).

Correctly laid pavers can have a long life time lasting and low maintenance. Also the valuable materials for the construction of walk ways, drive way, hard surface outdoor, outdoor step, pathways can also be constructed with paver. The environment can also be beautified by hard and soft landscape which must be given a proper attention with use of paving tiles, kerbs and ornamentals (Cateriona, 2002).

Hard and soft landscapes materials are also used to control noise, direct sunlight, and wind, even protect the soil or environment from erosion and flood. It has been observed that the production of pavers, kerbs and their uses like created an impression of neat and beautiful environment (Steve, 2007).

Yusuff, A. Q.*; Adewole,A. T.; Shaib-Rahim, H. O.; Awotedu, O. L.; Alarape, A. B. Adedeji, M. S. (2016). Comparative and Statistical Analysis of the Strength of Pavers made from *Milicia excelsa* and *Gmelina arborea* Sawdust. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 386-393

Pavers or paving stones are increasingly being used by corporate bodies and individuals for its function, ability and aesthetic values. The demands for those expensive landscaping materials are increasing steadily, hence the need to look for close substitute or alternative that was drastically reduce the cost of the production (Cateriona, 2002).

Sawdust is a material made from wood or wood waste, in consideration for low cost and locally available materials meet desired needs, enhancing self-efficiency and leading to an overall reduction in construction cost and sustainable development. Sawdust made from *Milicia excels* and *Gmelina arborea* wood or waste agricultural product was developed in this research, intending to achieve the strength properties of pavers, since other recovered wood available are also large. Sawdust could be loose particles or wood chipping obtained as by product from sawing of timber into standard useable sizes (Aigbomain, 2013).

The occurrence of frequent or frequent collapsed structures due to poor quality construction materials had stirred up the researchers concern on how to produce pavers with different production materials to test for its strength, physical properties and how the cost of production can be reduced. Paving stones have been used for thousands of years in which it plays a vital role in our environment and have generated a lot of attention; hence the demand for it has greatly increased. The environmental and friendlities have also contribute to the promotion of the use of pavers. However, the materials use in the production (stone dust, cement and grave etc) is becoming too expensive and scarce thereby raising the overall cost of production. Therefore the need of using by-product (saw dust) in replacement of stone dust wholly or partially without any diverse effect on the quality of pavers is necessary. It is always available, it reduces light reflection and making the environment more conducive for living. Therefore, there is need to use saw dust (*Milicia excelsa* and *Gmelina arborea*) in production of pavers.

This study was designed to determine the strength of pavers using of saw dust and other binding materials such as stone dust, pigment, and cement in the production of pavers and also to know the durability of *Milicia excelsa* and *Gmelina aborea* wood saw dust on pavers.

LITERATURE REVIEW

Concrete block paving is versatile, aesthetically attractive, functional, and cost effective and requires little or no maintenance if correctly manufactured and laid. Most concrete block paving constructed in South Africa has performed satisfactorily but there are two main areas of concern; occasional failure due to excessive surface wear, and variability in the strength of blocks. This technical note covers basic principles and aims to assist manufacturers, particularly new manufacturers to produce a durable and consistent product. It discusses: requirements for blocks; selection of materials; materials for manufacture; manufacturing equipment; proportioning of ingredients; manufacture and quality control. Scope is limited to blocks with a relatively small top surface area, i.e. about 50 blocks per square meter of paving (Adenihun, 1994).

Pavers or paving stones are flat slabs which are designed to be used outdoors. Paving is a stylist, low cost way to create feature or utility area in outdoor space. One classic use of pavers is in garden pathways, and pavers are also used for making or producing patios and other recreation areas, or to line pools, ponds, and water features, along with raised beds and other decorative landscaping features. There are wide varieties of colour, textures and formats available. Pavers are more versatile than other hard surfaces. (Adenihun, 1994).

Correctly laid paver has a long lifetime lasting and low maintenance. Also the valuable materials for the construction of walkways, drive way, hard surface outdoor, outdoor step, pathways can also be constructed with pavers. The environment can also be beautified by

hard and soft landscape which must be given a proper attention with use of paving tiles, kerbs and ornamentals (Cateriona, 2002).

Gmelina arborea wood (in English Beech wood) is a fast growing tree, which grows on different localities and prefers moist fertile valley with 750-4500mm rainfall. It does not thrive on ill, drained soil and remain stunted on dry, sandy or poor soils, drought also reduced it to a shrubby form. The tree attain moderate to large height to 30m with girt of 1-2 to 4 chlorophyll layer just under the outer back. It has pale yellow white inside. The wood is pale yellow cream coloured or plukish – buff when fresh, turning yellowish brown or exposure and is "soft to moderately hard", light to moderately heavy, lustrous when fresh, usually straight to irregular or rarely wavy grained and medium course textured. It is commonly planted as a garden and an avenue trees. It is a light demander tolerant (Olowogbon, 2011). *Gmelina arborea* wood is a popular timber for making pictures and slate frame, turnery articles and various types of brush back, brush handles and toys also for handles of chisels, files saws, screw drivers sickles. *Gmelina arborea* wood comes from conifer, which usually remains evergreen and it grows in huge tracks of trees which may spread for miles. Softwood comes from types of tree known as gymnosperm. It has less complex structure which has a simple anatomy with only few different cell types. (Putheti et al., 2008).

Milicia excelsa wood (Iroko or Africa teak), is a large deciduous tree growing to 50 meter (160ft) high. The trunk is bare lower down with the first branch usually at least 20 meter (66ft) above the ground. It often has several short buttresses root at the base. The bark is pale or dark grey, thick little fissured. There are few thick branches in the crown all fairly horizontal giving an umbrella shape. The leaves are 10 centimeters (2.0 to 3.9in) long, ovato or elliptical with a finely toothed above the slightly downy beneath. Older leaves turn yellow, and all leaves have a prominent rectangle mash of veins visible on the undesired. The trees are deciduous. Distribution is found in Angola, Benin, Ghana, Ivory Coast, Nigeria. African teak has strong dark brown hardwood resistance to termites and is used for construction furniture, joinery, paneling, floors and boats etc (Bizoux et al., 2008). *Melicia excelsa* wood is a deciduous trees that loses its leaves annually. *Melicia excelsa* wood tend to be slower growing and are therefore usually more dense, but not always, hard wood tend to be found mixed with a variety of other species. *Milicia excelsa* wood have a more complex structure; it is a wood from angiosperm trees which have more cell types, including large vessels known as "pores" and hardwood has also been reported to have a lower compatibility with cement (Weiy et al., 2000).

Pigment is a material that change the colour of reflected or transmitted light as a result wavelength selective absorption. Material that human have chosen and developed for use as pigment usually have a special properties that makes them ideal for colouring other materials. Pigment must have high tinting strength relative to the materials it colour. It must be stable in solid for at ambient temperatures, pigment are use in manufacture of pressed concrete product such as paving walling, in roof tile and wet cast concrete paving. The hardened cement paver by which the particles are held together is coloured by adding finely ground pigment. The aggregate itself cannot be colour, its particles merely being surrounded by the coloured cement paste. The pigments used for this purpose are generally light fast and have a high resistance to alkali and weathering. Adding pigment to concrete enhances easy and strong paving stone, it prevents easy penetration of water and it is resistant to insect attack to the pavers. Inorganic pigment such as iron oxides, Chromium oxides, Cobalt oxides and titanium dioxide are generally regarded as the best found pigment used for the colouring of concrete. (Egbert, 2003).

The cement content to achieve the required strength level will depend on the type of cement, rate of strength gain, degree of compaction (Cement and Concrete Institute, 2001). The Optimum Moisture Content (OMC) for molding depends on the materials being used, quality of vibration. Generally, the coarser the particles are graded and the greater the compactive effort, the lower will be the OMC. Using moisture content below OMC will hamper good compaction and may necessitate longer periods of vibration which in turn will reduce output. Lack of compaction will reduce durability. Using too much water will result in a reduction of density and may cause units to stick in the mould and thus make extraction difficult, or cause deformation of the units after extrusion. It must be noted that certain pigments because of their particle shape, can have a significant effect on OMC. Newly molded blocks was subjected to some form of curing. The form of curing ranges from the prevention of moisture loss to the use of temperature and high humidity (Cement and Concrete Institute, 2001).

Materials and Methods

Materials used are: *Milicia excelsa* and *Gmelina arborea* wood (saw dust), cement (Elephant), Stone dust, water, lubricant, universal testing tensile machine and pigment. The following tools were also used for the research; spade, plastic moulds, mason trowel, wheel barrow, head pan, sieve, foam, bowl, glove, stove and pot.

Source of the materials

***Milicia excelsa* saw dust:** The saw dust was collected from Industrial Development Unit (IDU) in Forestry Research Institute of Nigeria (FRIN), Ibadan, Oyo State.
***Gmelina arborea* saw dust:** The saw dust was collected from Bodija Sawmill at Bodija market.
Cement: Elephant brand of cement was purchased from depot at Dugbe.
Stone Dust: The stone dust was purchased from Aleshinloye Market, Ibadan, Oyo State.
The method used are as follows:
Step 1: The mould was cleaned and lubricated with lubricant (engine oil)
Step 2: The different mixing ratio was used as treatment combination.
Step 3: The materials was mixed thoroughly and equal amount of water was added to the aggregate.
Step 4: The treatment was poured into the mould and was placed in surrounding or environment
Step 5: The treatment was demoulded after 48hours.

The collected saw dust was sieved in order to have homogenous materials in terms of the particles sizes and also to remove unwanted materials. The saw dust was divided into two, the half was pre-treated separately in hot water at about 80^0C for a soaking period of 2hours and the other was socked in cold water for period of two days. This pre-treatment was carried out in order to remove extractives such as tannin, gum, resin etc. which may retard the setting and cutting of the cement binder. At the end of the soaking period, the hot water was drained off while the saw dust was washed in cold water before used.

Treatment Combination

Treatment 1: 4:1:0 = Four headpans of stone dust with one head pan of cement and no saw dust.
Treatment 2: 3:1:1 = Three headpans of stone dust, one head pan of boiled *Milicia excelsa* (saw dust) with one head pan of cement.
Treatment 3: 3:1:1 = Three head pan of stone dust, one head pan of cold *Gmelina arborea* (Saw dust), and one head pan of cement.
Treatment 4: 3:1:1 = Three headpans of stone dust, one head of boiled *Gmelina arborea* (saw dust), and one head pan of cement.

Treatment 5: 3:1:3 = Three headpan of stone dust, one head pan of cold *Melicia excelsa* (saw dust) with one head pan of cement.

Table 3.1: Mixing ratio (Treatment Combination for the production)

Treatment	Stone dust	Boiled saw dust *Milicia excelsa*	Cold saw dust *Gmelina arborea*	Boiled saw dust *Gmelina arborea*	Cold saw dust *Milicia excelsa*	Cement
T_1	4					1
T_2	3	1				1
T_3	3		1			1
T_4	3			1		1
T_5	3				1	1

Research Variables

The following are the specification of the research variables for this study:

Selection of Subject: The pavers or paving stones

Treatment: These are treatment combination for the production. The parameters are:

T_1 = Stone dust and cement

T_2 – Boiled saw dust *Milicia excelsa* and cement.

T_3 = Cold saw dust *Gmelina arborea* and cement.

T_4 = Boiled saw dust *Gmelina arborea* and cement.

T_5 = Cold saw dust *Milicia excelsa* and cement.

Data analysis:

Based on the field layout and process taken in this research, the appropriate experiment design to be used is cell means model because data are from observational studies or data from experimental studies based on a complete randomized design (Michael, 2005).

The general statistical model for single factor studies is a cell means model/design which is:

$$Y_{ij} = \mu_{ij} + \varepsilon_{ij}$$

Where Y_{ij} is the value of the response variable in the jth trial for the ith factor level or treatment.

μ_{ij} are parameters or the general means.

ε_{ij} are random error effect associated with the Y_{ij} (experimental error).

i = 1, 2, 3, 4, 5; j = 1,2,3,4

Procedure for testing compressive strength (N/mm^2)

Each treatment was taken to the laboratory to test for its compressive strength parallel or not parallel to grain properties at the Ministry of Works and Transport, Oyo State Secretariat, Ibadan.

RESULTS

Table 4.1: Mean weights (kg) of pavers before and after curing

Treatments	Mean weight before curing (kg)	Mean weight after curing (kg)	Different of mean weight (kg)
T_1	2.95	2.80	0.15
T_2	2.65	2.45	0.20
T_3	2.42	2.35	0.07
T_4	2.65	2.50	0.15
T_5	2.50	2.30	0.20

Table 4.1 above contains the average weight of pavers before and after curing operation. The samples were determined using a weighing scale. The difference in values, obtained ranged from 2.30 to 2.80kg after 3 days immersion in water, water absorption increased in the proportion of *Milicia excelsa* (T_2, T_5) because of its high density. The density of wood is in general related to wood anatomy and hence the relative proportion of cell types of tissues most especially in hardwood species (vessels, fibre, axial and radial parenchyma). In this study, the density of *Milicia excelsa* was higher than *Gmelina arborea* and this was reflected in the pavers produced from *Milicia excelsa* saw dust. *Milicia excelsa* have great strength and

hardness and is very resistant to insect and fungal attack because of its high tannin content. This observation agrees with the findings of (Bartoutis, 1991) that moist enhance the durability of concrete that is, pavers having higher absorption has the tendency of hasting longer due to rain or constant contact with water.

Table 4.2: Percentage damage during demoulding

Treatment	**T_1**	**T_2**	**T_3**	**T_4**	**T_5**
Percentage damage	0	0	60	40	0

Table 4.2 above shows that stone dust and hard wood recorded the zero damage. Compare with the stone dust + *Gmelina arborea* that recorded the highest damage (60%), that means stone dust is preferred when hard wood saw dust in any form is to be included as constituent of pavers.

Furthermore, it was also noticed during production of pavers that the *Gmelina arborea* saw dust was lighter in weight coarse texture than the *Milicia excelsa* saw dust which made compaction in the mould more difficult than when using the saw dust from *Milicia excelsa* which was finer and dense thus making more compact.

Table 4.3: The Compressive Strength (Kn) of the pavers

Treatment	**T_1**	**T_2**	**T_3**	**T_4**	**T_5**
Crushing load (kn)	90	138	250	260	135
Crushing strength (kn/m^2)	1051	1612	2921	3037	1577

Table 4.3 shows that T_1 (stone dust and cement) recorded the highest value of 1051kn while T_2 and T_5 which has the value 1612 and 1577 (3 ratio of stone dust + 1 ratio of boiled *Milicia excelsa* saw dust + 1 ratio of cement and 3 ratio of stone dust + one ratio of cooled *Milicia excelsa* saw dust + one ratio of cement) also recorded the best value, due to its great strength and hardness and are usually more dense. It is very resistant to insect and fungal attack because of its high tannin content. (Mitani et al., 2010). The density of wood is in general related to wood anatomy and hence the relative proportion of cell types or tissues most especially in hardwood species (vessels, fibre, axial and radial parenchyma). In this study the density of *Milicia excelsa* was higher than *Gmelina arborea* and this was reflected in the pavers produced from *Milicia excelsa* saw dust. But compare with the pavers produced with *Gmelina arborea* saw dust (Treatment 4), which recorded the lowest value. Furthermore, it was noticed that *Milicia excelsa* Pavers compressed less and have more strength than *Gmelina arborea* pavers which is total damage during compression therefore has less strength.

Table 4.4: Cost of production of pavers

S/No	**Tools**	**Cost(N)**
1.	Head pan	270.00
2.	Hand trowel	100.00
3.	Shovel	300.00
4.	Wheelbarrow	1000.00
5.	Pointing trowel	100.00
6.	Mould (Rentage Double T)	4000.00
S/No	**Materials**	
1.	Labour	2500.00
2.	Cement (25kg)	900
3.	Stone-dust	2400.00
4.	Pigment	3000.00
5.	Cost of Test Strength	3000.00
6.	Transportation	1000.00
	Total	**18,750.00**

Table 4.4 above highlights the cost of producing the pavers which amounts to ₦18,750.00

CONCLUSION

This study shows that it is possible to produce pavers from stone-dust that is durable by incorporating *Milicia excelsa* and cement. Conclusively, pavers made from *Milicia excelsa* saw dust with the incorporation of stone-dust and cement will still be as durable as that of cement and stone-dust alone. The nature of the wood sawdust also aids the strength and durability of pavers. It also shows that, comparably, stone-dust that has highest compressive strength is a good indicator of durability. The variable, stone-dust and *Milicia excelsa* saw dust, used in paver's production had serious effect on the strength properties examined.

Therefore, pavers produced for stone-dust and *Milicia excelsa* saw dust can be satisfactory used to produce pavers for the construction of walk way.

Hardwood saw dust is suitable for the production of pavers. Hardwood saw dust can absorb more water and withstand environmental stress. This research project work therefore recommends that saw dust should be included in the production of pavers. The cost of producing paver will be reduced with the presence of saw dust because it reduced the cost of cement used since saw dust also serves as a binding agent.

Reconceptualising Research on Housing Quality and Conditions in Nigeria

Adetokunbo O. Ilesanmi

Department of Architecture, Faculty of Environmental Design and Management, Obafemi Awolowo University, Ile-Ife, Nigeria
aoikcom@yahoo.com

ABSTRACT

There is a growing body of literature on housing quality and housing conditions in Nigeria. These terms are often used interchangeably even within the same studies, suggesting that they are synonymous. The seeming definitional ambiguity makes the findings of such studies not readily amenable to objective comparative analysis. A more coherent conceptualization of these terms, their interrelatedness, and appropriate applications may therefore be required. Through a critical review of the literature and analysis of case-studies, this paper aimed at delineating the notions of housing quality and conditions, and highlighting the related issues, with a view to enhancing research in these areas. This study reveals the significance of the research aim, context, and methodology in resolving the conceptual incongruities. It concludes that the interrelationships between these concepts do not diminish their critical distinctions, which could add value to further studies in this vital area of housing research, especially in developing countries.

Keywords: Conditions, Housing, Needs, Quality, Research

INTRODUCTION

There is an expanding body of literature on 'housing quality' (HQ) and 'housing conditions' (HCs). The terms are often used interchangeably even within the same studies, suggesting that they are synonymous (Streimikiene, 2015; Adjei and Kyei, 2013; Toyobo, Muili and Ige, 2011). Mandic and Cirman (2012) attest to a definitional dilemma which may be due to the complex nature of housing. This definitional ambiguity makes the findings of such studies not readily amenable to objective or comparative analysis. Moreover, perceptions may vary in the same location due to differences in personal and socio-economic characteristics. While the terms are used interchangeably in some studies, others focus exclusively on either HQ (Lee and Oh, 2012; Buckenberger, 2012) or HCs (Zainal, Kaur, Ahmad and Khalili, 2012; Govender, Barnes and Pieper, 2011; Bagaeen, 2006). This implies that the two concepts may be distinct in certain respects. A more comorehensive conceptualization in terms of their interrelatedness and applications would therefore be useful. The following review of literature examines the issues related to HQ and HCs, their definitions, indicators, relevance to quality-of-life (QoL) and health implications.

LITERATURE REVIEW

The literature on HQ and HCs vary in contexts, purposes and approaches. The contexts range from rural housing, slums, squatter settlements and informal low-cost housing, to public housing and high-rise condominium apartments; and from developed countries to developing countries. Studies range in purpose and method from conceptual to empirical surveys or case-studies. This review section addresses three broad areas: conceptual and definitional issues; measurement and indicators; and health-related issues.

Conceptual and Definitional Issues

Housing Quality

Housing quality (HQ) is a complex multi-dimensional concept, which has been defined in diverse ways, depending on the stakeholders' rationale and objectives (Franklin, 2001). It is widely acknowledged that HQ transcends the physical structures of dwellings (Buckenberger, 2012). Meng and Hall (2006) define HQ as "the grade or level of acceptability of dwelling

Ilesanmi, A. O. (2016). Reconceptualising Research on Housing Quality and Conditions in Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 394-402

units and their associated and immediate residential environment, including the design and functionality of housing structures, building materials used, the amount of internal and external space pertaining to the dwelling, housing utilities, and basic service provision." HQ is however more complex, with broader social and economic meaning, and incorporates both quantitative and qualitative dimensions. The quantitative aspect refers to objective structural, material, social and economic constituents or measurable outcomes, such as price, quantity, tenure, economic impacts, and structural housing standards. The qualitative dimension includes the perceived meanings and values of factors such as 'comfort' or 'quality of life' afforded by different dwelling types, lifestyles and residents' preferences and aspirations.

Irrespective of the dimension however, HQ is a relative rather than absolute or static concept; it varies over space and time (Teo and Kong, 1997). Lawrence (1995) proposed a reappraisal of the concept of HQ to extend beyond the traditional, architectural, technical and qualitative dimensions, to embrace economic and political dimensions. In a study of suburban Auckland, New Zealand, for example, Buckenberger (2012) reveals that owner occupants perceived the physical housing qualities to be central for families. To the cohort of elderly people however, intangible qualities such as the meaning of nature, gardens and lifestyle, and accessibility to shops and public transport outweighed physical qualities. This suggests a life-cycle shift in qualities from physical to intangible, emotional qualities in later life.

Housing Conditions

The word 'condition' refers to a state in which something exists. Discussion and study of HCs have an extensive tradition in the social sciences and suggest that HCs focus mainly on the physical attributes of dwellings and denote a concern for an acceptable, adequate level of housing. Much of earlier literature focused on the shelter function – housing as a physical resource for the satisfaction of basic need for shelter, while giving less attention to other functions of housing such as privacy, location, investment and social indicators.

Gwedu (2003) reports the evaluation of environmental problems at a low income urban area of Gaborone, Botswana. The study restricted evaluation to the quality of structures, apart from access to water, sanitation facilities and waste disposal, and interpreted HQ from a HC perspective. Bagaeen (2006) profiles the conditions in the Palestinian quarters of the old city of Jerusalem relative to the buildings, structures, utilities and services. He emphasizes the measurement of physical condition: provision of living space, aesthetic qualities of buildings, construction materials used, state of disrepair and the provision of services and environmental conditions. Similarly, Reuschke (2012) relates commuters' objective dwelling conditions and subjective dwelling preferences to multi-locational lifestyles.

According to Mandic and Cirman (2012), HCs tend to focus more on physical characteristics that reflect the ideas of 'adequate' or 'decent.' They denote mainly those physical attributes of dwellings that are significant for residents' wellbeing and meeting basic social norms, expressed in terms of 'decent', 'adequate' or 'acceptable' housing. These socially constructed norms are usually incorporated into public policies for intervention purposes. However, HCs do not only refer to the conditions of dwelling unit, but also wider living conditions of the environment, including basic facilities and supporting services (Konadu-Agyemang, 2001).

Some studies have related HCs to the quality-of-life concept (Daly, 2007), while others focused on the health implications of HCs (Adjei and Kyei, 2013; Shortt and Hammett, 2013; Milstead, Miles and Robbel, 2006; Evans, Saltzman and Cooperman, 2001). Housing improvement campaigns were undertaken in many European countries during the 19th century, as part of large-scale public health interventions to respond to inadequate housing conditions relating to crowding, hygiene, sanitation, ventilation, lighting, and structural deterioration (Braubach, 2011). Filali's (2012) analysis of HCs of households in Tunisia

focuses mainly on dwelling attributes and household size, related to five housing deprivation thresholds, with a view to reducing housing deprivation and preventing health vulnerability among deprived households. Housing conditions are often discussed in terms of inadequate housing of deprived groups, such as poor households, ethnic minorities and immigrants (Buckley and Mathema, 2008). They have also been referred to as 'slum severity' (Patel *et al.*, 2014) and 'slum conditions' (Gulyani, Bassett, and Talukdar, 2014; Omole, 2010).

Quality-of-Life

A number of studies have linked HQ or HCs to quality-of-life (Streimikiene, 2015; Ilesanmi, 2012; Zainal et al., 2012; Torrington, 2007). The 'quality of life' (QoL) perspective defines and conceptualizes HQ and HCs as elements of overall well-being (Daly, 2007). The QoL concept recognizes housing as one of nine components, which include: health and access to health care, employment and working conditions, economic resources, education and skills, family and social integration, security of life and property, recreation and leisure time, and culture and political resources (Wadley, 2011; Moser, 2009). Zainal et al. (2012) provide empirical evidence that relates poverty, HCs (dwelling types and physical conditions, house tenure, surrounding environment and availability of amenities) and QoL in Malaysia. Housing condition may therefore be viewed as a socio-economic indicator of urban poverty.

Indicators and Measurement Issues

Indicators are tools that measure, simplify and communicate phenomenon and trends, usually for the purposes of tracking progress, developing policies, monitoring their effectiveness and results, or deciding on interventions (Streimikiene, 2015). Due to the context-specific nature of HQ and HCs, there has been little consensus about defining indicators for measuring them. Konadu-Agyemang (2001) examines population growth trends and HCs in Accra, comparing the situation in the 1950s and 1990s in terms of tenure pattern, dwelling type, household size, occupancy rate, privacy, facilities available, and dwellings' material composition. The author found that HCs in the city were worse than they were in the 1950s. Fiadzo's (2004) indicator for estimating the determinants of HQ in Ghana, is a composite of items such as: type of lighting fuel, type of cooking material, main source of water, and type of wall material, as well as distances to nearest public transportation, hospital, market, water source, and secondary school – items which appear to be unique to the context.

The basic measures of HCs are 'number of persons per room' and 'amenities' – indicators that emphasize the physical condition of housing. Other factors which may affect HCs include: dwelling type, room size, provisions of bathrooms and toilets, construction materials, in-house facilities and services, and the neighbourhood (Torrington, 2007). Sanusi (2008) uses a three-dimensioned indicator similar to Human Development Index (HDI), comprising housing facilities (toilet, bathroom and kitchen), adequacy/space (house renting, squatting, spill-over population, occupancy ratio, bedroom, sitting room, cross-ventilation, internal open space); and solid waste disposal, to assess housing deprivation. Filali (2012) identifies overcrowding, ownership rates and basic public services as primary indicators individually employed to appraise household HCs, especially for international comparisons.

Yakubu *et al*. (2014) examine the effect of wealth on HCs of households in the Tamale, Ghana, based on three components of HCs: (a) residential density (average room occupancy rates); (b) material composition of the houses (wall, roofing, flooring and ceiling materials – their durability, maintainability and susceptibility to damp conditions); and (c) in-house facilities and services (potable water supply, toilets, waste disposal, cooking options, access to electricity and street lighting). In summary, physical conditions of dwelling units, availability of facilities and services, and environmental quality are critical elements in

assessing HCs (Lawrence, 2006). Streimikiene (2015) proposes a comprehensive set of indicators under three main groups, all of which have impact on quality of life, namely:

i. Dwelling's socio-physical and physical characteristics: overcrowding rate; housing deprivation rate (lack of basic facilities); deterioration or otherwise of roofs, floors, doors and window frames; and availability of electricity, water supply and cooking facilities.
ii. Housing environment: subjective perception of residents to exposure to crime, violence or vandalism in the area, noise from neighbours or from the street, pollution, grime or other environmental problems; and the proximity of public services (schools and hospitals).
iii. Housing expenditures burden: housing cost overburden rate, inability to keep home warm, share of housing costs in disposable household income, and inability to pay utility bills.

Health-related Issues

Much of the literature focuses on the health implications of HQ and HCs. Tanaka, Nakano, Nakamura and Takeuchi (1996) found significant correlation between residential-condition indicators and health levels of residents in Tokyo, after adjusting for socio-economic differences between communities. Evans *et al.* (2001) relate a standardized HQI to children's psychological distress and motivation. Milstead *et al.* (2006) associate increased cockroach infestations with housing and neighbourhood conditions in three European cities. Gifford and Lacombe (2006) link the socioemotional health of children 9-12 years old to physical quality aspects of their residence and neighbourhood in a Canadian city. Northridge, Ramirez, Stingone and Claudio (2010) reveal how factors associated with HQ explain the clustering of childhood asthma in public housing in New York. Govender *et al.* (2011) associate the structural living conditions of government-subsidized low-cost housing settlements in Cape Town, South Africa with inhabitants' health conditions. The study reveals how structural aspects of HCs contribute to an increased risk of communicable diseases. Adjei and Kyei (2013) confirm a positive correlation between poor housing conditions and disease occurrence in selected rural communities in Ghana. Ogundahunsi and Adejuwon (2013) draw similar conclusions regarding HCs and residents' health in villages of Osun State, Nigeria.

RESEARCH METHOD

This study employed a qualitative research approach involving the collection of secondary data from research reports and case-studies on housing quality and housing conditions. Sixty-eight (68) pieces of literature were consulted or reviewed to varying degrees. These included 6 conceptual papers, 47 peer-reviewed journal articles, 4 theses, 7 technical reports and 4 conference proceedings (See Table 1). Content analysis of thirty-four (34) of the journal articles which reported empirical evaluations of housing quality or housing conditions was conducted and the findings briefly discussed in the section following.

Table 1: *Summary of Reviewed Literature*

Type of Literature	No. of Units	Consulted/Reviewed
Journal articles	Conceptual Papers	6
	Empirical Research Papers	47
Theses		4
Technical Reports		7
Conference Proceedings		4
Total		68

ANALYSIS, FINDINGS AND DISCUSSION

The qualitative analysis and findings of this study are presented and discussed under three subheadings, namely: purposes of HQ and HCs evaluation; perceived shifts in nomenclature;

distinguishing between 'housing quality' and 'housing conditions.' These are with a view to minimizing the conceptual ambiguities.

Purposes of Housing Quality and Conditions Evaluations

Studies on HQ and HCs may be intended for academic research, to formulate and implement housing policies, to identify targets for improvement or upgrading of housing stock, and to disseminate information to the professions or the public. Table 2 summarizes some of these.

Table 2: *Some Purposes of Housing Quality and Conditions Evaluation*

S/N	Case-study	Primary Purposes
1	Fiadzo *et al.* (2001) Ghana	To evaluate housing needs and effects on spatial inequity To estimate the extent of poverty
2	Meng and Hall (2006) Lima, Peru	To identify areas of deficient HQ; in greatest need of improvement; clearly visualize areas with high HQ inequity. To reveal spatial distribution of HQ and map disparities. To provide government housing planners with household and area-based information for identifying areas of HQ deficiency.
3	Sanusi (2008)	To assess housing deprivation in urban Minna, Nigeria.
4	Zainal et al. (2012)	To show HC as a socio-economic indicator of urban poverty.
5	Filali (2012)	To identify households suffering from housing deprivation.
6	Lee and Oh (2012)	To provide information on housing choices in Korea.
7	Adjei and Kyei (2013)	To explain the relative incidence and severity of disease occurrence as public health implications of poor rural environment in Ghana.

Perceived Shifts in Nomenclature

It appears from the literature on HQ and HCs in Nigeria and Ghana, that there have been shifts in nomenclature over time. Older studies seem to have focused on HCs, especially with regard to housing the urban poor. Jagun (1983) estimated 'urban housing need' as a proxy for HCs; Ozo (1987) analyzed HCs of the urban poor in Benin City; while Awotona (1988) examined the perceptions of HCs in Nigeria by the urban poor. However, Ogu (1994) examined rural HQ in Imo State; Fiadzo *et al.* (2001) view HQ as a basis for poverty evaluation and development policy analysis. Pacione (2003) and Coker, Awokola, Olomolaiye and Booth (2008) extend the scope of evaluation beyond housing units to neighbourhood environmental quality, relative to health and well-being. Ilesanmi (2010, 2012) focus on the quality of housing and neighbourhoods in public housing estates.

Other recent studies freely mix HQ and HCs. Olotuah's (2010) appraisal of environmental degeneration in Nigeria emphasizes physical housing conditions. Omole (2010) assesses HC and socio-economic lifestyles of slum-dwellers in Akure. Toyobo *et al.* (2011) highlight the socio-economic correlates of HQ in Ogbomosho. Amao (2014) integrates the concepts of HQ and HCs in a case-study of selected urban fringes of Ibadan; while Jiboye (2014) isolates the effect of house-type on residential quality in Osogbo. Ogunleye (2013) relates socio-economic characteristics to HC – physical state of buildings – in the low-income core area of Akure, Nigeria. With the growing interest in the qualitative dimensions of housing, it is important that conceptual ambiguities be reduced, so that concepts are better operationalized for more useful application of research results, especially of studies in contiguous contexts.

Between Housing Quality and Housing Conditions

Based on the review and case-studies, it is possible to draw few distinctions between HQ and HCs. 'Housing quality' often assumes the form of a 'measure' – such as Housing Quality Index (HQI) – which enables comparison between contexts, and may relate to housing satisfaction. While HCs may also assume the form of a measure – Housing Condition Index (HCI) – it is often more descriptive than defined as a single index. Studies that develop single composite indicators have been more common in developed countries due to the availability

of more comprehensive and consistent housing data. Such studies are gradually evolving in the developing countries based on residents' evaluation (Sanusi, 2008).

While many studies on 'quality' have focused on contexts of planned housing developments such as public housing, 'conditions' are usually descriptive of less organized settings such as informal private housing, slums and squatter settlements. It is usual for example, to refer to 'slum conditions' rather than 'slum quality' (Omole, 2010; Garau, Sclar and Carolini, 2005). Moreover, while HQ usually refers to conventional standard(s), 'conditions' relate more to socially-constructed basic needs that households perceive, relative to local norms.

Although both concepts usually transcend the scope of the dwelling unit to embrace its surrounding, 'quality' will often encompass broader issues of the neighborhood, supporting amenities, facilities or infrastructure – availability, affordability, and adequacy. Older studies on HCs emphasized the physical conditions of dwellings and living conditions, viewing it essentially as an issue of inadequate housing of disadvantaged or deprived groups, such as low-income households, ethnic minorities, immigrants, and run-down neighborhoods. In order to decide what form of evaluation to conduct therefore, important consideration should be given to the study's aim or purpose, context and method. The framework in Figure 1 and summary in Table 3 illustrate how aspects of HCs (shaded boxes) could be conceptualized as being subsumed within the broader concept of HQ, and their possible applications.

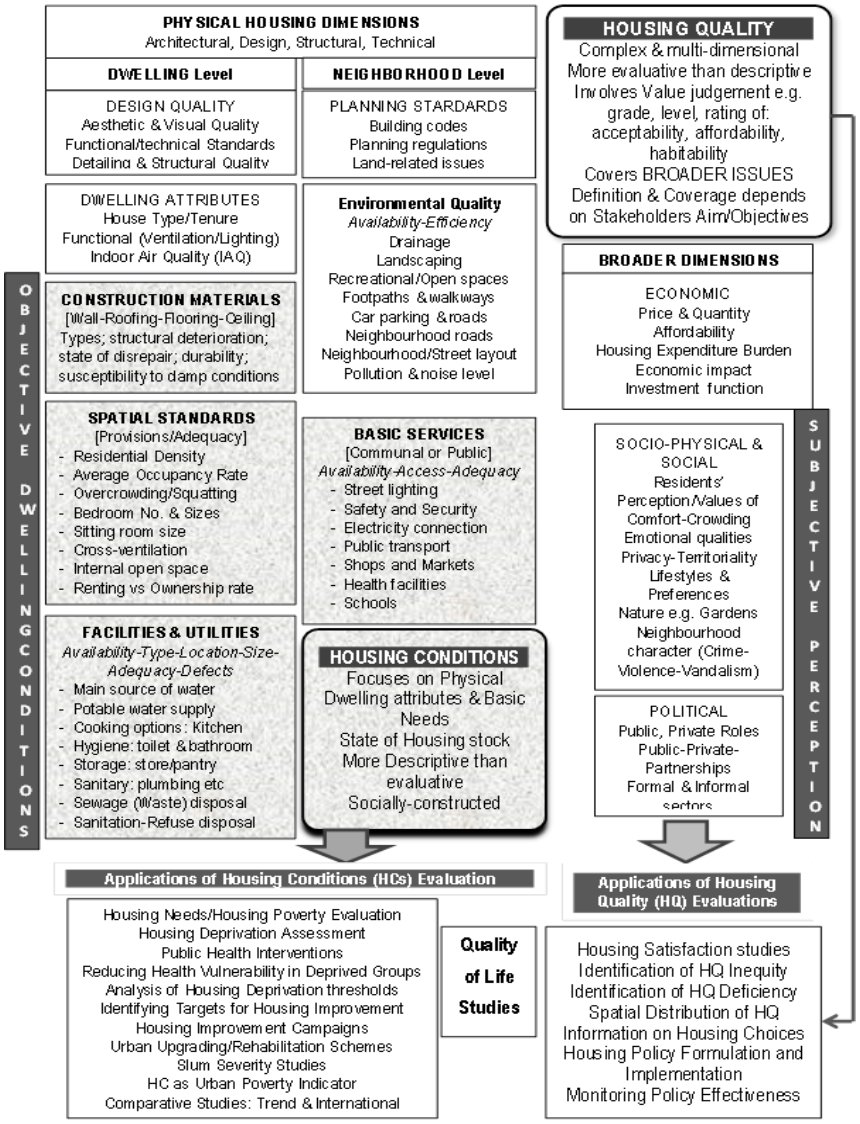

Figure 1: Conceptual Framework Relating Housing Quality and Housing Conditions

Table 3: Contexts and Methods of Evaluation

	Housing Quality	Housing Conditions
Context	- Formal Housing - Public Housing - Institutional housing (e.g. staff housing) - Apartment blocks/Condominiums	- Informal private housing - Slums and squatter settlements - Housing for the low-income - Rural housing - Temporary housing
Purpose	- Information to policy-makers and planners on areas of HQ deficiency. - Policy formulation and analysis - Information on housing choices - Cross-city/national comparisons	- Evaluation of housing needs and effects on spatial inequity. - Mapping of poverty profiles. - Assessment of housing deprivation. - Public health and housing conditions.
Methodology	Rigorous analysis e.g. correlation, regression, principal component analysis (PCA), factor analysis	Descriptive analysis e.g. frequency, cross-tabulation, Chi-square

CONCLUSION

The seeming definitional dilemma regarding the terms 'housing quality' and 'housing conditions' forms the thrust of this paper. By means of a literature review and appropriate case-studies, the paper examined the notions of housing quality and housing conditions in terms of their definitions, indicators, relevance to quality-of-life and health impacts. These were with a view to gaining clearer insight and drawing applicable distinctions between the terms, even though they appear to be synonymous. The interrelationship between the concepts of housing quality and housing conditions do not diminish their critical distinctions, an understanding of which could add value to the conceptual basis of further studies in this vital area of housing research, especially in developing countries.

Effect of Blended Cement on the Hydration Properties, Compressive Strength and Environmental Compatibility of Concrete

Folagbade, Samuel Olufemi

Department of Building, Obafemi Awolowo University, Ile-Ife, Nigeria
samuelfolagbade@yahoo.com

ABSTRACT

This paper investigated the effect of blended cement (or cement combination) containing Portland cement, fly ash, silica fume and metakaolin on the hydration properties (using the standard consistency, setting times, workability and pozzolanic reactivity), compressive strength and environmental compatibility (using the embodied carbon-dioxide contents) of concretes or pastes. The results showed that cement combination concretes have lower embodied carbon-dioxide contents and are therefore more environmentally compatible than Portland cement concrete. Fly ash would reduce water demand and superplasticiser dosage (to improve workability), increase setting times and reduce early-age strength development. Silica fume and metakaolin will increase water demand and superplasticiser dosage and reduce setting times to support early-age strength development. While silica fume and metakaolin are more reactive than fly ash due to their higher fineness, the ternary combinations coupled with the slow but long-term pozzolanic reaction will make the supplementary materials to produce concrete with good workability and support both early-age and later-age strength development. Due to its higher fineness and particle shape, silica fume would perform better than metakaolin at equal replacement levels. Also, for optimum performance, the metakaolin content should be limited to 10%. Blended cement concretes would acquire equal strength with Portland cement concrete at lower water/cement ratios (thus requiring higher quantities of the cements). Nevertheless, if appropriately proportioned, blended cement concretes that are cheaper and more workable and environmentally compatible than Portland cement concrete are available at equal strengths.

Keywords: Blended cement concrete, compressive strength, hydration properties, pozzolanic reactivity, environmental compatibility

INTRODUCTION

The production of conventional concrete is faced with the problem of high level of carbon dioxide (CO_2) emissions which stands at about 930kg per tonne of Portland cement produced (The Concrete Industry Sustainable Construction Forum, 2009). With about 10% of CO_2 emissions being generated by the cement industry (Oxley, 2003), the partial replacement of Portland cement content of concrete by supplementary cements like fly ash, silica fume and metakaolin which are more environmentally compatible due to their low embodied CO_2 content (Table 1), became inevitable in concrete construction. Fly ash is characterized by low water demand and improved workability of concrete (Dhir et al., 2002) and low cost and quality fly ash could be made available for future use (Jones et al., 2006; Antiohos et al., 2007). However, the use of fly ash would result in increased setting times (Langan et al., 2002). This is because the pozzolanic reactivity of fly ash depends on the $Ca(OH)_2$ produced by the hydration reaction of Portland cement and would be delayed when the alkalinity of the pore water is low (Fraay et al., 1989). While this would result in poor performance at early ages (Hassan et al., 2000; McCarthy and Dhir, 2005), its improved pozzolanic reactivity with curing age would produce better performance at later ages (Lam et al., 1998).

Despite their high water demand and workability problems (Bouzoubaa et al., 2004) and high cost (Table 1), the fineness of silica fume and metakaolin would result in more nucleation sites to accelerate hydration reactions (Mehta and Aitcin, 1990), reduce setting times (Ambroise et al., 1994; Bouzoubaa et al., 2004), enhance strength (Day, 1992; Uchikawa and Okamura, 1993; Korpa et al., 2008), refine pore structure to increase the resistance of

Folagbade, S. O. (2016). Effect of Blended Cement on the Hydration Properties, Compressive Strength and Environmental Compatibility of Concrete. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 403-416

concrete to permeation (Bentz et al., 2000; Frias and Cabrera, 2000; Poon et al., 2006; Korpa et al., 2008) and offset the poor performance of fly ash at early ages. Hence, to exploit their complimentary roles in concrete performance, ternary combinations of Portland cement, silica fume or metakaolin and fly ash became worthwhile. This is because, while silica fume or metakaolin would contribute to the early age performance of concrete, fly ash would continue to refine the properties of the hardened concrete as it matures (Thomas et al., 1999; Khan et al., 2000, Khan and Lynsdale, 2002; Bai et al., 2002). However, these supplementary cements are underutilized in construction. Since these cements are more environmentally compatible than Portland cement and their use is supported by cement and concrete standards like BS EN 197- 1, BS EN 206- 1 and BS 8500, among others, it becomes necessary to investigate their implication for concrete construction.

For good quality of workmanship, hydration properties of concrete like standard consistency, setting times and workability would assist contractors and concrete suppliers in making appropriate decisions on handling (transportation), placing (including choice of formwork), compacting and finishing of concrete. While the engineering or durability performance of the supplementary cements would depend on their pozzolanic reactivity, their patronage would depend on their economic and environmental implications. Hence, this paper presents the effect of the supplementary cements on the hydration properties, compressive strength, cost and environmental compatibility of concrete.

EXPERIMENTAL MATERIALS AND METHODS

The cementitious materials consist of ordinary Portland cement (PC, 42.5 type) conforming to BS EN 197- 1, siliceous or Class F fly ash (FA) conforming to BS EN 450, silica fume (SF) in a slurry form (50:50 solid/water ratio by weight) conforming to BS EN 13263- 1 and metakaolin (MK) conforming to BS EN 197- 1. The physical and chemical properties of the cements are presented in Table 1. The aggregates consist of 0/4mm fine aggregates and uncrushed 4/10 mm and 10/20 mm coarse aggregates of varied shapes. While the 4/10 mm aggregates were rough, the 10/20 mm aggregates were smooth. Potable water, conforming to BS EN 1008, was used for mixing and curing the concrete specimens. To achieve good cohesion and finishability within a consistence level of S2 (BS EN 206- 1) defined by a nominal slump of 50-90 mm, a superplasticiser based on carboxylic ether polymer conforming to EN 934- 2 was applied to the concrete mixes during mixing. The concrete mix design was based on the BRE Design Guide (Teychenne et al., 1997), selected cement combinations (Table 3) and a free water content of 165 kg/m^3 to avoid an excessively sticky mix.

Cement paste was prepared to BS 196- 3 using a small mixer bowl conforming to BS 196- 1. The materials were carefully added to water in the mixer bowl and mixed carefully to avoid loss of materials and ensure thorough mixing and uniform consistency. Tests were carried out on the fresh specimens of the cement pastes to determine the standard consistency and setting times and on the hardened specimens of cement paste at the water/cement ratio of 0.50 to investigate the pozzolanic reactivity of the cement combinations. Concrete was prepared to BS EN 12390- 2. Tests were carried out on fresh specimens of concrete to investigate the workability, superplasticiser dosage, cohesion (or stability) and finishability and on the hardened concrete specimens to determine the cube compressive strengths. The paste and concrete specimens were cast, cured under a layer of damp hessian covered with polythene for about 24 hours, demoulded and cured in water at about 20^{o}C until the tests' dates.

b) In accordance with EN 450- 1
c) Obtained with the Laser Particle Sizer
d) Obtained by x-ray fluorescence (XRF)

The standard consistency test involves determining the quantity of water, by trial and error, which will give a standard consistence in accordance with BS EN 196- 3. The test is time specific and the procedure involves preparing the mould, calibrating the Vicat apparatus and raising the plunger to a standby position ready for the test. 500 g of cement or combinations was carefully mixed with an initial amount of water (e.g. 125g) on a low speed to avoid loss of water or materials at a known time recorded as the 'zero time' on which the determination of the initial and final sitting times was based. After thorough mixing, the mould (with the base plate) was filled with paste, tapped gently to remove the voids, finished smooth surface and positioned centrally on the calibrated Vicat apparatus before releasing the gently lowered plunger to penetrate vertically into the centre of the paste. The reading on the scale was recorded 5 seconds after penetration has ceased or 30 seconds after the release of the plunger, whichever is earlier. The test was repeated by varying the water content until a distance of 6±2 mm between the plunger and the base plate was obtained.

The setting times were determined with the automatic Vicat apparatus launched on the computer and test machine complying with BS EN 196-3. The machine drops a 300g needle into the paste prepared at standard consistency and the depth of penetration was recorded. The initial setting time was obtained as the time from when water was added to cement to the time when the needle can only penetrate a distance of 36±1 mm while the final setting time

was obtained as the time from when water was added to cement to the time when the needle can only leave a mark on the surface (i.e. when the penetration is less than 1mm).

The quantity of $Ca(OH)_2$ consumed at a particular age, obtained as the difference between the quantity of $Ca(OH)_2$ present in the Portland cement paste specimen and the quantity of $Ca(OH)_2$ present in the other cement paste specimens at that age, was used to assess the pozzolanic reactivity of the cement mixes. The quantities of $Ca(OH)_2$ present in the cement paste specimens were determined by thermogravimetric (TG) analysis which involves measuring the weight loss of a sample with respect to temperature change. From the plot of the sample weight against the temperature, physical and chemical changes that involve thermal decomposition (or weight loss) were identified and measured. To avoid weight gain which could result if the sample reacts with atmospheric gases, the experiment was conducted in an inert atmosphere using Nitrogen gas. The TG equipment also allows a constant replacement of its internal atmosphere in order to flush out the gases evolved and prevent reactions between the volatilized substances in the material which could complicate the interpretation of the thermogravimetric plots. The TG equipment (a STA- 1 installation unit fitted with a 1500^{o}C capacity furnace) is connected to a computer which automatically log and analyse the data generated. Fragments from the core of paste cubes were selected, quenched in acetone to stop the hydration process, oven-dried at 40^{o}C to avoid carbonation, cooled to room temperature in a dessicator containing silica gel and ground into powder. A minimum powder sample of 10mg was placed in a platinum crucible, installed on the TG equipment and heated to a temperature of 1000^{o}C at a rate of 10^{o}C/minute. The TG plot produced was used to determine the quantity of $Ca(OH)_2$ left in the samples at the respective ages as stated below. The % water loss (wL) from the dehydroxylation region (defined by a temperature range of 400-500^{o}C on the graph of the first derivative) was obtained and used in conjunction with equation 2 to determine the %$Ca(OH)_2$ content as stated in equation 1.

$$\%Ca(OH)_2 = \frac{wL}{18}\ x\ 74 \qquad (1)$$

$$\underset{(74\text{g/mole})}{Ca(OH)_2} \rightarrow \underset{(56\text{g/mole})}{CaO} + \underset{(18\text{g/mole})}{H_2O} \qquad (2)$$

To investigate the effect of cement combinations on workability, the superplasticiser dosages, cohesion and finishability of the concretes were assessed with the aid of slump test carried out in accordance with BS EN 12350- 2. The slump test could be used to determine the capacity of concrete to hold water and coarse aggregates (Metha and Monteiro, 2014). The superplasticiser dosages for the cement combinations were determined at a consistence level of S2 defined by a nominal slump of 50-90 mm in BS EN 206- 1. A dampened truncated cone (100mmΦ x 200mmΦ x 300mm) placed on a horizontal base plate and held firmly in position with the aid of the foot rests, was filled with fresh concrete placed in three layers, each approximately one-third of the height of the cone when compacted. Each layer was compacted with 25 strokes of the tamping rod (16mmΦ x 600mm) uniformly distributed over the cross-sections and depths of the layers. The top layer was over-filled and the excess, after tamping, was removed by the sawing and rolling movement of the compacting rod. After this, the spilled concrete was removed from the base plate and the cone was carefully lifted vertically and placed inverted next to the slumped concrete. The difference between the height of the mould and the highest point of the slumped concrete was then measured, to the nearest 5mm with the aid of a ruler, as the slump and the quantities of superplasticiser used to achieve a consistence level of S2 were recorded for the mixes. Cohesion and finishability of concrete were visually assessed. While cohesion was assessed by the extent of firmness or looseness of the slumped concrete when tamped many times with a rod, finishability was assessed by the quality of finish.

The compressive strength of concrete was obtained in accordance with BS EN 12390- 3. The test specimens were loaded to failure using the Avery Denison crushing machine with a base load of 10kN at a loading rate of 7.0 kN/m^2. Two water-cured 100mm cubes were tested at the curing ages of 28, 90 and 180 days after casting.

The material cost of concrete, used in this research, was obtained as the summation of the costs of the constituent materials. Hence, it excludes all costs associated with profit and overhead and the use of other construction resources (i.e. equipment, manpower, money and management). The embodied carbon dioxide (eCO_2) is a measure of carbon dioxide emitted owing to the energy used in heating the kiln and in the chemical reaction that takes place in the kiln when cement is manufactured. The material costs and eCO_2 contents of concrete mixes (Table 7) were obtained with the aid of the mix proportions as the summation of the costs and eCO_2 contents of the constituent materials at the different water/cement ratios using the costs and eCO_2 values presented in Table 2. The costs, eCO_2 contents and strength values were interpolated or extrapolated to obtain the values at equal strengths (Table 8).

RESULTS AND DISCUSSION

Hydration Properties of Cement Combination

Water requirements of cement combination

Table 3 shows that the water requirement of cement pastes reduced with increasing fly ash (FA) content and increased with increasing silica fume (SF) and metakaolin (MK) content. But, despite the increasing water demand of these ternary cements, the Table shows that ternary cement combinations at not more than 5%SF still have same water demand with Portland cement (PC). Table 3 also shows that water required by the finer and spherical SF is lower than that required by the coarser and angular MK at equal replacement levels. It therefore follows that water demand would be influenced by particle shape than by particle fineness. While the replacement of 5% FA in 65%PC+35%FA with 5% MK increased water demand by 1.5%, the comparison of the water requirements of 80%PC+15%FA+5%MK paste and 65%PC+30%FA+5%MK paste shows a slight reduction of 0.5% in water demand despite the fact that the FA content reduced by 15%. Since similar trend was observed in the other ternary cement pastes despite the reducing effect of FA, it shows that the water requirement of ternary cement pastes would be primarily influenced by the SF or MK content than by PC or FA content.

Initial setting times of cement combination

Table 3 shows that fly ash, as a binary cement component, increased the initial and final setting times of the cement pastes with increasing content. This would be due to the reduced content of Portland cement (dilution effect) resulting in low alkalinity of the pore water and the subsequent delay in the reactivity of fly ash (Fraay et al., 1989). Although the control of

the particle size of fly ash is based on residue larger than 45µm, particle sizes less than 10µm are most reactive (Metha, 1985). Since Table 1 shows that a higher proportion of the fly ash particles falls above 10µm, the particle size distribution of fly ash might have contributed to the slow reactivity and increased setting times of fly ash binary cement pastes.

90%CEM I+10%SF	29.0	125	150

1) % Total cement content

The addition of silica fume and metakaolin, as binary cement components, increased the initial setting times (due to the non-commencement of their hydration reactions until the release of $Ca(OH)_2$ into the pore water) and decreased the final setting times of cement pastes because enough $Ca(OH)_2$ is available to allow their higher reactivity. The initial setting times increased with increasing content of silica fume and metakaolin up to 10% and 15% respectively and there was no difference between their final setting times at 5% and 10% contents of either silica fume or metakaolin. However, the final setting time at 15% metakaolin content was higher than at 10% metakaolin content. The ternary combinations mostly have higher initial and final setting times than Portland cement. However, while the the initial and final setting times reduced with increasing content of silica fume and metakaolin up to 10% content, the setting times at 15% metakaolin content was higher than at 10% metakaolin content. Hence, 15% would be more than the optimum content of metakaolin as both binary and ternary cement. Due to higher fineness resulting in more nucleation sites, silica fume binary and ternary cement pastes have lower initial and final setting times than metakaolin pastes at equal replacement level. The setting times were also observed to increase with increase in the total cement addition content.

Superplasticiser dosage of cement combination

Table 4 shows that superplasticiser dosage reduced with increasing water/cement ratio. While fly ash, as a binary cement component, reduced superplasticiser dosage with increasing content, silica fume and metakaolin, as both binary and ternary cement component, increased superplasticiser dosage with increasing content at equal water/cement ratio. Also, the superplasticiser dosages of the ternary cement concretes reduced with increasing content of fly ash. Metakaolin required higher superplasticiser dosage than silica fume at equal replacement level. As silica fume is finer than metakaolin and should require higher content of superplasticiser than metakaolin at equal water/cement ratio, the higher superplasticiser

dosages recorded for metakaolin concretes would therefore be due to the fact that the effect of angular shape of metakaolin supercedes the effect of the higher fineness of silica fume on water requirement.

The cohesion of the concrete mixes was assessed as described earlier with the aid of the slumped concretes. Cohesion of concrete was observed to generally reduce with increasing water/cement ratio. Compared with Portland cement, the use of supplementary cements resulted in improved cohesion and stability of the concrete mixes at equal water/cement ratio. This is probably due to improved particle packing, improved viscosity or higher water content needed by the fine materials (especially silica fume and metakaolin). Compared with the fly ash binary cement concrete, the higher fineness of silica fume and metakaolin also resulted in ternary cement concrete with higher cohesion. However, increasing cohesion was observed to have a negative effect on finishability. This is because the higher the cohesion, the higher the stickiness and the difficulty in obtaining a smooth finish.

Pozzolanic reactivity of cement combination concrete at equal water/cement ratio

The $Ca(OH)_2$ contents and consumption of the cement pastes, at the curing ages of 28, 90 and 180 days at the water/cement ratio of 0.50, are presented in Table 5. As expected, the quantity of $Ca(OH)_2$ in the Portland cement paste increases with increasing curing age. On the other hand, due to the dilution effect (reduction due to Portland cement replacement) and the consumption of $Ca(OH)_2$ by the pozzolanic reactions of the supplementary cements, the quantity of $Ca(OH)_2$ in the binary and ternary cement pastes reduced with increasing curing age and increasing content of the cement additions.

The quantities of $Ca(OH)_2$ consumed by the binary cement pastes increased with increasing curing age due to the pozzolanic reaction of the supplementary cements but they were generally low at 28 days probably due to the delay in the commencement of the pozzolanic reaction. The addition of 20%, 35% and 55% fly ash shows no consumption of $Ca(OH)_2$ at 28 days. However, the $Ca(OH)_2$ consumption levels increased progressively with increasing curing age to 2.5%, 3.3% and 2.0% respectively at 180 days. The $Ca(OH)_2$ consumption

increased with increasing content of fly ash up to 35% and reduced at fly ash content of 55%. The latter might be due to the reduced content of Portland cement (dilution effect), resulting in $Ca(OH)_2$ content lower than needed for pozzolanic reaction at that higher contents of fly ash. Hence, for better reactivity, fly ash content of a fly ash binary cement combination should not exceed 35%.

Table 5. $Ca(OH)_2$ consumption of cement combination pastes

MIX COMBINATION	$Ca(OH)_2$ CONTENT AND CONSUMPTION OF CEMENT PASTE, % Cement Mass

90%PC+10%SF	18.5	1.7	17.0	4.0	16.2	5.1

1) $Ca(OH)_2$ content measured. 2) % $Ca(OH)_2$ consumed by additions
= (Expected % $Ca(OH)_2$ released by PC minus % $Ca(OH)_2$ content measured).
Expected % $Ca(OH)_2$ released by PC is assumed = 100%PC content x %PC content of mix.
Hence for 80%PC+20%FA, the expected % $Ca(OH)_2$ released by PC at 90 days = 23.3 x 0.8 = 18.6
% $Ca(OH)_2$ consumed by 80%PC+20%FA at 90 days = 18.6 – 17.2 = 1.4

Silica fume at equal age and replacement level consumed more $Ca(OH)_2$ than metakaolin. At 28 days, the quantities of $Ca(OH)_2$ consumed by silica fume and metakaolin, as binary cement components, increased with increasing curing age and decreased with increasing content of the cement additions. Since silica fume binary cement combinations consumed higher quantities of $Ca(OH)_2$ than metakaolin binary combinations at equal replacement levels, silica fume would be preferred to metakaolin where higher reactivity is required for early age performance up to 28 days. Also, lower content of silica fume or metakaolin (5% SF or MK) would be preferred to 10% content of silica fume or metakaolin as binary cement component. Beyond 28 days, while there is little or no difference in the quantity of $Ca(OH)_2$ consumed at 5% and 10% silica fume content or at 5% and 10% metakaolin content, the quantities of $Ca(OH)_2$ consumed at 15%MK content were lower than at 10%MK content. While silica fume would consume more $Ca(OH)_2$ than metakaolin at equal replacement level, there is no difference between their performances at 5% or 10% contents. Hence, the choice of content between 5% and 10% would depend on other factors like cost and environmental compatibility. Since the quantities of $Ca(OH)_2$ consumed at 15%MK content were lower than at 10%MK, it shows that 15%MK content might be more than the optimum content of metakaolin as a binary cement component.

Compared with the fly ash binary cement pastes, the addition of silica fume and metakaolin reduced the $Ca(OH)_2$ contents of the pastes with increasing curing age and increasing content

of the ternary cement. Hence, the addition of silica fume and metakaolin as ternary cement components would result in increased consumption of $Ca(OH)_2$ and therefore increased pozzolanic reactivity of the ternary cement pastes. Also, silica fume ternary cement pastes at equal replacement levels, consumed more $Ca(OH)_2$ than metakaolin ternary cement pastes. Hence higher pozzolanic reactivity would be expected in silica fume pastes than in metakaolin pastes and concretes. The quantities of $Ca(OH)_2$ consumed by the binary and ternary cement pastes at 180 days were much lower than the quantity of $Ca(OH)_2$ released by the hydration reaction of Portland cement. This also shows that the pozzolanic reaction is somehow slow and would take a long time to complete.

Compressive strength of cement combination concrete at equal water/cement ratio

The cube compressive strengths of concretes at 28, 90 and 180 days at water/cement ratios of 0.35, 0.50 and 0.65 are presented in Table 6. As expected, compressive strength decreased with increasing water/cement ratio and increased with increasing curing age. At equal water/cement ratio, the cube compressive strengths of the fly ash binary cement concretes are lower than that of ordinary Portland cement concrete and they reduced with increasing content of fly ash at all the test ages. This must be due to the slow pozzolanic reaction of fly ash at early ages as a result of its delayed reactivity until the alkalinity of pore water is high enough for its pozzolanic reaction and its low fineness (Table 1). Compared with Portland cement concrete, the strengths of fly ash binary cement concretes improved with curing age due to improved pozzolanic reaction of fly ash. Hence, the reduction in the disparities between the strength values of the Portland cement concrete and fly ash binary cement concretes shows that fly ash would support later-age strength development.

The addition of silica fume and metakaolin resulted in binary cement concretes with comparable strengths with Portland cement concrete. Hence, due to their higher fineness (Table 1) resulting in more nucleation sites for hydration reaction and improved pozzolanic reactivity, silica fume and metakaolin would contribute to strength development than fly ash. The partial replacement of fly ash in the binary cement concretes with silica fume and metakaolin resulted in ternary blended cement concretes with better strengths at equal ages. Also, silica fume ternary cement concretes exhibited higher strength than the metakaolin ternary cement concretes at equal replacement levels.

Cost and environmental implication of cement combination

The environmental impact of blended cement on concrete construction was examined with the aid of the embodied CO_2 (e-CO_2) contents of the concrete mixes. The supplementary cements are by-products from industrial wastes and their use as raw materials would reduce the environmental impact of opening up of pits for their disposal. Their use would also reduce the quantity of Portland cement used in construction and therefore reduce the pressure on the raw materials for its manufacture as well as the environmental impact associated with its manufacture. Since the patronage of these supplementary cements would partly depend on cost, Table 7 presents the embodied carbon-dioxide contents and the material costs of the concretes.

The embodied CO_2 of the concretes decreased with increasing water/cement ratio. The addition of fly ash as binary cement reduced substantially the e-CO_2 of the binary cement concretes with increasing fly ash content. The addition of 20%, 35% and 55% fly ash reduced the e-CO_2 contents by an average of 20.7%, 34.9% and 55.0% respectively. Hence, compared with Portland cement concrete, the addition of 1.0% fly ash would lead to a reduction of about 1.0% e-CO_2. Silica fume and metakaolin as binary cements also reduced the e-CO_2 of concretes with increasing silica fume or metakaolin content. The addition of 5% and 10% SF reduced the e-CO_2 by an average of 5.1% and 10.0% respectively while the addition of 5%, 10% and 15% metakaolin reduced the e-CO_2 by an average of 3.5%, 7.0% and 10.4% respectively. These show that, compared with Portland cement concrete, the addition of 1.0% SF or MK would lead respectively to a reduction of about 1.0% and 0.7% e-CO_2 respectively.

a) % Superplasticiser (SP) is related to the total cement content. b) Plastic density of concrete

The ternary cement concretes have lower e-CO_2 than Portland cement concretes at all the water/cement ratios. While the metakaolin ternary cement concretes have slightly higher e-CO_2 values than that of their respective fly ash binary cement concretes, there is no considerable difference between the e-CO_2 values of the silica fume ternary cement concretes and that of their respective fly ash binary cement concretes at all the water/cement ratios.

Hence, silica fume concretes would have lower e-CO_2 values than metakaolin concretes at equal replacement level.

As expected, the material cost of concrete decreased with increasing water/cement ratio. This is because the quantity of the costliest materials, the cements and superplasticiser, decrease with increasing water/cement ratio. While fly ash as binary cement would reduce material costs with increasing content, silica fume and metakaolin as binary cement would increase material costs with increasing content. The materials costs of the ternary cement concretes (though higher than that of their respective fly ash binary cement concretes) are lower than that of ordinary Portland cement concrete at all the water/cement ratios. Hence, the use of cement combinations could make concrete more economical.

Concrete is specified in practice on the basis of strength and in order to examine the cost and environmental implications of blended cement on concrete construction, Table 8 presents the costs and e-CO_2 contents of concrete options at the 28-day strengths of 40 and 45 N/mm^2. Table 8 shows that equal strength with Portland cement concrete would be achieved at lower water/cement ratios (and therefore at higher cement contents) by the blended cement concretes. Hence, equal strengths at equal ages, would be achieved at different water/cement ratios, material contents, material costs and embodied carbon dioxide contents. While all the cement combination concretes at the strengths of 40 and 45 N/mm^2 were generally more environmentally compatible than ordinary Portland cement concrete because of their lower embodied carbon dioxide contents, concrete options cheaper than ordinary Portland cement concrete are available. These are the fly ash binary cement concretes and ternary cement concretes with not more than 5% silica fume or metakaolin at a total replacement level of not more than 35%. Hence, at equal strength, fly ash has the propensity to improve the strength of concrete.

CONCLUSION

The following conclusions have been drawn from this investigation:

i. While fly ash would reduce water demand and silica fume and metakaolin would increase it. Nonetheless, ternary cement combinations with not more than 5%SF would have equal level of water demand with Portland cement at equal consistence.

Also, water demand would be influenced by particle shape than by particle fineness and by silica fume and metakaolin content than by Portland cement and fly ash content.

ii. Due to its low reactivity, fly ash would increase both the initial and final setting times. Silica fume and metakaolin would increase the initial setting times due to delayed hydration reaction and reduce the final setting times due to the availability of enough $Ca(OH)_2$ for high pozzolanic reactivity. The ternary combinations mostly have higher initial and final setting times than Portland cement.

iii. While fly ash would reduce superplasticiser dosage, silica fume and metakaolin (as binary and ternary cement component) would increase superplasticiser dosage with increasing content. Hence, the superplasticiser dosages of the ternary cement concretes would reduce with increasing content of fly ash.

iv. The supplementary cements would generally improve the viscosity and cohesion (or stability) of concrete. Cohesion would be higher in silica fume and metakaolin concrete than in fly ash concrete and too much of silica fume or metakaolin would result in higher cohesion, stickiness and poor concrete finish at equal water content.

v. $Ca(OH)_2$ is required for pozzolanic reaction and its consumption would increase with increasing age and increasing content of the supplementary cements. The $Ca(OH)_2$ consumption increasing with increasing content of fly ash up to 35% and reducing beyond 35% shows that, for optimum performance, fly ash content should be limited to 35%. Due to the higher fineness of silica fume and metakaolin than fly ash, the $Ca(OH)_2$ consumption and reactivity of the ternary cement pastes is higher than that of the binary cement pastes. Also, since the quantity of $Ca(OH)_2$ released by Portland cement is far greater than the quantities consumed by the supplementary cements at 180 days, pozzolanic reaction is slow and long-term.

vi. Fly ash concretes have lower compressive strengths than Portland cement concrete. But because the strengths improved progressively with age to reduce the disparity in their strength values, fly ash would contribute to later-age strength development. Due to their higher fineness, the strengths of silica fume and metakaolin binary and ternary cement concretes were found to be comparable with that of Portland cement concrete. Hence, they would support both early and later age strength development.

vii. All the blended cement concretes have lower e-CO_2 contents and are therefore more environmentally compatible than Portland cement concrete. The e-CO_2 contents reduced at an average of 1% per 1% fly ash or silica fume content and 0.7% per 1% metakaolin content.

viii. Fly ash would reduce the cost of concrete and silica fume and metakaolin would increase it. However, while the ternary cement concretes would be costlier than the fly ash binary concretes, it is possible to have ternary cement concretes that are cheaper than Portland cement concrete.

ix. Equal strengths of concrete would be achieved at different water/cement ratios, material contents, material costs and embodied carbon dioxide contents. At equal strengths, blended cement concretes are more environmentally compatible than Portland cement concrete and fly ash has the propensity to improve concrete strength. Hence, all the fly ash binary cement concretes and ternary cement concretes with not more than 5% silica fume or metakaolin at a total replacement level of not more than 35% would produce cheaper and more environmentally compatible blended cement concrete than Portland cement concrete at equal strength for concrete construction.

x. Since the final setting times were lower at 10% metakaolin content than at 15% metakaolin content and the quantities of $Ca(OH)_2$ consumed were higher at 10%

metakaolin content than at 15% content, 10% metakaolin content would likely be the optimum content of metakaolin as a binary or ternary cement component.

xi. At equal replacement level, silica fume specimens have lower initial and final setting times, exhibited higher compressive strengths and lower eCO_2 contents, consume more $Ca(OH)_2$ and require lesser superplasticiser dosage than metakaolin. Hence, silica fume probably because of its higher fineness and spherical shape would perform better than metakaolin at equal replacement levels.

Degradation of Paint used as External Finish in Buildings: A Review

Aluko, Olaniyi Olanipekun

Department of Architecture, Federal University of Technology, Akure, Nigeria
allan2k5@yahoo.com

ABSTRACT

The assessment of both private and public buildings is usually based on their external appearance simply because it is the first point of attraction to the people and the most visible element directly linked to the environment. Paint which is used in buildings worldwide for walls, not only because of its decorative but also protective functions is manufactured in different shades of colour, quality and make. It has been the most popular aesthetic expression in Nigeria both for interior and exterior walls. The early deterioration of the exterior of both private and public buildings envelopes however reflects their low durability. Unfortunately, an increasing number of cases of poor maintenance of painted facades characterized by early onset of defects and damages to the surface have been reported. This paper presents comprehensive and qualitative factors that affect the performance of paint and its service life on building facades of private and public housing. The review shows that the main sources of degradation which are controllable fall under design/ construction problems and material deficiencies while the uncontrollable sources are climatic factors. Also, interaction between the different materials that compose building elements lead to selective decay.

Keywords: Degradation, service life, building facade, paint, external image

INTRODUCTION

Paint is used extensively as an external finish on cement plastered facades and concrete surfaces. Fawehimi and Adeosun (2001) asserts that paint application on building surfaces is the most popular aesthetic expression in Nigeria and is used in the surface treatment of both interiors and exterior walls of residential and public buildings. Onibokun and Agboola (1990) reports that about 60% of the total cost of the housing expenditure goes into building materials, in which the surface treatment of a building is represented by approximately 5% of the initial cost of construction

The maintenance and upkeep of the external finish of the building is seen as an essential component of any building programme because of its decorative or aesthetic purpose thus epitomizing the image of the building and providing protective functions to the underlying layers of the building (Boussabaine and Kirkham 2004). Building components however require varying degrees of maintenance, repair and replacement during the life cycle of a building. The extent and intensity of maintenance, repair and replacement varies significantly, depending on how appropriately the service life of materials, assemblies, and systems are harmonised, accessed and replaced.

Building materials especially those used in the building envelope are exposed to physical, mechanical, chemical, biological weathering and other factors acting in combination, or even all at the same time. The principal climatic elements that affect the external paint finish are rainfall, solar radiation, wind and moisture which lead to rapid deterioration and ultimately reduce the life span of the finish especially in the tropics necessitating frequent maintenance.

Therefore, the degradation of the exterior surfaces of buildings is one of the major concerns of building owners and maintenance managers since in most cases maintenance actions are often based on the outward appearance of the buildings (i.e. building aesthetics) (Balaras et al., 2005) Teo etal (2005) submits that paint finish may not perform in the manner intended and fails to provide the desired functionality for the intended time period possibly due to i)

Aluko, O. O. (2016). Degradation of Paint used as External Finish in Buildings: A Review. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 417-425

exposure to adverse environmental conditions, ii) poor workmanship during application, iii) inadequate quality of the finish material and/or substrate. Defects on the facade or external finish of a building are a common maintenance problem caused by improper design, poor material quality, inferior workmanship, inadequate maintenance or adverse environment (Assaf, Al-Hammad and Al-Shihah 1995). Aluko and Akingbohungbe (2010) opined that the defects in buildings that call for maintenance are usually caused by inappropriate design, faulty construction techniques, substandard building materials, weathering of materials; cumulative effect of rain, wind and sun; pollution, earth movement and load bearing capacity

Kashim, Fadairo & Adedeji (2013) observe the constant revisit of the painted surface of buildings gulp more money than when some other lasting materials like mosaic, tiles and laterite's blocks are used. They argue that tropical weather that Africa is endowed with do not help matters and that long months of rainfall and severe sun shine usually impact negatively on the paints and make them to fade as soon as they are painted. Furthermore, interaction between the different materials that compose building elements can lead to selective decay (Cultrone et al. 2007).

The need to identify and evaluate the different nature and influence of the degrading factors and their influence on the external paint finish in order to mitigate the negative effect on maintenance activities and ensure that the paint finish reaches its desired lifespan is the thrust of this paper.

EFFECT OF DESIGN ON EXTERNAL PAINT FINISH

The envelope or enclosure of a building or structure serves a variety of basic functions. As noted by Straube and Burnett (2005), the enclosure is a separation between the interior and exterior environment that experiences a variety of loadings, including, but not limited to, structural loadings- both static and dynamic, heat, air, and moisture loads. The enclosure must then control and support these loads. This includes both short-term and long-term loadings. These enclosures will have several aesthetic attributes, which can be summarized as finishes. Enclosure can also be used to carry or distribute some services within the building. Straube and Burnett (2005) have defined four general building enclosure function categories to include:

i. Support

Enclosures, including exterior wall systems, must be capable of withstanding all internal and external forces applied to them. The majority of these forces are structural loading. The loads include both static and dynamic loading including, but not limited to, dead load, live loads, wind loads, earthquake loads and possible blast loads. These loads have to be properly supported, resisted and transferred.

ii. Control

Enclosures, including wall systems, have to be able to control mass, energy, and particulate flows both within and across the system. These include, but are not limited to, heat, air, moisture, smoke, odour, fire, blast, birds, and insects

iii. *Finish*

The finish expresses the aesthetic functions of both the exterior and interior surfaces for people and is expressed in terms of colour, texture, reflectance, pattern and other aspects the designer wishes to convey with the visible elements of the system. Of the elements of an enclosure, wall systems typically have the largest consideration for finish.

iv. Distribution

This function relates to the distribution of services through a building both within a single element and also through multiple elements. Ishak, Chohan and Ramly (2007) identified the inadequate detailing of components in the design as a factor that can lead to building deterioration especially on the exterior façade. This agrees with Ali, Keong, Zakaria, Zolkafi

and Akashah (2013) that suggests that adequate attention should be paid to the design of the main fabric especially the walls if unplanned maintenance will be avoided. According to Chew and Harikrishna, (2005), the poor performance of the paint finish can also stem from defective building design and detailing and inappropriate construction methods. The possibility of accident, loss of equipment, loss of life and multiple litigations is also a reality. While maintenance can go on unhindered in the interior spaces, the elements of weather such as rain, snow, sun and turbulent wind most often hinder the smooth running and schedule of works on the external surface.

It requires proper planning with precise forecast of weather in most cases to avoid waste of materials, man-hour, loss of profit and patronage. The spaces allowed in-between buildings in most urban cities as setback are usually inadequate for maintenance works. This constitutes a serious hindrance to the manoeuvring of needed equipment for maintaining the buildings The resistance of an exterior wall to the elements of climate depends largely on the design of the wall structure. A multi-storey building that is designed and built with plain wall without any ingress and egress overhang is exposed totally to the elements. Walls without self-shading will reduce the ability of the building to protect itself from external forces of climate (Capeluto, 2003).

A building that will be maintainable must inculcate at the design stage elements that will aid the ease of maintenance works. Some maintenance equipment's are required to be designed with the building while adequate provision is made for work space in and around the building. The poor performance of the paint finish can also stem from defective building design and detailing and inappropriate construction methods (Chew and Harikrishna, 2005). It is important to give proper attention during the building design phase so that defects arising from such factors can be minimized

External Paint Finish and Climatic Factors

External surfaces of building enclosures and its coatings are directly affected by climate. Climate is one of the factors causing deterioration of building envelope and coatings (Chew and Harikrishna 2005). Buildings nowadays are deteriorating at an alarming rate due to the erratic nature of the climate with its attendant consequences (Stewart, Wang and Nguyen, 2011). Norvaišiene, Miniotaite and Stankevicius (2007) classified atmospheric factors into natural (precipitation, wind, temperatures, solar radiation) and complex chemical and biological processes caused by air pollution. Ramanauskas and Stankevičius (2000) maintained that the durability of external finishes is determined by the following properties:

a. Frost resistance, i.e. the capability of a moisture-saturated material to resist temperature fluctuation through freezing and thawing cycles
b. Moisture resistance, i.e. the capability of a material to resist the periodical moisturizing and drying cycles
c. Corrosion (chemical impact) resistance, i.e. the resistance to solutions of dissolved aggressive destructive chemical agents. Ultraviolet radiation, causing photochemical reactions on surfaces, can also be considered as a chemical impact.

Haneef, Dickinson and Johnson (1999) summarized the mechanisms that contribute to deterioration as;

a. Physical mechanisms. The presence of water is known to be a key factor in promoting the fracturing and erosion of building envelope and coating. Water penetrates the pores and cracks and causes mechanical stresses both by freezing and by the hydration and subsequent crystallization of salts.
b. Chemical mechanisms. Some deposited chemical agents react with surfaces. Sulphur compounds have been indicted as the most critical factors in this regard, mainly

because they are often acidic and can have high concentrations in city and suburban air; however, nitrogen compounds should be considered as well. Fluxes of trace gases (e.g., sulphur dioxide) can be high, especially when promoted by biological activity. Dissolution by chemical reactions with contaminants contained in precipitation is one of the most familiar eroding processes, particularly in the case of carbonaceous stone.

c. Biological mechanisms. Many different biological factors have been found to be important. Growths of lichens, mosses, algae, mould, fungi and bacteria are capable of promoting surface deterioration. Some bacteria can synthesize sulphuric (or nitric) acid from airborne sulphur dioxide (or nitrogen oxides).

Buildings that are sensitive to the climate have been built by almost all indigenous builders for centuries. However, of recent owing to obvious climate change, builders have hitherto lost the skill and expertise of building in harmony with the climate (Hyde, 2000). The Oxford Advance Learners‟ Dictionary defines climate as the regular pattern of weather condition of a certain place. It is the synthesis of weather or as it is generally known – the average weather condition of an area under studied over a period of time not less than 25 years. Site conditions and prevailing climatic conditions determine the longevity or otherwise of any chosen finishes. Hyde (2000) opines that the basic idea behind climate responsive design is the understanding of the characteristic of the climatic condition in which the building is situated.

Different climatic conditions impose different requirements on the use of materials. Due to high relative humidity, high temperature and precipitation prevalent in the warm humid zone in the tropics, the rate at which buildings and especially the external walls absorb moisture and building materials used for wall finishes that are exposed to climatic elements are therefore seriously affected. Materials undergo dilatations and contractions with temperature variations. In extreme cases, like fires, the rate of change and the amplitude of the temperature can generate a thermal shock capable of disrupting the material. Even though theoretically possible, the surface temperature required to produce damage by thermal gradient is unlikely to occur through the sun's action ((Groot et al. 2009). In most cases, temperature-induced decay is caused by stresses at the interface between distinct materials produced by different thermal and hygric expansion coefficients (Palomo et al. 2002). Mechanical differences, especially of strength, deformability and elasticity modulus, can also be an underlying cause of decay, as seen by Sanchez-Moral et al. (2005) in Roman catacombs

Besides extreme events such as tornados, wind can participate in the deterioration of wall renders by dragging rain, solid particles or other deleterious substances (e.g., salts) across them. Except for earth constructions, wind-driven rain has been proven to be essentially responsible for enhancing the impact of other agents of degradation, i.e. water, bio deterioration and pollution (Tang et al. 2004; Abuku et al. 2009). Wind driven solid particles can erode material surfaces and the degradation potential depends on local wind intensity and availability and size of solid particles to be carried.

Tropical Climate and Its Effect on External Paint Finish

The climate of each locality presents a unique natural environment and is an effective factor on the architectural design and material use. Identifying, understanding and controlling climatic influences at the building site are perhaps the most critical part of the design process (Ozay, 2005). Tropical regions are the areas within latitudes 23^0 27^1 North and South of the Equator (Horby 1974). Henderson-Seller and Robinson (1986) noted that tropical climates are usually characterised as climates where there is no true temperature distinction between summer and winter. Blair (2014) categorised them into:

i. Hot Wet Equatorial Climate with about 80mm annual rainfall

ii. Tropical Monsoon and Tropical Marine Climate with about 60mm and 70mm respectively.
iii. Sudan type with about 30mm rainfall mainly in summer and
iv. Sahara and mid Latitude type with little rainfall of about 5mm.

The external walls of building in the equatorial climate zone is subject to rapid degradation as a result of torrential rain, the exterior paint of building is easily washed and also provides a fertile atmosphere for other agents of paint destruction (Akinbogun, 2001). Givoni (1976) remarked that the high temperature and humidity levels in the equatorial zone encourage insect breeding and the growth of fungi are agents of destruction. Ultraviolet radiation is another climatic element that leads to pigment discolouration. Addison and Rice (1991) alluded that sunlight is the source of ultraviolet radiation which is responsible for the breakdown of organic compounds and discolouration of pigment. Direct solar radiation and diffused radiation reach very high intensities in tropical region. Chen and Chen (2013) noted that due to the earth's inclination, the mid – day sun is almost overhead within the tropics and the sun rays heat the tropics in straight lines while the regions outside the tropic at shorter distance, temperature diminishes from equatorial regions to the poles. Fading of pigments is likely to be more rapid in the tropics than other climatic regions as a result of ultraviolet radiation, which tends to be higher in the tropics.

The tropical climate is characterised by raining and dry seasons which are brought about by the prevailing South East Trade winds and North East Trade winds respectively. In West Africa, between November and March, the North East Trade wind blows off shore from the Sahara Desert and reach the West Coast as a dry dust-laden wind referred to as harmattan (Blair, 2014). The accumulating effect of the dust on building surfaces particularly the exterior is highly noticeable as it acts as agent of discolouration.

DEGREE OF WORKMANSHIP

A good degree of workmanship plays an important role in preventing or minimizing the occurrence of defects or in prolonging their onset. Paintwork is a labour intensive operation and is hence subject to the quality of the labour and work execution. Site conditions essential for good paint application are adequate protection from both weather and dirt. Also simple tasks like making sure the plaster is sufficiently dry before painting over would reduce the possible occurrence of defects in the future.

Factor	Characteristic features	Associated defects
Poor surface Preparation	Inadequate surface preparation in the form of no treatment of existing loose paint films results in poor adhesion with the underlying layers	Flaking/ Peeling
Insufficient drying Time	Application of a subsequent coat on a partially dry coat leads to mixing of the two coats together. Can have implications for durability by not allowing the coats to perform their individual functions effectively	Discolouration and Chalking
Surface Discontinuities	Disturbance or non-uniformity to be avoided during paint application	Loss in Appearance and Peeling
Uneven paint Spreading	Coverage in specification provided in terms of consumption rate measured in kg. of paint used per sq. m of area per coat to avoid use of excess or insufficient amount of paint	Loss in appearance and desired thickness of paint finish
Over dilution of Paint	Lead to reduction in protective properties and performance degradation of paint finish	Greater risk of Weathering. Loss of adhesion with substrate
Poor substrate Condition	Unacceptable condition of substrate (plaster or brick) over which the paintwork is applied can be responsible for occurrence of defects on paint finish Common points to be borne in mind include ensuring sufficient curing time for the underlying cement plaster and moisture entrapped in the substrate layers	Cracking Efflorescence

Source: Teo, Chew and Harikrishna (2005)

Building Characteristics

Some of the problems of external wall according to Wood (2009) are: spalling or delamination of surfaces, cracks, discolouration and staining, dampness and dislocation. Others are erosion of mortar, high level of penetrating damp, salt contamination on internal plaster, high level of mould and algae growth, spalling bricks and erosion of pointing joints. They also include peeling of paints, tiles and moisture accumulation. The major factors under building characteristics that affect the durability and service life of paintwork and their effects according to Chew and Tan (2003) as summarised in Table 2 are orientation, height, surrounding environment, age and shape of plan view.

Table 2 Building characteristics that affect the durability and service life of External finishes

Factors	Characteristic features/ Considerations	Associated Defects
Orientation	Façades directly exposed to sunlight undergo greater physical weathering leading to chalking of paint. Facades facing away from direct radiation are comparatively colder and damper providing ideal conditions for algae and other microbial growth The intensity and duration of sunlight that a surface receives affect the limit of runoff flow, the type of biological stains and hence the pattern of staining.	Chalking Algae Growth Staining
Height	Tall buildings are at greater risk to deterioration due to their direct exposure to impacting rain and ultraviolet radiation [Choi 1994] Wind speed varies with height due to the level of openness as well as the instability of air at higher levels Costs of maintenance and repair of defects to the façade higher for higher storeys due to additional costs in the form of scaffolding Safety during work in higher storeys is another concern	Greater rate of weathering and discolouration at higher storeys
Surrounded by other buildings	Presence of adjacent buildings provides a sheltering effect May result in slower drying period for façade after it has been wetted, leaving it damp for longer periods and therefore promoting biological staining	Biological staining Algae growth
Age	Natural tendency of material to undergo deterioration with time Condition and serviceability period of the underlying substrate layers of the building has an effect on the exterior paint finish Gradual loss of protective and other properties of the paint finish itself with age	Cracking Chalking Flaking/ Peeling

Source: Teo, Chew and Tan (2005)

Teo and Harikrisha (2007) in the development of a defect index identified crazing, crackliness delamination, efflorescence, chalking, algae growth, peeling, and uneven discolouration as major defects that are associated with paint while Chai etal (2015) grouped the main defects that affect paint coatings as follows:

i. Staining and color change mostly affects the visual quality of a façade and generally appears in the very early years of the service life of paint coatings.
ii. Chalking usually occurs after loss of gloss and causes the wear, detachment, and loss of material.
iii. The ranking by degradation level of cracking is based on visual patterns, in terms of cracking frequency. Contrary to cracking in other materials, in paint coatings it is usually less than 1-mm wide, which makes it difficult to distinguish the size without magnifying equipment
iv. Loss of adherence generally arises because of the combined effect of various defects and degradation agents. Its degradation mechanisms are thus complex and tend to be preponderant as the material ages.
v. Blistering and peeling.

Sousa, Almeida, Meireles and Brito (2011) grouped the anomalies into five broad categories;

i. aesthetic/visual, which comprise stains, dust, superficial growth and other non-structural defects;
ii. superficial deterioration, including, along with erosion/abrasion, anomalies such as pitting and sanding;
iii. internal deterioration designates anomalies that can produce a general destruction of the mortar over the entire depth resulting at the end in crumbling (it may also manifest itself in a similar way to interfacial deterioration);
iv. interfacial deterioration, comprising anomalies such as flaking, delamination, blistering, spalling; and
v. cracks/fissures, related to situations where a tension is created able to produce a visible crack or fissure without being a consequence of other phenomena (e.g. crypto florescence resulting in superficial fissures).

ANOMALIES IN PAINTED SURFACES

The incidence of anomalies on the external envelope of buildings appears to have a great importance. (Census 2001) assert that about 50% of anomalies recorded negatively affect the external building envelope. Moreover, according to a survey of BRE (1998), these anomalies directly contribute to the decrease of about 50% in the performance of important building functional requirements (waterproofing, durability and maintenance) and substantially influence others (thermal insulation and acoustic performance) in over 10% of related requirements.

According to Harris (2001), the decay noticed in buildings is a natural process and unavoidably takes place in time, not being necessarily the result of design error or construction deficiency. In fact, the mechanisms of deterioration are the consequence of the interaction of two independent variables: the building, as a physical object and the environment, as a source of agents. The degradation of building components is a normal consequence of the ageing process, there is a set of factors influencing that process, such as building quality, weather conditions, lack of maintenance, and so on. These factors will increase the building operation costs and expand the rehabilitation needs, if no actions are taken to halt the degradation process (Fernanda etal, 2011).

Pires etal (2016) identified 14 main anomalies divided into 5 groups that distinguish between the various forms of pathological manifestation as; Adherence to the substrate anomalies; Film cohesion anomalies; colour anomalies; stains and texture anomalies. Sa etal (2014) classified the anomalies in wall renderings to include;

a. aesthetic anomalies: graffiti, corrosion stains, dirt/deposits of particles, colour change/discolouration
b. anomalies associated with humidity: infiltrations/dampness, stains, efflorescence/cryptoflorescence, biological colonization. carbonation, vegetation growth
c. mechanically-related anomalies: adherence loss/detachment, map cracking, cohesion loss/crumbling, scratches/grooves and linear cracking

EXTERNAL PAINT FINISH AND HUMAN FACTOR

Sousa. Almeida, Meireles and Brito (2011) asserts that human influence on the deterioration of buildings is often forgotten, but it also contributes directly and indirectly to wall render degradation. Direct influences include the execution of renders itself, in which the selection of unsuitable materials, the preparation of the support, and the application of the mortar or curing cause many cases of premature deterioration.

Among the human activities that may pose the most significant indirect threat to wall renders on historical building are tourism which can be a significant cause of degradation due to building use (e.g., abrasion, impacts) and the creation of microclimatic conditions favourable to other degradation agents. Sanchez-Moral et al (2005) observed that micro environmental conditions resulting from the presence of visitors in Roman catacombs created temperature, humidity and light conditions propitious for the development of biological agents.

CONCLUSION

A comprehensive evaluation of the various factors that cause degradation and ultimately reduces the service life of external paintwork on building facades has been discussed in this paper. The multitude of factors influencing the degradation of buildings in general makes it extremely complex to identify all the underlying causes, their relative importance and eventual interrelation. However, the understanding of various factors that are within human control as well as the uncontrollable is germane so as to cater to their effects during the paint formulation, design and application process; this would ensure that the desired service life for the paint finish is attained. This is crucial for the subsequent development of any quantitative model that would serve to establish the timing of the various maintenance and repair costs that would need to be incurred to rectify the defects and damage to the paint finish during its intended lifetime. The system can be applied to buildings in Nigeria and can be extrapolated to any other country that has similar climatic conditions since painted renderings are common worldwide.

Utilization of Fly Ash in Road Construction in South Africa: Environmental Assessment

Heyns, Michiel W[1], Adedeji, Jacob Adedayo[2] & Mostafa Hassan, Mohamed[3*]

[1,2&3]SURT Research group, Civil Engineering Department, Central University of Technology, South Africa

ABSTRACT

Using fly ash as alterative material in place of conventional materials is continually gaining interest over decades. This results from its international recognition as non-hazardous construction material. However, fly ash composition varies and thus it cannot be generalized that every fly ash is non-hazardous. In South Africa, fly ash is produced in large quantity, yet its utilization on annual basis remains at 6 percent which is majorly utilized in cement and concrete production. Thus, this study focuses on investigating leaching of major elements in South Africa Class F fly ash when used as a stabilizer in road construction. Three different specimens of fly ashes, namely; Kendal Dump Ash, Durapozz and Pozzfill enhanced with different cements were used as stabilizer for G5 soil use in road construction. Using an X-Ray spectrometry analyser the samples were tested for any possible leach elements. Leach tests results show that fly ash enhanced with cement as soil stabilizer in road construction is not harmful as the fly ash constituents' exhibit limited mobility. However, results also indicated that fly ash left in dump sites can be harmful, if some of the leached elements find their way to the ground water. Thus, utilization of fly ash for road construction is an environmental sustainable option and has engineering advantages when properly used for soil stabilization.

Keywords: Class F fly ash, drinking water, leach tests, pavement materials, and soil stabilization

INTRODUCTION

Material Shift

Material selection for pavement design is based on a combination of suitable materials, environmental consideration, construction methods, economics and previous experience (Bureau for Industrial Cooperation, 2012). Previously, road construction had depended mainly on the virgin materials from the nearest borrow pit, but in situations where the available soil lacks some geotechnical properties or need some improvement for a particular work such soil needs to be stabilized. Soil stabilization aimed at increasing or maintaining the stability of soil mass through mechanical or chemical means (Takhelmayum, Savitha & Krishna, 2013). However, stabilizing soil using lime, cement, chemicals, plastics, rice husk ash, millet husk ash, corn cob ash, coconut shell ash, foundry sand, cement kiln dust, granular blastfurnace slag (GBS), or fly ash increases the soil's resistance, strength and permeability (Marto, Latifi & Sohaei, 2013). Furthermore, results and experience show that lime as a stabilizer yields better results than others, but its use will make pavement structure uneconomical, which in turn makes fly ash an alternative stabilizer.

South Africa: Fly Ash Producer

South Africa is the fourth largest producer of fly ash at 30 mega ton per year after the likes of China, USA and India. This results from the fact that coal plays an important role in its economy and it serves as the primary energy source for electricity generation (National Inventory, 2001; Furter, 2011). Thus, the disposal of fly ash is increasingly becoming a major concern due to possible environmental disaster. Yet, this ash has recognition as a suitable pozzolanic material and successfully used as construction materials, even on large scale. Globally, fly ash is being used for various purposes such as; raw material for cement and concrete production, soil and asphalt stabilizer, embankment works, flow-able fill, and waste stabilizer, all owning to its cement-like property (Li, Benson, Edil & Hatipoglu, 2008; Torii, Hashimoto, Kubo, & Sannoh, 2013). Withal, South Africa only utilizes 6 percent of the

Heyns, M. W., Adedeji, J. A. & Mostafa H. M. (2016). Utilization of Fly Ash in Road Construction in South Africa: Environmental Assessment. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. annual production. However, one of the major factors contributing to its low utilization is the concern of contamination of the surface and ground water during leaching process. Therefore, this study focuses on investigating leaching of major elements in South Africa fly ash when used as a stabilizer in road construction.

LITERATURE REVIEW

Chemistry of Fly Ash

Fly ash, a finely divided residue that results from the combustion of pulverized coal, an amorphous ferroaluminium silicate with a matrix very similar to soil and its elemental composition varies with types and source of coal (Comberato, Vance & Someshwar, 1997). These ash particles are transported from the combustion chamber by exhaust gases as a result of their light weight and collected in control devices such as filter bags and electrostatic precipitators. They are spherical in shape and range in size from 0.5 micron to 100 micron. Its chemical and physical properties depend greatly on several factors such as production type, raw feed and the handling method. This in turn gives the two classes of fly ash based on the chemical composition. Class C ashes are from sub-bituminous and lignite coals and may contain more than 20 percent CaO with 1 percent to 3 percent free lime, while Class F ashes are generally obtained from bituminous and anthracite coal and contain less than 20 percent CaO with no free lime ASTM C618 (ASTM-C618, 2011).

In addition, fly ash is a heterogeneous material, which consists of major element such as; Silicon (Si), Calcium (Ca), Aluminium (Al), Magnesium (Mg), Iron (Fe), Sodium (Na) and Potassium (K) (Oppenshaw, 1992). Various trace elements also contained in Fly Ash are Cobalt (Co), Cadmium (Cd), Arsenic (As), Selenium (Se), Zinc (Zn), Molybdenum (Mo), Manganese (Mn), Lead (Pb), Boron (B), Copper (Cu), and Nickel (Ni) (Ojo, 2010; Snellings, Mertens, & Elsen, 2012). These chemical compositions give it variability in properties (Gitari, 2009). In the United States, the Environmental Protection Agency issued reports on the environmental friendliness of fly ash and protected legislatively as non-hazardous waste. In like manners, it was successfully used in transportation projects and thus, regarded as an important component of the high performance designs in Europe (American Road and Transportation Builders Association, Transportation Development Foundation (ARTB-TDF) (ARTB-TDF, 2014)).

Fly Ash as Stabilizer

Various studies have been conducted on fly ash utilization as soil stabilizer and as an alternative to the use of virgin materials. Senol, Bin-Shafique, Edil & Benson, (2002) carried out a study on the use of self-cementing class C fly ash for the stabilization of soft sub-grade. In this study, the optimum mix design and stabilized layer thickness were estimated by strength and modulus-based approaches. The results obtained showed that the engineering properties such as unconfined compressive strength (UCS), California bearing ratio (CBR) and resilient modulus increase substantially after fly ash utilization. Also, in 2002, Pandian and Krishna conducted laboratory CBR tests on the stabilized fly ash-soil mixtures and observed that fly ash is an effective admixture for improving the soil quality. In addition, Brooks (2009) reported the soil stabilization with rice husk ash and fly ash mixed together with natural soil, the study showed improvement in CBR values and UCS. Also, researchers have proven that mixtures of fly ash with inert materials reach 50 percent to 70 percent of the strength of the corresponding cement-inactive materials (Eskioglou & Oikonomou, 2008).

According to literatures, it was noted that the use of Class C is more dominant especially in road construction while Class F is only finding usage in concrete works; this however, results from Class C self-cementing properties and its endorsement as non-hazardous material from international bodies. Generally, fly ash landfill sites are an environmental concern due to

possible release of contaminants to the ground and surface water, however according to Heebink and Hassett (2001) when fly ash is used as stabilizer; chemical reaction takes place, which binds the particles of fly ash and consequently, reduce the chances to pollution. Furthermore, Heebink and Hassett conducted laboratory leaching and field run-off sample; results indicated that fly ash constituent's exhibit limited mobility. Consequently, fly ash Class C is an environmental option and of engineering advantages when used properly for soil stabilization. In essence, leachate test should be conducted on fly ash to analyse its solubility (Oppenshaw, 1992; Solc, Foster, & Butler, 1995). However, studies show that leachate of fly ash is highly variable as it's depends on the type of coal and plant in question, and also decreases with age (Moolman, 2011).

However, in South Africa, the public has not yet been convinced that fly ash is environmentally safe, due to the fact that European and American countries completed research on Class C Fly Ash and South Africa only produces Class F. Nevertheless, for a Class F to use as stabilizer, a reaction starter such as lime and cement is needed because it is low calcium (American Coal Ash Association, 1995). Yet, there are only limited studies on the environmental friendliness of Class F produced in South Africa. Considering its production per year in South Africa, the government is at the stage where it is strategically finding ways to reduce fly ash through treatment, re-use and beneficiation. Overall, the use of fly ash in road construction provides viable alternative to non-renewable primary aggregates, yet the question remains; what is the environmental impact of using Class F fly ash as soil stabilizer in road construction?

MATERIALS AND METHODOLOGY

In this study, basic construction materials for road construction are used. A G5 granite material specified for sub-base construction and this material will be stabilized using three different Class F fly ash which are; Kendal dump ash, Durapozz and Pozzfill. Kendal dump ash was sampled directly from the dumpsite while other samples were sourced from processed fly ash suppliers. Durapozz is the highest quality processed ash in South Africa that conforms to international standards while Pozzfill only conforms to certain international standards. However, both Durapozz and Pozzfill are successfully utilized for cement production in South Africa.

As early mentioned, cement would be use to start-up the reaction process, cementing agent such as; LAFARGE CEM II 32,5 VA(S-V) and AFRISAM CEM II 32,5 B-M(S-V). The justification for the selection of these cements is because they are specially developed for stabilization purpose and commonly used for road works here in South Africa. In addition, these cements are more effective for low clay content and gain strengths early, and both cement types have an improved durability and is effective across a wide range of materials.

Based on the scope of this study, leach testing was conducted on classified G5 material stabilized with cement and fly ash with the following mixtures:

- 1% LAFARGE
- 1% AFRISAM
- 1% LAFARGE mixed with 16% Dump Ash
- 1% LAFARGE mixed with 16% Pozzfill
- 1% LAFARGE mixed with 16% Durapozz
- 1% AFRISAM mixed with 18% Dump Ash
- 1% AFRISAM mixed with 18% Pozzfill
- 1% AFRISAM mixed with 18% Durapozz

The above mixtures were subjected to leach testing and compared to maximum allowed trace elements in water. Stabilization with fly ash and cement is not only to gain strength and meet required specifications but it can also be used to "entomb" the harmful elements that can enter and contaminate the ground water system. Once these elements are shown to be less than the maximum allowed elements found in drinking water, then it can be concluded that the use of fly ash in road stabilization can be used and that the risk of harmful elements being released to the environment will be negligible.

FINDINGS AND DISCUSSIONS

Using an X-Ray spectrometry analyser, elements similar to those found in other fly ash around the world were noticed in typical Class F fly ash. Some of the elements with their range in part per billion (ppb) are; Bi (3.8), Br (<2), Ce (235), Co (16), Cs (7.8), Zr (476), and those listed in Table 1 were found in this South Africa Class F fly ash. However, in order to environmentally assess this ash and understand these elements, a comparison analysis must be conducted to show the impact of their on the environment, if any. Water is the main source for human and environmental survival; therefore, elements are compared to the maximum allowed concentrations in water fit for human consumption (Bicki & Hirschi, 1993). Table 1 further showed the comparisons of required maximum allowed elements also found in fly ash with possible health effects. It must be noted that these results are from ash found in dump sites without any treatment; therefore, it is critical that leach tests are conducted for potential hazards before considering the use of fly ash in any destined road construction project. Fly ash with no treatment shows that leached elements namely: Barium (Ba), Chromium (Cr) and Lead (Pb), are of a concern once the elements have leached into the groundwater and the possible effect is also reflected in Table 1. Arsenic (As) however, is low and does not create a concern if leached into the groundwater.

Furthermore, table 1 shows higher levels of Ba and Cr in fly ash, thus this implies that fly ash left in dump sites can be harmful once leached elements find their way into the ground water. However, when samples enhanced with cement as stabilizer for G5 soil were tested, results show that the leach elements have limited mobility (Table 2) when compared with those of table 1. In addition, comparing table 1 and 2, one must keep in mind that the results in table 2 are shown as ppm while those in table 1 are shown as ppb. Considering this, the cement enhanced fly ash can be said to have experience a tremendous reduction in leach element as a result of the entombed reaction that takes place between the soil, fly ash and cement. Also, it is worthy to note that G5 soil stabilized with only cement did produced these leach elements yet, the results are all below the maximum allowable in drinking water.

Table 1 Some elements in typical Class F Fly Ash and maximum allowable in drinking water

Element	Class F Fly Ash (ppb)	Maximum Acceptable Level (ppb)	Possible Effects of Higher Levels
As	20	50	Lung Cancer, kidney damage
Ba	1502	1000	Heart damage
Cr	190	50	Liver, kidney damage
Cu	49	49	Metallic taste, blue-green stains on fixtures
Pb	54	50	Brain damage
Se	2.8	10	Growth inhibition
Zn	49	N/A	Metallic taste

Conclusively, fly ash at fresh stage has an approximate pH of 11.5; this pH tends to reduce to about 8.5 due to weathering process as a result of being left on dump sites (Surridge, van der Merwe & Kruger, 2009; Ayanda, Fatoki, Adekola & Ximba, 2012). However, considering the results presented in table 3, the pH of the G5 soil stabilized with cement enhanced fly ash, shows that the material maintain an alkalinity pH position. This implies that when Class F fly

ash is enhanced with cement, it can perform as a stabilizer without affecting the environment negatively.

Table 2 Leach results of G5 soil stabilized with cement enhanced fly ash

	Leachate (parts per million (ppm))						
	As	Ba	Cr	Cu	Pb	Se	Zn
G5 + 1% LAFARGE	5.36	< 4	8.56	18.89	< 6	< 0.4	< 60
G5 + 1% AFRISAM	5.32	< 4	8.18	15.91	< 6	< 0.4	< 60
G5 + 1% LAFARGE + 16% Dump Ash	7.59	< 4	23.97	16.39	< 6	< 0.4	< 60
G5 + 1% LAFARGE + 16% Pozzfill	13.65	< 4	58.11	14.88	< 6	1.56	< 60

G5 + 1% AFRISAM + 18% Durapozz	10.77	60.05	0

CONCLUSION

Using fly ash as alterative material in place of conventional materials is continually gaining interest over decade. This results from its international recognition as non-hazardous construction material. However, it must be noted that fly ash composition varies and thus it cannot be generalized that every fly ash is non-hazardous. Although, fly ash is produced in large quantity in South Africa, yet it utilization on annual basis remains at 6 percent which is majorly utilized in cement and concrete production. Thus, this study investigated the environmental effect of Class C fly ash when used as a soil stabilizer for road construction.

The results of this study showed that trace amounts of elements which might be leached to the ground water when fly ash is used in road project is not harmful. This is based on the laboratory leach test results which indicated that fly ash constituents when used as soil stabilizer exhibited limited mobility, thus it can serve as an alternative stabilizer in road construction when used properly and environmental sustainable. Results also show that elements in fly ash vary from different classes and if South Africa Class F fly ash is left on dumps sites without utilization; potential hazardous elements can be release into the ground water and thus, before utilization for any project a full comprehensive test must be conducted at the design stage.

Furthermore, critical variables which include the sample size and particles size distribution, leachant volume, pH, and duration of leachant test. The project objective, type of material and type of data desired will determine the most appropriate method. It must be kept in mind that when tests are performed with some methods, extraneous variables, such as analytical

sensitivity and sample inhomogeneity may influence the reproducibility of the results. The leach results have shown that the elements in the ash were "entombed" and the possibility of leachant releasing agents of a dangerous nature are to a minimal. The results have shown a tremendous reduction in leach agents and have shown that it is even safe if the minor leach agents do enter the drinking water tables. The leach tests in this study have shown that the fly ash enhanced with cement as stabilizer is environmental friendly. It also shows that the fly ash particles that are normally released are bound within the soil due to chemical reactions and continue to be bound as long as reactions take place.

Trash to Treasures Exploring 'Re-Material' In Architecture as a Means of Reducing Waste Generated in Urban Centres

[2]Department of Architecture, Abubakar Tafaw Balawa Univeristy Bauchi, Nigeria

ABSTRACT

Sustainable Architecture seeks to minimize negative environmental impacts through a conscious approach to energy efficiency and ecological conservation. The use of recycled building materials and low impact materials often termed "Green Materials" are common, but in most cases solid non-biodegradable wastes generated in our urban centers are neglected. Wastes generated from construction and demolition (C&D) debris, remodeling, renewing the furniture in our offices, homes, schools, and hospitals gather up daily and become an eye-sore to our environment. Huge amounts of resources are spent daily to dispose or recycle these wastes and a lot of heat is generated when they are eventually incinerated. However, when creativity meets resourcefulness, these wastes can be converted to remarkable pieces of art and architecture. This paper explored the concept of "Re-material", how solid wastes generated within our urban centers can be sorted, re-used, redesigned, reconfigured, and transformed to become a useful material for architecture with minimal processing. It examined previous studies on how architects approached construction waste minimization and how they have been able to convert wastes to remarkable Architecture. The findings revealed that most of the wastes that we dispose are not truly waste. They can be utilized in many ways in residential designs, schools, parks, recreation, sculptures, water fountains, landscaping and building components that can give lasting impressions to our environment and help reduce project costs. Re-material can also help reduce volume of municipal solid waste (MSW) by about 10%. Architects and other allied professionals should see waste as a material to re-use for better and more efficient project delivery. The use of material efficiently which is termed 'material resource efficiency' is a highly effective sustainability strategy for better environmental conditions in urban centres.

Keywords: Re-material, Re-use, Sustainable Architecture, Urban Centers, Waste minimization

INTRODUCTION

Waste management is not usually seen as a priority in the design process. Most Architects, developers, and other stake-holders in the building industry seem to take the view that waste is mainly produced during site operations and rarely generated during the design stages. This can be said to be the consequence of having so many considerations to deal with in the initial design stages. According to Osmani (2012), major issues such as waste generation are often neglected at the initial stage of a design and emphases are only given to problems that may arise at the construction phase of a project. However, about one-third of construction waste could essentially arise from design decisions. The current thinking on construction waste minimization is heavily focused on several issues relating to the physical construction waste and waste recycling guides (Richard, 1999).

Waste can be used in different forms for architecture; Reynolds (2015) opines that waste materials could be used as a complete building material for construction through the concept of *Eco architecture*. He further said that construction waste could also be used as a complimentary material to reduce cost and waste generated from site. Some researchers such as; Lennon (2005) and Ekanayake et al. (2008) are also of the opinion that waste materials could be used as finishing in normal construction in form of decoration, cladding, landscape elements in form of sculptures, artworks on buildings, and furniture.

According to Ferguson (1995) in Hassan et.al (2012), different forms of waste are suitable for different categories of 'Re-material'. This is a concept that explores the utilization of waste

Sani, A. A.; Hassan, O. S.; Sani, M. & Kawuwa, A. S. (2016). Trash to Treasures Exploring 'Re-Material' In Architecture as a Means of Reducing Waste Generated in Urban Centres. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 433-439

used as material in construction within the same site, in another site, or as a material in re-use. It provides practical means of prioritizing waste saving strategies and of systematically considering waste reduction alternatives. Larger and structurally stable materials such as steel, wood, plastics, paper, and glass have been used to form the building envelope, while smaller debris comprising of a mixture of different materials can be used as additives to other stronger materials for surface claddings in interior and outdoor elements, and for decoration (Reynolds, 2015).

This paper focuses on the possibility of using waste materials with minimal processing that is commonly used in recycling, with the view of encouraging professionals and artisans to take advantage of the research at minimal cost to add value to the environment.

Waste Generation in Urban Centers

The World Bank in 2013 estimated that about 3 billion residents are generates 1.2 kg per person per day (1.3 billion tons per year). By 2025 this will likely increase to 4.3 billion urban residents generating about 1.42 kg/capita/day of municipal solid waste (2.2 billion tons per year). The cost of solid waste management is projected to rise from $205 billion to $375 billion by 2025. This was reported in a global review of a World Bank report titled "What a Waste". This is an issue of major concern to the built environment and its administrators. Wastes in our environment have been on the increase basically due to increase in the population of urban centers arising mainly from rural urban migration and increase of commercial and industrial activities in our cities. As the city grows, the problems of the city also grow.

The excavation, construction and demolition (C&D) waste arising in England was estimated at 91 million tons in 2003 (Dolan et al 1999). In the United States C&D waste accounts for an estimated 35 to 40 percent of the municipal solid waste (MSW) generated. The countries with the highest per capita rates are islands, likely due to waste generated by the tourism industry. The annual waste generation in East Asia and the Pacific Region is approximately 270 million tons per year. This quantity is mainly influenced by waste generation in China, which makes up 70% of the regional total. Waste generation in sub-Saharan Africa is approximately about 62 million tons per year, from 0.09 to 3.0 kg per person per day, with an average of 0.65 kg/capita/day.

A significant amount of debris resulting from these activities is currently disposed of in landfills for recycling, composting, or incineration. Land filling debris results is a large burden on the world's natural resources and an increasingly expensive problem for solid waste management due to its effects on the environment and its ever increasing volume.

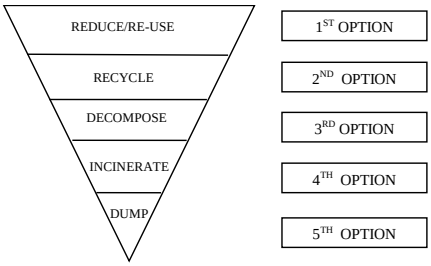

Fig. 1: Waste triangle showing the priority in waste management.
Source: Author, 2015

In Nigeria, waste generation rate is 25 million tons annually at a daily rate of 0.44-0.66 Kg/capital/day (Ogwueleka, 2009). The Per capital rate of MSW production in Lagos, Nigeria is reported to range from about 0.21 kg/day/person (Bamgbose et al., 2000; World Bank, 2004) to about 0.35 kg/day/person (CSL, 2002; Aboyade, 2004). This is equivalent to about 49 million kg waste per day (17.9 million metric tons/year). With an estimated

population of about 170 million and a growth rate of 3.2% annually the waste generation is on a rapid increase.

Most cities spend 20-50% of their annual budget on solid waste disposal yet only 20-80% of the waste is collected (Achankeng, 2003). This is a similar problem to most developing countries where the standards of waste management is still poor and outdated, coupled with poor documentation of waste generation rates and its composition, inefficient storage and collection systems, disposal of municipal wastes with toxic and hazardous waste, indiscriminate disposal or dumping of wastes and inefficient utilization of disposal site space (Ayuba et al, 2013). These problems have contributed to increased floods, health deterioration, and excessive pollution of the environment. The increase in squatter settlements and slums give rise to illegal dump sites that are mostly not properly documented or efficiently managed. The rapid growing waste generation rates and high cost of waste disposal, depletion of landfill space and the problem of obtaining new disposal sites resulting in open dumping are unresolved issues (AEPB, 2012).

Most waste generated in urban cities in Nigeria, consist of about 80% recyclable and re-use materials but the main and popular methods of it management are incineration and dumping in landfills. These methods according to Ayuba et al, (2013) are considered less economic environmental friendly. They posit that re-use and recycling methods are the best ways of waste management. See fig. 1 above and table 1.

Table 1: Waste Generation in Some Urban Cities in Nigeria

THE COMPOSITION OF WASTES IN URBAN CENTERS

The different categories of wastes common to our landfills in order of volume include organic materials, paper, polythene, plastics, glass, metals, e-waste and other organic materials. The first seven materials in the waste category excluding organic waste that is biodegradable can be re-used in buildings. Paper waste, plastics, glass and metals can be used directly as a material on site. This research will focus on these materials and the possible ways they can be used in buildings that are suitable to the tropics.

Table 2 Municipal Waste Characterization for the Federal Capital City, Abuja, Nigeria

Composition of municipal waste	**Quantity (tons)**	**(%)**
Paper	16,112.94	25.30
Textile	1,930.30	3.03
Plastics	5,357.68	3.40
Water sachets	9,257.82	14.50
Glass	2,250.38	3.00
Metals	2,642.80	3.14
E-waste	1,786.32	2.80
Organic materials; food and garden waste	2,8420.76	42.60
Other organic materials	1,948.06	2.15
Total	6,3707.10	100%

Causes of Waste in Design and Construction

Construction wastes account for about 35% of waste generated in urban centers that have a lot of construction activities. The major causes of waste in construction are numerous. The major ones include the following:

i. Design decisions (Clients, Architects, and Contractors)
ii. Lack of detailed brief and feasibility study of projects
iii. Changes in Design
iv. Errors in design
v. Lack of proper detailing
vi. Change of use
vii. Lack of on-site waste management plan
viii. Lack of proper supervision
ix. Poor craftsmanship
x. Complex and excessive designs

The major stakeholders in these major causes in design waste are the architects and engineers. It is not enough to think of a good design for a project without considering the process and effect of the project waste to the environment. The method and the process of construction chosen are very crucial to the amount of waste that will be generated. Wastes that are unavoidable need not necessarily be disposed. They can be utilized for landscape elements or other smaller elements of the design.

DESIGNING-OUT WASTES

There are several publications on ways to improve on-site waste management and recycling activities but very few attempts made to address the effect of design practices on waste generation (Fishbein, 2008). However, there is a consensus in literature that the architect has a decisive role to play in helping to reduce waste by focusing on 'designing out waste'. According to Whatt (1978) in Hassan et.al (2012) the factors underlying material waste during construction include inadequate material scheduling, inadequate design and lack of proper planning by the architect. An architect can explore designing out waste in his own site, or using waste generated from other sites or within the urban center. Simple and flexible design options generate less waste than complex rigid ones. Research carried out by WRAP (Waste and Resource Action Program) in the United Kingdom has identified five basic design principles that can be adopted to reduce the waste burden of projects through design. These principles provide a proven practical method of achieving waste reduction through the design process. These principles are:

i. Design for reuse and recovery:
ii. Design for off-site construction:
iii. Design for materials optimization:
iv. Design for waste efficient procurement:
v. Design for deconstruction and flexibility:

Designs for Reuse and Recovery

Major considerations at initial design stages can help in reuse and recovery of materials. These materials include excavation material, cut and fill soil, demolished building components, material off cuts, and pilferage from construction activities. These can be minimized through detailed standard specification that matches design to product specification. It can also be achieved by creating balance from cut and fill soil, re-using excavated soil, and minimizing excavation. Building redesign can make best use of the existing building elements and foundations to reduce demolition debris thereby reducing waste.

Designs for Off-site Construction
Waste generated during production, transportation and fabrication can be minimized by paying attention to details and proper packaging and delivery systems. Damage to pre-fabricated materials, pre-stressed and precast concrete elements is very commonly caused by handling and transportation. However, prefabrication offer better optimization of materials when properly handled.

Designs for Materials Optimization
This approach focuses on "material resource efficiency". Less material used in the specification (lean design) can help reduce construction waste without compromising the design concept. Good practice advocates adopting a design approach that focuses on material resource efficiency.

Designs for Waste Efficient Procurement
Designers must consider how the work sequence affects the generation of construction waste. Omitting an installation in construction can generate a lot of waste when it is later installed. Unavoidable waste can be reduced through manufacturer cut-off take back scheme and waste utilization plans on site.

Designs for Deconstruction and Flexibility
The use and function of buildings change and expand with time. Designers need to consider how materials can be recovered effectively during maintenance and refurbishments. Use of demountable methods of construction can help reduce waste arising from remodeling. This can achieved through the use of coordinated modular grids and materials that can be easily demounted for re-use within the site or in other construction site. We must also consider that the building will eventually be demolished at the end of its life cycle. Designs that do not consider flexibility limit the future potentials of the building. The consideration is about re-usability, recyclability and recovery of materials used.

Other Methods of Designing-out Waste
There are several other methods of designing out wastes used over time to reduce construction waste. The commonest methods include, but are not limited to the following:

i. On site construction waste sorting.
ii. Professional body incentive for waste reduction.
iii. Legislation.
iv. Creating stake-holder awareness.
v. Design competitions.
vi. Research and development in wastes that can easily be converted to materials.
vii. Reducing rates of accidents on site through proper packaging and transportation.
viii. Good safety and security standards on site.
ix. Strict penalties on improper construction waste disposal.

WASTES THAT CAN BE UTILIZED FOR ARCHITECTURE

Different categories of waste can be utilized in the site in a variety of ways depending on the function of the building. Several attempts by architects and artists provide insight on how useful waste can be to the architect. Alejandro Bahamon & Maria Camilla San-Jines''re-material' focused on projects that rescue discarded materials from cargo containers to cups, and change them into buildings and projects that are sustainable and practical. These materials are slightly modified and reconfigured to create a building. Movements of diverse professionals who reuse materials with architecture projects in mind are growing daily. Lucy Wang in South Africa used reclaimed wood artwork to beautify the exterior of a brick

building in downtown Johannesburg that was built with bricks. Glass, metal and plastic bottles have been used to build classrooms, houses and furniture.

This gave birth to the first Nigerian bottle house built with discarded plastic bottles in Yelwa village. Each house was built with one bedroom, living room, bathroom, toilet and kitchen using an estimated 7,800 plastic bottles (See Fig. 1 and 2). This "bottle brick" technology started nine years ago in India, South and Central America providing a cost-effective, environmentally-friendly alternative to conventional building bricks that is much stronger than bricks.

Fig. 1&2: Nigeria's first house built from discarded plastic bottles under construction.
Source: globalwasteideas.org (2015)

Sand bags, paper bags and fabrics have been used to create walls of the building in several projects. Architects and engineers should however explore use of these materials in contemporary construction in form of aggregate or additives in concrete and processed raw materials for producing cheap wall cladding and roofing tiles.

Smaller debris of waste that cannot be used directly can be utilized in different ways to create useful elements of the building or the landscape or additives to other materials. Interesting example of this is seen in projects that utilized shredded tyres, plastics, and paper as aggregates in concrete (see Fig. 3).

Plate 3: Conversion of discarded tyres in to an earthship.

CONCLUSION

For waste to be reduced, hard wastes such as Glass, metal and plastic bottles must be used as sustainable building materials especially now that the most countries are looking for ways to control and manage the environment successfully. The conversion of these generated wastes for use as material, art or landscape elements creates a more sustainable and pleasing environment and can help reduce wastes to landfills by an estimated 10%. Suggested waste

reduction initiatives target halving waste to landfills, this cannot be done through recycling alone, but it can however be achieved through Re-material.

Architects and engineers are however advised to engage in collaborative researches to experiment the provision of housing using wastes generated within a community. This will however provide alternative materials from waste that can be used as aggregate in concrete and other building materials.

ABSTRACT

Nigeria is a signatory to the Millennium Development Goal (MDGs) target but the country is far below meeting its water and sanitation target. A recent report by the World Health Organisation (WHO) and the United Nations Children's Fund (UNICEF) shows that access to potable water has increased from the advent of the MDGs in 1990 from 45.6% to 64% of the population, this increase still leaves over 65 million Nigerians; a population of many African countries combine together without access to safe drinking water. On sanitation, the report indicates that there is actually decrease in access to sanitation from 36.9% to 27%, with over 23 million of Nigerians still practicing open-defecation. This means over 120 million people about two third of the country's population lack access to good sanitation. Therefore, this study attempt to uncover challenges facing the sector and proffers sustainable solution that could mitigate this trend. A quantitative research approach was deployed to conduct, collect and analyse data obtained from major water and waste water industry stakeholders in Nigeria and Statistical package for social scientists software (SPSS) used to analyse the data. Findings from this study indicated that the water sector could attract renewed interest by investors due to its scarcity thus a very large market. However, the country's inability to make significant service increase could be blamed on lack of political will on the sector, the dearth of policies and good governance strategies for regulating the water and waste water industries. The research also discovered that managing this important but neglected social sector efficiently would help boost the availability of potable water supply and waste water infrastructure to meet the expectation of the Sustainable development goals (SDGs).

Keywords: Service Provider, Stakeholder, Waste Water, Water governance, Water infrastructure

INTRODUCTION

Literature reveals that while the world population has increased by a third in the 20th century, access to clean water for human used has grossly decreased (Wibowo 2009). Over 90% of portable water supply and access to sanitation in developing countries such as Nigeria is being provided by Public utilities because public ownership is seen as the best way to protect the market and ensure access to this vital social service, UNDP (2013). Management of these utilities however has not been efficient, (WUP 2001). In most cases as stated by Omoregie and Ehiorobo (2013), existing institutions and Governance methods aimed at reproducing or maintaining effective infrastructure in areas that require them has been grossly unsuccessful, especially in sub-Saharan Africa due to poor governance. Nigeria has an estimated population of over 170 million people and of this population, 36% do not have access to safe drinking water while about 73% lack access to sanitation, (JMP 2012) resulting in various diseases affecting the Nigerian public particularly children under the age of five. Even in Abuja the Nigerian capital, a large proportion of the residents get their drinking water from local water vendors selling in jerry cans popularly called "Mairuwa" thus putting their lives in danger due to uncertainty of the source and its quality causing diseases and thus putting pressure on the city hospitals and clinics. This ugly scenario could be attributed to poor governance and efficiency of the water sector despite its essential need for human existence, (Shaw, 2005).

Water governance can be said to be a system requiring the participation of all stakeholders, anti-corruption equity, transparency promotion of water legislation and regulation (Kajenthrira, 2013). Improvement in the water and waste water sectors in Nigeria has always been claimed to be an important goal for each successive government. Adequate provision of

Sanga, J.; Renukappa, S. & Suresh, S. (2016). The Nigerian Water and Waste Water Industry: Governance, Efficiency, Procurement and Infrastructure. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 440-448

water and sanitation services is also critical to the achievement of other economic objectives of the country (Hawkins and Wells, 2007) and Unicef/WHO (2015).

DEMANDS FOR WATER AND SANITATION SERVICES

At The Hague, March 2000, which was the second World water Forum (WWF2) the World water vision for 2025 was developed which is "Making Water Everybody's Business", (Cosgrove and Rijsberman 2000). It develop a consensus for gaining universal access to water and sanitation by 2025, which led the UN member states to adopt (on 18th September, 2000) water and sanitation as part of the MDGs. The goal was to ensure that the proportion of people living without sustainable access to safe drinking water and basic sanitation are reduced to halve by the year 2015. 'Water for Life' a United Nations International Decade for Action 2005 – 2015 was also lunched at the 2005 World Water Day followed by an International Year of Sanitation in 2008. All these unequivocally outline the global need for adequate and efficient clean water and waste water governance.

Table 1 indicates that nearly a billion people globally will still lack safe drinking water and more than that lacking sanitation at the end of MDGs in urban areas. With Nigeria being one quarter of Sub-Saharan Africa population, more than 70 million citizens is thus in need of water and sanitation services presently and effective Governance of water and waste water is the only panacea to these ugly incidence. Lipinska, (2012) went further to estimate that over 90% projected population growth will be in developing countries by the year 2050 and the regions are already water scarce with increase competition among water users to gain access to limited water supply.

Table 1: *Urban demands for access to safe water and sanitation by 2015*

Eastern Asia & Pacific	290,000,000	330,000,000
Sub-Saharan Africa	175,000,000	178,000,000
South Asia	243,000,000	263,000,000
South-Eastern Asia	115,000,000	208,000,000
Latin America and Caribbean	121,000,000	132,000,000
Former Soviet Union	27,000,000	24,000,000

***Source**: UN Millennium Project Task Force on Water & Sanitation, Interim Report, 2015*

The quality of life for a community both urban and rural is directly or indirectly affected by the availability or lack of access to water and sanitation for their daily needs "First, we have to have water simply to exist because we can only survive for short periods of time without drinking it" (Shaw 2005). Water is the common factor to the other four of the five basic human needs; water, food, health, shelter and peace. But of all the different uses of water, its use for consumption and sanitation activities are of higher social and economic relevance, ((Anand 2007 and Gbadamosi 2012). Water and waste water infrastructure assets form a large portion of all cost of public utility in any given city, (Cardoso et al 2012). Goldman (2008) estimated the size global water sector market to be above USD 425 billion with about 4-6% annual growth rate, he also stated that it will in the nearest future be compared only to the petroleum industry. This sector however varies from one country to the other depending on each country's population, geographical size, reputational frame work, business model adopted and stakeholders involved, (Abbott and Cohen, 2009 and JMP, 2012). This means Nigeria most developed sustainable governance system that she can effectively govern.

The Nigerian Water and Waste Water Industry: Key Issues

In addition to naturally being blessed with much water resources, the country invested significantly on water resources during the oil boom of 1970s and early 1980s especially in the construction of large multipurpose dams meant for drinking water supply, irrigation, flood

control and hydropower. Since then nothing much has been added despite double in population, operation and maintenance of these aging infrastructures has also been very poor resulting to a higher percentage of the population without access to clean water.

While water supply and waste water management problems are not unique to Nigeria but common to most developing countries; presently Nigeria is one of the most stressed in terms of water accessibility per person due to rapid urbanization and population growth. The growing pressure on water resources globally might see water as a major cause of conflict internationally and even nationally in most part of the world in the future (Lukenga, 2015).

The planning, development and delivery in the water and waste water sector in the country is generally dominated by the public sector with unnoticeable involvement of the private sector except in private Boreholes mostly drilled in residential areas for private sales. The bulk of planning, funding and major projects are undertaken by the federal government with a top-down approach, thus dictating the pace of sector development. But in smaller water and waste water projects, each agency or government level adopts its own management style to achieve its objectives with a very weak coordination for all the projects.

The first policy enactment on Nigerian water sector was the Water act 101 of 1993 followed by the National Water Resources Master Plan of 1995, the Water Resources Management Reform Programme of 1997, the National Water Supply and Sanitation Policy (2000) and finally the National Water Policy 2004. A review of the NWRMP (1995) commences since 2012 but is still ongoing. This policy are intended to regulate the Nigerian water and waste water sectors covering Legal and Regulatory Framework, Institutional Framework and Participatory Approach, Water Resources Infrastructure, Information and Water Resources Database, Assets and Assets Management, International Waters, Water Resources Economics and Financing and Environment and Resource Sustainability.

The poor water and waste water coverage in the country over the years is also blamed on lack of transparency in the implementation of water and waste water projects. Water governance is spread across different political boundaries, organisations and agencies in Nigeria making effective regulation, monitoring and oversight often difficult with many outlets of corruption to exploits. (Jacobson and Tropp, 2010).Adequate monitoring and maintenance of water and waste water infrastructure has also not been effective majorly due to inadequate funding. Corruption in the water sector keeps people thirsty and vulnerable to waterborne diseases, making families struggle for survival to escape poverty. Unfortunately, the less there is water availability, the higher the risk of corruption, (TI 2008) and (Lukenga, 2015).

Sustainability/Integrated Water Resources Management

Water and waste water management cut across many interest, stakeholders and businesses, hence there is the need for sustainable water management because “water is a renewable but finite natural resource” (Samuels *et al,* 2006). Its sourcing, supply and disposal is of fundamental to the economy and sustainability of nation and the quality of life of its citizen and business and the economics of how to sustainably manage the water cycle.

Harvey and Reed, (2003) defines sustainability in the water sector as that in which the water sources are naturally replenished after exploitation, facilities adequately maintain to ensure reliable and adequate water supply to all users over a long period of time in a cost effective manner that can be replicated. Water saving should become a priority to all people and “sustainable water policy promotes the formation of a water-saving culture”, (Lipinska 2012).

Because the environment is under pressure from many developmental spares like increase housing, population growth, transport systems etc affecting climate change; (Samuels *et al* 2006) outline issues that need to be considered in delivering sustainable water managements

in UK which include raising public awareness on impact of water use on the environment and ways of sustainable management.

To find the best answers and institutional models that are best and appropriate for addressing these and many other water sustainability issues has not been easy. There is now a better global focus on water governance, IWRM, participatory approaches and partnership, emphasis on ecosystem conservation and the consideration on cultural, social and economic of the water industry with adequate stakeholder participation.(Lipinska, 2012). At United Nations convention on Environment and Development held at Rio de Janeiro in 1992, and also at World Summit on Sustainable Development held at Johannesburg in the year 2002; the global water institutions developed a water used policy for Sustainable Development (SD) through Integrated Water Resources Management (IWRM) and Integrated Watershed Management (IWM) which has been adopted by many countries. Table 2 below shows characteristics of water and waste water management systems within a sustainable sanitation framework. In Africa and Nigeria in particular, the use of the word 'sustainability' is found repeatedly in many government policy and documents in the water sector but most agencies are not committed to its concept and inclusion in developmental planning and implementation of programmes.

Table 2: *Characteristics of water and waste water management systems in a sustainable sanitation framework*

Items	Characteristics
Water Resources	Extraction of fresh water from protected areas; reuse from treated water
Water Quality	Treatment of sufficient quality and quantity; novel and decentralized facilities
	Meeting health risk requirements
Treatment objectives	
Water Distribution	Piping system with chlorine residual; bottled drinking water
Generation of sewage	Toilets, kitchen, bathrooms; separation at source
Collection of waste water	Centralised system for sewer networking: Combine or separate system; on-site decentralized waste water treatment requires no sewer network
Centralized waste water treatment	Removal of pollutants: solids, organics, nutrients; reused of effluent and sludge
Advanced treatment	Removal of micro-pollutant, eco-hazard; reuse of effluent and sludge
Sludge management	Sludge conditioning and disposal, reuse
Financial Mechanism	Providing facilities based on the capacity of the general public and industries
Capital operating cost	Emphasis on cost-benefit analysis with reuse and recycling as requirements
Socio-cultural management	Clear policy on pollution and water sustainability, human resource

RESEARCH METHODOLOGIES

Qualitative method of research was adopted for this study in a bid to solving a qualitative problem (Biggam,2011)and has analysed various water and sanitation governance models using the concept of Strengths, Weaknesses, Opportunity and Threats (SWOT) analysis. This involved searching for documents and information by investigation and reviewing of similar articles and literature in order to reveal the efficiency or otherwise of the Nigerian water and waste water management. Different literature and information sources were used for facts finding include peer reviewed journals, conference proceedings, government publications, newspaper articles, water and waste water reports, books and other international organisations and bodies publications involved in water and sanitation issues such as the UN, WHO and UNICEF. Reviewing these literatures has exposed the efficiency, governance, procurement and infrastructural positions and challenges facing the water sector in Nigeria. Also, surveys and interview has been carried out using data collection instruments such as psychometrics and document analysis from records of water and sanitation activities available Rugg (2007).

There were two methods of approach for data collection used for this research work: Primary data/responses obtained from face to face interviews, questionnaires and personal observation carried out on key Federal government players within the water and sanitation industries and

Secondary data, information and records obtained from Journals, Magazines, Books, related published articles, documentaries and policy documents from water and sanitation related.

RESULTS AND DISCUSSIONS

The study examines the challenges facing the Nigerian Water and Waste Water industry and there after categorized the overarching issues critical to effective water and waste water management and improve performance in Nigeria in to four, they are; Water and Waste water Governance and efficiency, Infrastructure and Procurement, Finance and Financing systems and finally Investment gaps and opportunities analyzing only the top four discovered to be the most critical in each category.

General profile of respondents

A total of 50 questionnaires were distributed however, completed and returned questionnaires were 42 indicating 84% success rates; this figure is very good and reliable sample as suggested by Dania et al (2007) in which 52% response was accepted as valid. All respondents selected are within the senior and management level of responsibility with over 70% having more than 10 years' experience working in the Nigerian Water sector. The questionnaire also requested to know from respondents the area of participation in the water and waste water industry based on planning, construction/construction supervision, procurement, advisory and others as depicted on table 3 below;

Table 3: *Respondents profile of water industry participation*

		Frequency	Percent	Valid Percent	Cumulative Percent
Valid	Planning	22	52.4	52.4	52.4
	Construction	10	23.8	23.8	76.2
	Procurement	6	14.3	14.3	90.5
	Advisory	3	7.1	7.1	97.6
	Others	1	2.4	2.4	100.0
	Total	42	100.0	100.0	

As indicated on table 3 planning accounts for 52.4% of respondents, construction account for 23.8%, procurement 14.3% and advisory 7.1% while others accounts for 2.4%. This should be because most of the actual construction works are contracted to private water contractors while the government concerns itself with the governance process despite the random sampling used in sharing the questionnaire amongst the water industry actors.

Challenges to Nigerian water and waste water sector

One of the objectives of this research work is to discover the current challenges facing the Nigerian Water and Waste water industry. Twenty of the challenges were discovered in literature and from the descriptive analysis, top ten major challenges from respondents are ranked 1-10 are further analyzed on table 4 based on the respondent's three major aspects of involvement viz: Planning, Construction and Procurement.

Table 4: Challenges to the Nigerian Water Sector Work Responsibility Analysis

Variable	Planners		Construction		Procurement		General	
	Mean	Rank	Mean	Rank	Mean	Rank	Mean	Rank
Power Supply	1.12	1	1.62	3	1.42	4	1.55	1
Inadequate Funds	2.05	8	1.97	5	1.32	2	1.64	2
Lack of maintenance	1.40	3	1.36	2	2.36	9	1.88	3
Lack of Political commitment	1.98	7	1.88	4	2.00	7	2.05	4
Lack of Manpower and skill	1.38	2	1.26	1	1.52	5	2.10	5
Corruption	1.64	4	2.75	9	1.33	3	2.10	6
Use of Non-professionals	1.88	6	3.50	8	2.00	7	2.10	7
Defiant Regulations	2.05	8	2.48	7	2.10	8	2.16	8
Non implementation of Budget	1.76	5	2.07	6	1.24	1	2.17	9
No Delineation of Responsibility	3.02	10	3.83	10	1.74	6	2.34	10

1 = Very challenging 5 = Not challenging

Planners score indicates that the 3 most important challenges to the water sector in Nigeria are Power supply, Lack of Manpower and lack of infrastructure maintenance with the score of 1.12, 1.38 and 1.40 respectively. This agrees the general mean ranking and with Chukwujekwu, 2000 that the economic growth of a nation is traceable largely to its power supply. The other two highest ranked challenges are also amongst the top five general ranking.

The opinion of respondents involved in construction activities shows that Lack of manpower, Maintenance and Power supply in that order with mean value of 1.26, 1.36 and 1.62 respectively are the major challenges. The three also falls within the top five of general respondents indicating their negative impact on the Nigerian Water sector. Construction companies need skilled manpower to function effectively and deliver quality infrastructure so also the need to maintain such infrastructure to prolong its life cycle.

In the view of Procurement officers, the three most important challenges facing the Nigerian water sector are: Inadequate funds, none implementation of budget and Corruption with the score of 1.24, 1.32 and 1.33. Ironically none implementation of budget which is the tenth challenge on this analysis is the second for procurement officers and corruption which is sixth is the third. This is not unconnected with the fact that procurement relies solely on the availability of funds.

The general opinion of respondents is that power is the major challenge to the development and efficient provision of water and waste water services to the Nigerian public, this is also the view of planners with a mean value of 1.12. Respondents involved in construction activities ranked it 2nd while it is the 4th according to procurement officers. In summary, although all the respondents work in the Nigerian water and waste water sector, Planners involved in the design of water infrastructure acknowledge lack of sustainable energy source in Nigeria as the greatest challenge, Construction workers went for lack of manpower and skill while procurement officers are of the view that none implementation of the country's fiscal responsibility act.

Water and waste water governance and efficiency

The following discuss the major aspects of the Nigerian water and waste water sectors as score by all respondents to come out with results and overarching issues critical to effective water and waste water management and improve performance in Nigeria.

Table 6 below summarizes descriptive analysis results of questions asked to acquire information regarding water and waste water status, governance, procurement and efficiency in Nigeria.

Table 5: Respondents view on water and waste water governance and efficiency

Variables	Mean	Rank
I am satisfy with current water and waste water governance in Nigeria	1.79	1
Nigeria has met MDG's goals on Water and waste water services	2.05	2
Publicly own water and waste water projects are better managed in Nigeria	2.05	2
Project beneficiaries decide project type and location	2.07	3
The current level of private sector participation in water Waste Water Sector is very encouraging	2.21	4
Much part of your expenditure goes to maintenance of project	2.34	5
Customers promptly pay for your services	2.38	6
Revenue from services could account for the cost of service delivery	2.38	7
The level of 2014 budget implantation is above average	2.40	8
There is a strong political commitment towards water and waste water management in Nigeria	2.41	9
There are regular tracking audits of projects after completion to ensure value-for-money	2.48	9
Small-scale independent water providers are monitored to serve unreached areas	2.48	10
Project sustainability is always considered in my organisations project design and implementation	3.05	11
There is adequate gender balance in water and waste water sectors in Nigeria	3.21	12
Decentralised water sector management with States Government playing key role is better	3.38	13
There is adequate monitoring and evaluation of water and waste water projects in Nigeria	3.40	14

Valid Number of Respondents = 42 1 = Strongly Disagree 5 = Strongly Agreed

From table 4.5 above, less than the mean (about 2.05) agreed that Nigeria has met the MGDs target on water and sanitation. From our literature review the UN has classified Nigeria as having met the target on water but not in sanitation. In 2002, the African Ministerial Conference on Water estimated that over $10 billion was required to meet the MDGs target on water supply; However, it is very clear that this funding was not met resulting in significant investment gap in Nigeria also making respondents not to be satisfy with the current water governance system as indicated by the mean score of 1.79. World Bank, 2007 stated that water management problems mostly stem out of overlapping and unclear functions of public agencies, I will agree with them and concur with Agberemi (2003) of the need to decentralized the water and water governance structure to give more control and management decisions to the states and local council due to the different water sources, topographical peculiarities and large population of the country as proposed on figure 1 below.

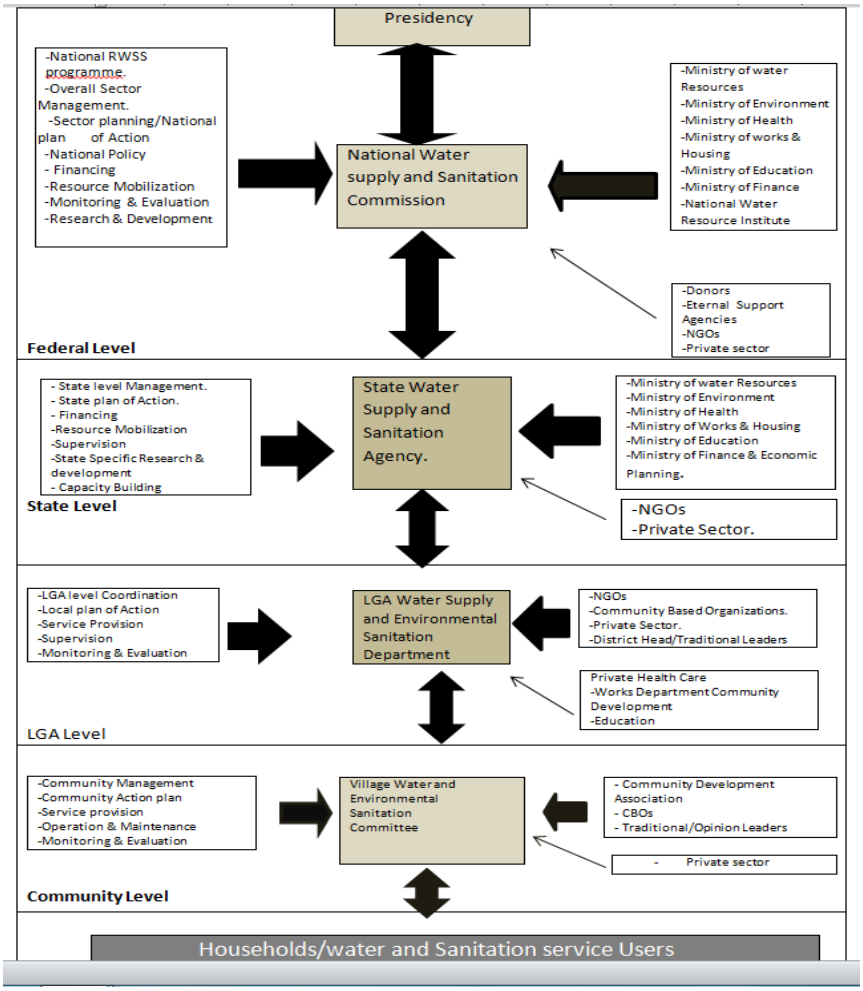

Fig 1: *Proposed Governance Model for the Nigerian Water and Waste Water Sector*

From the analysis on Table 6; many of the respondents agrees that most decision on water and waste water project location is decided by the political class and/or government as less than the average mean of 2.07 indicates that the end user have less voice on project execution. Gbedemah (2009) illustrate how participatory approach by NGOs in Ghana is regarded as the third sector on project procurement which is lacking in Nigeria. End users only may not be able to decide type and location of water and waste water infrastructure in Nigeria but effective infrastructure procurement should involve the combine commitment of the government, Designers, Civil society and end users, thus "Making Water Everybody's Business", (Cosgrove and Rijsberman 2000) to ensure all voice are heard .

The mean value of 2.05 for Public service provider suggest that the Private sector could play an important role in the water sector in Nigeria if better organisation, policies and regulatory frameworks are put in place with creative incentives and structures that will guarantee its profit margin on their investment. There should also be a broad based consensus, capacity building, a well-defined financial autonomy and obligations of all parties in the contracts (AfDB, 2005) and the choice of a PPP model that could suit the country's peculiarity (Akintoye and Renukappa, 2015). An autonomous body could also be set up to mediate between private investors and government with also the aim of protecting customers of the service that is delivered. Other areas of concern for water sector financing in Nigeria from the analysis above are that government finance the water sector in Nigeria (with 2.34 score), customer payment of services cannot account for the cost of service delivery (2.38), Federal government budget for the industry is not being fully implemented (2.38) and there is no value for money tracking for the water industry in Nigeria (2.41).

An investment gap brought out by this analysis with mean of 2.34 is the lack of Planned Maintenance of water and waste water infrastructure in Nigeria.(Gbadamosi ,2012 and Lukenga, 2015) affirm that "however small or however well designed, all water treatment works require regular attention and maintenance".

CONCLUSIONS

This research was able the discover Nigerians inability to expands its citizen access to potable water and effective management of waste water to government apathy towards the water sector, the dearth of laws, regulations and legal frameworks and their implementation, insufficient funds and funds misappropriation, corruption and lack of transparency in implementation of water projects, inadequate power supply to run the few existing infrastructure and none incorporation of all stakeholders in the planning, design, construction, operation and maintenance of projects. There is the need to urgently address these challenges in order to lay a solid foundation for the soon coming Sustainable Development Goals (SDGs) beginning in 2016. This can be achieved through participatory approach to water governance by all stakeholders, strong political commitment, increase financing and private sector involvement, transparent and accountable procurement process and planned maintenance of infrastructure. Further study could be developed on best alternatives approach for private sector participation that is best for the country peculiarity.

Energy Balancing in Buildings as a Sustainability Design Strategy in Nigeria

Louis Gyoh[1]* & Masud Abdulkarim[2]

[1&2]Department of Architecture Ahmadu Bello University Zaria, Nigeria [3]S.Subashini@wlv.ac.uk

ABSTRACT

The paper presents findings of Energy modeling of the wall and window components of the PIND office Building Warri. The study demonstrate how building envelop components assembly may achieve energy balance through electronic energy modeling. The paper illustrated how this strategy was used in the design process to achieve energy balance in the Architectural Designs of the Chevron – PIND office complex. Evidence suggests that, in Nigeria, Energy Balancing has not been sufficiently explored as a means of achieving Energy Efficiency in buildings. Architects, in Nigeria, are currently not required to design to energy standards. This has hampered the up-take of Energy Balancing as a sustainable design technique. This paper explores how Passive House Institute Standards has used in the Energy Balancing of the Chevron PIND office complex, Warri. The study method includes, Focus Group Discussions, the review of literature and Case Study of the Chevron PIND office complex. The significance of this study is that the strategy would enable better energy balance, less CO_2 emissions by the Nigerian building stock. The main-streaming of PHI standards or similar would be an effective climate change mitigation strategy for Nigeria - in line with the United Nations Local Agenda 21. The findings highlight the significant contributions of the latent cooling and sensible cooling loads to the Total Energy Demand and the Primary Energy Demand of buildings in Nigeria. The study findings also indicate that building costs in Nigeria are limited to cost of Labour and materials; hardly any consideration is given to the environmental and socio-cultural impact. The results also suggest the achievement of Energy Balance of the Wall and Window elements is significant to the total energy demand and also with GHG emissions. Quite often, the public is unaware of the dangers of non-environmental sustainable buildings. The deliverables are intended to form part of a conceptual Energy Performance Framework to which Architects are expected to design to by law.

Keywords: building, energy, efficiency, balancing, simulation, sustainability

INTRODUCTION

In almost all Western Countries and increasing developing countries (that signed up to the 1992 Rio Climate Change Agreement) architects and other construction professionals are now expected to design to pre-determined statutory energy performance standards. Energy modeling has become part of the design process. This technique is the quickest and most cost effective of achieve Building Energy Balance early in the design process.

Energy efficient buildings are those which consume less energy while maintaining or even improving the comfort conditions for their occupants compared to standard buildings. Energy efficient buildings result not only in less environmental impact but are also economically sustainable and resilient. The development of energy efficiency standards is likely to ensure that Nigeria has more access to electricity at lower cost (Monteyne H & Gyoh L 2013)

The Building Energy Efficiency Guideline for Nigeria was commissioned by the Federal Ministry of Lands, Housing and Urban Developement, Abuja Nigeria with support from Deutsche Gesellschaft fur Internationale Zusammenarbeit (GIZ) GmbH, UN Habitat and the European Union under the Nigerian Energy Support Programme (NESP). It aims to give practical advice to professionals in Nigeria on how to design, construct and operate more Energy Efficient Buildings. The guide also aims to educate the general public about energy efficiency measures and help clients when specifying buildings to ensure that they obtain a "green" building. The development of the Building Energy Efficiency guidance has become necessary as energy used in residential buildings in Nigeria account for 78% of the total

Gyoh, L. & Abdulkarim, M. (2016). Energy Balancing in Buildings as a Sustainability Design Strategy in Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 449-458

national electricity energy consumption, whilst approximately, 55% of the population has no access to electricity supplies (GIZ August 2015). A World Bank study suggests that approximated 40% of global Energy Demand may be shaved off by building energy efficient improvement alone (World Bank 2012).

The building sector accounts for the majority of electricity consumption in Nigeria and will inevitably increase significantly in absolute terms in the coming years driven by a rapidly increasing population, migration from low energy consuming rural dwellings to urban centres, and improvements in living standards. Set against a chronic shortage of electrical generation and transmission capacity, energy efficiency measures represent the cheapest way of improving the state of energy supply in Nigeria, now and in the future as the grid plays catch-up with demand. This may be achieved by exploiting Environmental Assessment pathways such as LEED, BREEAM, Green Star and Passive House, to mention a few.

Significance of Passive House

Why Passive House

Passive House focuses on energy, indoor air quality and comfort; It performs exceptionally well in this areas (Monteyne and Gyoh 2013). Passive House as compared to other Environmental Assessment systems has a narrow but rigorous method. It is simple, flexible and easily adaptable to the local environmental situation in Nigeria and elsewhere.

The benefits of the Passive House Institute (PHI) methods are that, the 'Passive House Performance Standards' are sensitive to local environment and climatic conditions. The performance standards factor in the local Latent Cooling Loads, Sensible Cooling Loads and Heat load demands.

Passive House Standards

Basically, Passive House Institute Standards is one in which comfort in interior spaces can be achieved without conventional cooling or heating systems. The standards are built round the 'Fabric First' Concept, based on five fundamental building blocks – namely:

i. Thermal Insulation
ii. Thermal-Bridge-Free Construction
iii. High Performance Window and Doors
iv. Airtight Construction (Moisture Control)
v. Controlled Mechanical Ventilation with Energy Recovery Ventilation (ERV)

Passive House is a building standard, which is energy efficient, comfortable, economic and environmentally friendly simultaneously. Passive House is not a brand, it is a building concept which is open to all and which has proved itself and constantly improving (PHI 2013). According to the Passive House Institute of Ireland, Passive House is the leading standard in energy saving in buildings worldwide. The energy saving for heating amounts to over 75% in comparison with the legally prescribed building standards (Bere 2013). The heating costs are very small – high energy prices make no differences to residents of Passive House in Germany (Vallentin R & Gonzalo R 2013)

According to the Passive House Academy PHPP official manual, the key Passive House Certification Criteria are as follows:

i. Heating Energy Demand (QH) $\leq$ 15 kWh/m^2.a
ii. Cooling Energy + Allowing for humidity control - Dry Degree Hours (DDH) $\leq$ 15kWh/m^2.a + DDH
iii. Building Cooling Load (PC) $\leq$ 10 w/m^2
iv. Building Heating Load (PH) $\leq$ 10 w/m^2
v. Primary Energy Demand (PE) $\leq$ 120 kWh.m^2.a

vi. Building Airtightness (n50) ≤ 0.6/h Air Changes per Hour (ACH)
vii. Summer overheating frequency < 10%

The Passive House recommended U-value for opaque elements ≤ 0.15w/m^2.k. This goes for the walls, floors, roofs. However, the U-value installed for windows ≤ 0.85w/m^2.k

Comparison of LEED and Passive House

Table 1: Comparison of LEED and Passive House

LEED	*Location & Transport*	*Sustainable Sites*	*Water Efficiency*	*Energy & Atmosphere*	*Material & Resources*	*Indoor Environmental Quality*	*Innovation*	*Regional Priority*
Passive House (PH)				PH - Energy Standards		PH- Indoor Air Quality & comfort		

LEED and Passive House are completely different approaches to sustainable building. LEED has been an incredible market transformation tool and has been seismic in raising awareness of sustainable building in North America and elsewhere. However, Passive House, on the other hand, is more narrowly focused on energy, indoor air quality and comfort, it performs exceptionally well in those areas – as illustrated in table 1. Passive House is still niche in North America, but is gaining traction and growing rapidly world-wide. Passive House performance is well proven globally, is backed by over 25 years of building physics and is achieved using the PHPP Energy Balancing verification tool (Bere, J. 2013)

METHODOLOGY

This paper emerges out of the preliminary findings of a wider study carried out by the authors at the Ahmadu Bello University, School of Architecture, Zaria, Nigeria. The study adopted mixed method research design approach, and in which qualitative method were applied in the interpretation and analysis of data on the perceptions and attitudes of participants to the early use of energy balancing methods in the design process and the potential benefits. A purposive sampling technique was adopted in order to identify the typical instances with relevant rather than aim for proportional representation (Castillo 2009). The empirical evidence was derived from the Case study experience of a Passive House Energy Efficient project design and construction of the Chevron PIND ATED Energy Efficient Office Building complex, Warri, Delta State, Nigeria. The study method also includes Focus Group Discussion, In-depth Interviews with design consultants, specialist contractors, user groups and the client organization.

Energy Efficient Building

The procurement of Energy Efficient Building (EEB) starts with the right design approach. It starts firstly, by considering the microclimate conditions of the site, orientation and shaping the building form. Secondly, by a conscious selection of building materials and envelope systems aimed at minimise building thermal transmissions – by shading, insulation, natural ventilation and thermal bridge detailing. Thirdly, active systems may be selected on the basis of high efficiency (e.g. high efficient ventilation and lighting systems) to enable a reduction of building cooling loads in hot and humid climate (e.g. dehumidifiers)

Energy Balance

Passive House is a building standard, which is energy efficiency, comfortable, economic and environmentally friendly at the same time. The Passive House Institute (2013) argues that, It is the leading standard in energy saving in building world-wide. Passive House Energy Balance refers to the Energy Gains versus Energy Losses in relation to comfort environmental conditions.

Space Cooling Demand

Qc = Space cooling demand (kWh/year)

Qc = QT + QV – Ƞ (QS + Qi)

QT = Transmission losses

QV = Ventilation losses

QS = Solar gains

Qi = Internal gains

Ƞ = Correction factor

qc = Specific space cooling demand (kWh/m^2.year)

ATFA = Total Floor Area (m^2)

qc = Qc/ATFA

The Passive House Criterion qH ≤ 15kWh/m^2.a + DDA

The Dry Degree Hours in Warri (DDA) = 54 kWh/year

Transmission Losses (Transmission Losses (QT))

QT = A x U x ft x Gt

A = Area of Wall

U = U-Value of Wall

ft = Temperature correction factor (unit less) usually = 1 above ground

Gt = Cooling degree hours (∑ΔT)

The Transmission Losses QT is equal to the product of the total wall surface area, the U-Value of the wall and the temperature difference (ΔT). The U-Value of the heterogeneous wall assembly was calculated by 'building-up' from the respective heat transfer coefficients (λ – values) of the individual components that constitute the wall assembly.

U-Value = 1/RTotal = 1/ Rsi + d1/λ1 + d2/λ2 + d3/λ3 + …..+ dn/λn + Rs**e**

RTotal = Total Resistivity

Rsi = Internal Surface Film Thermal Resistance

Rse = External Surface Film Thermal Resistance

Wall Specification for the PIND Passive House Warri Project

Hydraform compressed earth bricks where used for the external wall of the Passive House PIND office Warri. Hydraform compressed earth blocks has a Heat Transfer Coefficient of λ = 1.0w/m^2K – much better than cement blocks. The Hydraform block work is 220mm thick, the sand cement plaster on the internal surface is 25mm, whilst the internal insulation is 50mm thick and the internal plasterboad finish is 25mm thick.

The wall assembly specification for the office complex are summaries in the table 1 and table 2.

Table 1: Lamda and delta values for wall PIND office wall assembly

Item	Hydraform Blocks	Sand Cement Plaster	Foam Insulation	Plaster board Finish
λ	1.0	1.4	0.03	0.35
d	220mm	25mm	50mm	25mm

Table 2: Surface film thermal resistance- for Internal and External Surfaces of Office Complex

Item	Surface Air Film Resistance (m2k/W)
Rsi (internal surface)	0.01
Rse (External surface)	0.04

RTotal = Rsi + 0.220/1 + 0.025/1.4 +0.050/0.03 + 0.025/0.35 + Rse

RTotal = 0.01 +0.220 + 0.0178 + 1.667 + 0.0714 + 0.04 = 2.02 m^2k/W

Insulated Wall U-Value = 1/RTotal = 1/ 2.02 = 0.49 W/m^2K.a

Non-Insulated Wall U-Value = 1/0.2878 = 3.47 W/m^2K.a (East and West Facades)

From the above results it can be seen that the heat transmission of the Non-insulated wall is seven (7) times more than the heat transmission of the insulated wall. This translates to a significant reduction of the building cooling load and energy costs.

Wall Area = 154m^2 (East and West Façade)
$\Delta T = \sum(Tse - Tsi) \approx 10$
QT = A x U x ft x ΔT
QT = 154 x 0.49 x 1 x 10 = 754.6 kWh/m^2 (insulated wall)
QT = 154 x 3.47 x 1 x 10 = 5343.8 kWh/m^2 (non insulated East and West Façade)

The heat transmission of the non- insulated wall is approximately seven times more than that of the Insulated hydraform wall. This is an indication of the energy load reduction achieved in the PIND Passive House Warri building by specifying insulation of East and West facing walls as well as the roof cladding of the building.

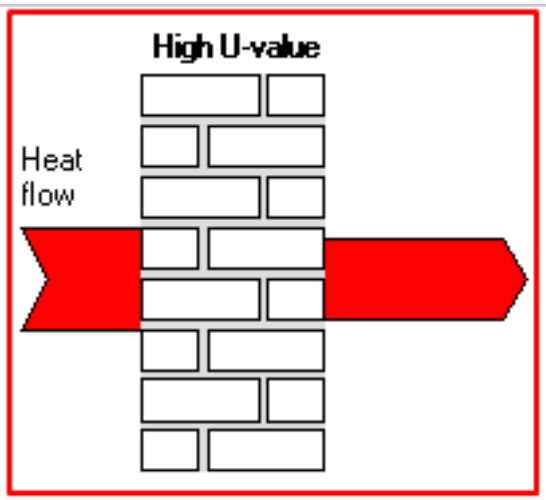

Figure 1: Uninsulated Wall

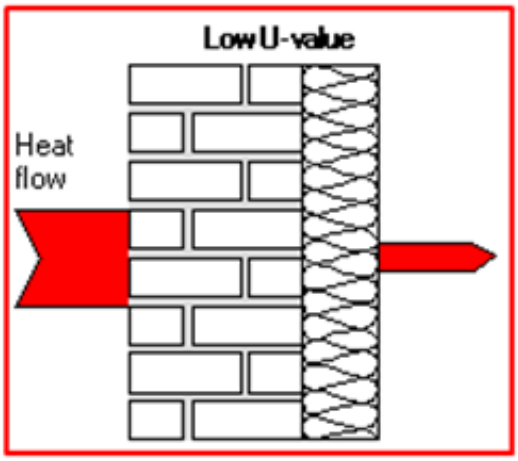

Figure 2: 50mm Insulated Wall

The calculation results indicate that the building cooling load reduces significantly by the introduction of 50mm insulation in the east and west facades of the building. Deep overhangs where provided in the south elevation to prevent overheating thereby further reducing the buildings energy loads.

PHPP Computer Simulation Results

The Passive House Planning Package Simulation results show that 50mm of insulation reduced the heat transferred through the wall by 85% - as indicated by the graph in figure 3.

The calculation results also indicate a seven (7) fold reduction in the wall thermal transmission from a U-value of 3.47w/m^2.K to 0.49w/m^2.K. This translates to massive cooling load energy savings throughout the buildings life cycle

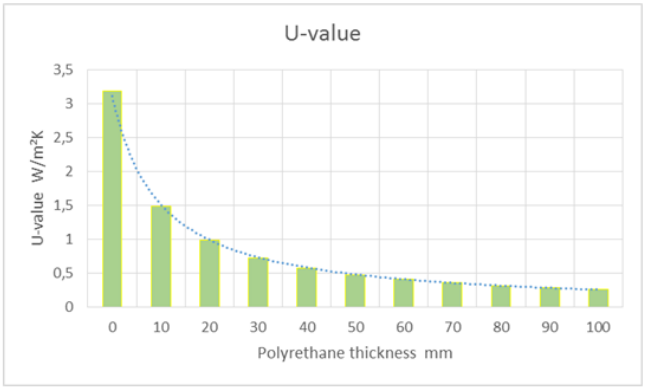

Figure 3: PHPP Graph showing the effect on insulation thickness on thermal transmission

The notable benefit was experience in the first 10mm of insulation up to 50mm. After 50mm, the marginal utility benefit drop as the insulation thickness increased beyond 50mm up to 100mm in Warri climate conditions.

Chevron PIND Energy Efficient Office -Building Project Warri

Chevron PIND office project is an Energy Efficient office complex designed by Yorkshire Consult and project managed by Sustainable Building Concept.

The project was designed to Passive House Energy Standards. The maximum Cooling Demand was ≤ 15 kWh/m^2. year, whilst the Latent Cooling demand was ≤ 54 kWh/m^2.year. Simulation results based on Warri climate data suggest the Specific Energy Demand as ≤ 69 kWh/m^2.year for Latent and Sensible Cooling. The design team allowed 6 kWh/m^2.a for energy efficient lighting and office equipment within the energy balancing strategy. The Total Energy Demand (PE) ≤ 120 kWh/m^2.a

Roof Component Assembly

Light colour roof-cladding material was used for the roof covering. The roof space was ventilated and 50mm spray insulation introduced at the ceiling level. The light coloured roof cladding increased reflection of direct solar radiation. This reduced heat absorption and surface film heat resistance (Rsi and Rse) of the roof. The desired U-value was determined by calculations, specification and iterative simulation of the roof element assembly.

Wall Component Assembly

The wall construction was of Hydraform earth brick construction with 50mm spray insulation. The inside wall is of stud timber construction. The external walls are shaded by large overhangs to reduce exposure to excessive solar radiation. The internal wall is finished with gypsum plaster board. The repeated thermal bridging effect of the stud walls was simulated and designed out by introducing OSB board sheeting. The Psi Ψ – value was calculated and design to Ψ = 0.01w/m^{2}K (this is equivalent to near zero thermal bridging).

Window Component Assembly

The window Energy Balance was simulated in Passive House Planning Package (PHPP). The window U-value is 1.1w/m^{2}K; its U-value installed is 1.3w/m2.K; whilst the Psi Ψ – value installed was Ψ = 0.05w/m^{2}K. The thermal resistivity (R) R = 0,7692m^{2}K/w. The window glazing specification, the Solar Heat Gain Coefficient (SHGC = 0.25), the g-value of 25%. The SHGS is a measure of solar energy allowed through the window glazing.

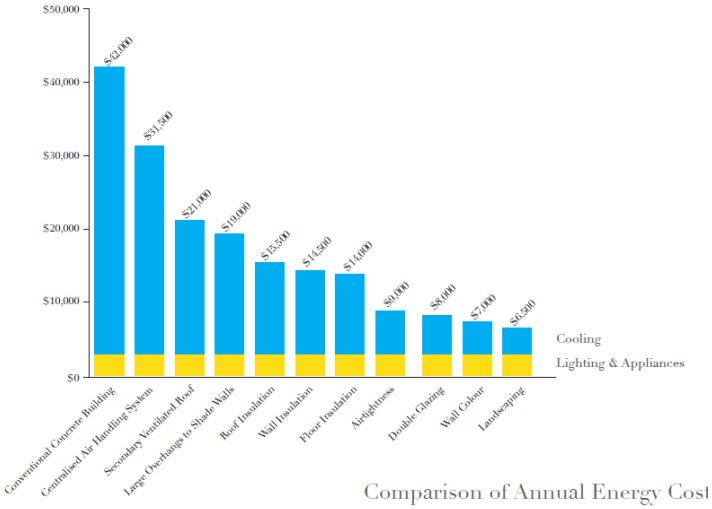
Energy Strategy

Building Physic formed the core strategy of the energy efficient design of the Warri office project. Renewable Energy Technology systems were also applied as follows:

i. Bio digesters where installed to the toilets and piped to provide cooking gas in the canteen area (see appendix 1)
ii. Solar photovoltaic panels provided most of the electricity required for the Energy Recovery Ventilation (ERV) system (0.45Wh/m^3) with dehumidification functions to address the higher humidity levels of Warri (60 to 80% RH). The ERV ensures a constant internal environment condition of between 30-60% RH, not exceeding 12.5g/m^3 and (20 – 26^{o}C)
iii. The Airtight test was 0.6 ACH (Air Changes per Hour)

The ERV system was provided to improve the air quality in the office complex. The ERV system brings in fresh air intake from the outside, filters the air and supplies it to the office spaces. Energy Recovery take place through a counter flow process in the ERV system. The intake air is cooled down from the relatively cooler temperature of the exhaust air (Intake Air ≈ 30^{o}C whilst the Exhaust Air ≈ 20^{o}C). The design provides supply of fresh air to the office spaces and extracts in the wet rooms, stores and machine room via the transition zones.

Figure 4: Summary of the Impact of individual Strategy to Energy Costs – PHPP Simulation, PIND Office Complex, Warri



Window Energy Balance – Chevron- PIND Office Building Warri

The windows at the Chevron PIND office were balanced to optimize the window-element energy performance of the office complex. This was achieved by appropriate design and specification to pre-determined Passive House standards.

The designs where simulated in the PHPP Electronic environment. This strategy was able to guide against overheating due to excessive solar gains – as well as transmission losses through the window element, thereby minimizing thermal transfers. The solar gains was calculated and optimised as follows:

Qs = r x g x Aw x G

Qs (Solar Heat Gains) = Reduction Factor (Unit less) x Solar Heat Gain Coefficient g-value
(Unit less) x Gross Area of the Window (m^2) x Global Irradiation = kWh/m^2.yr

However, the reduction factor ‘r’ is determined by the four individual elements

i. Shading on the window (from external elements) reduces the sunlight falling on the window (the varies with the window design)
ii. Dirt on the glass itself blocks some solar radiation from penetrating the glass (0.95 is used as a default – assuming PHPP simulation figures)
iii. Non-perpendicular Radiation given that the sun moves through the sky (east-to-west each day, higher and lover in the sky each season) (0.85 default - assuming PHPP – simulation figures)
iv. The proportion of the window which is glass (the frame eliminates a certain portion since it is opaque)

Once the solar energy strikes the face of the glass, the amount of energy that passes through to the interior is determined by the Solar Heat Gain Coefficient (SHGC). The required SHGC can be provided by the window manufacturer (within reason) For the PIND Warri office project, Metallum the Lagos based window manufacturer was able to provide the full window specification details

The typical size for most of the windows (WDG-1200) has a typical dimension of 1200x1500mm with a frame thickness of 25mm.

i. g-value of the glass (SGHC = 25%) = 0.25
ii. U-Value of glass Ug = 1.1w/m^2K
iii. U-Value of frame Uf = 2.8w/m^2K
iv. Ψ spaces = 0.02w/m^2K
v. Ψ installed = 0.03w/m^2K
vi. VLT = 40%
vii. G (ΔT) = 10 kKh

The solar gains was calculated as follows

Qs = r x g x Aw x G
But r = (Reduction factor) = (1) Shading x (2) Dirt x (3) Non perpendicular incident radiation and (4) Glazing %
r (reduction factor) = 0.95 x 0.85 x 0.85 x 0.92 = 0.63
Qs = 0.63 x 0.25 x 1.8 x 10 = 2.835kWh/year

A separate calculation was made to optimize the performance of each window type taking into consideration the orientation of individual windows. This was achieved by calculating the U-values of the windows-installed in their respective orientations. The U-value is the measure of the thermal transmission. The global irradiation 'G' is site-orientation dependent and usually highest in the south facing equator – i.e. in the Northern hemisphere

i. Area of glazing = A_{glass}
ii. Area of frame = A_{frame}
iii. Length of Glazing = L_{glass}
iv. Length of Window = $L_{installation}$
v. Area of Window = A_{window}
vi. Global irradiation = G

U window-installed = (Ug x A glass) + (Uf x A frames) + (Ψ spacer x L glass) + (Ψ install x L install)/A window
U window-installed = (1.67 x 1.1) + (2.8 x 0.13) + (0.02 x 5.2) + (0.03 x 5.4)/1.8 = 2.467/1.8
U window-installed = 1.37 w/m^2K

The study demonstrates how the Psi Ψ – value of the spacers and of the window installed can have a major impact of the Energy Balance of a window. It is not always possible for

buildings to have their shorter sides oriented in the East West direction. One of the major determinants of building-orientation is the location of the access road. The window specifications in terms of its energy transmission properties and the solar heat gain coefficient (SHGC) may be used as design strategies to reduce excessive heat gains. The U-values of the window glazing and frame both have effects on the window performance.

The U-value of the window glassing is 1.1w/m^2K. However, the U-value of the window installed is 1.37w/m^2K. The drop in performance is due to the Psi Ψ values of the spacer and the Psi Ψ value of the window installed. The Psi value is a measure of the thermal bridging in w/m^2K.

CONCLUSION

It is not always possible to optimize building energy performance using passive means such as building orientation and cross ventilation alone. Significant development has been made in the area of Energy Balancing of buildings using the principles of Building Physics. On-going studies world-wide are continuing to make remarkable progress in building physics using various environmental simulation packages. Passive House, LEED, BREEAM, Green Star, and Energy Plus are some of the systems that have emanated from these studies.

The study highlights how energy balance may be achieved through the design and specification of the Window and Wall elements. The paper also shares the experience of the Chevron PIND Energy Efficient Office complex designed and built to Passive House performance standards.

The window component plays a significant role in the energy balancing of building. The energy transmission through windows could be balanced through appropriate design and specification of the window component. The critical elements that determine the performance of the window component include the U-value of the glazing, window frame and the U-value installed. The Psi value Ψ of the spacers and the Psi Ψ value of the windows installed are both crucial to the performance of the window element. These variables can all be influenced by the architects designs and specification of the window element.

RECOMMENDATIONS

Energy Balancing

Architects and Building Services Engineers should consider the use of Building Physics as a strategy in improving building performance through the balancing of individual building components

Wall Component

Architects and M&E consultants should aim at designing to some voluntary energy standard where mandatory standards do not exist. Designers should endeavor to keep the U-Value of the external wall assembly build-up to below 2w/m^2K. Insulation may be used in the east and or west elevation to cut out excessive thermal transmission. Insulation may also be applied in the roof space in addition to its ventilation. Insulation thicknesses seem to have a more significant impact in thermal transmission reduction up to 50mm. The above strategies where applied to the Chevron PIND office complex in Warri; results for PHPP Energy models indicated a 75% reduction of the buildings cooling loads – as compared to a business as usual scenario.

A Comparative Analysis of Sustainable Building Material: A Focus on Perceived Qualities of Timber versus Concrete in Nigeria

Ikudayisi, Ayodele Emmanuel[1*] & Omoyajowo, Nicholas Ipinlaye[1]

[1]Department of Architecture, Federal University of Technology, P. M. B. 704, Akure, Nigeria
**ayoikudayisi@gmail.com*

ABSTRACT

This paper presents a comparative analysis of quality perception between timber and concrete with a focus on sustainability. The objectives of the study were to determine the environmental potentials, availability and level of adoption of these materials in building construction. It also sought to evaluate the perceived quality of the timber and concrete from Nigerians perspective. With a thorough literature analysis, the global understanding of sustainability potentials of the materials was established in term of CO_2 emission and storage, fossil fuel release into the atmosphere, thermal conductivity, energy consumption, and affordability amongst others. Structured questionnaires were used to collect relevant data from ninety six (96) building owners at Oluyole Local Government Area, Ibadan, Nigeria on their perception of the quality of these materials. Descriptive statistical analyses and analysis of variance were carried out using statistical software. Findings revealed that timber offers more sustainability potentials even as the integrity of concrete is currently under scrutiny. However, the level of adoption of timber in building construction in Nigeria is relatively low due to inadequate technological deployment required for its processing. The study recommends a collaborative effort among stakeholders geared towards developing timber-based structures in Nigeria.

Keywords: Building materials, Concrete, Perception, Sustainability, Timber

INTRODUCTION

Building construction is increasing daily worldwide due to accelerating population growth and the need for people to be well sheltered. With the advancement in technology, building materials have been developed to provide better living condition for the man in terms of safety, health, economy and functionality of built form. Meanwhile, climate change emerged as one of the most significant issues facing mankind in the 21st century. Environmental sustainability and energy efficiency are the focus of growing concern on human activity as well as contemporary life. Effort towards reducing greenhouse gas emissions, most especially CO2 is currently getting top priority across the globe (IPPC, 2007).

It has been ascertained that human activities can induce detrimental effect on the world we live (IPPC, 1996; IPPC, 2001). Building construction and operation largely responsible for one third of greenhouse gas (GHG) emission with building related activities also consuming 40% of energy use globally(UNEP, 2009; Robertson *et al*., 2012). According to the report of International Energy Agency (IEA, 2007), 70% of electricity use in developed countries were accredited to building sector alone. The detailed energy consumption as reported by International Energy Agency (IEA) shows that Commercial sector takes 9% energy, Industry 29%, Residential 27%, Transport, 30% while other sectors captures 5% (IEA, 2007;Chen, 2010; Parameshwaran *et al*., 2012)

In most of the developing countries, energy generation is mostly through fossil fuel combustion processes. Consequently, these activities result in the emission of greenhouse gases such as carbon dioxide, methane, sulphur dioxide, among others into the environment resulting in ozone layer depletion aftermath of which is global warming and climate change (Penner *et al*., 1989; UNEP, 2007; Abimaje and Baba, 2014). In another perspective, the growing challenges of affordable housing and environmental sustainability led to increased

Ikudayisi, A. E. & Omoyajowo, N. I. (2016). A Comparative analysis of Sustainable Building materials: A Focus on Perceived Qualities of Timber versus Concrete in Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 459-471

concern for alternative material in developing country. For instance, Nigeria's population has recently been estimated at about 180 million, with population growth rate of 2.55%, GDP growth of 6.81% and 3.5% annual urbanization rate (UN, 2015), therefore need of affordable homes for the citizenry. Most conventional building materials which are often imported into the country with gross foreign exchange resulting to escalating cost, hence the need for adoption of locally available building materials which are affordable for the populace. This alternative method of construction geared towards sustainability and affordability is highly essential in order to cater for the housing needs of the average Nigerians (Adedeji, 2007).

It has been established that a sustainable building material must be affordable, durable, environmental friendly and flexible in usage (Okereke, 2006; Chen, 2010; Schmidt & Griffin, 2012; Abimaje and Baba, 2014). Research activities are now been sponsored, supported and carried out by government, organizations and academia in an effort at analyzing, quantifying and comparing environmental impact of building materials and design with alternatives been sort in natural products. However, little research effort has been directed towards quantitatively determining the level of awareness and perception of populace on the sustainability potentials of building materials especially in Nigeria. Although, building materials specifications ideally comes from the building consultants (especially architects), this cannot be without the input and agreement with the client. Evidently, public perception of qualities of a building material could to a great extent influence their choices. According to Florez *et al.*(2010) market demand is a critical factor to be considered in realizing sustainability goals since inappropriate materials choices may hinder the desired sustainability objectives.

This research work sets out to examine the perceived sustainability potentials of timber and concrete in the study area, in view of this, the study will attempt to answer the following questions; what is the level of usage of timber and concrete in the study area?; what is the level of availability of the materials? and what is the perception of sustainability qualities of timber and concrete? The hypothesis of this research is thus; *Ho*: Building owners will not differ significantly on their perception of sustainability qualities of timber versus concrete in the study area. *Ha*: Building owners differ significantly on their perception of sustainability qualities of timber versus concrete in the study area.

This study aim at examining perception of sustainability potentials of timber and concrete comparatively with the view of suggesting strategies for achieving sustainability goals in Nigeria. The objectives were thus to determine the sustainability potentials of timber and concrete from global perceptive, examine the level of adoption and availability the materials in Nigeria and carry out a comparative analysis of Nigerian's perception on the qualities and sustainability potentials of these building materials. This article begins with a literature review by comparing the sustainability potentials of timber and concrete in terms of carbon dioxide released and storage, fossil fuel release into the atmosphere, thermal conductivity amongst others. Then, the result of the empirical survey was discussed. The article concludes by summarizing the benefits of developing sustainable building materials in Nigeria and required actions to achieve these benefits.

LITERATURE REVIEW

Nature and adoption of Timber and Concrete in Building Construction

For many centuries, wood has been used by man in building construction. The ancient timber structure of the Chinese dated back to 7000years ago (Liv, 2002). Timber was the most predominantly used building material until the second half of the 19th century (Douglas, 1995). Today, advocates of timber as a building material opined that the material is attractive while its opponents argued that its unreliable strength and weak fire resistance are the most

critical disadvantages. However, the use of wood in construction of buildings has been limited due to life-safety concern and structural quality as well as the perceived poor fire control quality which has led to restriction of wood as a structural material in building codes. Andreas (2005) argued that architects and clients are limited not by the material, but by their low understanding of its potentials and method of adaptation in building construction.

Much recently, new innovations and technology advancement in wood production, experimentation and test has revealed that wood products could be adopted as a structural material for storey buildings such as high rise family dwelling units (FPI innovations, 2010; Schmidt & Griffin, 2012; Mohammed *et al.,* 2015). Timber has been innovatively developed into varieties of products especially in the developed countries with the introduction of engineered wood such as Cross laminated timber, Glue-laminated timber, Laminated Veneer lumber, structural composite lumber amongst others. For instance, Cross Laminated Timber (CLT) was developed in Austria and Germany and has been predominantly used in Europe both in residential and non-residential building (Chen, 2010; Schmidt & Griffin, 2012; Mohammed *et al.,* 2015). The product has gained popularity in Europe as structural building element for multifamily high rise building up to eight floors with proposal underway for seventeen storied CLT made building (Gagnon & Pirvu, 2011).

The perceived weak fire resistance of wood structures is one of the limiting factors affecting its usage in building construction. Notably is the great Chicago fire of 1871 and the 1906 San Francisco earthquake in which large portion of the cities were wiped away by fire (Schmidt & Griffin, 2012). Gagnon & Pirvu (2011) asserted that Cross laminated timber CLT has been tested and proven to have a 0.67mm per min fire resistance. Another primary limitation in timber is the distance its able to span. Today, new engineered wood products (such as CLT) are used as a major structural material for taller and larger building types (See Fig. 1 & 2) even than what code currently permits.

Fig. 1: Seven-story CLT house tested at E-Defense Laboratory in Miki (Source; Mohammad et al., 2015)

Fig. 2: Eight-Story Building under Construction Protected with a Tent in Sweden (Source; Mohammad et al., 2015)

Acoustical performance of wood products is another challenge. However, with the introduction of wall covering, acoustical insulators and sleeper studs, the sound control is highly enhanced. Other important factors for the choice of a structural system include the construction costs, building codes, and seismic performance. FPInnovations (2011) comparative study on CLT's cost against other materials such as concrete, steel, masonry revealed that CLT has a quicker construction time and lesser foundation costs. The repetitive system and modular components are responsible for the shorten construction time and much less labour. Also, when compared with Post-tensioned concrete, CLT has a faster assembly time up to 50% lesser construction duration (Crespell & Gagnon 2010).

Concrete is a building material prepared out of cement together with other different cementatious materials, for example, fly ash, slag content, coarse aggregate (for the most part rock, limestone, or stone), fine aggregate (stream sand), water, and compound admixtures (Srinivasa *et al*., 2013). The discovery of concrete as a construction material remains a landmark innovation in the field of science and engineering. Although, Concrete is known for its low tensile, this actually limited its prior years of development. Today, the adaptability of concrete has extensively expanded (Zongjin, 2011). The introduction of steel reinforcement to solid mix makes up for the tractable tensile shortcoming of concrete. The consolidated blend of both cement and steel support is called reinforced concrete and is the second era of concrete after the unreinforced mass concrete. Thus, reinforced concrete is a man-made material gotten from the mixture of cement, aggregate (smooth and coarse) and water, more importantly the imbedded steel rods which boost its tensile strength.

Today, reinforced concrete stand out as the most essential material utilized as part of the structural elements in construction around the world. It is an excellent composite material gotten through the capacity of both concrete and steel to give correlative backing to one another, making up for the shortcomings in the properties of each material (Arya, 2009; Ede and Agbede, 2015). In another perspective, the excellent fire resistance performance of concrete is another property that has propelled its usage, concrete has the ability to restrict the spread of fire within a compartment as well as support the structure from failure despite exposure to serious fire. Srinivasa *et al.* (2006) studied of the impacts of raised temperatures from 500C to 2500C on the compressive quality of High Standard Concrete (HSC) made with both standard Ordinary Portland bond (OPC) and Portland pozzolana concrete (PPC). The report revealed that HSC made with Portland pozzolana cement performed better by holding the compressive strength contrast to Portland made concrete

Environmental/Sustainability potentials of Timber versus Concrete

The 1987 report of the World Commission on Environment heralded the popularized statement "Our Common Future'', in a quest for a possible solution to environmental challenges through the concept of sustainable development. Fundamentally, sustainable development signifies ''meeting the needs of the present without compromising the ability of the future generations to meet their own needs'' (WCED, 1987; Cunninghan, 1992; Gustavsson *et al*., 2005). It also means the consumption of resources available to the current generation without depriving the future generation of resources for their effective living. Sustainable building material is thus an important theme within this broad ideology of preventing our world from human activities that has detrimental impact on the environment.

Over several decades, concrete has become the most predominantly used building material, however recent inquires has made the integrity of the material to be subjected to further scrutiny. Findings revealed that cement manufacturing only is responsible for (5%) of annual anthropogenic CO2 production worldwide even as over 2 billion tone quantities is been produced annually (IPPC, 1996). On the contrary, forest products have potential of reducing

emissions as well as increase the absorption of carbon dioxide in the atmosphere and storing it. Wood products are natural, exceedingly renewable and lighter, could reduce discharge of greenhouse gas and ecologically preferred over CO2 concentrated materials such as concrete, aluminium or steel (Schlamadinger and Marland, 1996).The qualities of timber as a building material include availability, aesthetic qualities, constructability and adaptability, environmental sustainability, reusability, flexibility, waterless construction, and comparative cost effectiveness (Gregory, 1984; Whitelaw, 1990 and Nolan, 1994).

Global discuss on sustainability emphasizes the comparative analysis of building materials in terms of quality of CO2 released by the material into the atmosphere, absorption and storage of CO2, amount of fossil fuel required in the materials production, amount of fossil fuel released into atmosphere, thermal conductivity etc. Ferguson et al.,(1996) and John(2003) studies on environmental impact of common building material revealed that fossil fuel required to manufacture rough sawn timber is 750 MJ/m3, concrete uses 4800 MJ/ m3, steel uses 266000 MJ/m3, and aluminum make use of 1,100,000 MJ/m3 of fossil fuel. Obviously, timber uses lesser fossil fuel in production than concrete, steel or aluminum making it more environmental friendly than most other materials. Similarly of all the material mentioned above, only rough sawn timber stores carbon dioxide (up to 250kg/m^3), concrete, steel and aluminum cannot withhold any amount of CO2. Not only does timber stores the highest quantity, it also releases the least amount of CO2 during production. Rough sawn timber releases 30 Kg/t of carbon dioxide, while steel and aluminum release 700Kg/t, and 8700 Kg/t respectively (Ferguson *et al.*, 1996).

For thermal conductivity of building materials, timber possess better heat resistance when compared to concrete, wood conductivity rate is 0.05-0.0.15 J/m-Ik-I, concrete 1.4-2.9 J/m-IK-I and steel 19.0-21.0J/m-I k-I, whereas fired clay has 1.0 J/m-IK-I, limestone gravel 0.6 J/m-I k-I, cement board 0.6 J/m-Ik-I and stone 1.5- 3.0 J/m-IK-I (John, 2003). Obviously, timber buildings will need lesser artificial insulation inside to maintain the interior temperature. Chen (2010); Schmidt & Griffin (2012); Ede & Okundaye (2014) also asserted that timber is environmental friendly since it requires lowest embodied energy when compared to other building material such as concrete. Although, a great effort had been put into experimental research on building materials development, little effort has been directed towards public awareness on sustainability potentials of building materials. Often, information on new innovation as well as opportunities offered by new building products takes a longer period to reach building consultants and prospective clients. According to Ljungberg (2007) sustainability goals should not only consider the environmental aspects, economic impact and customer needs but also the market demands. In the quest for sustainability, effort should be directed towards public awareness of opportunities and environmental demerits of building materials so that prospective clients and consultants could make best choices for collective benefit of our environment.

Development and Usage of Timber and Concrete in Nigeria

Over the years, Nigerians have used sandcrete blocks and concrete in building construction more than any other building material. In Nigeria today, the escalating cost of cement, steels and other components of reinforced concrete has made housing affordability a serious challenge. Often, the quality of concrete is compromised in a bid to save construction cost which frequently results into incessant cases of building collapses (Ede & Okundaye, 2014). Adoption of concrete as a building material requires strict adherence to specifications especially in areas of properties prerequisite, sizes, proportion/ mixing ratio as well as quality control measures. As noted by Pansuk (2011), any deviation in the specification, for example, the aggregate size has a significant effect on the overall quality, durability and compressive

strength of the concrete. Exposure of concrete structure to excessive load also poses a threat to it.

Ede and Odunkaye (2014) noted that timber is abundantly available in Nigeria; notwithstanding, timber usage has been limited to few building components, temporary structure and construction of buildings in riverine areas. The Raw Materials Research and Development Council of Nigeria (RMRDC) (1998) asserted that workability and durability potentials of timber had made it the mostly used material for roof carcass and ceiling noggins. Also a yellowish hardwood known as Opepe (*Nauclea diderrichii*) is also commonly used in doors and windows due to its hardness and ability to resist insect attacks. Adesogun (2013) opined that housing shortage and urban challenges associate with building affordability could be solved with the construction of wood based structures since the product is readily available in Nigeria. With the advancement in timber production and widely proponents for timber based structure, it is important to know the level of usage, availability and perception of citizenry about these two mostly used building materials in Nigeria. The details of the empirical research are therefore enumerated in the next sections of this research paper.

RESEARCH METHODOLOGY

Study area

The study was conducted in Ibadan, Nigeria. Ibadan is the capital of Oyo state in southwest Nigeria. The city lies approximately between latitude $7^{o}23'$ to $7^{o}55'$ North of the Equator and longitude $3^{o}5'$ to $4^{o}36'$East of the Greenwich Meridian at 145 km north of Lagos. Ibadan has Eleven (11) local government areas out of which Oluyole local government area was selected for this study since its one of the most populated and urbanized area within the state. Oluyole local government area covers an area of 629km2 with a population of 202, 726 by 2006 census (NPC, 2006). Three residential neighbourhoods namely; Ashipa/ Olosan Area, New-garage Area and Podo Area were selected within the local government area because these areas were newly developed with most buildings recently completed. Hence, most participants of this survey have the latest opinion on building materials quality.

Instrument

The research approach involves a cross-sectional survey through quantitative research targeted at examining the level of availability, usage and perceived quality of concrete and timber in building construction in Nigeria. Questionnaires administration was used as a data collection instrument. The questionnaire has three sections: Section A contains the general information about the respondents, while Section B draws the information on availability and level of material usage in building parts. Section C draws the respondent's perception of the qualities of these two materials in terms of cost, maintenance, environmental impact, fire resistance, thermal comfort, acoustics, reusable potentials, aesthetic and strength/durability. The instrument measured the availability of material on a Five-point-Likert type scale of; Strongly agreed- 5, Agreed- 4, Neutral - 3, Disagreed - 2, and Strongly disagreed – 1 whereas Two-point scale; Timber- 2 and Concrete-1 was used to determine adoption of the materials in buildings as well as the comparatively measure the respondent's perceived sustainability qualities. The research data were collected between October and November 2015 through the assistant of students on industrial training that administered, collected and collated the questionnaires.

Sample size

The targeted populations are the building owners of the residential neighbourhood. Building owners were selected as participant for this study since they have a predominant influence on building material choices especially for residential building projects in Nigeria. According to Glavic & Lukman (2007), for a product to be sustainable, it must be affirmed to be socially

and innovatively rewarding for all stakeholders both on short and long term bases. Previous study by Castro-Lacouture *et al.* (2009) considered market preference using customer's perception instrument on sustainable products to assess customer's attitude. Hence, building owners were judged to be suitable for this study since they satisfied the conditions to be classified as stakeholders as well as customers for sustainable building materials. Samples of 120 households were drawn from 1200 residential buildings identified within the study area. A systematic sampling method was adopted by randomly selecting 1 out of every 10 buildings. A total of One hundred and twenty questionnaires were administered within the study area with 40 questionnaires been administered at each of the three selected areas. Of all questionnaires administered, a total of ninety six (96) sets of questionnaires were retrieved from the three areas which represent 80% of total questionnaires administered. In all, thirty three (33) questionnaires were returned from Ashipa area, thirty one (31) from Podo area while thirty two (32) questionnaires were returned from New-garage area.

Data Analysis

The data extract from the survey were analysis through Statistical package for Social science (SPSS 17.0). Descriptive statistics were presented with frequency distribution charts while analysis of variance (ANOVA) was used to test the hypothesis.

RESULTS AND DISCUSSIONS

Socio- Economic Characteristics of Respondents

Table 1: Analysis of Socio-Economic Characteristics of Respondents

Social-Economic characteristics	No of respondents	Percentage (%)
Age of Respondents		
18-30 YEARS	11	11.5
31-45 YEARS	20	20.8
45-60 YEARS	37	38.5
61 AND ABOVE	28	29.2
Sex		
Male	56	58.3
Female	40	41.6
Educational Status		
No Formal education	12	12.5
Primary Education	18	18.8
Secondary Education	37	38.5
Tertiary education	29	30.2
Employment Status		
Retired	9	9.4
public sector workers	24	25.0
private sector workers	48	50.0
Unemployed	15	15.6
Average Monthly Income		
below #38,000(lower income)	18	18.7
#38,000-#144,999 (middle income)	48	50.0
145,000 and above (high income)	38	39.6
Age of Buildings		
1-5 years	12	12.5
6-10 years	43	44.8
11-20 years	24	25.0
Above 20 years	17	17.7

Source: Author's Fieldwork, 2015

Table 1 above shows the socio-economic characteristics of the respondents. 11.5% of the respondents have their ages ranging between 18-30years, 20.8% are between 31-45 years of age, 38.5% (45-60 years) while 29.2% are 61 years and above. Evidently a significant number of the respondents are above 45 years old. Also, the table revealed that 58.4% of the

respondents are male, whereas 41.6% are female. On educational status, the highest percentage of the respondents have up to secondary education, this represents 38.5% even as 30.2% and 18.7% have their education up to tertiary and primary school level respectively. However, 12.5% have no formal education. Since a good number of the respondents have formal education, it was easier for them to understand the sustainability qualities in the products under study and respond to the questionnaires effectively, hence the result of this research are highly reliable.

The table also shows the employment status of the respondents with 50.0% been private sector workers (such as traders, artisans or private sectors employees), the public sector workers are 25.0%, unemployed 15.6% and retired are 9.4% of respondents. Furthermore, most of the respondents are middle income earners representing 50.0% of the respondents, followed by high income earners who are 39.6% while low income earners are 18.7% of the respondents. The age of the buildings of respondents differs as follows; 12.5% of the buildings were constructed in the last 5 years, 44.8% within the last 6-10 years, 25.0% (11-20 years) and 17.7% were above 20 years. This indicates that the higher percentage of the respondents have their buildings constructed within the last 10 years, apparently, most of the building are relatively new. Thus, this empirical survey represents a relatively current insight on this study's objectives.

Adoption on Timber and Concrete in Building Parts

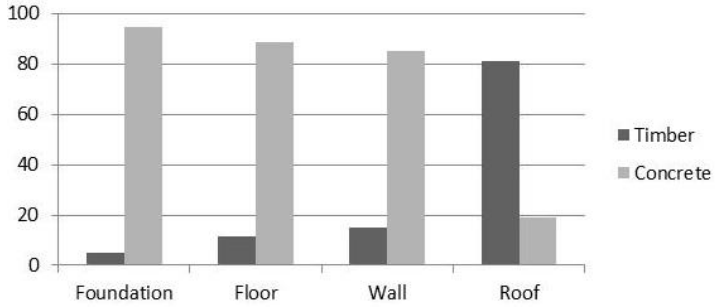

Figure 1: Analysis of level of adoption of timber and concrete

Figure 1 above shows the part of the building where timber or concrete is mostly used. The result indicates that 1.8% of the respondents used timber for their building foundation, whereas 98.2% used concrete for their foundation. For the floor, 11.5% used timber while 88.5% used Concrete. Also, 15.0% of the respondents used timber as their walling material, while 85.0% used concrete/sandcrete blocks for their walls. The roofing elements differ as follows; 81.2% used timber for their roof even as 18.8% have concrete slab on their roof. The above analysis revealed that timber is mostly used for roof carcass in the study area, whereas concrete is predominantly used for the foundation, floor slab and walls. This supports the report of the Raw Materials Research and Development Council of Nigeria, RMRDC, (1998) that timber is mostly used material for roof carcass and ceiling noggins in Nigeria.

Availability of Concrete and Timber in Respondent's Area

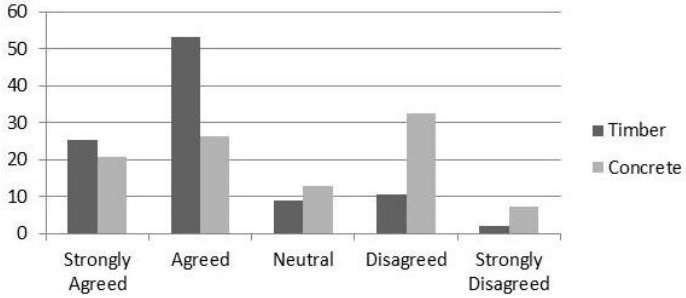

Figure 2: Availability of Concrete and Timber Material

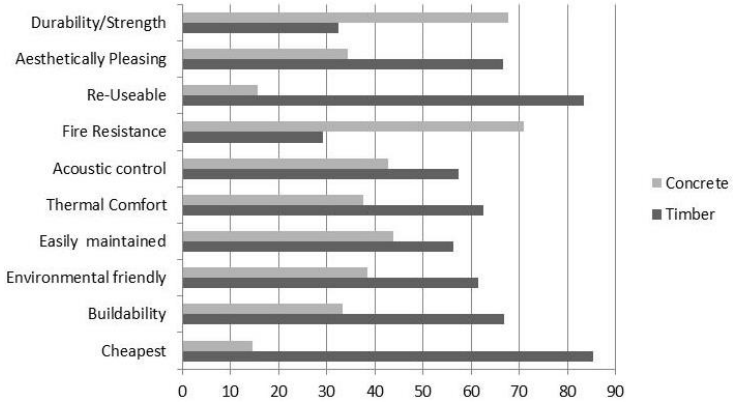
The result shown in Figure 2 above reveals that 25.2% strongly agreed that timber is readily available, 53.2% also agreed that the material is sufficiently available, 9% were neutral, 10.5% disagreed that timber is sufficiently available in addition to 2.1% who strongly disagreed. This result affirmed the position of Adesogun (2013) that timber is abundantly available in south-western part of the Nigeria. As for availability of concrete, 20.9% of the respondents strongly agreed that concrete is sufficiently available, 26.2% agreed whereas 13% were neutral. On a contrary, 32.5% disagreed that concrete is readily available in their locality at the same time 7.4% strongly disagreed that concrete is sufficiently available.

Comparative analysis of perception on Qualities and Sustainability potentials of Concrete and Timber

Figure 3: Comparing Perceived Qualities and sustainability potentials of Concrete and Timber



The respondents were asked to compare timber and concrete by indicating which of the two materials is the cheapest, easier to construct, most environmental friendly etc. based on their opinion. The chart above (Fig 3) show the respondent's assessment as follows; comparing the affordability of timber and concrete, the analysis shows that 85.4% opined that timber is cheaper than concrete while 14.6% believed that concrete is cheaper. As regarding buildability, 66.7% viewed timber as a material that requires lesser time to construct whereas 33.4% stated that concrete structure is easier to construct. The respondents were also asked to choose the most environmental friendly material out of timber and concrete, the result shows that 61.5% indicated that timber is most environmentally friendly while others (38.5%) choose concrete as a more environmentally friendly material. Hence, we can deduce that most people are aware that timber offers better environmental conditions and sustainable characteristics.

Ease of maintenance was also examined with the result showing that 56.2% perceived timber to be easier to maintain, whereas 43.8% opined that concrete is easier to maintain. The thermal comfort quality assessment shows 62.5% in favour of timber and 37.5% for concrete. The respondents also assessed the material based on their knowledge of its acoustic quality with 57.3% indicating that timber controls sound better whereas 42.7% opined that concrete has better acoustic quality than timber.

The fire resistance quality of these materials were also assessed and the respondents differs as follows; 29.3% opined that timber has high fire resistance quality while 70.8% indicated that concrete resist fire better than timber. Comparing the aesthetic and visual quality of the two materials, the outcome shows that 66.6% agreed that timber is more aesthetically pleasing, whereas 34.4% indicated that concrete-based buildings are more aesthetically pleasing. The analysis also revealed that 32.3% of the respondents believed that timber is more durable while 67.7% opined that concrete has more strength and durability potential than timber. The analysis above reveals that most people are aware of qualities of timber as a building

material, notwithstanding the perceived poor fire resistance quality and durability have been the duo hindrance affecting its usage. This validates the opinion of Ede *el at*. (2014) that in developing nations, timber is yet to attain its full potentials in building construction due to doubtful good structural quality among the people. Inadequate technology and skill has primarily hindered timber from realizing its full potentials in areas of durability and reliability in developing countries (Kohler, 2007; Ede *et al.*, 2014) whereas an appreciable knowledge and awareness has enhanced development of timber-based structures in developed countries (Fewell, 1997). Consequently, if the latest technological advancement is appropriately harnessed; the material could be better adopted as commonly used building material in Nigeria. It is therefore imperative that technology be deplored towards better processing and improved quality of timber products.

Perception of sustainability qualities of timber and concrete across the three selected areas

A one-way analysis of variance was applied to mean scores on perceived sustainability potentials across the three study areas. Hypotheses were tested at 0.05 level of significance (i.e. Significant if P< 0.05). The table 2 (See appendix) shows the significance values of 0.833, 0.179, 0.700, 0.547, 0.503, 0.379, 0.059, 0.574, 0.766 and 0.144 for the perception of durability/strength, aesthetics, re-usability, fire resistance, acoustic control, thermal comfort, ease of maintenance, environmental friendliness, ease of construction and affordability respectively across the three study areas. This result revealed that significance values for all the variables are higher than 0.05 significant levels implying that there are no significant difference in the means of perceived qualities of these materials (i.e. all P >0.05). Hence, we can accept the null hypothesis that building owners will not differ significantly on their perception of sustainability qualities of timber versus concrete in the study area.

CONCLUSION AND RECOMMENDATIONS

Recent global concern for reduction of CO2 and other greenhouse gases requires a thorough study into sustainability potentials of the building materials. Building materials, construction processes and building operations have an impact on the quality of life. In this study, building owner's perception on sustainability potentials of timber and concrete is explicitly compared. The study reveals that timber is perceived to offer more sustainability potentials than concrete. Timber is thus recommended as an alternative material in place concrete due to its sustainability quality, flexibility, affordability, visual quality amongst others. This paper urges that timber processing and products should be developed in Nigeria through a collaborative effort of public and private sectors. The country could also take some lessons from developed nations on application of Cross Laminated Timber especially for multi-storey residential apartments. In the quest for a better environment, effort should be directed towards developing sustainable building materials while complimentary effort should also be geared towards public orientation on sustainability qualities of building materials both for the consultants and prospective clients. Mass production of timber will immensely boost up the level of housing affordability, job generation and ultimately improve environmental sustainability.

Why Sustainable Infrastructure Development and Provision Continues to Defy Africa

Ebohon, Obas John

Developing World Built & Natural Environment Research Unit, Leicester School of Architecture, De Montfort University, Leicester, UK
**ebohon@dmu.ac.uk*

ABSTRACT

Sustainability is used here in the original deployment of the word in development literature to denote infrastructure projects that outlast multilateral and unilateral financial and technical assistance. Such infrastructure projects have some unique inbuilt characteristics that reflect the inputs and needs of intended beneficiaries, and for which they would have both financial and technical capacities to sustain. In the latter use of the concept of sustainability, environmental consideration is deeply emphasised, underscoring the apparent contradictions inherent in infrastructure development. If the purpose of infrastructure is to spur growth and development, which are deemed necessary to facilitate and enhance better standards of living, it must be achieved in manners that satisfy the needs of current generations without having to compromise the ability of future generations to fulfil their own needs. The capacity to develop infrastructure in sufficient quantity and quality, and with the speed necessary to deliver them, cannot be taken for granted in Africa, particularly sub-Saharan Africa compared to other regions of the world. This is exemplified, not only by the dearth of growth inducing and life enhancing infrastructure and services, but also, by the inability to maintain and replicate infrastructure and services to areas of dis-amenities. If Africa is to challenge the ever increasing poverty and inter and intra-regional growth inequalities, not only must infrastructure be adequate both in quantity and quality, the necessary delivery and maintenance capabilities must also exist. The literature is replete with debates about the factors constituting a bottleneck to Africa's capacity for sustainable infrastructure development and delivery, spanning technological, institutional, and human and financial capital constraints. The main aim of this papers is to critically evaluate these challenges and determine on the one hand, the extent to which these challenges still hold in the 21st century globalised economy, on the other, derive affective strategies for sustainable infrastructure development, particularly in sub-Saharan Africa. Fulfilling these aims requires a brief general overvif the role of infrastructure in economic development, a critical evaluation of the current state of infrastructure in Africa, particularly the capacity to develop and deliver to the quantity and quality required, leading to mapping a research informed road map for the development and delivery of sustainable infrastructure in sub-Saharan Africa.

Keywords: Sustainability, Infrastructure, Development, Delivery, Africa, Sub-Saharan African

INTRODUCTION

Infrastructure is a nebulous term and variously defined but a common thread running through the various definitions confirms that it consists of physical structures, facilities, and networks that facilitates essential services for society (Chambers, 2007). This definition recognises the shift from the physical, hard, or tangible meanings and understandings of infrastructure to the concepts of soft or intangible infrastructure (Button, 2002; UN-Habitat, 2011). Often when infrastructure was discussed in the past, it was always in respect of tangible assets such as roads, sea ports, airports, railways, water distribution and sanitation systems, electricity, and telecommunications.

Intangible or soft infrastructure on the other hand is exemplified by effective and enabling environments, and underpinned by effective policy and regulatory frameworks - governance mechanisms; systems and procedure; social networks; and transparency and accountability of procurement systems (UN-Habitat, 2011). Although this latter understanding and definition of infrastructure is a welcome development, ***it is nevertheless an enduring fact that capacity defines infrastructure development and provision***. In the wake of numerous failed

Ebohon, O. J. (2016). Why Sustainable Infrastructure Development and Provision Continues to Defy Africa. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 472-482

development projects in the 1970s and early 1980s, where projects often seize to function beyond multilateral and unilateral technical and financial assistance, it was decided that only sustainable projects, meaning projects with the capacity to outlast technical and financial aid will from henceforth be the focus of international development assistance. Fused with the current understanding of the concept of sustainable development, and the role that infrastructure have come to play in explaining possible causes and solutions to global environmental sustainability; it assumed further significance in the global pursuit for sustainable growth and development.

Thus, the broader definition and understanding of infrastructure indicates that tangible or hard infrastructure does not occur in a vacuum of functional systems and institutions; open and transparent governance processes; and a deep knowledge-base (UN-Habitat, 2011). In other words, soft infrastructure constitutes a major building block, not only for new infrastructure to meet new demands but also to maintain existing stocks of infrastructure capital. For example, project preparation, procurement policies and strategies, stakeholder engagement policies and processes, and administrative and operating procedures are all critical factors in infrastructure development and supply. Unfortunately, these aspects of infrastructure development and provision are often taken for granted in most developing economies, particularly Africa (UN-Habitat, 2011; Opong, 2014).

Where these key prerequisites are absent, as they most are in Africa, it comes as little surprise why most efforts devoted to infrastructure development and delivery produce little results. As a result, managing the rapidly unfolding globalisation process to its advantage, and competitively engaging with the rest of the world has become major challenges to Africa. All available evidences show that countries with effective and functional are those able to generate and sustain growth and development, allowing employment and income generating opportunities to be sustained. Infrastructure in sufficient quantity and quality affords the mechanism for deepening socio-economic policies aimed at addressing social problems of poverty and inequality.

Despite the inexorable link between infrastructure and socio-economic development, Africa remains one continent that is continually faced with formidable challenges to meet its infrastructure needs. Several factors have been advanced, over the years, as possible explanations for Africa's inability to fulfil its infrastructure needs. The task of this paper is to critically evaluate the nature of the challenges to sustainable infrastructure development and delivery, determine the extent to which they still hold true in the 21st century global economy, and suggest possible way forward for Africa's infrastructure development. To achieve these aims, a general overview of how infrastructure contributes to economic development is revisited. This is followed by a critical evaluation of the current state of infrastructure in Africa, allowing the nature and enormity of infrastructure challenges to be gauged. Finally, and in relations to the understanding of these challenges, possible measures to arrest infrastructure gaps in the region are discussed.

Sustainable Infrastructure and Economic Development

Infrastructure and socio-economic development are inextricably linked (World Bank, 1994; Aschauer, 1989; Foster and Briceno-Garmendia, 2010; Devarajan, 2010; UN-Habitat, 2011). Adequate and efficient infrastructure is widely considered a necessary prerequisite for economic growth, and apart from providing the underlying foundation for economic growth and development (Sanchez-Robles, 1998; Roller and Waverman, 2001; Calderon and Chong, 2004), it deepens the impact of macroeconomic policies, particularly measures aimed at alleviating poverty and bridging national, regional, and global inequality (Pouliquen, 2000). Core infrastructure such as water and sanitation systems, energy, transportation, and

information and communications technology influence economic growth and development through their impacts on output and productivity (Aschauer, 1998). Some of these impacts are felt through reductions in production and distribution costs, and these are critical to competitiveness. Effective and competitive transport and communication infrastructure facilitate movements of goods and people to markets quickly and cheaply, and in the particular case of perishable produce, it is crucial to output expansion decisions. The benefits to consumers, particularly in developing economies characterized by poverty and growing inequality are enormous. Some of these benefits manifest in lower consumer prices and huge varieties of goods and services, facilitating affordability and choice.

Other areas where infrastructure contributes to economic development is inward investments; business location decisions are decidedly influenced by availability of effective and functional infrastructure and services (Fay and Morrison, 2005; Seethepalli, et. al., 2008). Health infrastructure and services also contribute to economic growth and development variously, not least in ensuring healthy population and workforce, which is relevant to productivity. As aptly demonstrated in the case of Ebola outbreak in West-Africa, the ability of Nigeria to contain the disease quickly, and the inability to do so in Liberia and Sierra Leone owed to relative differences in tangible and intangible health infrastructure. Similarly, the impact of infrastructure on quality of life is well documented, not only does it facilitate meaningful engagement with public spaces, but also facilitate recreation activities, and in the process, helps in promoting and enhancing healthy living and quality of live. This is particularly relevant to bridging spatial inequality and containing urban sprawl, which are largely defined by absence of basic infrastructure and services in such areas of dis-amenities (Grant, 2010). Generally, infrastructure is widely considered a necessary prerequisite to sustainable growth and development.

State of Infrastructure and Attendant Consequences for Development in Africa

Despite the well documented relevance of infrastructure to sustainable growth and development, Africa lags seriously behind other regions of the world in infrastructure development and supply, and this is evidenced by the huge divergence between demand and supply of infrastructure and services (UN, 2011). Of all the infrastructure problems facing Africa, the energy sector is the most severe, particularly electricity. A critical look at sub-Saharan Africa, where Africa's energy problems are most pronounced reveals chronic supply shortages. The enormous size of Africa is illustrated by Figure 1; although larger than the United States, Japan, China, and most of Europe combined, it accounts for only 4% of global electricity generation, and only able to manage 43 percent household electrification rate. This implies that more than 600 million African have no access to electricity (Foster and Briceno-Garmendia, 2010).

ICA further reveals total current power generating capacity for the whole of sub-Saharan to be 68 gigawatts. Of this, 25 percent is out of reach (Foster and Briceno-Garmendia. 2010). Figure 2 compares sub-Saharan Africa's power generating capacity with other developing regions of the world, and the result shows it presides over huge capacity underutilization. As Table 3 further reveals, sub-Saharan's per capita electricity consumption is peaked at 124 kilowatt-hours per year, and declining rapidly. This compares unfavorably with countries Qatar, USA, Thailand, and India. The consequences continues to manifest low productivity and output, with estimates as high as 40 percent and 2 percent lose in productivity and output respectively for the region.

Figure 1 Africa in Global Perspective
Source: http://www.reddit.com/r/gadgets/comments/30e8fg/facebooks_drone_prototype_has_wingspan_greater/

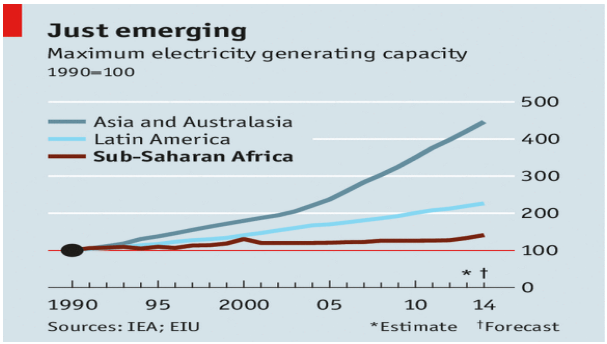

Figure 2 Electricity Generating Capacity for Selected Regions of the World

While other factors are involved, inadequate power supply remains owe to chronic lack of investments and neglect. Given current trends in the power sector, it is forecast that 40 percent of sub-Saharan African countries will still be unable to adequately access electricity by 2050.

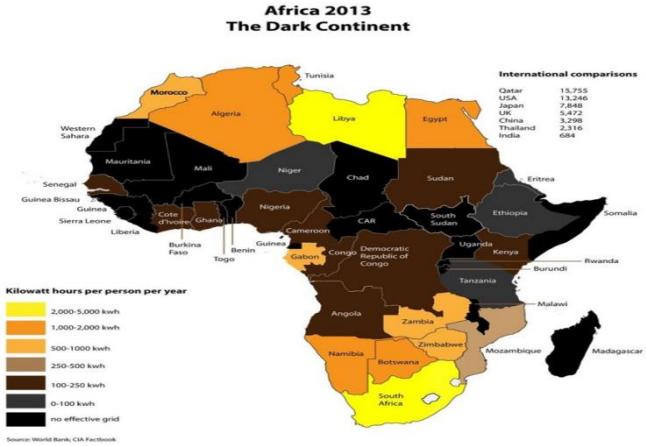

Figure 3

The situation is exactly the same in other areas of energy such as petrol, kerosene, and natural gas where women and children travel long distances searching for energy. Other key economic infrastructure and services are similarly underdeveloped and underperforming. While progress is being made in some sectors such as telecommunication, it is rather very slow. Road and other transport infrastructure is far below the quantity and quality required to propel growth and development. Not only is 53 percent of all roads in Africa unpaved, all-season access roads are available to less than half of the population. This has huge implications for the agricultural sector, which is the mainstay of the economy of the region in

terms of employment and income generating opportunities in terms of expansion and modernization of such an important economic sector.

Another area where inadequate transport infrastructure is mostly felt is road congestion, and this owes to the fact that transport infrastructure has failed to keep pace with the rate of urban expansion. Road congestion is pronounced in most African cities, and restricts efficiency in movements of goods and people, imposing costs and rendering businesses uncompetitive (Kumar and Barrett, 2008). For example, transport congestion on the N1 Freeway between Johannesburg and Pretoria in South Africa costs US$35 million annually (Guatrain, 2012), this can be higher, as is the case with St. Louis in Mauritius where the cost of congestion amounts to 1.3 percent of annual GDP (Curnow and Kermeliotis, 2012). Given the woeful state of Africa's rail infrastructure, road congestion and associated impacts on the economy and the people of the region will remain, unless urgent actions are taken to address the perennial problem.

Water and sanitation infrastructure is another source of constraints on Africa's development; it is estimated that more than 40 billion work hours are forfeited each year in Africa, being productive hours devoted to fetching water (ICA, nd). While the impact is mostly felt by the weak and vulnerable, these being women and children, the more punitive and enduring social costs of forfeited education and life improving opportunities are often ignored. The cost of inadequate water and sanitation infrastructure to Africa is estimated at 5 percent of GDP equivalent (ICA, nd). As Figure 4 shows indicates, it is difficult for sustainable growth to be achieved without adequate water and sanitation infrastructure, particularly in sub-Saharan Africa where 43 out of 48 countries are water stressed.

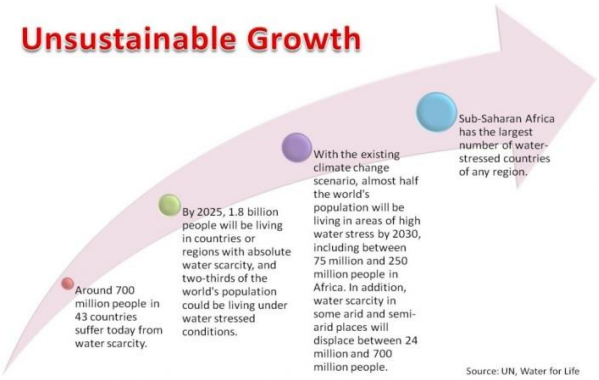

Figure 4

Generally, Africa is seriously challenged in all areas of infrastructure development and provision, severely limiting its capacity to realise the soon to be replaced Millennium Development Goal (MDGs). As Table 1 indicates, infrastructure features prominently in all the target indicators that are necessary to the improvement and reposition of Africa's economy towards sustainable growth and development.

Source: Willoughby (2004), as cited in UN-Habitat (2011)

The urgency with which Africa needs to address its infrastructure challenges is driven by many factors, not least rapid population growth, urbanisation, inequality, growing unemployment, climate change, and enduring and deepening poverty. The demographic transition of the 20th century witnessed for the first time, urban population living in cities bridged the 50 percent mark. By 2050, more than 90 percent of the global population will be living in cities, given that OECD and Latin American countries have attained this level of urbanization, Asia and Africa, particularly sub-Saharan Africa, as Figure 5 shows, is where this phenomenal transition is widely expected.

Given the facts steering Africa directly in the eye, the need for sustainable infrastructure development and provisions has never been greater and more urgent for many critical and complex interrelated reasons (UN-Habitat, 2011; Estache and Wodon, 2010). Firstly, globalization has drastically reduced the world into a global village where events occurring anywhere in the world are relayed in real time for global consumption. This has galvanizing effects on the hopes and aspirations of young people around the world, upon these hopes and aspirations are the economic and prosperity of nations built. Closely related to this is the scenario where young people in the developing countries are educated and equipped with skills and knowledge for economic prosperity yet no supporting infrastructure offered to anchor their experience of economic prosperity and development. The combination of these factors continues to precipitate brain drain in Africa, sapping it of the very foundation upon which to build current and future prosperity. As this analysis indicates, time is not on the side of Africa, it must seriously address its chronic and endemic infrastructure problems.

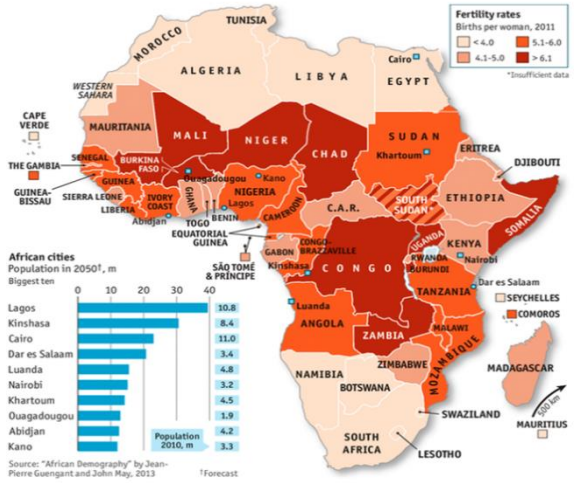

Figure 5

However, Africa is confronted with several constraints, and addressing them requires a clearer understanding their nature, particularly within the context of the rapidly globalising 21st century world economy. It is necessary to unpack the domestic and global dimensions to Africa's infrastructure challenges primarily to inform appropriate and strategic policy response. Otherwise, the capacity to develop, sustains, and deliver infrastructure and services for effective development will continue to defy Africa.

Challenges to Infrastructure Development and Supply in Sub-Saharan Africa

The nature of Africa's infrastructure problems itself is a major challenge. Not only is the dearth of new investments to satisfy growing demand a debilitating constraint, the inability to rehabilitate, upgrade and modernise existing infrastructure services continues to exacerbate the problems. The reason for this is easily articulated; new infrastructure services become prohibitively expensive owing to the dysfunctionality of existing ones. The financial challenge is therefore overwhelming, particularly given the narrow capital base and the

mono-cultural structure of most African economies, government revenue has been dwindling rapidly.

While various annual estimates of investment expenditure Africa requires to bridge its huge infrastructure gaps is estimated at between US$31 to US$91 billion dollars (UN-Habitat, 2011; Konnidaris and Allenstown, 2011), spending estimates in both public and private sectors fall drastically short of actual spending needs across all key infrastructure sectors. Figure 6 shows the huge gaps in infrastructure funding, and most pronounced in the power and water and sanitation sectors.

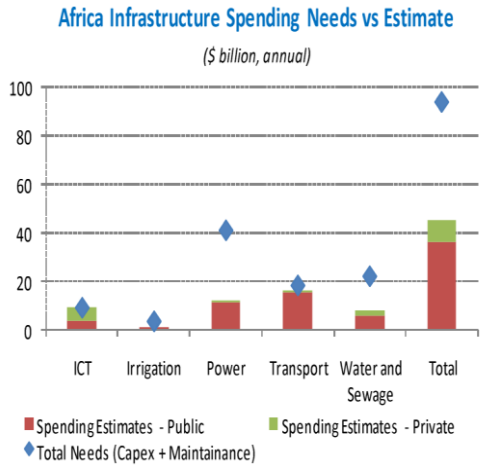

Figure 6

Source: *Africa's Infrastructure: A Time for Transformation, World Bank*

These gaps persist despite the actions by multilateral and unilateral organizations to complement the investment efforts of African governments. Figure 7 clearly shows the various bodies currently participating in Africa's infrastructure delivery, and it is against this background of insufficient investment funds that private capital is being openly canvassed to compliment efforts of governments and funding agencies. This is seen as a realistic proposition for delivery sustainable infrastructure to Africa. The much favored source of private capital remains pension funds and private equity participation in infrastructure development and delivery, with the delivery vehicle being Public Private Partnerships (PPI).

As with other initiatives aimed at mediating Africa's problems, the developed countries are again looked upon to leverage the investments necessary for infrastructure development. A critical look at this strategy reveals, as with many of its predecessors, a series of shortcomings. Firstly, evidence abound that continuing dependence on the developed economies for financial and technical assistance is unsustainable both in the medium and long-term. Secondly, there are grounds to doubt whether the infrastructure types needed in sub-Saharan Africa will attract equity participation from the developed economies. It is on these two grounds that leads to the conclusion that the real issues with Africa's seeming inability to develop the capacity for new infrastructure investments, and the inability to ensure effective and efficient maintenance of existing stocks, has been posed. The important questions to come are whether sub-Saharan Africa's incapacity to produce and deliver sustainable infrastructure are symptoms of intrinsic structural problems whose solutions must precede other forms of interventions.

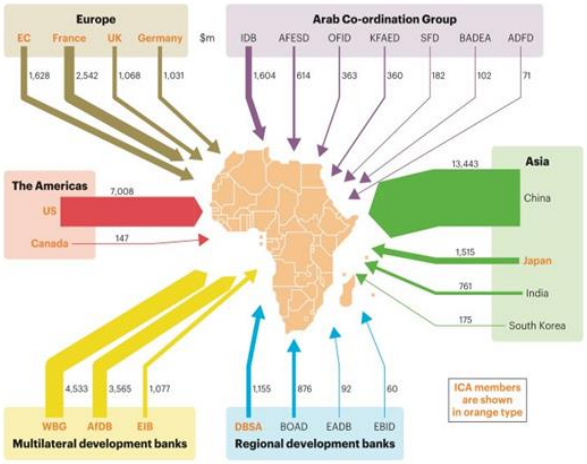

Figure 7
Source: ICA (n.d)

Why are individual countries, trade blocks, and other funding bodies in Figure 7 able to offer development assistance of all types to Africa, and for how long can Africa continue with the '***beggar thy neighbour policies***' state of affairs?

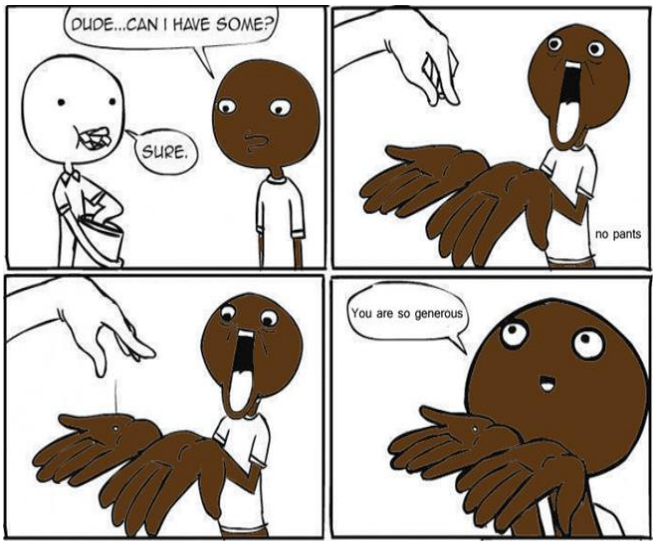

Figure 8 Dependencies on Foreign Aid

For example, does Africa have the management capacity and technical skills in the quantity and quality required to facilitate infrastructure development and delivery, especially given the complexities visiting new emerging procurement arrangements such as the Public-Private Partnership (PPP) strategy?

Is Africa really financially poor, as we are made to believe, or is it the case of lacking appropriate administrative capacity and legal framework, or indeed, the lack of political will to use available institutions and framework to effect sustainable infrastructure delivery and supply? A critical look at Africa's financial sector, what one is confronted with is an underdeveloped financial sector with extremely limited capacity to go beyond offering more than basic banking services. Secondly, effective administrative capacity to allow expansion and diversification of the financial sector, block pervasive leakages, enhance policy formulation and implementation, is what Africa needs to meet its infrastructure financial commitments. For example, the annual capital flight from Africa hovers around US$1.26 – US$ 1.44 trillion dollars a year, and various means are used to facilitate such flows, ranging

from under-pricing of raw materials by extractive multinationals for the purpose of tax avoidance and evasion (Syd, 2011).

While pension fund is the most appropriate source of infrastructure financing, owing to the long term view of investment often adopted, Africa's pension industry is rudimentary and undeveloped. In North America and Europe more than 90 percent of the population are covered by pension fund, in sub-Saharan Africa, only between 5-10 percent of the population are covered by pension funds. For example, while pension funds are the equivalent of 5% of GDP in Nigeria, this compares unfavourable to the UK, Netherlands, and America where pension funds are the equivalent of 131 percent, 170 percent, and 113 percent of GDP respectively. This simply show huge scope for growth, and apart from South Africa, countries such as Namibia and Botswana have US$10 billion and US6 billion in pension funds respectively, representing 80 percent and 42 percent of GDP respectively.

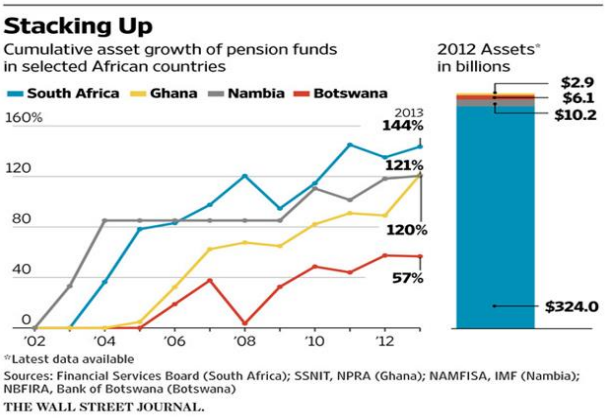

Figure 9 Performances of Pension Funds in Africa

Indeed, it is forecast that sub-Saharan African pension funds will increase to US622 billion by 2020 in assets, and this is expected to grow to US$7.3 trillion by 2050. However, it is important to stress that the criteria used by external fund managers are not essentially different from those used by local fund managers who are equally seeking to maximise returns on clients' investments. In these regards, Africa must overcome several critical challenges, the most critical of them all, is how Africa can enhance its macroeconomic and institutional environments to support infrastructure development and delivery (Estache, 2006). Until this is given the desired consideration, the Africa's capacity to absorb the huge indivisible capital requirements for infrastructure development and delivery will remain the concerns of multilateral, unilateral, and local stakeholders in infrastructure development and delivery (Esteche, 2006; Ebohon and Rwelamila, 2000; Ebohon, 2002).

This presents Africa with a huge dilemma, which is that Africa must first endow itself with basic physical infrastructure and effective institutional arrangements to reassure local and international stakeholders that it possess the essential capacity to absorb the huge and indivisible capital required to transform Africa's infrastructure landscape (Esteche, 2006; Lumbila, 2005). As already indicated, effective institutions and institutional building capacity constitute the soft infrastructure and services that are currently the missing links in Africa' infrastructure development.

Roadmap for Africa's Infrastructure Development

Africa must see multilateral and unilateral infrastructure financial and technical assistance as complementary to concerted local efforts. These efforts must be drilled in effective policy formulation and implementation strategies specifically devised for infrastructure development and delivery. In the 21st century, there are no reasons why effective infrastructure

development and delivery strategies should defy Africa; huge scope exists for adopting and adapting tried and tested policies from successful nations and regions of the world.

Supra-national approach to infrastructure development is an option Africa must seriously consider, this owe to the narrow capital base from which most African economies operate. Additionally, the huge and indivisible capital requirements for infrastructure development and delivery can overwhelm nation states, this is one area where the role of the private sector can be crucial to Africa's infrastructure development. Evidence of this is emerging, though early days yet, giant African companies capable of operating across Africa are being established; the Dangote Cement, MTN mobile communications, ABSA Bank are cases in point.

The need to bring the financial and educational institutions closer to the real economy is overwhelming, and critical to infrastructure capacity building in Africa. Floating long-term infrastructure bonds is one of the many ways attracting local investments to the infrastructure sector, but this will need to be complemented with appropriate policy measures not just to allow user charges but the upward revisions of such charges when there is economic case for doing so. External borrowings and over-reliance on expatriates, particularly in areas of project development and management often attract huge costs to render most capital projects economically unsustainable. Developing regional capacity in infrastructure development and management skills is key to instituting and implementing the necessary reforms to drive infrastructure development in the region.

Similarly, the culture of maintenance must be embraced in Africa, the capacity to maintain existing infrastructure is arguably more important than developing the capacity for new infrastructure and services. The reason for this is clearly evident in the role absorptive capacity plays in facilitating local and international investments. Developing economies with efficient and functional infrastructure and services attract lower risks premium, and likely investment destinations for local and international investors, as this is seen as a demonstration of the absorptive capacity of these economies. Inadequate roads, traffic and ports congestions, poor power are typical manifestations of lack of the necessary absorptive capacity to turn new capital inflow into sustainable infrastructure investments.

Finally, Africa must take steps to depoliticise infrastructure development and provisions, and the need for urgent actions on this front cannot be overemphasised, as it constitutes one of the most formidable bottle-neck to infrastructure development and delivery. Africa is awash with failed and dysfunctional infrastructure that have been procured as a political necessity and thereby wrongly located where they are likely to have the least impact on growth and development. Dams are built on seasonal rivers that should never have been the case but for political necessity, and so are roads constructed where they have minimal effects for political reasons. The paucity of resources available for infrastructure development on the continent is a clear evidence that this practice is unsustainable. If Africa is serious about developing and delivering effective infrastructure capable to reducing its infrastructure gap with the rest of the world, the sector must stop to being the conduit for rent seeking behaviour. The practice of inflating contract prices, outright diversion of infrastructure budgeted sums, awards of infrastructure contracts to none construction industry professionals must seize. This practices have been used to deny Africa the infrastructure it needs for effective and sustainable growth and development.

CONCLUSIONS

To effectively address the growing poverty and inter and intra-regional growth inequalities, Africa must address its infrastructure deficits. Several challenges and constraints have been

identified, and most prominent amongst these are financial and institutional constraints, which must be addressed in order to build the necessary capacity for effective infrastructure delivery. The continuing reliance on multilateral and unilateral institutions for infrastructure provisions and delivery is no longer sustainable; Africa must build its own capacity. However, this requires putting the necessary institutional arrangements in place. In the experiences of other regions with sufficient and functional infrastructure and services, institutional arrangements constitute the soft infrastructure that is the necessary prerequisites to physical infrastructure development and delivery.

Similarly, the need to broaden its capital based, devise appropriate fiscal measures are Africa must broaden its capital base and develop robust fiscal policies to attract local and international investments to Africa's infrastructure sector.

ABSTRACT

The philosophy behind sustainable architecture is all about reducing waste, making judicious use of available resources and passive intervention means. This not only means physical waste but minimizing energy loss as well. Sustainable architecture therefore, holds the key to an environmentally positive future. Only by living more economically with our resources can we hope to protect our environment and climate. So, what better way to live more sustainably than by making sure the very structure of our built environment is greener & more sustainable? This is to enable us reduce fossil fuel emissions prevalent especially in large cities, as well as to reduce our carbon footprints and design our individual dwellings/structures not only as a unit, but as a sustainable whole. The paper aims to simplify the meaning of sustainability as it relates to architects in practice and architecture as seen in the case study of the Idea House, Malaysia where passive means were employed as well as careful orientation of the building. This is done through a clear definition of sustainable architecture, highlighting the methods of achieving this and the alternative means to fossil power available the world over. It also discusses the many obstacles that make the cross from conventional building methods to sustainable ones more appealing, some of which include sincerity in government policies, corruption and high cost of initial acquisition, poverty and lack of awareness.

Keywords: Sustainability, fossil fuels, passive strategies, alternative energy

INTRODUCTION

Sustainable architecture holds the key to an environmentally positive future. Only by living more economically with our resources can we hope to protect our environment and climate. So what better way to live more sustainably than by making sure the very structure of our built environment is greener? The philosophy behind sustainable architecture is all about reducing waste. This not only means physical waste but minimizing energy loss as well. By keeping the energy we consume within our buildings for as long as possible, we need less supply in the first place. Using less energy to keep us comfortable means that we can become environmentally responsible and more resource efficient, which are both vital to reducing the effects of climate change. Perhaps the major philosophy of a sustainable building for it to be truly called sustainable is that it should be designed to able to service the needs of many generations of diverse users (Shore, 2008).

Wines (2000) argues that today, architecture finds itself at a crossroads. He argues that this is so because building materials and new construction, along with the operation and maintenance of buildings, account for a significant sum of the world's greenhouse gas emissions. Faced with this fact, how are architects to responsibly pursue the act (and art) of architecture without further deteriorating the planet's environmental make-up or depleting its resources? What forms of high and low technology can be developed to curtail the injurious side of building? Can good—or even great—architecture is sustainable? (McKnight, 2014).

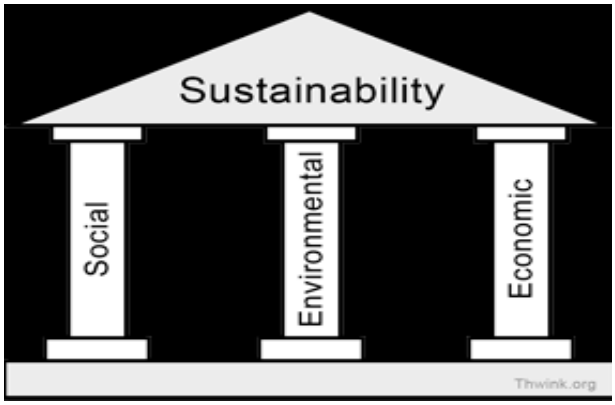

Figure 1 Three Pillars of Sustainablity
Source: twink.org/sustain/glossary/three pillars of sustainability.htm

Figure 1 illustrates the thrust upon which sustainability is built. Environmental sustainability is the ability to maintain rates of renewable resource harvest, pollution creation, and non-renewable resource depletion that can be continued indefinitely. Economic sustainability is the ability to support a defined level of economic production indefinitely. The social sustainability is the ability of a social system, such as a country, to function at a defined level of social well-being indefinitely. As architects, we can identify with the environmental sustainability as our task is all about the built environment – to build individually, but as part of a whole. This built environment must be within the economic realms of the clients whilst upholding their social status (Tukur, 2013).

The philosophy behind sustainable architecture is all about reducing waste. This not only means physical waste but minimizing energy loss as well

i. Sustainable architecture holds the key to an environmentally positive future.
ii. Only by living more economically with our resources can we hope to protect our environment and climate.
iii. So what better way to live more sustainably than by making sure the very structure of our built environment is greener?

When designing a green building, there are some a few salient points to consider as itemized by the Green Building Bible (2008). These include but not limited to:

i. Site and Climate
ii. Form and Function
iii. Fabric and Elements
iv. Infiltration and Ventilation
v. Energy and Renewables
vi. Lighting
vii. Cooling / Heating
viii. Water Conservation
ix. Energy Management and Monitoring

However, sustainable buildings are a broad multi criteria subject related to three basic interlinked parameters: economics, environmental issues and social parameters (Dimitris, Giama and Papadoupoulous 2009). Roaf, Horsley and Gupta (2004) observed that the climate change may bring more sunshine hours, more intense radiation and temperatures. As such, there will be a significant impact on the thermal and lighting performance of buildings which may result in over-heating of the highly glazed and unshaded, as well as increased glare. It is therefore important to design buildings that have a low energy form

Furthermore, it is generally accepted that green buildings can help mitigate climate change, and as by so doing generally improving quality of life (Shore 2008). Some of the problems that can be associated with climate change include severe weather change, high risk of air pollution, massive increase in disease vector ecology leading to ill health in both humans and other animals. Political problems could also be influenced thereby encouraging conflicts, wars and eventually causing forced migration, which is illustrated in Figure 2.

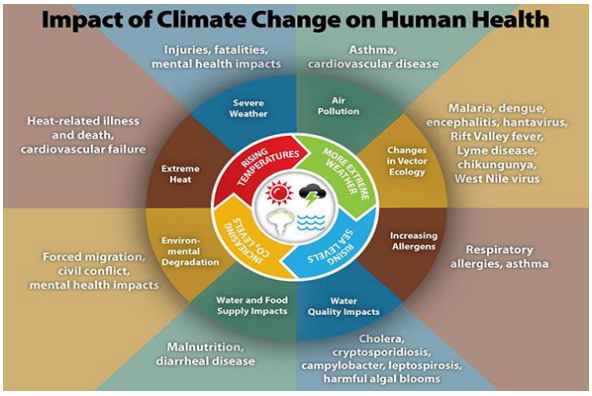

Figure 2 Effects of Climate Change on Human Health (Source: U.S. Climate Resilience Toolkit)

Sustainability and Renewable Architecture

In 1987, the world Commission on Environment and Development sought to address the concern about the accelerating deterioration of the human environment and natural resources and the consequences of that deterioration for economic and social development (Pomeroy, 2011) and published its findings in "Our Common Future". It is from this report that the phrase sustainable development was first coined (ibid).

Varied and different forms of renewable energy sources are available to us today, as is shown in Figure 3, as well as the projections for the year 2013. The variables range from the high and wide availability of solar power and wind power, to a host of other combined non-renewable energy sources.

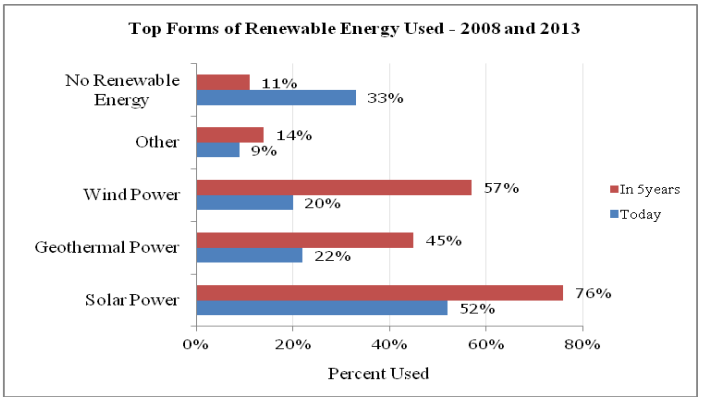

Figure 3:Top Forms of Renewable Energy Used - 2008 and 2013 (Source:Global Green Trends Smart Market Report)

There have been many agitations and reasons as to why the globally green buildings have still not got the popularity required for it to be seen as standard method for construction of all buildings now and in the future. These reasons range from high initial cost of construction, to lack of political will, as well as poverty and extreme harsh weather conditions. This variability is demonstrated in Figure 4.

Figure 4: Key Obstacles to Global green Buildings (Source: Global Green Trends Smart Market Report)

Further statistics from Global Green trends Smart Market Report (McGraw Hill, 2008) as can be seen in Figure 5 show that great efforts have been made around the world to attain the goal of sustainability and the involvement of industry has also helped in bringing to the fore, buildings that that have achieved various levels of sustainability.

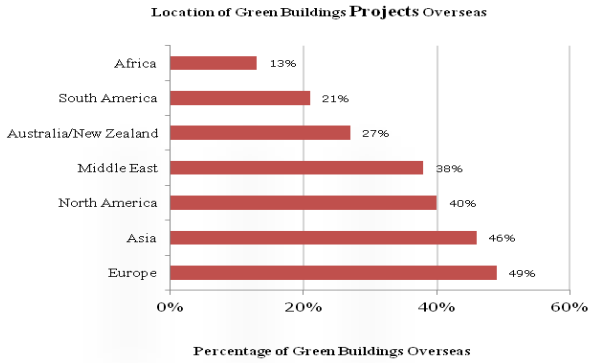

Figure 5 Location of Green Buildings Overseas (Source: Global Green Trends Smart Market Report)

Sustainable Buildings in the Tropics: A Case Study of the Idea House, Malaysia

The Idea house designed by Jason Pomeroy Studio is the first zero-carbon residence South-East Asia, located in Shah Alam, Malaysia, modelled under the concept of the *"Malay Kampung"* house. This house as seen in Figure 6 was conceived with the intention to serve as a test bed, as well as to provide an insight into tropical living in terms of modern terms of sustainability.

Figure 6a: Idea House, Malaysia- approach view (Source: http://www.simedarbyproperty.com)

Figure 6 Idea House, Malaysia – Aerial view (Source: http://www.simedarbyproperty.com)

Due to the careful orientation of the Idea House, with the shorter faces to the east and the west, there was a minimization of solar heat gain as well as that of glare through low angle sun path (Pomeroy, 2011). This was further complimented by deep overhangs so as to provide shading from the sun and torrential rain

The narrow plan form aided in the optimisation of daylight penetration which provided illumination exceeding 150 lux (beyond Nigerian Building Standards of 100-300lux for habitable areas). Daylight factors on ground and first floor respectively were 4.16% and 2.90%. Thus, it can be concluded that there are good levels of natural daylight in these rooms (ibid).

With respect to harnessing the sun's rays as renewable energy source, a 90panel photovoltaic (PV) array was incorporated on the roof to provide an estimated 17,008kWh/year. With the estimated annual consumption (based on a household of 5) being 16,271kWh/year, there is an expected excess of 4.33% which can be fed back into the grid (ibid).

In terms of materials used in construction, timber flooring was used for living areas, ceramic floor and wall tiles for wet areas e.g kitchen and bathrooms. Windows were 8mm double glazed, double layer of plaster board on steel studs with glass studs with glass wool acoustic/thermal insulation was used for internal partitions. For the ceilings, Medium Density Fibreboard (MDF) tile, mineral wool based tile and wood wool based tile were considered but rejected due to heavy weight of the former and high cost of the latter. As such the concensus was to use suspended plasterboard ceiling.

Grey Water and Water Management

The design plans to capture 50 % of the 'grey water' from wash hand basins and showers via a filtration system. The water can then be re-used to flush the WC's, thus reducing water consumption and therefore utility costs. Water wastage is set to be further minimised by aerating the showers, resulting in less water being consumed by the room occupants. Based on an occupant using 133litres of water per day, the aeration of showers could reduce consumption to 64 litres per day.

Green Roof and Rainwater Catchment:

Green roof technology is incorporated into the roof garden, helping reduce storm water run-off and thus minimise the loading onto storm water drains. The green roof can also be replaceable. Whilst currently proposed as a roof garden, the space can be converted in the future to a further habitable room. The rainwater captured by the sloping roof would be collected into water storage tanks from which the water harvested would be used for irrigating the vegetation within the development.

CONCLUSION

There is no doubt that if indeed we are to plan for future generations, then we have to make more meaningful use of the resources that we have, such that we use less to achieve more. In sub-saharan Africa where we are plagued by war and ravaged by diseases, there is doubt that it is amongst the category of regions that will be worst hit by the climate change issues. It is therefore imperative that architects and try to embrace the culture of sustainability as it related to the built environment so that the profession can contribute its quarter to creating a safe and worthy environment this generation and generations yet unborn. This can achieved through appropriate choice of site, careful planning, thoughtful use of building materials, as well as judicious use of locally available resources.

Furthermore, governments need to bring in more sincere policies that will encourage the use of alternative power means. By so doing, this will cut down the cost of acquisition, encourage more research and thereby extending its popularity and reach to even the most remote area. These efforts combined, will go a long way to helping the world reach its sustainable development goals.

Development of Cement Mortar from Reusable Industrial By-products

Aaron Joseph Ango[1]; H.T. Kimeng[2]; Mustapha Sani[3] & O.O Ekundayo[4]*

[1, 2& 3]Department of Architecture, Ahmadu Bello University, Zaria, Nigeria
[4]Department of Building, Federal University of Technology, Akure, Nigeria

ABSTRACT

The present work involves mixing a high ratio of reusable industrial by product from the steel-making process, Ground Granulated Blast Furnace Slag (GGBFS) with ordinary Portland cement at a ratio of 75%:25% to produce cost effective, environmentally friendly, eco-efficient, yet mechanically and structurally viable cement. Activation of the steel by-product (GGBFS) was done with compounds of different alkalinity. Mortar molds developed were tested for Compressive Strength, Autogenous Drying Shrinkage, Conduction Calorimetry, Scanning Electron Microscopy (SEM), X-ray Diffractometry (XRD), and Porosity. Results obtained showed that a high ratio of GGBFS to Ordinary Portland Cement mixtures produced cement based products with low permeability, improved cementing results, improved workability, and excellent density control.

Keywords: Activator, Cement, Eco – efficiency, GGBFS, Mortar

INTRODUCTION

Environment and human health effects are intricately linked therefore the need for waste reuse is a fact of healthy life. Bentur, (2002), suggested that waste utilization is an attractive alternative to disposal in the sense that disposal cost and potential pollution problems are reduced or even eliminated along with the achievement of resource conservation. Higgins, (1995) reported that the utilization strategy must be coupled with environmental and energy considerations to use available materials most efficiently.

Lane, and Ozyildirim (1995) discussed the production of Portland cement as one involving the grinding of cement clinker, gypsum and calcination of raw materials at a high temperature (approx. 1500°C). This process of production is highly energy intensive and demands a great deal of both power and energy for manufacture to commence.

Öner M, et.al (2003) reported that blast furnace slag is a by-product obtained in the manufacture of pig iron in the blast furnace and is formed by the combination of earthy constituents of iron ore with limestone flux. When the molten slag is swiftly quenched with water in a pond, or cooled with powerful water jets, it forms into a fine, granular, almost fully noncrystalline, glassy form known as granulated slag, having latent hydraulic properties. Such granulated slag, when finely ground and combined with Portland cement (PC), has been found to exhibit excellent cementitious properties.

Usage of slag as a cementitious component requires only grinding. The energy required to grind granulated blast furnace slag is only approximately 10% of the total energy required for the production of Portland cement. As shown in figure 1, this less complex process saves substantial amounts of energy compared with the production of Ordinary Portland cement.

Ango, A. J.; Kimeng, H. T.; Sani, M. & Ekundayo, O. O. (2016). Development of Advanced Cement-based Products from Reusable Industrial By-products. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 489-499

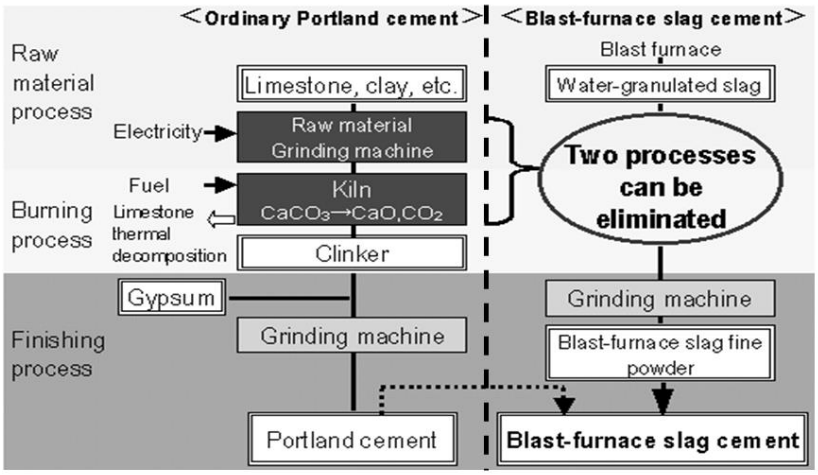

Fig. 1 Comparison between Production Processes of Portland Cement and Blast-furnace Slag Cement

Ganesh and Kumar (2000) opined that ground granulated blast furnace slag (GGBFS) is a pozzolanic material (termed by a few as a supplementary or complimentary cementitious material) and can be used as a cementitious ingredient in either cement or concrete composites. They results of their work also concluded that the utilization of supplementary cementitious materials is well accepted due to the overall economy in their production as well as their improved performance characteristics in aggressive environments.

Kjellsen et.al (1991) reported that blended cements are produced by intimately and uniformly intergrinding or blending ordinary Portland cement (OPC) with one or more supplementary cementitious materials (SCMs). Most SCMs, such as ground granulated blast-furnace slag (GGBFS) are industrial by-products. These materials are generally not used as cements by themselves, but when blended with OPC, they make a significant cementing contribution to the properties of hardened mortar or concrete through hydraulic or pozzolanic activity.

V.D. Glukhovsky, et al., (1980), suggested that since oxides containing in slag are similar to those of Portland cement, the application of the slag for construction material is fully attractive. The industrial manufacturing process of cements based on the alkaline activation of blast furnace slag (AAS) started in Ukraine between 1960 and 1964.

S.D. Wang, et al., (1995), Tailing and Brandstetr (1989), Puertas (1995) reported that these AAS cements present some technological advantages over ordinary Portland cements. These are: the development of earlier and higher mechanical strengths, lower hydration heat, better resistance to chemical attack, better behavior upon carbonation, higher resistance of the aggregate-matrix interface, better behavior to freeze-thaw cycles, among others.

S.D. Wang, et al., (1994) published extensive investigations about the main factors affecting the development of mechanical strengths of AAS cements when used in the development of mortars and suggested that these factors include slag specific surface, curing temperature, type of activator, activator concentration, and alkaline activator nature. In all the studies, the influences of these factors are independently studied. Slags are by-products of metallurgical (iron and steel) industry and consist mainly of calcium-magnesium aluminosilicate glass. As by-products they have a variable composition depending on the raw materials and the industrial process; hence, each slag differs in response to activation.

S.D Wang, (1995) reported activation with waterglass. However, waterglass solution (Na_2SiO_3) is relatively expensive and cannot be readily acquired in some parts of the world. In Scandinavian countries, F-activator, composed of NaOH, Na_2CO_3, and lignosulfonate as the main ingredients together with sodium gluconate and tributyl phosphate as additives, was successfully used as activator. For the purpose of this research, GGBFS was activated with various alkaline activators. These activators are non-expensive and can be acquired from the market.

ACTIVATION OF SLAG

Different alkali-containing activators were used for activation of slag, e.g., liquid sodium silicate, sodium hydroxide solution, compound activator, sodium carbonate, and sodium orthophosphate. Corresponding to the concentration of the alkaline activator added in a solution, the amount of water was varied to maintain a constant w/b ratio.

MATERIALS

The chemical composition of the blast furnace slags used in this work is shown in Table 1. The mortar samples were prepared according to the Okamura et al. (1993) method. The size of the prism samples was 50 x 50 mm. The sand/slag ratio used was 1: 2.45 and the slag to Ordinary Portland cement ratio was 70% :20% for samples activated with powder alkali activators.

Table 1 *Chemical and physical properties of materials used*

	Oxide Composition									
Blaine	SiO_2	Al_2O_3	CaO	Fe_2O_3	MgO	Na_2O	TiO_2	SO_3	LOI	Specific gravity
8000	34.72	11.87	41.05	0.44	8.24	0.11	0.53	2.43	0.29	119
OPC	20.88	5.39	64.73	2.38	1.51	0.27	1.33	1.65	2.04	3.13

All samples were first cured in moist air at 25^{o}C and 60%RH in a curing room for 1 day and then water cured progressively for 3, 7, and 28 days. Samples were then tested for compressive mechanical strength for the preceding days respectively. Tables 2 and 3 present the mix proportion for mortar samples. Four (4) mortar samples were successfully activated with powder activators.

EXPERIMENTAL

The raw materials for the experiment were prepared with sufficient mixing and their formulations are shown in Table 2. The mixing and molding procedure followed ASTM C 109-92. Cubes of fresh cement were put into a Chandler duplex curing chamber at 125°C or 175^{o}C, which was filled with water and kept at a pressure of 1 ± 0.1 MPa (gauge pressure). The Chandler duplex curing chamber was used here due to availability and the "compressed water" situation in it is not normally practicable in fabricating precast concrete. The cubes were at room conditions for nearly one hour between initial molding and processing. The desired processing temperature was reached in 1.5 hours and was held for various lengths of time. Cooling time was more than 1.5 hours. Fragments of tested cubes were taken for physico-chemical examination. Granulated blast furnace slag cement was used in the production of mortar samples which were subjected to laboratory experimental tests. Specimens for determining strength were moist-cured at 23^{o}C until the time of test. The compressive strength was determined using ASTM C 78 (third-point loading) on 10 x 10 x 150 mm specimens at 3, 7, and 28 days. Mix proportions for producing high volume slag mortar using various alkali activators is shown in table 2.

Table 2 *Mix proportions of concrete*

Type	Mix proportions of GBFS (%)						Mixing Proportion (kg/m^3)			
	OPC	GBFS	$CaSO_4.2H_2O$	Na_2SO_4	Na_2CO_3	NaOH	W	C	S	G

TEST, RESULTS AND DISCUSSIONS FOR MORTAR SAMPLES

Compressive Strength

The test results of the compressive strengths are shown in Fig. 5.1.1. As seen, the compressive strength of the mortar samples seems to increase with increasing Na_2SO_4 content.

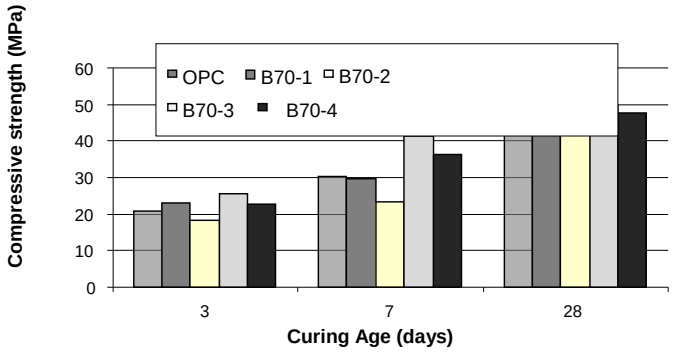

Figure 5.1.1 Compressive strength of powdered – modified slag cement mortars with different curing periods

As seen from Fig.5.1.1, the high early strength development of the high volume slag cement mortars has almost completed in 28 days and in all cases, the compressive strength is equal to or even a bit higher than that of ordinary cement mortar. From the compressive strength graph, it can also be seen that there is a probability for further or future strength development for the high volume slag cement mortars. Though the high early strength was achievable, this was at the expense of the fineness of the slag and its reactive activity index. Since the CaO content of the slag is about 1.5 times less than that of the OPC (see Table 1), a higher replacement of the OPC by the slag would bring to a lower ultimate strength. On the contrary, in this work, the strength increases with increasing the slag contents.

Heikal, et. al, (2000), Linhua, and Yugang, (1999), believed to be due to some properties of the slag other than its CaO content, such as magnetic property, size, and shape. In general, admixtures have very little effect on the ultimate strength of mortar except when they affect the w/c ratio or the porosity of the mortar sample. In this work, it is explained that, due to its texture, the fine slag functions as filler to reduce the porosity. This in turn upgrades the strength of the samples (filler effect).

Isaia et al. recently proved that pozzolanic and filler effects increased as the mineral addition increased in the mixture. They also concluded that the filler effect, however, increased more than the pozzolanic effect.

Autogenous Drying Shrinkage

A report on the relationship between autogenous shrinkage and hydration evolution for different types of cement mixtures and varying activators is hereby presented. The plotted

results in Figure 5.2.1 confirm that the cumulative autogenous shrinkage for all activated slag mixes is higher than that of opc and that it increases with the silica content of the mix. It can also be seen that most of the total autogenous shrinkage takes place during the early hydration stages just immediately after hardening. The average result of the autogenous shrinkage of the silicate mixes increase with the SiO_2 content. The GGBFS mix shrinkage displayed higher shrinkage compared to mixes of OPC.

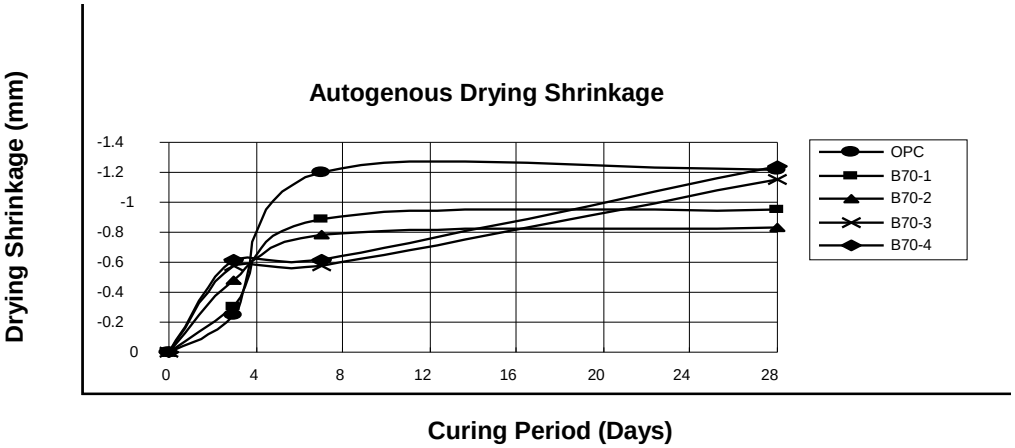

Fig. 5.2.1 Autogenous Drying Shrinkage of Alkali Activated GGBFS

Conduction Calorimetry

Conduction calorimetry, were performed for the investigation of the hydration evolution on paste samples prepared with water/binder ratio of 0.50. All mixes were tested after 6, 8, 10, 12 hours and 1, 2, 3, 7, 14, 28 days.

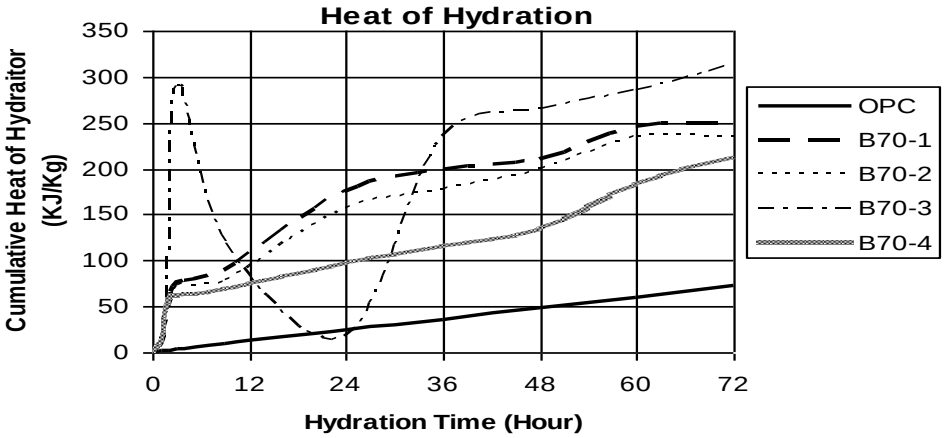

Fig. 5.3.1 cumulative heat of hydration of alkali – slag cement

For the calorimetry tests, samples of paste were prepared by mixing 20g of slag and water + activator in a plastic bag and immediately transferred to a JAF Wexham conduction calorimeter at 20°C. The heat output was recorded after 30 minutes, and the time needed for the system to reach equilibrium. The heat of hydration was determined up to 72 hours after mixing.

Figure 5.3.1 shows the profile of the heat liberation during 72 hours. The GGBFS showed the fastest heat evolution, with a maximum at 6 hours and no induction period. The induction period of all slag activated mixes correlates well with the Na_2O content, increasing as its content decreases, showing the effect of the alkaline media on the solubility of the slag and hydration evolution.

Jiménez, and Puertas, (1997), Shi, (1997), Richardson, and Cabrera, (2000) reported that after the induction period, diffusion is the mechanism that controls hydration. The slag

solubility also influences the reaction sequence, and the total cumulative heat diminishes as Na_2O content decreases. Because the silica modulus is constant, it can be said that the degree of reaction increases with silica content. The influence of the activators on heat evolution rates is clear:

SEM (Scanning Electron Microscopy) Analysis

From the strength and pore structure tests, it can be seen that according to the hydration mechanism of alkali activated slag cement and Portland slag cement, the mixed activation mechanism of sodium-calcium-sulfate was promoted forward. At the same time, by using the powdered chemical admixtures containing C_4A_3S and/or $C_{11}A_7 \cdot CaF_2$ were synthesized. It

played an important part in ettringite formation in early stages and in the enhancement of strength.

With this background, compound admixtures with three components have been developed that substantially improved the strength and pore structure at early and later periods. Improvement of these properties can be explained by the analysis of hydration products and polymerization degree measurement of silicate anion. At early stages of hydration, although polymerization of hydration products made uni-poly and bi-poly ratio decrease, the breakage of slag made uni-poly and bi-poly ratio increase. Thus, these two actions offset each other. At later stages of hydration, the polymerization of hydration played an important part; thus, the high-poly ratios increased. At early stages (3–7 days), uni-poly and high-poly ratio all increased. This shows the breakage rate of slag and the polymerization rate of hydration products. This is due to the action of compound admixtures.

Figs. 5.4.1, 5.4.2., 5.4.3,and 5.4.4 show the microstructure of hydration products at different ages. At 3 days of hydration, due to fast hydration of early strength ore, the dissolution rate of gypsum was lower, so there was AFm evident in scanning electron microscopy. At 7 days of hydration, because of the continuing dissolution of gypsum, breakage of slag and dissolution of anion are very beneficial to production of ettringite. It played the action of advancing skeleton and microsteel fiber.

Connecting and filling between the ettringite and C-S-H gel have important influences on improvement of the early stage functioning and dense structure formation. At 28 days of hydration, much of the ettringite was wrapped in C-S-H gel and coated by slag particles. It is shown that the hydration of slag surface was greater. More and more C-S-H filled into the pore of hardened paste, so that the later properties could be improved.

X-Ray diffraction

XRD was employed to identify the phases present in hydration products, using standard monochromatic CuKa radiation and operating at 40 kV and 20 mA. Scanning was performed at 0.05_ 2q step size, at 2 s per step, between 5 and 50. Samples were prepared by crushing paste specimens into fine powder. To stop hydration at the desired ages, the crushed materials were slurried with 200-proof ethanol. The powder was vacuum filtered, air-dried, and reground before mounting in the XRD sample holders. This was done in order to identify the phases formed during hydration. Figs. 5.5.1, to 5.5.4 show the XRD pattern corresponding to slag activated with powdered alkali activators, up to 28 days of hydration. C – S – H hydration products are known to produce broad diffusion peaks however, XRD patterns in this region overlap with the major peak for calcite and silicate. This characteristic peak of the calcite dominates the diffractogram at all ages. Calcite and silicate peaks remain constant indicating that carbonate particles are inert and do not participate in any hydration reaction releasing Ca^{2+}. The reactivity of the slag is a function of the alkali and free lime content. The chemical and mineralogical analysis of slag showed the presence of negligible amounts of free lime and excessive amounts of carbonates, which is indicative of the limited availability of Ca^{2+}. At 3 days, hydration products were ettringite and an AFm phase.

Ettringite is a stable hydration product only while there is a sufficient supply of sulfates. When the sulfate source is not able to readily supply enough sulfate ions before the alumina content has completely hydrated, ettringite is converted to monosulphoaluminate. In place of sulfates, other ions such as chloride ions can appear and these phases are known as AFm phases. The AFm phase identified in this blend is the calcium monochloroaluminate hydrate, also known as Friedel's salt, which is the result of the high chloride content (1.8%) of the slag. From 3 days of hydration, the ettringite and the Friedel's salt coexist. At this time, a decrease of the Friedel's salt peak occurs due to the presence of sulfate ions. Further, a

decrease in the amount of dolomite was observed at 3 days, although no products associated with the dedolomization reaction were detected. It should be noted that it was not possible to identify any $Ca(OH)_2$ peaks up to 28 days of hydration.

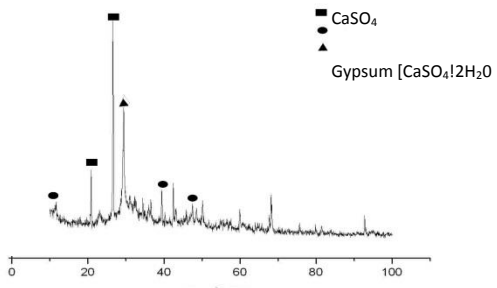

Figure 5.5.1 XRD Pattern for B70-1 ($CaSO_4.2H_2O$(3%) + Na_2CO_3(7%))

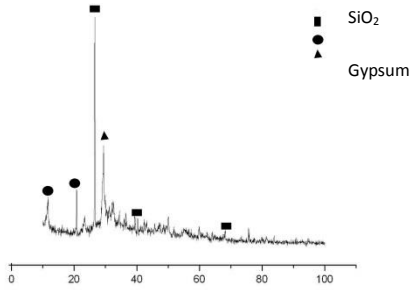

Figure 5.5.2 XRD Pattern for B70-2 (Na_2CO_3(7%) + NaOH (3%))

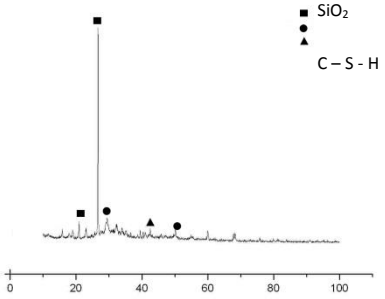

Figure 5.5.3 XRD Pattern for B70-3 ($Ca_2SO_4.2H_20$(2%) + Na_2SO_4 (8%))

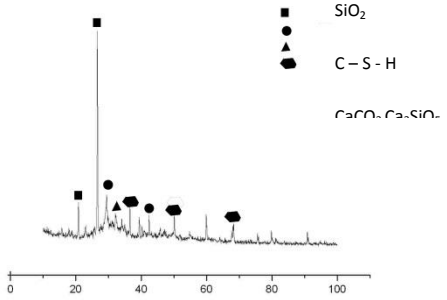

Figure 5.5.4 XRD Pattern for B70-4 ($Ca_2SO_4.2H_20$(1%) + Na_2SO_4 (8%) + NaOH (1%))

Figs. 5.5.1., 5.5.2., 5.5.3., 5.5.4. show XRD patterns for slag activated with powdered alkali activators. This blend unexpectedly exhibited a very long setting time. A more detailed examination of the diffractogram at 3 days of hydration revealed the existence of syngenite peaks, $K_2Ca(SO_4)_2$, at 2q = 31.3 28.2.The precipitation of syngenite occurred due to the high potassium content of the dust, resulting in the removal of sulfate and potassium ions from the pore solution. The peaks were no longer detectable after 28 days of hydration. The subsequent release of sufficient sulfate ions from the dissolution of syngenite and the favorable ratio of SO_4^2 to $Al(OH)_4$ caused the formation of well-crystallized ettringite, which persisted up to 7 days of hydration. Some calcium aluminate hydrates were also detected. Traces of $Ca(OH)_2$ were detected after 7 days of hydration indicating that the available lime was not totally consumed. The diffractogram of the blend with powdered alkali activators is shown in Fig. 5.5.1. At 3 days of hydration, the formation of gypsum due to the rehydration of the anhydrite was observed. Gypsum was not consumed and was detectable even after 28 days of hydration. Ettringite was formed within the first hour of mixing and by 3 hrs was responsible for the very short setting time of the mix. SiO_2, $CaCO_3$, and $CaSO_4$ remained the principal matrix phases up to 28 days of hydration. For this type of blend, slag was essentially activated with calcium sulfate such as in the case of supersulfated cement. Fig. 6.5.2 shows the XRD pattern corresponding to slag activated with Na_2SO_3. At early hydration, the

evolution of the peaks of ettringite and monosulfoaluminate (2q = 9.85) is shown. The Friedel's salt formation is quite evident at 1 day of hydration. Its peak increases up to 3 days, then it decreases and a small amount may be detected at 7 days. A further release of aluminum from the decomposition of Friedel's salt causes the formation of ettringite. Its peaks increase again at 7 days and small amounts of monosulfoaluminate appear up to 28 days of hydration. Both phases are very stable and, as in Portland cement pastes, can coexist. Unreacted $Ca(OH)_2$ can be detected in the mix even after 28 days.

Porosity

At both 3 and 7 days, significant hydrate is found in the system, but this does not effectively fill in the interface, where a higher level of porosity than in the bulk pastes is still found. To some extent, the extra space at the interface is the result of shrinkage cracking on drying for sample preparation; but nevertheless, this indicates a paste that is more porous and fragile in the region of the interface.

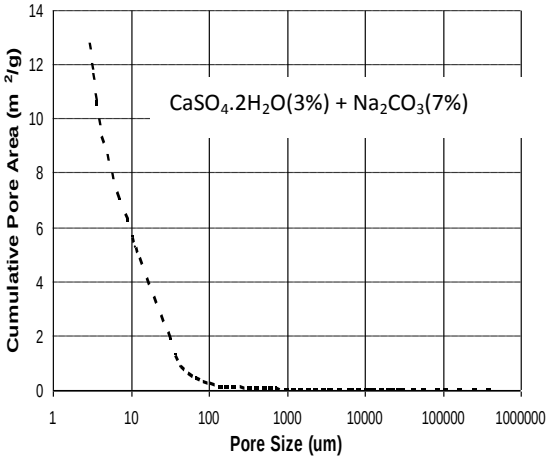

Fig. 5.6.1 Pore Volume for $CaSO_4.2H_2O(3\%) + NaCO_3(7\%)$

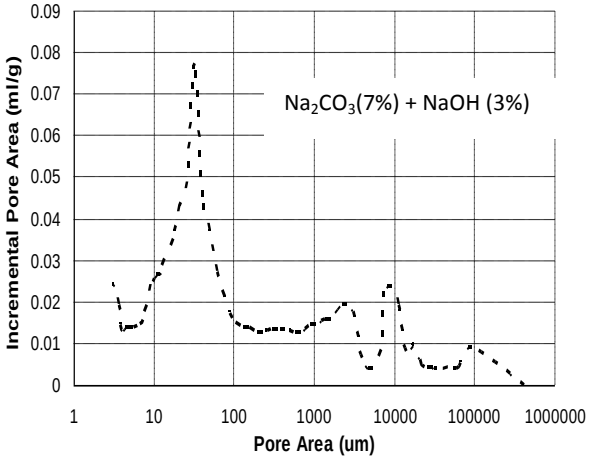

Fig. 5.6.2 Pore Volume for $NaCO_3(7\%) + NaOH(3\%)$

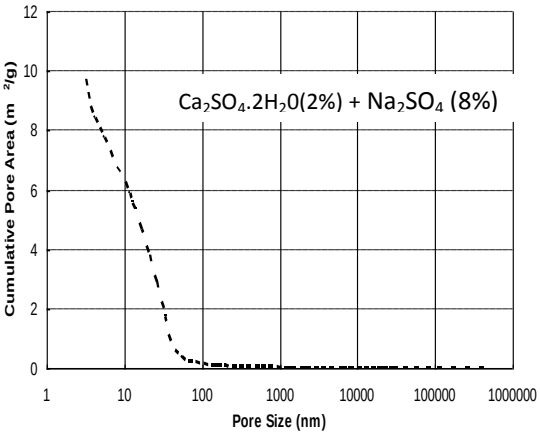

Fig. 5.6.3 Pore Volume for $CaSO_4.2H_2O(2\%)+ NaSO_4(8\%)$

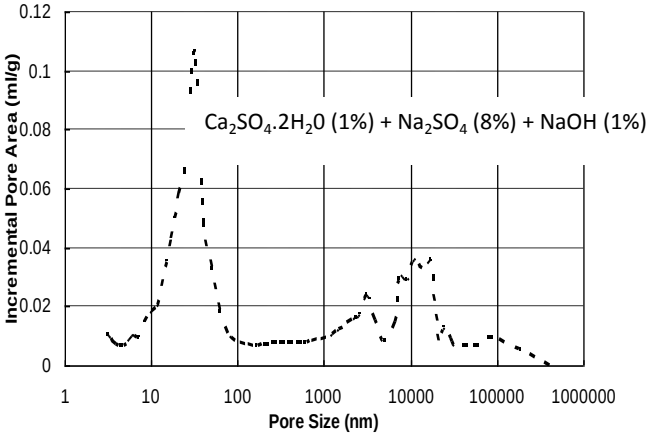

Fig. 5.6.4 Pore Volume for $CaSO_4.2H_2O(1\%)+ NaSO_4(8\%) + NaOH(1\%)$

Figs. 5.6.1, 5.6.2, 5.6.3, 5.6.4., Cumulative pore volume curves of powdered alkali activated blast furnace slag with different curing ages. (3 days – 28 days).

Further hydration to 28 days leads to a system with improved microstructure, with the hydrates much more effectively filling in the space in the system. Considerable hydrate is found in a region where there was originally very little slag, indicating considerable mass transport over a significant distance. In Figures 5.6.1, 5.6.2, 5.6.3, and 5.6.4 the cumulative curves of pore size distribution show the different profile of powdered – alkali Activated slag.

It can be seen that silica plays an important role in the gel densification, being the maximum pore sizes for all the 4 mixes. The activated slag systems have a typical microstructure, which differs from that of hydrated OPC. In the case of alkali-activated slag, the volume of pores in the micropore size range tends to be bigger than that of Ordinary Portland cement.

The volume of pores within the capillary range is smaller than that of Ordinary Portland cement. Under normal application conditions shrinkage depends on loss of water from macropores and mainly from mesopores. The volume of smaller pores is larger for the silicate mixes than for ordinary Portland cement. .

Jiménez, and Puertas, (1997), Xi, and Jennings (1989), Wittman, (1982) suggested that The threshold limit for silicate mixes are in the region of mesopores, whose value diminishes as the silica content increases. The results obtained are in good agreement with other studies on Alkali – Slag - Cement porosity. As measured by the amount of methanol – accessible pores, NaOH of alkali - activate Blast furnace slag pastes changed with time. The concentration of NaOH in the mixing solution is inversely related to NaOH.

Christensen, (1993), and Christensen, et al., (1994) noted that alkali – activate Blast furnace slag pastes have significantly larger volumes of porosity in comparison to OPC pastes when one assumes that only capillary pores are methanol accessible. The volume of pores before reaction is 55.7% of the total volume of the paste, calculated from the density of GGBFS ($2.79 g/cm^3$). The measured amount of pores after 3 days of hydration was about the same for every paste. It is possible that some portion of gel water was exchanged with methanol, in addition to capillary water, since methanol is very small. The difference in NaOH results from either the different degree of hydration or the formation of different microstructural features in alkali - activate Blast furnace slag pastes.

Also, Hydrotalcite was observed in higher pH pastes along with C – S – H. A more sophisticated study is required to determine its effect on various properties of GGBFS pastes.

CONCLUSION

The use of slag when making mortar is interesting because of the savings realized by substituting less expensive slag to a certain volume of cement. From the strength point of view, the results obtained with mortar developed with slag in replacement of the cement are interesting and from analysis of results obtained in the present work, with the factors considered at the selected levels, it is deduced that:

i. The nature of alkaline activator is the most significant factor. As a function of the strengths obtained.
ii. The increase of curing time favours the increase of mechanical strengths at later ages, but has a positive effect at early ages when the activator is Na2SiO3 □ nH2O □ NaOH or Na2CO3.
iii. The fluidity of mortar containing GGBS is associated with Pore Size Distribution of GGBFS. The narrower the Pore Size Distribution of GGBFS, the larger is the fluidity of mortar. The influence of morphological characteristics of GGBFS on the fluidity of mortar is not remarkable.
iv. The strength of mortar incorporating GGBFS is both related to the surface area and Particle Size Distribution of GGBFS. Given the same surface area for GGBFS, when the mortar contains fine particles (<3Am) of GGBFS, the higher its early strength. And, when the mortar contains 3–20Am particles of GGBFS, the higher its long-term strength.
v. GGBFS can be used to develop cement for mortar with high degree of reliability.

ABSTRACT

Decline in labour productivity in the construction industry has been an issue of concern to professionals in the industry. This concern has sparked series of research efforts which have been reported in many studies. The aim of this research was to assess how labour motivational incentives affect productivity improvement in the construction industry. The objectives included identifying the motivational incentives used by construction companies and examining the effectiveness of such incentives on productivity. Questionnaire survey was used in data collection and descriptive statistics was used in the analysis. Findings from the research revealed that providing required materials for workers, provision and implementation of standard company policies, increase in wages and timely payment of entitlements are among the effective motivational incentives that can lead to improved productivity. Improving productivity is therefore, essential if the industry is to live up to its expectations in terms of project delivery on time, at the budgeted cost and the required quality of finished work. It is recommended that increased attention be given to benefits enjoyed by construction workers in terms of wages, working condition, bonus payment and management of workers' welfare.

Keywords: Labour, Motivation, Productivity Improvement, Project Delivery

INTRODUCTION

The present low levels of productivity in the construction industry and disproportionate dependence on unskilled workers is unsustainable and incompatible with the aspirations for growth of Nigeria's economy. Low productivity cannot be attributed to a single cause but occurs as a result of convoluted interface of individual characteristics and issues in the work environment. There is hardly a single 'cure' for low productivity as such, several intervention approaches are certainly required. Construction performance and productivity improvement are key focus areas of concern in the nation's construction industry, since the construction industry's contribution to the national economy is substantial. Decline in construction productivity across the world has been reported by many researchers such as Karasek and Theorell, (2009). Therefore, evolving ways of improving construction productivity and implementing productivity enhancement measures in terms of labour and management will save billions of naira and make construction a more profitable and attractive business.

Labour is the engine room of the construction industry which plays a key role in the economy of any nation because the industry is among the largest employers of labour. However, despite the importance of the industry, its productivity has been declining. This decline in workers' productivity has caused failure to deliver projects on time and within cost and quality standard (Aiyetan & Olotuah, 2006). Factors such as provision of poor tools and equipment, lack of incentives, unbalanced work gangs among others have been observed to create productivity problems (Akindele, 2003). The benefits of productivity improvement are manifold. At the national level, productivity growth raises living standards because more real income improves people's ability to purchase goods and services, enjoy leisure, improve housing, education and contribute to social and environmental programs. Productivity growth is also important to the firm because more real income means that the firm can meet its (perhaps growing) obligation to customers, suppliers, workers, shareholders, and government (taxes and regulation) and still remain competitive or even improve its competitiveness in the

Abdullahi, M. E.; Bena, A. L.; Adamu, N.; Jimoh, A. A. & Abdullahi, H. (2016). An Assessment of Labour Productivity Improvement in Construction Project Delivery. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. market place (Kusanyanagi, 2011). The way forward therefore is to evolve ways of improving productivity especially in terms of labour. This research, therefore, assesses labour productivity improvement strategies in selected northwestern states in Nigeria.

Productivity is an omnibus term that refers not only to the measure of efficiency of material input, labour/management input, or technological input, but also time and financial resources input or a combination of some or all of these critical input factors to produce a finished product. Although, what may account to efficiency or inefficiency of critical input factors of productivity in one organization may differ from the other organization and across locations or regions, Flanagan et al., (2003) describe productivity as a relationship between output and input which varies in terms of the context and the objectives behind measurement. However, looking at it from the materials and human resources point of views, the Encarta Dictionary, (2009) defines productivity as the rate at which a company produces goods or services, in relation to the amount of materials and number of employees needed. Generally, all these approaches attempt to measure the effectiveness with which management; skills, workers, materials, equipment, tools, time and working space are employed at or in support of workforce activities to produce a finished building structure or other fixed facilities at the lowest possible cost (Allardyce, 2007). The aim of this study is to assess how labour motivational incentives affect productivity improvement in the construction industry. Objectives include: identifying factors responsible for low productivity, identifying the motivational incentives used by construction companies, and assessing the effectiveness of these motivational incentives on productivity.

Projects evolve in rapidly changing environments because of the pace of technological development, increasing complexity, new methods and tools, new markets, increased competition, novel business opportunities and demanding customers. This implies that construction projects are dominated by objectives based on time, cost and quality (Nigel, et. al., 2006). Furthermore, the benefits an organisation gains from labour efficiency apart from the aforementioned elements of cost, time and quality; can be about avoiding, reducing, absorbing or transferring risk and exploiting potential opportunities, including profit maximization**.** All of these benefits must be harnessed and calculated above the point of break-even for a construction organisation to feel at ease and avoid being bogged down by inefficiency.

The benefits of high construction productivity cannot be overstated the same way that the dilemma faced by contractors for low productivity cannot be exaggerated. Projects with high productivity share features that include;

i. high degree of standardization in grid layout and sizes of components,
ii. design which shows high buildability, use of pre-fabricated components or pre-assembled forming systems,
iii. architectural details which minimize the use of wet trades, replacing them with dry components,
iv. presence of skilled workers in the relevant trades,
v. high level of construction mechanization, and
vi. not too many workers on site

The essence of all motivational efforts is to increase employee productivity. Motivated workers out-produce unmotivated employees. The factors that influence employee productivity are different from the factors that influence satisfaction. Chike-Okoli, (2002) identified factors that influence productivity of employees to include: Ability, Technological know-how or skill, Physiological drive, Attitude and technology employed, and Managerial ability. The construction pattern in Nigeria is largely traditionally based, justifying the

employment of huge labour gangs; nevertheless, too many workers on construction site usually do not perform proportionately to their output capacities, resulting in reduction in productivity of labour, waste of time and loss of profit.

REVIEW OF RELATED LITERATURE

Low productivity of Nigerian contractors is an unspoken guarantee that accompanies companies' profiles and usually, they seem to always live up to this guarantee. This is because the most significant problems being identified as affecting productivity in Nigerian construction industry which are listed to include; shortage of materials, incomplete drawings, incompetent supervisors, lack of proper tools and equipment, labour absenteeism, poor communication, instruction time, poor site layout, inspection delays and rework still exist at various levels in Nigerian construction companies. However, quality and cost are equally important in assessing the factors that affect productivity. Rose and Mill (2006) argued that any measure of construction productivity that does not account for the changes in design and quality would lead to low, if not negative measures of construction productivity.

Poor productivity of construction workers is one of the causes of cost and time overruns in construction projects. Productivity of labour is of particular importance especially in developing countries, where most of the building construction work is still on manual basis. The most significant problems affecting labour productivity were identified as incompetent supervisors, lack of skills from workers, rework, lack of tools/equipment, poor construction methods, poor communication, inaccurate drawings, stoppages because of work being rejected by consultants, political insecurity, tools/equipment breakdown, and harsh weather conditions (Wahab, 2000).

Productivity Improvement Program

Productivity improvement program offers the single best opportunity to optimize resources utilization, shorten schedule, and achieve dramatic cost saving on capital project, plant turn around and routine maintenance. The productivity improvement program is designed to synergize the expertise and experience of the industry leaders and practitioners in identifying management strategies and execution of initiatives that will improve productivity, accelerate implementation of pragmatic solutions developed during the program which help companies to achieve up to 10-20% productivity gains not only on field execution, but, also for other management functions and support services.

Value Added Feature

The productivity improvement in project program provides the following special value added features.

i. Multi–functional productivity focus: instead of merely focusing on field labour or productivity, all other management functions and support service are also giving much needed attention e.g. inspection, engineering/designed procurement, and planning.
ii. Cost–effective learning: this is the cost effective approach to learn productivity from a wide range of expert and practitioners. The program fee is nominal as compared to the enormous costs of on the job learning or accepting the status and continually suffering from poor productivity.
iii. Accelerated knowledge transfer: this is structured to turn productivity novice staff into smart manager and supervisors with valuable knowledge about all aspects of productivity (Dasaki, 2000).

Management Ability

One of the functions of management is to utilize people in the accomplishment of organization objectives. To accomplish this, management must not only create favourable

environment in which the employee must work, but must motivate the employee to greater performance. When management fails to motivate an employee, the employee becomes a liability to the organization. Liska (2013) observed that the average construction craft worker is only about 40% productive. He argues that workers are only as good as they are trained and they don't produce as well as they could because they are not managed well. He breaks down the other 60% as follows:

i. 20% due to admin delays, waiting for materials and other kinds of resources.
ii. 20% due to inefficient work methods.
iii. 15% due to restrictions in the workplace.
iv. 5% due to personal time.

An organization's productivity depends on how labour is utilized because labour sets the pace, influences the choice of technology, and molds the organizational climate that prevails. An employee with a poor attitude towards his work and the organization is a low producer. Chike-Okoli (2002) posited that attitude is observable and can be infectious and that employees who have bad attitude to their work tend to work because of the compulsion of their economic circumstances, although poor attitude may not be unconnected to lack of motivation. It must be emphasized that there is the need to have a good process in place to monitor performance and assess it during the job in order to increase productivity.

In general, people tend to behave in ways that the organization rewards their efforts. Therefore, the anticipation of rewards can operates as a strong incentive motivating a certain level of behavior and job performance or motivating the choice of an organization as a place of work (Chike-Okoli, 2002). Furthermore, reward motivates performance, leads to reduce turnover, reduce absenteeism, and attract qualified job applicants.

Motivation Studies in the Construction Industry

McGregor (1960) espoused two fundamental theories about workers in the work environment (Theories X and Y). Theory X assumes workers are inherently lazy; Theory Y assumes they are self-motivated. Within Nigerian context, the average workmen belong to Theory X and managers with this type of employees must employ conventional wisdom and goad workers into becoming productive cogs in the machine. Succinctly put, theory X depicts the average Nigerian workers' laziness to work with tendency to avoid work if he could. He is inherently lazy and dislikes work unless he is coerced or forced by economic circumstance. While not clearly on the side of Theory Y, Chike-Okoli, (2002) opined that McGregor seems to lean toward the idea that management should ultimately set the workplace conditions to allow people to not only do well at work, but to want to do well.

The leading exponent of humanistic psychology, Maslow (1954) theorized that the human desire to satisfy ones needs act as motivator influencing their performance positively. He presents these needs as a hierarchy of five categories: physiological, safety, social, self-esteem and self-actualization. Based on Maslow's theory, Schrader (1992) proposed a need of construction workers and identified appropriate techniques which could be included as part of a motivational program. Heseltine (2010) observed that the lower level needs are mostly fulfilled and the higher level needs require attention. He posits that motivational potential inherent in construction work can be used to fulfill the higher level needs of workers.

In order to keep construction workers motivated, their needs must be addressed as construction project goals are reached. Satisfying workers requirements can be viewed as distributing incentives, when certain objectives are achieved. To satisfy the need of both the employers and their employees, workers who are motivated to reach the goals of the employer, should be recognized with an incentive/reward.

Productivity Challenge

When it comes to productivity gains, the construction industry has been ranked at the bottom compared to other industries. Poor productivity has been recognized as a serious problem for years, and unfortunately many companies have accepted this adverse trend as a *fait accompli* and as a result, companies or firms are losing billions of Naira due to poor productivity, schedule slippages, excessive overheads, unnecessary support services and lost production revenues. On the other hand, smart companies are achieving 10-20% productivity gains by implementing innovative approaches and optimizing resources utilization. Companies must recognize that in order to achieve higher productivity they must focus their effort on management effectiveness, value added planning, construction friendly design and procurement and logistical support (Kisako 2004).

METHODOLOGY

The research looked at motivational incentive efforts directed at improving productivity of labour in medium scale construction companies in three states in north-western Nigeria (i.e. Sokoto, Kebbi and Zamfara States). The instrument used for data collection was a structured, Likert-type, close-ended questionnaire. The questionnaire was divided into two parts, section A for personal data and section B for questions pertaining to the research. It was composed of nominal scale with items ratings as 5 - strongly agreed, 4 - agreed, 3 - undecided, 2 - disagreed, and 1 - strongly disagreed. The population of the study comprised some selected professionals from both the client's and the contractor's organisations. In Sokoto, Kebbi and Zamfara states a total of one hundred and twenty (120) questionnaires were distributed to contractors and their workmen in construction site, and professionals within clients' organisation. One hundred and seven (107) questionnaires were returned representing about 89% of the administered questionnaires.

Data analysis was done by descriptive statistics. The mean item score of factors that cause low productivity, the motivational incentives used by construction companies, the effectiveness of the motivational incentives on productivity, and ways of minimizing the negative effect of low productivity in construction industry were calculated and results were ranked in ascending order.

DATA PRESENTATION AND ANALYSIS

Data for this research were obtained from the three states selected in the northwestern Nigeria. Consultants and contractors in these three states were the target population. Each of these states was administered forty (40) questionnaires

Table 1 Distribution of Respondents

Consultants (N = 47)			Contractors (N = 60)		
	Frequency	%	Company Size	Frequency	%
Architects	14	30	Medium	40	67
Quantity surveyors	11	23	Small	20	33
Engineers	10	21			
Builders	12	26			
Total	47	100		60	100

In Table 1, there are two categories of respondents – consultants (with 47 respondents) and contractors (with 60 respondents). For the consultants, the table shows that 30% of the respondents are architects, followed by builders with 26%, Quantity surveyors and Engineers with 23%, and 21%. With regards to the contractors, 67% are medium scale contractors while 33% are small scale contractors. This classification of contractors is based on the number of workers employed by the companies.

Table 2 Educational Qualification

Consultant	Frequency	Percentage
OND/NCE	8	17
BSC/HND	26	55
Postgraduate	13	28
Total	47	100

From table 2, 55% of the respondents are B.Sc/HND holders, 28% are holders of posgraduate certificate, and 17% hold OND/NCE certificates. This signifies that all the respondents have the requisite knowledge to respond to the questions.

Table 3 Working Experience

	Consultants		Contractors	
	Frequency	%	Frequency	%
1-5years	9	19	9	15
6-10years	13	28	15	25
11-15years	15	32	21	35
16years & above	10	21	15	25
Total	47	100	60	100

In Table 3, majority of the consultants have work experience of between 11-15 years representing 32%, followed by 6-10 years with 28%. The respondents with the experience of 16 years and above are represented by 21%, and 1-5 years has 19%. On the contractors' side, 11- 15 years has the highest frequency of 35%. 6-10 years and 16 years and above each has percentage frequency of 25% While, 1-5 years has percentage frequency of 15%.

Table 4 Relationship between motivation, productivity and deliberation on incentives

Question	Consultants			Contractors		
	Agree	Disagree	Undecided	Agree	Disagree	Undecided
Relationship between employee level of motivation and productivity?	83%	17%	0%	100%	0%	0%
Would you agree to any management-employee deliberation before any type of incentives scheme is implemented?	71%	29%	0%	86%	14%	0%
Can motivational incentives result in optimum performance	87%	13%	0%	75%	25%	0%

In table 4, 83% of consultants indicated that there is relationship between motivation and productivity while 17% indicated contrary view. On the other hand, all the contractors (100%) affirmed that relationship exist between motivation and productivity. This signifies that, there is good relationship between employee levels of motivation and productivity.

On the deliberation on the incentive scheme, 71% of the consultants are of the opinion that there is need for deliberation/negotiation between parties on types of motivational incentive schemes to be implemented on employees, while 29% see it differently. On the contractors' side, while 86% agree that deliberation is necessary on types of motivational incentive scheme to be implemented 14% of the contractors did not see any need for deliberation. Higher percentage from the consultants and the contractors implies that deliberation/negotiation is important before any incentive scheme is implemented.

On whether motivational incentives results to optimum performance, 87% of the consultants agree and 13% disagree. On the side of the contractors, their responses show that 75% agree while 25% disagree. This signifies that good majority of the consultants and contractors agreed that motivational incentives lead to optimum performance of employees.

Table 5 Extent of employees' preference of monetary to non-monetary incentives

Question	Consultants		Contractor's	
	Frequency	%	Frequency	%
1. To a little extent	8	17	9	15
2. To a great extent	13	28	30	50
3. To a greater extent	26	55	21	35
4. I don't think so	0	0	0	0
Total	47	100	60	100

Based on table 5, 17% of the consultants indicated that employees prefer monetary to non-monetary incentives to a little extent, while 28% shows it is preferred to a great extent, another 55% shows it is preferred to a greater extent. On the contractors' side, 15% said it is preferred to a little extent, 50% said to a great extent and 35% said monetary incentives is preferred to a greater extent than non-monetary incentives. This signifies that the respondents prefer monetary incentives to non-monetary incentives.

The decision rule to table 6 below is based on the lower limit of the mean, thus: very effective 4.00-3.50; effective 3.49-2.00; partially effective 1.99 - 1.50; not effective 1.49 and below. Therefore, any mean score above 2.00 is considered as effective, while any mean score below 2.00 is considered as not effective (Onoh, 2013).

Table 6 Mean response of the respondents on the effectiveness of motivational incentives

S/N	Types of motivational incentives	Mean for Consultants	Decision	Mean for Contractors	Decision
1	End of year bonus	2.10	Effective	2.40	Effective
2	Accident free bonus	1.47	Not effective	2.25	Effective
3	Free medical bill	2.56	Effective	2.25	Effective
4	Increase in wages	3.43	Effective	3.10	Effective
	Bonus payment	1.73	Not effective	2.75	Effective
6	Conducive environment for work	1.67	Not effective	2.10	Effective
7	Timely payment	2.87	Effective	2.90	Effective
8	Praise of work effort	1.50	Not effective	2.00	Effective
9	Management of workers welfare	3.00	effective	2.95	Effective
10	Training and use of modern technique	3.43	effective	2.30	Effective
11	Job security assurance	3.10	Effective	2.50	Effective
12	Timely supply of adequate material	2.16	Effective	2.00	Effective
13	Cash reward for outstanding performance	2.50	Effective	2.50	Effective

Table 6 shows the mean response of the respondents on the effectiveness of motivational incentives. From the consultants' side, it indicates that the types of motivational incentives that are effective; increase in wages, training and use of modern techniques management of workers,' welfare, timely payment, and cash reward for outstanding performance. The table further indicates that; praise for work effort, favourable working environment and bonus payment are ineffective motivational incentives.

However, on the contractors' side, all the incentives are effective such as; increase in wages with mean score of 3.10, management of workers' welfare with a mean of 2.95, timely payment with a mean of 2.90, bonus payment with mean score of 2.75 and cash reward for outstanding performance with a mean of 2.50.

The decision rule to table 7 is based on the lower limit of the mean, thus: strongly agreed 4.50-5.00; agreed 3.50- 4.49; undecided 2.50 - 3.49; disagreed 1.50-2.49; strongly disagreed below 1.50. Therefore any mean score above 2.50 was considered as agreed, while any mean score below 2.50 was considered as disagreed (Onoh, 2013).

Table 7 Mean response of the respondents on the problems of motivational incentives

S/N	The problems of motivational incentives	Mean for consultants	Decision	Mean for contractors	Decision
1	Lack of advancement	3.60	Agreed	3.30	Agreed
2	incentive not usually prompt and timely	2.87	Agreed	2.50	Agreed
3	The incentives not always worthwhile	2.33	Disagreed	2.25	Disagreed
4	Non attention to non-monetary incentives	3.90	Agreed	3.05	Agreed
5	Lack of possibility of growth	2.93	Agreed	2.50	Agreed
6	Lack of good company policy	3.67	Agreed	2.75	Agreed
7	Inadequate extra payment	3.50	Agreed	2.60	Agreed
8	Lack of increase in salaries	2.70	Agreed	3.05	Agreed
9	Lack of fringe benefits	4.43	Agreed	3.25	Agreed
10	Lack of free education for managers	3.67	Agreed	2.80	Agreed
11	Lack of equity and fairness	3.47	Agreed	2.40	Disagreed
12	Lack of training among the workers	3.33	Agreed	2.75	Agreed

Table 7 shows the mean response of the respondents on the problems of motivational incentives. From consultants' side, the problems of motivational incentives in construction industry are; lack of advancement with mean score of 3.60, lack consideration to non-monetary incentives with mean score of 3.90, inadequacy of extra payment with mean score of 3.50 and lack of free education for managers with a mean score of 4.43. However, the consultants do not see sufficiency of incentives as a problem since it has a mean of 2.33.

On the contractors' side, lack of increase in salary with mean score of 2.70, lack of possibility of growth with mean score of 2.93, lack of advancement with mean score of 3.30 and lack of free education for managers with mean score of 3.25 are among the problems of motivational incentives. However, lack of equity and fairness and sufficiency of the incentive are not much of a problem in their opinion.

The decision rule to table 8 below is based on the lower limit of the mean, thus: strongly agreed 4.50-5.00; agreed 3.50-4.49; undecided 2.50-3.49; disagreed 1.50-2.49; strongly disagreed below 1.50. Therefore any mean score above 2.50 was considered as agreed, while any mean score below 2.50 was considered as disagreed (Onoh, 2013).

Table 8 Mean response of the respondents on the factors of low productivity

S/N	Factors of low productivity	Mean for consultant	Decision	Mean for contractor	Decision
1	Inadequate skill	3.56	Agreed	4.15	Agreed
2	Poor supervision of workers	3.06	Agreed	4.15	Agreed
3	Poor organization	3.27	Agreed	2.50	Agreed
4	Non-availability of machines	2.60	Agreed	3.50	Agreed
5	Lack of career growth path	4.00	Agreed	4.15	Agreed
6	Lack of motivational incentives	3.67	Agreed	4.00	Agreed
7	Shortage of skilled labour	3.30	Agreed	3.20	Agreed
8	Un-conducive environment	3.83	Agreed	3.75	Agreed
9	Delay in supply of materials	3.83	Agreed	4.25	Agreed
10	Lack of training to workers	3.33	Agreed	3.25	Agreed
11	Lack of adequate company policy	3.77	Agreed	4.20	Agreed
12	Additional task not normally part of work trade	3.60	Agreed	3.00	Agreed
13	Inadequacy of material	3.50	Agreed	2.80	Agreed
14	Ineffective communication between management and employees	3.83	Agreed	2.45	Disagree

Table 8 shows mean response of the respondents on the factors of low productivity. From the consultants' side, the factors of low productivity are shortage of skilled labour with mean score of 4.20, lack of motivational incentive with mean score of 4.00, lack of adequate company policy with mean score of 3.77, un-conducive working environment with mean

score of 3.83, then delay in supply of materials with mean score of 3.83 and lack of career growth path with mean score of 4.00. On the contractors' side, the respondents agreed on these factors of low productivity; inadequate skill with mean score of 4.15, poor supervision of workers with mean score of 4.15, lack of motivational incentives with mean score 4.00, lack of training to workers with mean score of 3.25 and shortage of skilled labour with mean score of 3.20. However, the respondents have disagreed that ineffective communication between management and employees (mean = 2.45) is a factor of low productivity.

The decision rule to table 9 below is based on the lower limit of the mean, thus: very important 4.00-3.50; important 3.49-2.00; partially important 1.50-1.99; not important 1.49 below. Therefore, any mean score above 2.00 was considered as important, while any mean score below 2.00 was considered as not important (Onoh, 2013).

Table 9 Mean response of the respondents on ways of minimizing low productivity

S/N	Ways of minimizing low productivity	Mean for consultants	Decision	Mean for contractors	Decision
1	Proving adequate working condition	2.50	Important	2.45	Important
2	Providing standard company policy	2.26	Important	2.00	Important
3	Qualitative technical supervision	2.17	Important	2.00	Important
4	Motivating construction workers	3.00	Important	2.25	Important
5	Good interpersonal relationship	2.67	Important	3.25	Important
6	Providing required material for workers	2.50	Important	2.17	Important
7	Avoiding delay and changes	2.50	Important	2.00	Important
8	Improving communication skill	2.17	Important	3.25	Important
9	Improving availability of machines	3.00	Important	2.00	Important
10	Providing adequate skill labour	3.00	Important	2.17	Important
11	Providing equity and fairness	3.00	Important	3.25	Important
12	Providing opportunity for promotion and self-development	3.00	Important	3.25	Important
13	Providing insurance on accident/death	3.00	Important	3.25	Important
14	Providing adequate training for workers	3.00	Important	3.25	Important

Table 9 shows the mean response of the respondents on ways of minimizing low productivity. On the consultants' side, the important factors of minimizing low productivity include; providing adequate working conditions with mean score of 2.50, improving availability of machines with mean score of 3.00, providing adequate skilled labour with mean score of 3.00.Providing adequate training for workers with mean score of 3.00. Improving communication skill with mean score of 2.17 and avoiding delay and changes with mean score of 2.50 are all considered as important. On the contractors' side, important ways of minimizing low productivity include; providing insurance on accident/death with mean score of 3.25, providing adequate training for workers with mean score of 3.25, good interpersonal relationship with mean score of 3.25 and avoiding delay and changes with a mean of 2.00. Quality of technical supervision with mean score of 2.00, providing required materials for workers with mean score of 2.17 and provision of standard company policies with a mean of 2.00 are all considered important.

DISCUSSION OF RESULTS

The most fundamental benefit that employees seek in the workplace according to (Hamukwaya, & Yazdanifard, 2014) is satisfaction, while employers seek maximum work performance. For these benefits to be attained, a relationship is necessary. This connection is indicated in table 4.4 which shows that employee level of motivation is related to productivity and the use of motivational incentives leads to optimum performance of employees. This result bears relation with Ou and Wang (2009) that rewards closely tied to key performance

measures will induce employees to perform above minimum expectations to maximize those performance measures and consequently maximize their pay level.

Finding in table 1.5 shows that employees prefer monetary incentives to non-monetary incentives. This is not surprising because the lower-level employees are at the physiological level of need according to Maslow hierarchy of needs and may not necessarily be in dire need of non-monetary incentive such as recognition. Wallace and Zeffane (2001), cited in Harunavamwe and Kanengoni (2013) reported that management depend upon rewards like money as the main factor of motivation because, money is a unique reward that can satisfy different needs such as physiological need for food. This is also in agreement with Arnolds and Venter (2007) whose findings show that financial rewards are the best motivators.

However, Harunavamwe and Kanengoni (2013) conducted a study which shows no significant relationship between monetary rewards and motivation. Non-monetary rewards according to Harunavamwe and Kanengoni (2013), have proved to be effective on lower-level employee, and suggested that non-monetary rewards be used to create a sincere focus of appreciation that is linked directly to compensation not necessarily motivation. So where deliberations are held as result indicates in table 4.4, management measures will be implementation of agreed incentives tailored towards meeting the desired performance. The management-employee deliberation underscores the need to identify and provide for the identified needs of the employees before implementation and also ensures that the incentives are timely and not misplaced. Furthermore, where discussions are held, apart from the sense of recognition accorded the employees, the motivation strategy serve to integrate workers needs into meeting the organization's need.

CONCLUSION AND RECOMMENDATIONS

The purpose of the study was to assess how labour motivational incentives affect productivity improvement in construction industry. The objective was to find an appropriate strategy for improving the productivity of labour in the industry. It was found out that providing adequate working condition, avoiding delays in supply of materials and enhanced salary package are among the motivational ways of improving labour productivity in construction works. It was therefore concluded that improving productivity is essential if the industry is to live up to its expectations in terms of project delivery on time, at the budgeted cost and the required quality of finished work. It was recommended that:

i. Management of construction companies should be concerned with the welfare of the workers. This will give the workers a sense of belonging and being appreciated and will make them to be more focused and committed to their work.
ii. Bonus payment should be used as motivators to increase performance of construction workers.
iii. Management of construction companies should provide favourable working conditions to their workers. This will reduce dissatisfaction with work on site.
iv. Regular payment of wages to operatives should be maintained. This will enhance their morale and thus increase their productivity.
v. The quality of technical supervision should be increased because when employees are not able to receive answers to job-related questions, they become frustrated.
vi. Good interpersonal relations among peers, supervisors, and subordinates should be encouraged.

ABSTRACT

Access to land for any type of development in the built environment is fundamental. Land defines the social, economic and political relations in the society and is the most crucial factor of production. Various means of gaining access to land since ancient times to the 21st century have ranged from first settlement, long time occupation, conquest, gift, inheritance, purchase and government allocation. This paper aims at revealing the sources of gaining access to residential land in Owerri by both male and female with a view to engendering appropriate policy response towards female housing ownership. The target population was home-owners in the core of Owerri. The sample size was determined from the 2006 population census figure of the Owerri Municipal Local Government Area using appropriate formula. A total of 396 questionnaires were administered to home-owners using stratified random sampling technique out of which 376 were found useful. Discriminant Function Analysis was used to determine which socio-economic variables were the best predictors of how access to land can be gained. Income, marital status and occupation emerged as the best predictors. The paper recommends public campaigns against gender discriminatory inheritance systems, joint titling of land documents by spouses and provision of enabling environment to boost informal employment which is predominant in the study area.

Keywords: Accessibility, Gender, Nigeria, Owerri, Residential land

INTRODUCTION

The centrality of land to any development in the human habitat cannot be over emphasized. Land is regarded as one of the most important factors of production without which development of any kind will be almost impossible. The ease with which individuals and organizations gain access to land goes a long way to determine the rate of development. Different factors interplay when it comes to the issue of gaining access to land especially in developing countries like Nigeria. Availability of finance is a major determinant of gaining access to land. An equally important factor affecting access to land is the societal perspective or norm of who should have access to land especially in traditional settings of Africa where gender distinction in access to land is prevalent. This paper reviews literatures on women access to land in different parts of Africa and examines the means through which males and females gain access to land in Owerri, Nigeria.

REVIEW OF LITERATURE

Gender Access to Land

Rights to land in Africa stem from many different sources, such as first settlement, conquest, allocation by government, long occupation or market transaction. In some cases, these rights are transferable to heirs or can be sold (Toulmin, 2006). Men gain access to land through being members of a social group, through labour and investment and through purchase (Shipton and Goheen, 1992). In Africa and South-Asia especially, women are systematically denied their human rights to access, own, control or inherit land and property. The vast majority of women cannot afford to buy land, and usually can only access land and housing through male relatives, which makes their security of tenure dependent on good marital and

Ajayi, M. A.; Asaju, A. S.; Bello, M. O. & Omole, F. K. (2016). Effect of Socio-Economic Variables on Residential Land Accessibility in Owerri, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 513-518

family relations (Marjolein, 2004). This is further authenticated by Kironde (2006) that "in many societies, women's claim to land within the customary systems is usually realized through men, as daughters, sisters but especially as wives. Such rights are known as secondary rights since they are of uncertain duration, are not well-defined and are subject to change based on maintaining good relations between parties." Property ownership, use and inheritance are regulated in practice in many African cultures by customary laws mostly unwritten but influential local norms that are based on gender distinctions (Okello, 2003).

Women's rights to land are also rights to use land not to control what to grow or the proceeds of the harvest. For instance, in Tanzania, as Kevane and Gray (1996) attest, women may have control over food banana trees but not over beer banana trees. They may also grow annual crops like maize, potato and beans but may not grow or own coffee trees. Toulmin and Quan (2000) reveal that in male-led societies, there is generally the fear that access of women to land may lead to increased independence of women. In Uganda, there is a stigma attached to a woman owning land. Such women used to be given little respect and it was believed that their marriage may not be stable. In Cameroon, men refuse to give their wives land for fear of losing their labour to work on their own fields. Women tend to be allocated less fertile lands and usually have smaller land holdings than men.

Duncan and Brant (2004) conducted a gender study in the Volta Region of Ghana on access to and control over land and found that ninety-six percent of women respondents indicated that both men and women had access to lineage, stool or clan land. A similar study was conducted by Owusu (2008) on land tenure dynamics in Volta and Central Regions of Ghana to determine the effect of gender and access to land on livelihood of males and females. Although gender did not have statistically significant effect, having access to land turned out to be the main determining variable for livelihood. This shows the importance of access to land.

Concept of Land Accessibility

There are four components of land accessibility which are availability of usable land, afforda bility of such land, ease of transaction with that land and security of the owner's right. For lan d to be said to be accessible to the end users, it must be physically available, economically aff ordable with ease of transaction and security of tenure (Ominrin, 2002; Bello, 2009). Accessi bility to land is significant for growth and poverty reduction in any society. Access to land an d security of tenure are necessary for people to raise and stabilize other income and to particip ate in economic growth. Physical overall supply of land within a geographical area is fixed w hile the demand for land is on the increase, leading to higher land values. Scarcity of land has been identified as one of the constraints of access to land and housing. To the Nigerian urban poor, the issue of affordability constitutes the major hindrance to land accessibility. The costs of land especially in urban areas are high and usually not affordable for low and medium inco me group. In this study, income is used as one of the predictors of how access to land is gaine d. Ease of transaction is related to the transferability of land right especially through purchase . Transferability of land is one of the qualitative parameters to measure access to land accordi ng to Komjathy and Nichols (2001).

RESEARCH METHODOLOGY

The setting for this paper is Owerri, the capital of Imo State. It is located in the eastern part of Nigeria. The people of Owerri are mainly Igbo tribe and the predominant culture of inheritance is patriarchy (Ajayi, Bello & Asaju, 2010).The study relied on the population figures of 2006 of the Owerri Municipal Local Government Area to which a formula for determining sample size was applied. Male and female respondents were sampled from

selected streets in the town using stratified and systematic random sampling techniques. The basic instrument for collecting needed data for this study was a set of questionnaire. Out of the 396 administered in Owerri, 376 were found useful for analysis. Discriminant Function Analysis was employed in order to determine the variables that are best in discriminating between groups of people based on how they gained access to land. The predictors or independent variables were the socio-economic characteristics of respondents which were sex, marital status, educational status, income level and occupation while the grouping or dependent variable was the means of gaining access to land namely purchase, inheritance, government allocation and gift. Mathematically, the model is given as:

$$d=a+b_1x_1+b_2x_2+b_3x_3+b_4x_4+b_5x_5 \quad \text{(equation 1)}$$

where d= discriminant score

a = constant $b_1, b_2.....b_5$ = discriminant coefficients

x_1= sex x_2= marital status x_3= educational status

x_4= income level x_5= occupation

DISCUSSION OF RESULTS

Data were got on the socio-economic variables of respondents as well as the means of gaining access to land. These variables were used in the Discriminant Function Analysis as the predictors and grouping variables respectively. The distribution of respondents is presented on a gender basis in Table 1.

Table 1: Socio-Economic Variables of Respondents

Response	Male	Female	Total
Marital Status			
Single	53(17.3)	12(17.1)	65(17.3)
Married	211(69.0)	38(54.3)	249(66.2)
Divorced	12(3.9)	2(2.9)	14(3.7)
Separated	13(4.3)	5(7.1)	18(4.8)
Widowed	17(5.5)	13(18.6)	30(8.0)
Total	**306(100.0)**	**70(100.0)**	**376(100.0)**
Education			
No formal education	25(8.2)	7(10.0)	32(8.5)
Primary education	19(6.2)	6(8.6)	25(6.7)
Secondary education	84(27.5)	16(22.9)	100(26.6)
Tertiary	161(52.6)	40(57.1)	201(53.5)
Total	289(94.4)	69(98.6)	358(95.2)
Missing	17(5.6)	1(1.4)	18(4.8)
Total	**306(100.0)**	**70(100.0)**	**376(100.0)**
Monthly income			
20,000 and below	65(21.2)	25(35.7)	90(23.9)
21-40,000	70(22.9)	11(15.7)	81(21.5)
41-60,000	78(25.5)	8(11.4)	86(22.6)
61-80,000	31(10.1)	8(11.4)	39(10.4)
Above 80,000	291(95.1)	65(92.9)	356(94.7)
Missing	15(4.9)	5(7.1)	20(5.3)
Total	**306(100.0)**	**70(100.0)**	**376(100.0)**
Occupation			
Civil service	95(31.0)	20(28.6)	115(30.6)
Self-employment	99(32.4)	24(34.3)	123(32.7)
Private sector employment	58(19)	16(22.8)	74(19.7)
Retired	37(12.0)	5(7.1)	42(11.2)
Others	6(2.0)	2(2.9)	8(2.1)
Total	295(96.4)	67(95.7)	362(96.3)
Missing	11(3.6)	3(4.3)	14(3.7)
Total	**306(100.0)**	**70(100.0)**	**376(100.0)**

Table 1 show that there were 306 male respondents and 70 females. The predominant marital and educational status of home owners was married and tertiary education respectively. The

highest percentage of income range (94.7%) was above N80000. Self employment was predominant for both genders, closely followed by private sector employment.

Table 2: Gender Distribution of the Means of Access to Land/ Housing

Response	Male	Female	Total
Purchase	136(44.4)	39(55.7)	175(46.5)
Inheritance	158(51.6)	27(38.6)	185(49.2)
Gift	6(2.0)	1(1.4)	7(1.9)
Government allocation	6(2.0)	3(4.3)	9(2.4)
Total	**306(100.0)**	**70(100.0)**	**376(100.0)**

Table 2 reveals that inheritance was the major means of gaining access to land in Owerri (49.2%). For male, inheritance was the greatest means of access to land and housing (51.6%) while only 38.6% of female home-owners got access through inheritance. More than half (55.7%) of female home-owners got access through purchase. Access through gift and government allocation was generally low in the study area.

The DFA was used to determine the best predictors of access to land and housing in the study area. Out of the 376 respondents, 326 (86.7%) were valid enough to be used for the Discriminant Function Analysis. 13.3% were excluded because there was at least one missing discriminating variable. The results of the DFA are in the next tables:

Table 3 Eigenvalues

Function	Eigen values	% of Variance	Cumulative %	Canonical Correlation	Proportion of variance (R^2) %
1	.215[a]	92.9	92.9	.421	17.7
2	.012[a]	5.1	97.9	.108	1.2
3	.005[a]	2.1	100.0	.069	0.5

Table 3 shows the efficacy of the Discriminant function. The canonical correlation of 0.421 for Function 1 suggests the model explains 17.7% of the variation in the grouping variable that is whether a home - owner gets access to land through purchase, inheritance, government allocation or gift. Function 2 and 3 having canonical correlations of 0.108 and 0.069 suggests the model explains 1.2% and 0.5% of the variation respectively.

Wilks' Lambda indicates the significance of the Discriminant functions and provides the proportion of total variability not explained.

Table 4 Wilks' Lambda

Test of Function(s)	Wilks' Lambda	Chi-square	Df	Sig.
1 through 3	.823	67.681	15	.000
2 through 3	.984	5.271	8	.728
3	.995	1.531	3	.675

In Table 4, only function 1 indicates a highly significant function ($p < .000$) and provides the proportion of total variability not explained, i.e it is the converse of the squared canonical correlation which gives 82.3%.

In the standardized canonical discriminant function coefficients table, the variables with the largest coefficients stand out as those that strongly predict allocation to the group.

Table 5: Standardized Canonical Discriminant Function Coefficients

	Function		
	1	2	3
Gender	.306	-.035	-.377
Marital status	.430	.846	.265
Educational level	.132	-.099	-.414
Occupation	-.231	-.280	.696
Income level	.875	-.301	.433

In Function 1, income level score was the strongest predictor (0.875), in Function 2, marital status score was strongest (0.846) while occupation score (0.696) was strongest in Function 3. This means that income level, marital status and occupation were more successful as predictors in allocating to the four groups of how land was acquired.

Table 6: Cross Tabulation of Means of Access to Land/ Housing and Occupation

Occupation	Purchase	Inheritance	Gift	Government allocation	Total
Civil Service	62(35.8)	51(28.3)	0(0.0)	2(100.0)	115(31.8)
Self-employment	51(29.5)	66(36.7)	5(71.4)	0(0.0)	122(33.7)
Private sector employment	44(25.4)	28(15.6)	2(28.6)	0(0.0)	74(20.4)
Retired	16(9.3)	26(14.4)	0(0.0)	0(0.0)	42(11.6)
Others	0(0.0)	9(5.0)	0(0.0)	0(0.0)	9(2.5)
Total	173(100.0)	180(100.0)	7(100.0)	2(100.0)	362(100.0)

The type of occupation of homeowners affected the means through which they gained access to land. Civil service or formal employment provides enlightenment and access to information on the availability and procedure of allocation of government land. Hence, it was found that the two respondents (100%) who got access through government allocation were civil servants. Self- employment had the greatest percentage of 36.7% for access through inheritance and it was the highest employment type that was predominant in the town. This reveals the importance of the informal sector to the Nigerian economy.

Table 7: Cross Tabulation of Means of Access to Land/Housing and Marital Status

Marital Status	Purchase	Inheritance	Gift	Government allocation	Total
Single	21(11.9)	41(21.6)	2(28.6)	1(33.3)	65(17.3)
Married	118(67.0)	129(67.9)	1(14.3)	1(33.3)	249(66.2)
Divorced	10(5.7)	3(1.6)	1(14.3)	0(0.0)	14(3.7)
Separated	9(5.1)	5(2.6)	3(42.9)	1(33.3)	18(4.8)
Widowed	18(10.2)	12(6.3)	0(0.0)	0(0.0)	30(8.0)
Total	176(100.0)	190(100.0)	7(100.0)	3(100.0)	376(100.0)

66.2% of respondents were married and inheritance (67.9%) and purchase (67%) were the predominant means of gaining access to land in the study area. This shows that inheritance is a major means of gaining access to land in Owerri; which is mainly patriarchal.

Table 8: Cross Tabulation of Means of Access to Land/Housing and Monthly Income

Monthly Income	Purchase	Inheritance	Gift	Government allocation	Total
20,000 and below	18(10.6)	38(21.6)	3(42.9)	0(0.0)	59(16.6)
21-40,000	33(19.4)	56(31.8)	1(14.2)	0(0.0)	90(25.3)
41-60,000	28(16.5)	49(27.8)	3(42.9)	2(66.7)	82(23.0)
61-80,000	56(32.9)	30(17.1)	0(0.0)	0(0.0)	86(24.2)
Above 80,000	35(20.6)	3(1.7)	0(0.0)	1(33.3)	39(10.9)
Total	170(100.0)	176(100.0)	7(100.0)	3(100.0)	356(100.0)

Table 8 reveals that 32.9% of home owners who got access to land through purchase were in the medium income group of ₦61- 80000 while 10.6% were in the least income group. Income is a major factor in land purchase and housing development.

CONCLUSION AND RECOMMENDATIONS

This study has examined the socio-economic variables that affect how access to land was gained by both males and females in Owerri. Using the Discriminant Function Analysis to determine the variables that best predict how access to residential land was gained, findings showed that occupation, income and marital status were the best predictors. This study is of

importance in advising policy makers and citizens in the study area on the issue of gaining access to land. The paper has revealed that majority of people who gained access to land through purchase were involved in informal sector of the economy (mainly self employment). This confirms the fact that the informal sector of the economy is very vital in contributing to economic growth of the nation. It therefore recommends the provision of enabling environment (such as stable power supply, access to microfinance for SMEs) to boost informal employment which is predominant in the study area. This will in turn increase the income level of the citizens and enable them to access land for housing development. The paper recommends public campaigns against gender discrimination in inheritance systems that inhibit women land rights. Joint titling of land documents by spouses as most respondents are married is also recommended to ensure that the titles of especially the wives are secured and safe from property grabbing by in-laws (Ajayi and Olotuah, 2005) This phenomenon of property grabbing at the demise of the household head by his relatives is prevalent in the Igbo culture and constitutes a hindrance to women's access to land and housing.

Cost and Value Management in Projects

Paul Ogbiti

Cebonai Associates, 2, Imasuen Close,Off Igbinosa Street, GRA, Benin City
emiosi2003@yahoo.com

ABSTRACT

The key features that define project success are twofold: managing costs to achieve efficiencies, and creating and enhancing value. These two elements enable project stakeholders to understand the activities and resources required to meet project goals, as well as the expenditures necessary to complete the project to the satisfaction of the customer. Unfortunately, in the field of project management today, significant cost and schedule overruns are the norm, rather than the exception. The document clearly delineates the objectives and requirements of the project, and identifies key activities in broad terms. Forecasting methods for projects fall into two broad categories: qualitative and quantitative. Qualitative methods are used where no reliable, historical, or statistical data are available. Quantitative techniques, on the other hand, are appropriate in project situations where measurable, historical data are available and are usually used in forecasting for short or intermediate timeframes. These techniques can be classified into two broad categories: time series analysis and causal methods. It should be evident that achieving project success hinges on effectively managing both project costs and value. The discussions, however, focused on the various issues and approaches to individually managing these two critical project success factors. We begin our discussion with the concept of a project value chain, which demonstrates the inseparable and interwoven nature of project costs and value. We present various approaches to simultaneously managing cost and value to achieve project success. To effectively manage for cost and value, a cross-functional mindset must prevail throughout the organization, so that ideas, alternatives, and creative solutions have the widest possible arena for exploitation.

Keywords: Cost Management, Value Management, Cash Flow Management, Project Budgeting, Quality Management

INTRODUCTION

The past 30 years have witnessed a dramatic increase in the number and variety of organizations engaged in project-based work. In addition to ‘‘traditional’’ project-oriented industries, like construction, aerospace, and pharmaceuticals, service industries as diverse as finance, utilities, telecommunications, and insurance are beginning to embrace project-based ventures.(AP Wire Reports, January 25, 2007)

This paradigm shift is due to growing recognition that projects and their effective management can provide organizations with a significant competitive edge through cost reduction, enhanced responsiveness, and overall value to customers. Consequently, a number of organizations have adopted many of the well-known techniques of project management, and professional project management organizations have witnessed marked increases in membership.

Despite this enormous interest in projects and project management practices, success rates in many industries are at alarmingly low levels. In addition, bad news about high-profile projects continues to dominate the headlines—in both the public and private sectors. Consider these recent examples:

Importance of cost and value management in projects

The key features that define project success are twofold: managing costs to achieve efficiencies, and creating and enhancing value (*Wall Street Journal*, January 16, 2007). These

Ogbiti, P. (2016). Cost and Value Management in Projects. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 519-527

two elements enable project stakeholders to understand the activities and resources required to meet project goals, as well as the expenditures necessary to complete the project to the satisfaction of the customer.

Unfortunately, in the field of project management today, significant cost and schedule overruns are the norm, rather than the exception (Pinto, J. K. (2007)). In fact, recent research that examined the success rates of information technology (IT) projects indicates that the majority of these projects neither met their cost objectives nor delivered the promised value. For example:

i. In a study of 300 large companies, consulting firm Peat Marwick found that 65 percent of hardware and/or software development projects were significantly behind schedule, were over budget, or failed to deliver value in terms of expected performance. (Millet, I. and Pinto, J. K. (1999)
ii. In a report on the current state of IT project implementation, the Standish Group predicted that out of a total of 300,000 projects that cost over $350 billion, approximately 43 percent will overshoot their initial cost estimates, while 63 percent will fall behind schedule and perform at only two-thirds of their expected capability. In other words, these projects will meet neither their cost nor their value objectives.(Standish Group (2001)

Why do these problems persist, despite the fact that tools for cost efficiency and value enhancement are widely used, and their benefits are well understood? One key answer is the lack of an integrated cost and value management framework. (Garvin, D. A. (1992)

Before we explore this integration of cost and value, a brief discussion of their concepts in relationship to projects is worthwhile. Both require well-defined and structured management processes, commonly referred to as cost and value management. Project cost management focuses on issues such as cost estimation and budgeting, cash flow management, and cost control. On the other hand, the emphasis of value management is on optimizing project value—given cost, time, and resource constraints—while meeting performance requirements such as functionality and quality.

Cost and value management remains a critical but often underrepresented issue for a couple of reasons. First, in this book, we define value as the relationship between meeting or exceeding the expectations of project stakeholders, as well as the resources expended to meet or exceed those expectations. This definition clearly implies that project cost and value are inextricably linked, to the point where any attempt to enhance project value without a thorough understanding of its impact on cost and associated trade-offs is meaningless.

Second, project value is a multidimensional concept. Different project stakeholders with different vested interests have different perceptions about what constitutes value to them. For example, the expectations of top management often leave IT project teams scrambling to complete projects as quickly as possible. Internal customers, however, may request additional features that will delay completion. Each stakeholder sees value in the finished project; however, the measures they use to determine value can actually conflict. And yet, despite these differences, the one constant in any attempt to enhance project value is its cost ramifications. The inability to clearly understand this complex relationship between project cost and value is one of the primary reasons why it is an under-represented issue. The following case example illustrates this point.

Keys to effective project cost management

Effective project cost management is an extremely complex process that begins very early during a project life cycle, and long before its actual start. Among the factors that influence

success is a reasonable and accurate system for estimating costs (Turner, J. R., and Simister, S. J. (2000). Table 1 drawn from Rodney Turner's work, highlights some of the most important considerations when creating a cost estimation system.

Keys to effective cost estimation are:

i. A clear, complete, and unambiguous definition of the project and the scope of work involved
ii. A thorough assessment of the potential risks involved, with well-thought-out action plans to minimize their possible impact
iii. A well-trained and competent project manager
iv. A thorough understanding, by all stakeholders, of the various types of costs that are likely to be incurred throughout the life of the project
v. A project organizational culture where there is a free flow of com-munication, so that all project participants clearly understand their responsibilities
vi. A well-defined project work structure where work packages are broken down into manageable sizes
vii. Meaningful budgets, where each work package is allocated its appropriate share of the total budget, commensurate to the work involved
viii. An accounting system and coding scheme that are well aligned with the work breakdown structure and are compatible with the organization's management information system
ix. A cost accounting system that will accumulate costs and allocate them to their relevant cost accounts as and when they are incurred
x. A prioritized and detailed work schedule, drawn from the work break-down structure, which assigns and tracks the progress of individual tasks
xi. Effective management of well-motivated staff, to ensure that progress meets or beats the work schedule
xii. A mechanism for comparing actual and planned expenditures for individual tasks, with the results extrapolated to cover the entire project
xiii. The ability to bring critical tasks that are late back on schedule, including providing for additional resources or taking other prompt remedial measures
xiv. Adequate and effective supervision to ensure that all activities are done right the first time.
xv. Supervision of staff time sheets so that only legitimate times are booked to various cost codes
xvi. Proper drafting of specifications and contracts
xvii. Discreet investigation to confirm that the customer is of sound financial standing, with sufficient funds to make all contracted payments
xviii. Similar investigation, though not necessarily as discreet, of all significant suppliers and subcontractors (especially those new to the contractor's experience)
xix. Effective use of competitive tendering for all purchases and subcontractors to ensure the lowest cost commensurate with quality and to avoid committing to costs that exceed estimates and budgets
xx. Proper consideration and control of modifications and contract variations, including charging all justifiable claims for price increases to the customer
xxi. Avoidance of all nonessential changes, especially those for which the project customer will not pay
xxii. Proper control of payments to suppliers and subcontractors to ensure that all invoices and claims for progress payments are neither overpaid nor paid too

soon

xxiii. Recovery of all incidental expenses allowed for in the contract charging structure (for example, expensive telephone calls, special printing and stationery, travel, and accommodation)

xxiv. Proper invoicing to the customer, ensuring that claims for progress pay-ments or cost reimbursements are made at the appropriate times and at the correct levels, so that disputes that could delay payments do not arise

xxv. Effective credit control to prevent payments from the customer from becoming long overdue

xxvi. Internal security audits to help prevent losses through theft or fraud

xxvii. Regular cost and progress reports to senior management, highlighting potential schedule or budget overruns in time for corrective action to be taken

xxviii. Cost-effective design, perhaps using value engineering

xxix. Prompt action to close off accounts at the end of the project, to prevent unauthorized time bookings and other items from being charged to the project (Turner, J. R., and Simister, S. J. (2000)

While this list is not all-inclusive, its elements do have a significant influence over the effectiveness of cost management for projects large and small. Of more immediate interest is the sheer complexity and breadth of an effective cost estimation system, suggesting that organizations intent on controlling their costs need to recognize that there is no such thing as a simple, quick fix. Rather, downstream project cost management rests heavily on the care and accuracy of detailed estimation occurring early in the project.(Pinto, J.K and Venkataraman,R.R Copyright 2008). As the old saying suggests, ‘‘we can’t fix what we can’t see.’’ Taken one step further, we can’t control what we did not plan for!

Essential features of project value management

‘‘Project value’’ refers to the relationship between the needs of different project stakeholders and the resources used to satisfy them. What constitutes project value, however, can be hard to pin down, because different stakeholders have different views. The challenge of value management is to understand and reconcile these differences.

Essentially, value management focuses on enhancing project value, given cost and time constraints, without any negative impact on the project facility’s functionality, reliability, or quality.(Ibid) Effective project value management includes the following key features (Ibid):

i. *Careful analysis and identification of project needs and scope*—the first step in effective value management lies in a clear project definition and scope analysis.

ii. *Thorough planning of the project and subsequent work* - Effective planning helps to ensure that the project is developed to maximum cost efficiency with no unnecessary steps or wasted effort.

iii. *Identification of key areas of opportunities that can influence project value*—The project team’s goal is to enhance positive features of the project while keeping control of costs. Carefully weighing the cost/benefit analysis for a project is the key to enhancing value.

iv. *Development of alternatives for exploiting the identified opportunities for improving project value*—Multiple paths may be available for enhancing value, some of which are cost effective than others.

v. *Evaluation of alternatives; development of proposals and action plans*—performing a clear trade-off analysis can help create alter-natives and select the best choices for improving value.

vi. *Use of a performance monitoring system for tracking project value*— The project team must have the means to accurately monitor the project, gain timely and

actionable information, and make ‘‘on-line’’ decisions and choices among alternatives.

vii. *Ensure a free flow of communication that cuts across organizational boundaries*—to effectively manage for value, a cross-functional mindset must prevail throughout the organization, so that ideas, alternatives, and creative solutions have the widest possible arena for exploitation.

Integrating Cost and Value in Projects

It should be evident that achieving project success hinges on effectively managing both project costs and value. The discussions will, however, focus on the various issues and approaches to *individually* managing these two critical project success factors. My goal, therefore, is to unify the concepts and processes of project cost and value management so that these two vital decision areas can be treated as an integrated whole.

I begin this discussion with the concept of a project value chain, which demonstrates the inseparable and interwoven nature of project costs and value. In subsequent sections, I will present various approaches to simultaneously managing cost and value to achieve project success.

The project value chain

The concept of ‘‘value chain’’ was first articulated by Michael Porter (Porter, M. (1985). The essence of Porter’s value chain concept is that an organization needs to manage a set of basic activities to create value that in monetary terms is greater than the cost of providing the organization’s product or service. The end result of effectively managing these activities is that the organization generates a profit margin and sustains its competitive advantage in the marketplace. The figure below presents the basic model of Porter’s value chain.

In Porter’s value chain model, there are two distinct sets of activi-ties: primary activities and support activities. In a typical organization, primary activities are directly responsible for creating or delivering the product or service. They comprise inbound logistics, operations, outbound logistics, marketing and sales, and service. The support activities that are linked to each of these primary activities help to improve their effective-ness or efficiency. Support activities can be grouped into procurement, technology development (including R&D), human resource management, and infrastructure (systems for planning, finance, quality, information management, etc.).

Value chain analysis evaluates the value that each particular activity adds to the organization’s products or services. The goal is to make it possible to produce a product or service that delivers the value customers want, and for which they are willing to pay a price. Porter contends that the ability to perform these specific activities and to manage the linkages between them is a source of value and competitive advantage to the firm (Recklies, D. (n.d.).

Project value chain analysis provides an entirely different perspective on what constitutes project success. While the traditional measures of project success, such as schedule, cost, and technical validity, are still relevant, project value is much more than these internal measures, and ultimately it is the customer who determines that value. In project management, the adoption of the value chain concept offers considerable potential for ensuring that projects meet the unique needs of customers.

A basic model of the project value chain is presented in Figure 1. It is similar to Porter’s value chain model in that the project value chain is also composed of primary and secondary activities.

The primary activities are procurement and inbound supply chain management, project design or fabrication, and project delivery or installation. All of these activities are directly

responsible for creating the project's facility, and therefore, project value. Secondary activities include the project infrastructure, management information, and human resource management systems.

The critical elements of the project infrastructure that enhance or optimize project value are cost management, scope management, schedule management, quality management, configuration management, and change control systems. Within the project infrastructure, cost management is an umbrella system that is concerned with all cost-related subsystems such as accounting and finance, and all cost-related activities such as project cost estimation, budgeting, and cost control.

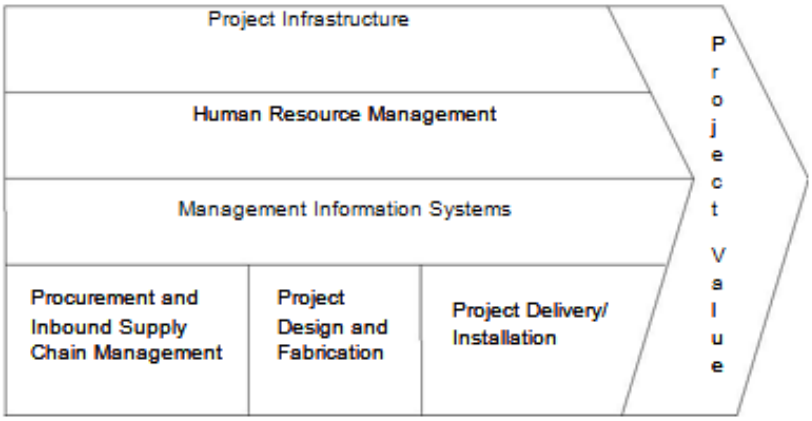

Fig. 1 Project value chain

Project value chain analysis

The primary thrust of project value chain analysis is to help companies understand, without any ambiguity, how they can create and deliver the value that is most critical to the customer and their activities. A project organization that can successfully accomplish this goal has a clear competitive advantage. An important prerequisite of a successful value chain analysis is that the company has thorough knowledge of not only its own strengths and weaknesses, but also those of the potential customer. Armed with this knowledge, the project organization is better equipped to address the unique and critical needs of the customer's business operations.

Performing a successful value chain analysis requires the following four steps:

Step 1*: Construct a value chain that is unique to the customer*—because each project is unique, the first step in developing a value chain is for the project organization to clearly understand its role in the customer's value chain. To review, a project value chain consists of a sequential chain of activities that begins with acquisition of raw materials from suppliers, progresses through the development of the project, and concludes with the delivery of the completed project to the customer. While each activity in the chain has the potential to add value, the key role of the project organization in the value-adding process is to provide superior quality at lower costs and risks by effectively designing and fabricating the project facility.

To develop a meaningful value chain strategy, the project organization should be fully aware of the areas in which they can make the most significant contributions that will benefit the customer. This requires that the project firm clearly understand its own competitive strengths—the activities that the organization does well, and that can add value. For example, one project organization may use superior technology and design capabilities to add value to client operations, while another may enhance value by using global links to suppliers and distribution capabilities to acquire high-quality raw materials at a lower cost.

Conversely, the project organization also needs to understand its weaknesses—those activities that it does not do well relative to the competition. The key is to recognize areas where the project organization can best use it competitive strengths, instead of attempting every aspect of the client's operations.

***Step 2**: Identify the client's value drivers*—At this step, value analysis should focus on identifying the activities and linkages of client operations that distinctly add value and are sources of competitive advantage for the client. For example, the focus should be on activities that enable the client to achieve a cost advantage or produce a distinctly unique product, which are value drivers that create differentiation. By focusing on the client's value drivers, the project organization can develop project design choices that can provide the customer with maximum competitive benefits.

***Step 3**: Clearly identify the weaknesses of the project organization*—to develop and deliver a successful project, it is necessary that the project organization be superior in every aspect of the project. However, the project organization cannot provide value enhancement in every aspect of the client's project—there will be areas in which the project firm is clearly not superior to the competition. The key is to recognize those activities in which the firm is inferior and operates at a competitive disadvantage, and to outsource them to those who can do them well. As long as the project organization can provide the client with a source of competitive advantage by engaging in activities where it can enhance value, while at the same time eliminating the sources of competitive disadvantage, the end result will be a successful project that can reap superior returns both for the client and the project firm.

***Step 4**: Target the activities and linkages that have the greatest impact on project value*—In the final step of the project value chain analysis, the project organization and the client should come to clear understand-ing of the options and alternatives for activities where maximum value enhancement can be achieved, and for activities that require improve-ment. This will ensure that sources of competitive disadvantages can be eliminated. It is in this final step of value chain analysis that the project organization can set the stage for achieving project excellence. To do so requires two things: first, the project firm must view project success from the client's perspective, instead of through the usual parameters of time, budget, and specifications. Second, the project firm must develop a partnership with the client so that it can play an active role in the success of the overall project, rather than playing the passive role of a contractor fulfilling a contractual obligation.

Table 1 Strategies for integrating cost and value

S/N	Method	Advantages	Examples
1.	Inbound supply chain management	Primary means to minimize costs through vendor management	Kaizen, international sourcing, reverse auctions, project partnering
2.	Project design	Allows integration of cost and value through enhanced design, creative problem solving, and collaboration	Value engineering, concurrent engineering, Kano modelling
3.	New product development	Links procurement and design to new product development, allows for gated reviews, rapid product modification response	Total quality management (TQM), Six Sigma, lean manufacturing, target costing
4.	Project delivery	Enhances value to customer through	Life cycle costing, turnkey project management

Project Cost and Value Integration process

There are some essential prerequisites to the process of integrating project cost and value. First, it requires a team approach, with representation from all project stakeholders, including the client, project team, designers, people responsible for implementing the project facility,

and all potential users. In essence, the team should be composed of all stakeholders who are knowledgeable about the project and have decision-making authority. It would helpful at this stage to bring the team together for ‘‘creative’’ workshops to generate ideas for integration. Second, the team should be willing to think ‘‘out of the box,’’ utilize imagination, and forego the penchant to exercise pet solutions. Third, the team should focus on overall project objectives, targeting only those areas that are likely to yield maximum benefits. Finally, the team should be led by an experienced, cost-oriented project management facilitator.

The objective of project cost and value integration is to obtain, for each activity selected for analysis, the optimum value for every dollar spent. The process involves a sequence of five steps.

i. *Generate information*—the objective of this step is to come up with an information base, or ‘‘cost model,’’ and to select areas or activities in the project for detailed study. For each project activity, information should be generated by asking the following questions:
   a. What is the exact nature of this activity?
   b. What is the activity intended to accomplish?
   c. What is the cost of performing this activity?
   d. What is the potential value generated by this activity? (i.e., is this activity necessary?)
   e. Is there another alternative than to do the same job, and at what cost?

   Some of the techniques that can be useful in answering these questions are functional analysis and cost–benefit analysis.

ii. *Generate alternatives*—the objective of this step is to generate creative alternative solutions. For each project activity, think about alternative ways of meeting the same requirements or performing the same functions. Brainstorming sessions by the project cost and value integration team can generate many new ideas.

iii. *Perform analysis*—the objective of this step is to evaluate each of the alternatives generated in the previous step, culminating in the selection of the one that presents the best combination of cost savings and required value. The appropriate questions to ask at this stage are
   a. Which of the alternatives will meet essential functionality requirements?
   b. What is the cost of each alternative
   c. Which will meet essential functions and still offer the greatest cost savings?

iv. *Generate a proposal*—the objective of this phase is to present the best sets of alternatives for achieving cost and value integration to appropriate decision makers. An important caveat in this step is to create a proposal that is most convincing, and to present it in the most effective way possible. A combination of techniques, such as narrative reports, schematic displays, graphic illustrations, and video clips of similar installations can be used to accomplish this.

v. *Issue a final report*—finally, at the last stage it is important to define and, if possible, quantify the results in terms of which recommendations were actually approved and implemented. Techniques such as standardized comparative reporting can be useful in generating the final report.

CONCLUSION

In the final analysis, integrating cost and value in a project cannot be viewed as a short-term, quick-fix solution. It is an ongoing improvement process that requires the total commitment of all project stakeholders, and, in particular, the commitment of the project organization’s

top management. To accrue long-term benefits, the process should be started very early in the project and should continue throughout its life cycle.

In other words, as we have attempted to show, cost and value management do not begin with the commencement of the actual project planning and execution. Rather, the seeds for successful cost and value management are sown much earlier in the project's life, during procurement and supply chain development, and they run well past the point of project completion. In fact, cost and value management involve a number of critical delivery activities as the project is transferred to its intended users. Thus, in understanding project cost and value management, it is first important to adjust our thinking toward Morris's ''management of projects'' paradigm.

Likewise, it is critically important to understand that successfully managing for value requires us to embrace a systems thinking perspective. Certainly, we can find ways to occasionally ''save money'' on our projects, or find features that add value as we move through a development cycle. However, the theme of this paper is to avoid a disconnected, fragmented mindset that treats cost and value management as issues to be addressed when it's convenient to do so.

The key is to understand that a model for cost and value management in projects involves a systematic, life-cycle philosophy based on their integration and used as an ongoing feature. This paper has attempted to offer just such a framework for systematically integrating these two critical elements in successful projects: cost management and creation of value. An unyielding commitment to this process is vital for developing the kinds of projects that will provide our firms with a decided competitive advantage.

ABSTRACT

The need for vehicle inspection operations in Nigeria is fundamentally to ensure vehicles meet all safety requirements. This will ensure sustainable movement on roads characterised with reduced environmental effect and traffic problems. This study therefore examines the challenges facing the sustainability of the operations of Vehicle Inspection Officers (VIO) under the Directorates of Road Traffic Services (DRTS) in Abuja, FCT Nigeria. The study made use of secondary data collected from the records of the DRTS on the number and status of vehicles inspected in the city from 2007 – 2014, and primary data collected through questionnaire survey randomly administered to a total of 107 respondents on the challenges facing sustainable vehicle inspection operations in Abuja. The study employed descriptive and a combination of factor and regression analysis as techniques for data analysis. The result of the factor analysis showed manpower shortage (76.3%) and inadequate equipment (87.6%) as the most significant challenges facing sustainable operations of vehicle inspection officers in Abuja. The results point out the need for recruitment of more vehicle inspection officers, as well as provision of equipment needed to assist the operations of the officers.

Keywords: Vehicle, Inspection, Traffic, Abuja, Sustainability

Introduction

Transportation had constantly played a dynamic role in the development of any nation. This is based on fact that the primary function of transportation is to move passenger or goods from a place of lesser value to a place of higher value (Oyerinde and Aregbesola, 2008). There are various modes of transportation and each with own its attendant problems, although the level of the problems may be reduced by certain level of measurement. In Nigeria, road transport sector remains the dominant mode for movement of goods and services. Road transport accounts for 99% of all domestic freight and passenger movement. Despite the huge Investments, the roads mode is still characterized by poor performance in term of vehicle administration, poor physical condition of the road infrastructures, level of service, traffic and safety regulation (Filibus, 2012). Oyerinde and Aregbesola, **(**2008) noted that the efficiency of road transportation relies heavily on the type and condition of vehicle under use, the road condition, the driver's competence, the attitude of the driver to traffic engineering, control, management as well as the policy strategies that give directions to the whole transport system.

It has been argued extensively that improper vehicle inspection before used on road often results to accidents (Aruwa, 2014; Gana and Emmanuel, 2014). In agreement with the above, Oyeyemi (2003) opines that drivers operate mechanically deficient vehicles on the roads, carrying passengers and property without safety consideration may result to accident. Such vehicles are not road worthy and they do not meet minimum safety standards. However, vehicle inspection is a process authorized by national or subnational governments in many countries of the world, through which a vehicle is inspected to ensure that it conforms to regulations governing safety, emissions, or both to ensure life and property for effective

Adenigbo, A. J.; Olorunfemi, S. O. & Aruwa J. (2016). Challenges facing the Sustainability Operations of Vehicle Inspection Officers in Abuja, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 528-533

traffic movement (Aruwa, 2014). In Nigeria, proof of inspection is required before a vehicle is registered or vehicle License can be renewed. According to Filibus, (2012) vehicles are supposed to be driven and maintained by a driver in accordance with the road traffic regulations. The purpose of vehicle inspection, whether the vehicle is a public, private or commercial, is to find out whether the vehicle is mechanically sound as the Law requires. The laws requires certain standards of efficiency of most mechanical components of a vehicle to ascertain the level of it safety such component are the brakes, lights, horn, steering, windscreen, wipers, mirrors, exhaust pipes, tyres etc. According to the author all the above components must be inspected before vehicle registration and must be dually conducted by the vehicle inspection officers.

Alade (2012) identified the function of vehicle inspection officers to include the following: inspect and certify vehicle before registration or renewal of vehicle particulars, collaboration with companies with large fleet for onsite vehicle inspection to ensure compliance that will enhance safety on roads, patrols on roads and highway to carry out routine checks and enforce compliance. This can be achieved through effective enforcement through vehicle impoundment and payment of fines. Unfortunately this has been hampered as a result of corrupt practices among officers in the country (Alade, 2012). The issue of poor funding was identified by Aruwa (2014) as major challenge facing vehicle inspection operations in Nigeria. Consequently, Alade (2012) also noted that over focusing on the revenue generating aspect of vehicle inspection operations at the expense of safety standards constitutes a major problem facing vehicle inspection offices. This paper aims at examining the challenges facing the sustainability operations of vehicle inspection officers using the Directorate of Road Traffic Services (DRTS), Abuja, Nigeria. The study is an attempt to look at the challenges of officers rather than the overall organisational challenges of vehicle inspection which has been the focus of many studies.

METHODOLOGY

The study relied on both primary and secondary sources of data collection. Secondary data were extracted from the records of DRTS on the number and status of vehicles inspected in Abuja from 2007 – 2014. The primary data made use of survey of vehicle inspection officers (VIO) who are staff of the Department of Road Traffic Services (DRTS) of the Federal capital Territory (FCT), Abuja, through questionnaire administration. A total of 242 vehicle inspection officers were surveyed using simple random technique. The sample size for the study is said to be adequate according to the suggestion of Hair *et al* (1995) referred to in Williams *et al* (2010) that sample sizes should be 100 or greater. The sampling technique ensures that vehicle inspection officers were surveyed with equal chance of probability. This was meant to certify that the information obtained reflects the intents of the officers as regards the challenges facing their sustainable operations. The instrument was designed on a multiple-item measurement scale fashioned on the 5-point Likert type of scale to allow for a wide measurement of the degree of the officers' consideration of each challenge presented in the questionnaire. The variables were tabulated for the officers to rank in order of significance from 1 – Not Significant to 5 – Highly Significant.

Factor analysis was employed as technique for data analysis. This is in the light of the need to reduce the variables to a few orthogonal ones that could be used to explain the major challenges facing sustainable operations of vehicle inspection officers. The main purpose of the factor analysis is to determine the number of common factors needed that can adequately describe the correlations between the observed variables, and estimating how each factor is related to each observed variable by estimating the factor loading (Oyesiku, 2000). This study

adopted the notation for factor analysis presented by Laudau and Everitt (2004) and used by Ubogu (2013) as a model for mathematical specification;

$$\chi_1 = \lambda_{11} f_1 + \lambda_{12} f_2 ... + \lambda_{1k} f_k + u_1$$
$$\chi_2 = \lambda_{21} f_1 + \lambda_{22} f_2 ... + \lambda_{2k} f_k + u_2$$
$$\chi q = \lambda_{q1} f_1 + \lambda_{q1} f_2 ... + \lambda_{qk} f_k + u_q \quad (1)$$

The equations above can be re-written as:

$$\chi = \Lambda f + u, \quad (2)$$

Where,

$$\chi = \begin{bmatrix} x_1 \\ . \\ . \\ . \\ xq \end{bmatrix}, \Lambda = \begin{bmatrix} xu ... \lambda_{1k} \\ . \\ . \\ . \\ \lambda q_1 ... \lambda qk \end{bmatrix}, \quad f = \begin{bmatrix} f_1 \\ . \\ . \\ . \\ fk \end{bmatrix}, \quad u = \begin{bmatrix} u_1 \\ . \\ . \\ . \\ uq \end{bmatrix} \quad (3)$$

Results and Discussion

DRTS FCT has routine inspection operations where vehicles can be spot checked whether occupied or not. If faults are discovered, a defect notice will be issued in which case the owner will be required to have repairs made, and obtain a full inspection from a licensed examiner with 14 days to clear the notice. If serious safety violations are found, the vehicle's registration can be suspended on the spot and the operator will need to have the vehicle towed. Table 1 presents the number and status of vehicles inspected in Abuja from 2007 – 2014.

An increasing trend in the total number of vehicles inspected in Abuja is observed in Table 1 in the sense that the total number of vehicles inspected stood at 65,397 in 2007 and by 2014; it has increased to 145,537 vehicles. This might be as result of the increasing car ownership rate in Nigeria due to increasing income of the people. Based on this, it is expected that the trend in the number of vehicles for inspection will continue to increase in the forward years. The status of vehicles inspected in Abuja from 2007 – 2014 shows the number of vehicles that failed or passed inspection test.

Table 1 Number of vehicles Inspected in Abuja from 2007 – 2014

Year	No Passed	No Failed	Total
2007	49,735	15,662	**65,397**
2008	29,134	17,134	**46,268**
2009	21,160	20848	**42,008**
2010	64,227	18755	**82,982**
2011	40,872	25,551	**66,423**
2012	105, 508	9,426	**114,934**
2013	97,858	1,680	**99,538**
2014	141,997	3,540	**145,537**
Total	**444,983**	**112,596**	**557,579**

Source: DRTS, FCT

Every vehicle inspection operation that will be sustainable requires that inspection officers are faced with less challenge to ensure efficiency in service delivery. It is normal that a data set to be used in statistics of this nature be subjected to test of suitability and adequacy. Therefore, to evaluate the suitability of the data, internal consistency checks were conducted using Kaiser-Meyer-Olkin (KMO) measure of sample adequacy and the Bartlett test of sphericity (See Table 2). These tests are employed based on the requirement of factor

analysis prior to extraction as suggested by Williams et al. (2010). The importance of the test is to determine if the samples were adequate to allow the use of factor analysis.

Table 2 KMO and Bartlett's Test to examine Challenges of Vehicle Inspection Officers

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.		.860
Bartlett's Test of Sphericity	Approx. Chi-Square	730.279
	Df	28
	Sig.	.000

The result in Table 1 shows a sampling adequacy value of 0.860, and significant at $p<0.01$, which indicates that the data obtained is adequate and suitable for the analysis. This is according to Cornish (2007) statement that a KMO result should be over 0.700 to be sufficiently correlated. Therefore, with a value above this threshold, the data is considered to be reliable for the use of factor analysis.

The various challenges facing the sustainable development of the operations of vehicle inspection officers in Abuja are naturally in varying degrees, which the response of the officers reveals the level of significance of each variable. The results of the analysis in Table 3 showing the communalities estimates of the variables after extraction indicates that little of the variance of the item "administration bureaucracy" (with 43.8%) and inadequate staff motivation (with 40.8%) can be attributed to the common challenge facing the operations of vehicle inspection officers in Abuja. However, the other variables with extracted values greater than 50.0% shows percentage variance that is high, and suggest the variables can be attributed to the common factors.

Table 3 Communalities

	Initial	Extraction
Inadequate Technology	.479	.500
Shortage of Manpower	.521	.624
Inadequate Funding	.492	.528
Inadequate Training	.514	.599
Administrative Bureaucracy	.405	.438
Inadequate Staff Motivation	.374	.408
Inappropriate Posting of Staff	.552	.609
Inadequate Equipment	.506	.872

Extraction Method: Principal Axis Factoring.

Furthermore, the total variance of challenges facing vehicle inspection officers presented in Table 4 indicates that the percentage of the total variance accounted for by the factor analysis shows two factors with eigenvalues greater than 1. The percentage of total variance explained indicates that factor one has an eigenvalue of 3.921 accounting for 49.0% of the total variance explained by the analysis. Similarly, factor two reveals an eigenvalue of 1.019 thereby accounting for 12.7%. The significance of these factor loadings provides a clear indication of the underlining dimensions of the variables that have been reduced to two major factors with eigenvalues greater than 1.00. These are the dominant loadings for each factor. These eigenvalues are the proportion of the total variation in the data set that is explained or at best summarized by a factor.

The cumulative percentage of the variance revealed that the two factors alone account for 61.76%, which indicates the proportion of the total variation that is explained by these two factors. Meanwhile, the third factor accounts for a very small proportion of the total variation of the explained variables of 11.3% (See Table 4).

According to Laudau and Everitt (2004), attempt must be made to identify the variables that can be used to explain the underlining dimensions of the issue under consideration. However,

the communality table alone cannot be relied upon to identify the factors that explain the challenges facing the operations of vehicle inspection officers in Abuja. Therefore, some method of factor rotation (varimax) is employed. The purpose is to maximize the variance of the squared loadings to produce orthogonal factors with a view to interpreting the results of the factor analysis. In practice, an arbitrary threshold value of 0.4 is equated as high loadings while the factor loadings are reordered according to size (Laudau and Everitt 2004).

Table 4 Percentage of Total Variance Explained by the challenges

Factor	Initial Eigenvalues		
	Total	% of Variance	Cumulative %
1	3.921	49.016	49.016
2	1.019	12.739	61.755
3	.901	11.269	73.024
4	.623	7.788	80.812
5	.442	5.519	86.331
6	.429	5.361	91.692
7	.374	4.676	96.369
8	.291	3.631	100.000

Extraction Method: Principal Axis Factoring

Table 5 shows the rotated factor matrix of the explanatory variables. It can be observed from the Table that all the variables are loaded on the two extracted variables. This indicates that the variables are significant in the discussion of the challenges facing the sustainable operations of vehicle inspection officers in Abuja.

Table 5 Rotated Factor Matrix

	Factor	
	1	2
Shortage of Manpower	.763	
Inadequate Training	.744	
Inappropriate Posting of Staff	.667	.406
Inadequate Funding	.666	
Administrative Bureaucracy	.630	
Inadequate Equipment		.876
Inadequate Staff Motivation		.562
Inadequate Technology		558

Extraction Method: Principal Axis Factoring.
Rotation Method: Varimax with Kaiser Normalization.[a]
a. Rotation converged in 3 iterations.

Loaded on Factor 1 are 5 variables, which are shortage of manpower, inadequate training, inappropriate staff posting, inadequate funding and administrative bureaucracy. Factor 2 has inappropriate staff posting; inadequate equipment, inadequate staff motivation and inadequate technology. All these variables are listed in order of their severity as challenges facing sustainable operations of vehicle inspection officers in Abuja.

For inappropriate staff posting (66.7% and 40.6% respectively) to load on the two extracted factors indicates a significant challenge facing the sustainable development operations of vehicle inspection officers. It is significant in a scenario where personnel with educational background in non-engineering fields are assigned to carry out vehicle inspection duties.

Policy Recommendation and Conclusion

The overall contribution of vehicle inspection operations to safety standard and compliance to traffic regulations in a country cannot be overemphasised. This calls for the need to ensure efficient and sustainable operations of vehicle inspection officers in Nigeria cities. This should be done out with a view to minimising the challenges facing the inspection officers while carrying out their duties. The government through the directorate of road traffic services (DRTS) should make effort to recruit more staff into the organisation so that there

will be adequate hands on desk to carry out the mandate of the organisation. The measures to mitigate the challenges facing sustainable operations of vehicle inspection officers need to be put in place in the light of the identified issues raised in this study. This will serve to motivate the officers to be committed to maximum delivery of service.

In conclusion, the study highlighted the number of vehicles inspected in Abuja from 2007 – 2014 and subjected 8 variables believed to be serving as challenges to the sustainability operations of vehicle inspection officers in Abuja to factor analysis. The study therefore concludes that shortage of manpower and inadequate equipment serve as the most significant challenges facing the sustainable operations of vehicle inspection officers in Abuja.

ACKNOWLEDGEMENT

The authors are grateful to the vehicle inspection officers that were surveyed for the purpose of the study.

ABSTRACT

Dispute has become a global epidemic in the construction industry, despite the considerable efforts that have been made to avoid it. Majority of construction projects in Nigeria experience disputes due to the problems associated with construction claims management process. This study evaluated the problems associated with construction claims management process and generates means of improving construction claims management process. A survey approach using questionnaire administered on clients, contractors and consultants was used. Data collected were analysed using percentile, mean item score and Kruskal Wallis K-test. Findings revealed that difference in awareness and interpretation of contract terms, too many bureaucratic procedure in claims management and delay in client or his representative response to claims were the top three problems associated with construction claims management process. The study recommended that contractors should improve their site staff potentials in construction management through on-the-job training. The study also recommended that public clients who are the major financial of construction projects in Nigeria should execute construction works in "business-like manner" instead of using the current complicated structures and procedures. The study concluded that the implementation of these suggestions would ensure amicable settlement of construction claims.

Keywords: Bureaucratic procedure, Business-like manner, Construction claims, Construction claims and management process and Nigeria

INTRODUCTION

In the recent years, only few number of construction projects in Nigeria were completed on time and within budget. This is due to construction claims that are outside the control of both the contractors, clients and other stakeholders. Indeed many of these projects have cost and time overruns as a result of the complexity of construction projects that makes claims inevitable. In most cases, management of these claims always leads to disputes that may end up in either arbitration or litigation. These may eventually lead to delay in the execution of the project or abandonment. These disputes occurred due to the problems associated with construction claims management process. Therefore, for effective management of construction claims these problems need to be recognised and mitigated by the stakeholders.

Over the years, significant literature on the problems associated with construction claims management process has been result of research conducted in Europe, Canada, America and Middle East, yet very little or none has been conducted in Nigeria. In view of the differences in culture, varying nature of construction claims based on the prevailing social and environmental factors, it has become necessary to bridge the gap in literature.

Therefore, the focus of this study is to evaluate the problems associated with the implementation of construction claims management process with a view to mitigating them and ensuring amicable settlement of construction claims.

LITERATURE REVIEW

Construction Claims Management Process

Enshassi, Mohamed and El-Ghandor (2009) opined that no construction project can be shielded from a potential claim and that such claim can lead to significant financial damages.

Akinradewo, O. F., Ogunsemi, D. R.; Dada, M. O. & Aje, I. O. (2016). Evaluation of the Problems Associated with Construction Claims Management Process in Ondo State, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 534-543

Therefore, the owner, consultants and contractor need to understand the construction claim management process, so as to be able to manage claim effectively. Enshassi *et al.* (2009) postulated that the objective of the construction claim management process is to resolve problem in an efficient way, in order to avoid litigation and arbitration. Singh and Sakomoto (2001) supported this assertion that all parties including owner, consultants and contractors should understand the construction claim management process in order to ensure proper claims management practice.

Kahssay (2003) concluded that construction claims occurred when the terms and conditions of the contract change in such a way that the contractor is unable to recover expenses and profit. According to Bunmi (2005) a claim means an assertion of a right to money, property or to a remedy. Powell-Smith and Stephenson (2000) described claims in general terms as the assertion of the right to money, property or to remedy. Polts and Ankrah (2013) observed that a claim may arise out of or in connection with contract relates to remedy which is not designate in the contract, such as breach of contract (contract law) or misrepresentation (law of tort) or unjust enrichment (quantum merit). From the above definitions, one important fact is that there would be an unpleasant or difficult situation arising from the problems encountered during the execution the contract that requires treat by the parties to a contract.

Tochaiwat and Chovichien (2004a) opined that in order to deal with or control construction claims in an effective way, all parties should establish good construction claim management process in their organizations. Kululanga *et al.,* (2001) concluded that the variables that form the construction claim process comprises six processes namely: Claim identification; claim notification; claim examination; claim documentation; claim presentation and claim negation. Levin (1998) and Nbabazi (2004) supported this standardisation by stating that the key to continuous occurrence of claims in the construction industry is claims management process which includes proper identification, notification, documentation, presentation and resolution. Enshassi *et al.,* (2009) also support this standardization, when they professed that the solution to the problem of claims management is claim management process which involves identification, notification, examination, documentation, presentation and negotiation. Most of the previous researchers on claim management agreed that in order to avoid disputes that may arise, it is better to follow claim's management process as discussed below:

Identification

Oyegoke (2006) opined that the contractor should recognise the occurrence of events that are likely to result in claims in advance (direct loss and/or expense suffered or incurred or extension of time) and document the characteristics of each event. Moura & Teixiera (2007), Enshassi *et al.,* (2009) emphasised that identification is the first and critically important ingredient of claims management process. Identification involves both "timely" and "accurate" detection of a construction claim. Kululanga *et al.,* (2001) observed that construction claim recognition and identification involves "timely" and "accurate" detection of a construction claim and it is critically important ingredient of claim process.

Notification

Enshassi *et al.,* (2009) asserted that the owner or representative must be formally notified of a claim or a change if the contractor intends to seek an equitable adjustment for additional time or costs. The initial letter of a claim notice to other party should be short, clear, simple, conciliatory and co-operative. Mitchell (1998) opined that the purpose of notification is to allow both parties to verify conditions, assemble facts and resolve disputes while the issues are fresh in their minds. Tochaiwat and Chovichien (2004a) opined that construction claim notification involves alerting the other party of a potential problem in a manner that is non-adversarial. The researchers concluded that the time limit requirements are very crucial and

critical and an initial letter of notice to the other party should be concise, clear, simple conciliatory and cooperative.

Kululanga *et al.,* (2001) concluded that the letter should indicate problem and alert the other party of the potential increase in time or cost and it is very hard to argue with someone who appear polite and sincere, hopeful and cooperative. For example, section 2 Clause 2.27 of JCT 2009 conditions of contract stated that the contractor is required to give a written notice to the Architect/Contract Administrator of the material circumstances, including cause or causes of the delay. Section 2 Clause 2.28 of the JCT 2009 also stated that if the Architect/Contract Administrator finds that any of the events stated by the contractor is a relevant event and will delay the work beyond the completion date, he shall in writing to the contractor give an extension of time that he considers to be fair and reasonable.

Examination

According Kululanga *et al,* (2001) claim examination involves establishing the legal and factual grounds on which claim is to be based and the estimate of the potential recovery. Chovichien and Tochaiwat (2005) confirmed that the objective of this sub process is to determine the impact of the change that occurs. Chavichien *et al,* (2005) explained that the claimant shall perform schedule analysis to calculate the time impact while breaking down the cost into various cost components to assess the impact. The researchers concluded that there are various methods used for calculating time and cost impacts and that this detailed cost description is necessary for understanding, negotiating and justifying extra contract costs. Enshassi *et al.* (2009) asserted that claim examination involves establishing the legal and factual ground upon which the claim is based. The researchers explained that this stage should also involve an estimate of the potential recovery sought and that the issues may be investigated by interviewing staff who worked on the project. The researchers concluded that primary sources for claim examination include project files, video, memos, minutes of site meetings e.t.c. which must be used to prove the time and cost elements of the claim. Tochaiwat and Chovichien (2004a) observed that there are two types of pricing namely: forward pricing and post pricing. Tochaiwat *et al* (2004a) explained that under the forward pricing, the price is negotiated before the work is done while in post pricing the risks have been incurred and the added costs have been known.

Documentation

Kululanga *et al* (2001) postulated that documentation is the collection of the hard facts that give the actual history of construction claims. Enshassi *et al* (2009) corroborated this assertion that a well prepared defence quickly demolishes evidence and claim costs that not supported by accurate records but a well-documented facts are the glue that holds the legal framework together. Kululanga *et al* (2001) explained further that a detailed cost record, a comparative programme (progress schedule, correspondence records of site meetings and site diaries are the essential documents required for construction claims. The researchers concluded that the contemporaneous record not only helps in claims but in other legal tussles especially in the project administration. Chovichien *et al,* (2005) observed that records and documentation play a very important role in the settlement of construction claims. The researchers concluded that events and details of the jobs must be documented to substantiate claim entitlements and prove damages.

Presentation

Chovichien *et al,* (2005) opined that presentation should be logically built up, well organized and factually convincing and that it can be divided into two sections; claim entitlement and claim quantum. Oyegoke (2006) suggested that it is important to start with an introduction which gives a brief outline of the contractor's submission, also to summarise the subject

matter, to be precise and concise. The researcher concluded that presentation of claim can be broken down into the following logical sequence: introductory, contractual basis, comprehensive assessment and auxiliary data.

Negotiation/Resolution

Ren, Anumba and Ugwu (2003) described negotiation as tool that help to sustain amicable relationship between the parties to a contract, before the application of other disputes resolution methods. Fidan *et al,* (2010) observed that negotiation entails exchanges between project parties to reconcile their differences with the aim of reaching a settlement. Zeleznikow (2002) affirmed that negotiation assist the construction parties to avoid the risk of extra cost and unfavourable outcome in claims management. Zeleznikow (2002) explained that the determination of facts of a case and careful exploration of legal documents in order to figure out legal arguments related with claim issues is one of the essentials of claim negotiation. Kululang *et al,* (2001) also observed that to benefit from this stage in claims process, a construction contractor needs experts that have skills for negotiation. The research confirmed that "it is more important to be prepared than it is right" because "right" is often difficult to determine and it is preparation for negotiation that really counts. Ren *et al* (2001) asserted that negotiation go on throughout the whole claims management process from justification of the settlement of a claim. The researchers explained further that basically there are two kinds of claim negotiation: qualitative and quantitative negotiation. Qualitative negotiation is the entitlement of contractor to a claim which is mainly regarding the justification of a claim based on the identified causes, liabilities and contract conditions while quantitative negotiation is the amount of compensation for the entitled claim, which deal with the amount of the quantity of claim items, rates of material or labour and indirect costs. Enshassi *et al,* (2009) confirmed that claim negotiation plays an important role in resolving claims, preventing disputes and keeping harmonious relationship among project participants. The researchers concluded that the most economical, practical, simplest and fastest method of settling claims is negotiation. Chovichien *et al,* (2006) concluded that the contractors in Thailand are able to negotiate the employer`s claims against them than those against the employers.

Evaluation

This sub-process is the link between presentation and negotiation, several researches on construction claims management process concentrated on the last six sub-processes that are related to the contractor`s activities at the expense of client or his representative activity which is evaluation. Aibinu (2007) observed that evaluation is the process of administering the claims by the certifier. In perform this important responsibility, the certifier is expected to form his view on the validity of the contractor`s claims and make recommendation on the quantum of the contractor`s entitlements. Perlman (1984) cited in Aibinu (2007) confirmed that before the certifier can form an opinion, the following question of facts that are potential causes of disagreements must be addressed:

i. Whether or not the works giving rise to the claims is required by the contract or is extra work
ii. Whether the delay is due to the contractor`s inefficiency or employer`s or his representative actions (hereafter referred to as Responsibility of delays)
iii. Whether the delay is on the critical path (hereafter referred to as Criticality of delays)
iv. Whether the employer-related delay is concurrent with another contractor-related delay (hereafter referred to as Concurrency of delay)
v. Whether or not the contractor actually incurred added costs.

Zack (2002) and Kumarswamy and Yogeswarm (2003) observed that the use of different approaches to claims substantiation and assessment may also constitute an area of disagreements because the contractor and certifier will produce different results from different approaches. Aibinu (2007) observed that reaching a decision on claims will also depend on the interpretation of the provisions relating to extension of time and additional cost claims, thus the following are the other potential issues that could generate disagreements: the type and amount of information used in substantiating claims; the methodology and technique used in substantiating and assessing claims; the quantum of contractor`s entitlements and contract interpretation.

Several researchers have developed various approaches to evaluation technique in the construction industry. Verster (2005) confirmed that evaluation is a vital sub-process that enable other party to consider claims submitted by the contractor in terms of its validity, contractual terms and possible outcome (quantum of contractor`s entitlements). Oke and Makinde (2011) observed that evaluation is necessary in construction project so as to ascertain the monetary value of decrease or increase from the contract sum which will be claimed by one of the parties to the contract accordingly. Bower (2000) proposed a mechanism for the 'evaluation of compensation due in the event of a variation order under the contracts for construction work'. The researcher developed influence curves that can be used to derive indirect costs of variation. Akpan and Igwe (2001) developed a suitable model for the evaluation of cost overrun during construction project execution, focusing on cost effect with respect of the extent of work done, payment schedule and government fiscal/monetary policies. Chovichien and Tocaiwat (2014) reported that a committee set up by the procurement regulatory act in Thailand is responsible for the evaluation of the contractor's claims by determine entitlement and the amount of compensation the contractor deserves.

Problems Associated with Construction Claims Management Process

Ren *et al*, (2001) observed that despite the extensive studies, theories and practices, the increasing incidence of claims and disputes imply that the current claims management principles and process are ineffective in meeting construction industry requirements. Chovichien *et al*, (2005) also observed that construction claim management is very important to all parties concerned in a construction project and several research works confirmed the insufficiency of the claim management processes resulting from associated problems. The researchers concluded that lots of the insufficiencies were caused by the negligence or ignorance on the implementation of effective claim management process by the stakeholders. Ren *et al*, (2001) explained that the current industry practice shows that the main challenge of claims management is not from the overall management process, but from ineffectiveness of management activity at each stage. The researchers recognized that identification of causes of claims and proper documentation are two most important and difficult factors to justify a claim.

A considerable number of prior studies have explored the issues associated with interpreting or understanding construction contracts and their impacts (Cutts, 2004; Broome and Hyes, 1997; Styllis, 2005; Rameezdeen and Rajapakse, 2007). Candin, Bhatia and Jensen 2002; Chong and Rosli, 2009; identify the use of legalise or technical terms or jargons as another problem associated with claims management process. Other empirical researchers have identified the use of language and characteristics in legal documents (Hill, 2001; Feinmann, 2003; Cutts, 2004). These studies reported that the construction contractors often encounter difficulties in understanding and interpreting contract documents due to non-legal background and the inherent legal terminologies stated in the contracts. Chovichien *et al*, (2005) opined that contract terms are sometimes incomplete, unclear in specifying each party's right and duties, lead to different interpretations by different parties. The study observed that some

contract provisions allowed insufficient time for both parties to handle their claims in Thailand.

Chovichien *et al,* (2005) explained further that some problems arise from the employer and his representative, such as intervening or impeding the construction process despite their to lack of construction knowledge, too much bureaucratic procedure, lack necessary data and lack of clear regulations. The researchers explained further that designers sometimes issue impractical drawings which cause delay or cost overrun in the construction phase, corruption by some employer's representative, supervising officer issue an incomplete or oral variation and delay in response to claims in Thailand. Chovichien *et al.,* (2005) concluded contractors sometimes caused problems to construction management process such as lack of contract knowledge; incompetence; lack of management skills; refusal to comply with the defective liability warranty or obligations; delay in response to claims and ignorance on some contract provisions and professional ethics. Ren *et al.,* (2001) supported this opinion that many contractors' management systems are ill designed to support claims.

Some researchers have identified inadequate information and poor documentation to support claims as major problems in current claims management practice. (Chvichien and Tochaiwat 2006, Enshassi *et al.,* 2009 and Ren *et al.* 2001) emphasised that lack of factual evidence is the prime cause of delayed payment and protracted disputes. Hassanein *et al* (2008) pointed out that 57% of the sampled projects indicated that change orders had been lost due to poor documentation practices in Egyptian industrial construction sector. Enshassi *et al.,* (2009); Chovichien and Tochaiwat (2006); Badger and Gay (1996) all stressed that lack of initial records, such as minutes of meetings, correspondence, progress reports, logs, photographs, records of delay and disturbance and revised drawings as the major reason for the failure of claims. Vidogah and Ndekugri (1998) concluded that the reasons for the problems of claims management are: a culture of bias against paperwork on site operations, poor design of recording systems, the relevant information and poor resourcing of the claims management role in contracting organisations. Hassanein *et al.,* (2008) linked the loss of change order in Egyptian industrial construction sector to lack of contract awareness of the site team and fear of consultant phenomenon. Enshassi *et al.,* (2009) pointed out that lack of awareness of contractor's site staff in detecting a claim is still a major contributor to the problem of claims management process in Palestine.

Bakhary *et al.,* (2013) stressed the need to develop structured instrument for auditing construction contractor's claims process. Ren *et al,* (2001) postulated that research efforts at seeking to develop effective tools to support claims management are very few when compared with such efforts on the legal basis and principles. The study emphasised it that claims management rely on very few project management tools especially systematically designed tools that are appropriate for claims management and that even with the support of Information Technology claim documentation is still perceived to be woefully inadequate in terms of record keeping. Chovichien *et al.,* (2006) in surveys research in Thailand observed that adoption of information system in the construction industry seems to be given less attention and documentation is still paper –based without sufficient document code. The study concluded that these problems affect the efficiency of the claims management process and it should be eliminated.

Enshassi *et al.,* (2009) confirmed that the main problem associated with claim negotiation in Palestine is conflicts arising during negotiation. The study linked this problem to lack of negotiation skills which usually impact on the ability of the contractor to convince the owner. Hu (1997) opined that most project managers consider claims negotiation as the most time and energy-consuming activity in claim management. Vidogah and Ndekugri (1998) observed

that the involvement of the client in negotiation is currently very low. Vidogah *et a.l,* (1998) explained further that there are several deficiencies in the consultant's claims management process such as ad hoc manner implementation of claim management, poor performance in claim management functions of the existing management information systems, inadequacies in the contents of the products of the basic good management practice (diaries, timesheets and programmes) and impossibility to quantify claims with precision.

Smith (1992) pointed out that negotiation has been labelled as a basic survival skill for today's project manager, but very few construction participants have adequate negotiation expertise. The study concluded that unnecessary concession and stubbornness are common mistakes which make the negotiations harder and inefficient.

Hypothesis

In accordance with the specific objectives of the study as mentioned above, a null hypothesis was postulated which will assist in assessing the statistical significant difference between the perception of the groups of respondents about the problems associated with construction claims management process. The null hypothesis is as follow:

H_o1: There is no significant difference in the perception of the clients, contractors and consultants about the problems associated with construction claims management process.

METHODOLOGY

The instrument used for data collection in the study was questionnaire administered to clients, contractors and consultant architects and quantity surveyors that were engaged in building projects executed for a period of nine years (from 2006 to 2014) in Ondo State, Nigeria. The population for the study was 322 respondents comprising of 52 clients and 168 contractors while the architects and quantity surveyors were 52 and 50 respectively. A total of 197 questionnaires which represented about 61% response rate were used for the study. Data collected were analysed using percentile, mean item score and Kruskal Wallis K-test. About 53.3% of the respondents are corporate or registered members of their professional bodies while 19.8% and 8.7% are probationer and fellow of their professional bodies respectively. This implies that they are well educated, professionally qualified and competent to answer the questions and their opinion could be relied upon.

FINDINGS AND DISCUSSIONS

In assessing the problems associated with construction claims management process, the three groups participated in the survey. Table 1 shows that the three major problems associated with construction claims management process in the studied area in the opinions of the clients are: too much bureaucratic procedure in claims management; corruption among the construction stakeholders and difference in awareness and interpretation of contract terms with mean values of 3.51, 3.47 and 3.42 respectively while the least problem is designers issuing impractical drawings which cause delay and cost overrun with a mean value of 2.80. In the contractor's opinion, the three major problems related to construction claims management process are: difference in awareness and interpretation of contract terms; delay in clients or his representative response to claims and too much bureaucratic procedure in claims management with mean values of 3.44, 3.27 and 3.21 respectively while the least problem is lack of necessary data (factual evidence) with a men value of 2.50.

In the opinions of the consultants, the three major problems that are related to construction claims management process are: delay in client or his representative response to claims, lack of proper documentation and too much bureaucratic procedure in claims management with mean values of 3.57, 3.46 and 3.38 respectively while the least problem is lack of adequate time for contracting parties to handle claims with a mean value of 2.76. The table further

shows that the overall opinion of the respondents is that the three major problems associated with construction claims management are: difference in awareness and interpretation of contract terms, too much bureaucratic procedure in claims management and delay in client or his representative response to claims with men values of 3.37, 3.31 and 3.30 respectively while the least problem is inefficient claims negotiation procedure with mean value of 2.71. This implies that the fifteen (15) identified problems were strong considering there mean that ranges from 2.71 to 3.37. Table 2 reveals that an asymptotic significance value of 0.421 was generated using Kruskal-Wallis K-test which is higher than 0.05. This implies that there is no significant difference in the overall responses of the groups.

The overall opinion of the respondents is that difference in awareness and interpretation of contract terms is the first major problem associated with construction claims management process. This agrees with prior studies such as (Ren *et al.,* 2001; Chovichien *et al.*; Cutts 2004; Broome *et al.,* 1997; Styllis 2005; Rameezdeen *et al*., 2007). In the overall opinion of respondents too much bureaucratic procedure in claims management was also ranked second as the problem associated with construction claims management process. This result disagrees with the outcome of previous studies like Tochaiwat and Chovichien (2004a) in Thailand; Hassanein and Nemr (2008) in Egypt and Enshassi *et al.,* (2009) in Palestine. This may be a peculiar problem to Nigerian construction environment. The result further ranked delay in client or his representative response to claims as the third major problem associated with construction claims management process. The result agrees with Hassanein *et al*., (2008) which revealed that the major problem associated with claims management in the Egyptian industrial construction is effective delay caused by the owner.

Table 1: Problems Associated with Construction Claims Management Process

The Problems	Client		Contractor		Consultant		Overall	
	MIS	Rank	MIS	Rank	MIS	Rank	MIS	Rank
Average	*3.13*		*2.87*		*2.84*		*2.97*	
Difference in awareness and interpretation of contract terms	3.42	3	3.44	1	3.32	4	3.37	1
Too much bureaucratic procedure in claims management	3.51	1	3.21	3	3.38	3	3.31	2
Delay in client or his representative response to claims	3.16	5	3.27	2	3.57	1	3.30	3
Lack of proper documentation	3.16	5	2.91	4	3.46	2	3.10	4
Corruption among the construction stakeholders	3.47	2	2.81	8	3.06	9	3.02	5
Contractor's lack of claims management skills or expertise	3.78	4	2.78	10	2.85	6	3.01	6
Supervising officers issuing incomplete or oral variation	2.98	8	2.84	5	3.13	5	2.98	7
Lack of involvement of client in claims negotiation	3.00	7	2.79	9	3.10	6	2.93	8
Intervening and impending of the construction process by the client or his representative	2.98	8	2.78	10	3.10	6	2.93	8
Lack of information management system	2.96	11	2.84	5	2.84	12	2.86	10
Lack of effective claims management tools	2.91	13	2.84	5	2.76	15	2.82	11
Designers ng impractical drawings which cause delay and cost overrun	2.80	15	2.77	12	2.97	10	2.81	12
Lack of adequate time for contracting parties to handle claims by contract provisions	2.98	8	2.54	14	2.81	12	2.73	13
Lack of necessary data (factual evidence)	2.96	11	2.50	15	2.81	12	2.72	14
Inefficient claims negotiations procedure	2.87	14	2.74	13	2.81	12	2.71	15

Table 2: Overall Significant Difference in the Opinions of the Respondents on the Problems Associated with Construction Management Process

S/N	Problem	Chi-Sq. Value	Asymptotic Sig. P
1	Problems associated with construction claims management process	1.732	0.421

Kruskal-Wallis K-test was used to test the difference in the opinion expressed in Table 3 on the problems associated with construction claims management process by the groups of respondents. This is to assist in decision making on the hypothesis earlier postulated in this

study. The result of Kruskal-Wallis analysis shows that the p-value of seven identified problems is 0.000; it implies that there is significant difference regarding the groups of respondents in 7 out of 15 identified problems. This is not enough to reject the null hypothesis. Hence null hypothesis is accepted. The decision on this aspect of the study was based on the overall asymptotic value of 0.421 which is higher than 0.05 using Kruskal-Wallis K-test as indicated in Table 2. This implies that there is no significant difference in the three groups assessment of the problems associated with construction claims management process.

Table 3: Difference in the Assessment of the Clients, Contractors, and Consultants about the Problems Associated with Construction Claims Management Proces

Problem	Overall rating		Chi-square Value	Kruskal-Wallis sig. p
	MIS	Ranking		
Difference in awareness and interpretation of contract terms.	3.37	1	3.296	0.348
Too much Bureaucratic procedure in claims management	3.31	2	2.276	0.517
Delay in client or his representative response to claims	3.30	3	4.636	0.200
Lack of proper documentation	3.10	4	9.846	0.020*
Corruption among the construction stakeholders	3.02	5	11.850	0.008*
Contractor's lack of claims management skills or expertise	3.01	6	13.213	0.004*
Supervising officers issuing incomplete or oral variation	2.98	7	4.962	0.175
Lack of involvement of client in claims negotiation	2.93	8	10.132	0.017*
Intervening and impending of the construction process by the client or representative	2.93	8	1.309	0.727
Lack of information management system	2.86	10	2.312	0.510
Lack of effective claims management tools	2.82	11	5.203	0.157
Designers issuing impractical drawings which cause delay and cost overrun	2.81	12	10.909	0.012*
Lack of adequate time for contracting parties to handle claims by contract provisions	2.73	13	4.953	0.175
Lack of necessary data (factual evidence)	2.72	14	15.429	0.001**
Inefficient claims negotiations procedure	2.71	15	9.987	0.019*

** = p less than 0.05, ** = p less than 0.01*

CONCLUSION

Findings revealed that difference in awareness and interpretation of contract terms, too many bureaucratic procedure in claims management and delay in client or his representative response to claims were the top three problems associated with construction claims management process. The study recommended that contractors should improve their site staff potentials in construction management through on-the-job training. The study also recommended that public clients who are the major financial of construction projects in Nigeria should execute construction works in "business-like manner" instead of using the current complicated structures and procedures. The study concluded that the implementation of these suggestions would ensure amicable settlement of construction claims.

ABSTRACT

The dynamism of the construction industry everywhere in the world requires no other skill, for stringent cost control and effective cost management in providing value for money for construction clients, than the skills of the professional quantity surveyor. The effectiveness in delivering quantity surveying service efficiently to meeting clients' requirements is entirely dependent on the products of designers in the design team. This research work assesses the effects of work attitudes put on by the design team and how it affects the service delivered by quantity surveyors. Primary data were collected via well-structured close-ended questionnaire. Percentile and mean item score were employed in the analysis using Statistical Package for Social Science (SPSS). This study revealed that the design team is a well-structured and organized team for quantity surveyors to perform their professional obligations, but designers' work attitudes reflected from their design products create a mundane and frustrating atmosphere for the quantity surveyors. This study finally recommended a need for personal improvement by the architects and the engineers in order to enhance a proficient service of the design team.

Keywords: Construction Industry, Design team, Quantity Surveyor, Service, work attitude

INTRODUCTION

The construction industry is a complex organisation which centres on the project under construction or adaptation, (Willis, et al. 1994). It embraces a wide range of loosely integrated organisation that collectively constructs, alter, refurbish and repair a wide range of different building and civil engineering structures. (Gavin, 2002) defined design as a combination of group of object and requirement which have been designed to create something new as a result of or in anticipation of their collective performance. The construction industry is also described as an assembly industry, assembling on site the products of other industries. Construction generally encompasses building and civil engineering works, building works such as residential houses, flats, schools, hospitals, shops, offices, factories and ware-houses; civil engineering works such as roads, bridges, reservoirs, waste water system, rail ways, power stations, harbours and dams. These construction works are undertaken in both the public and private sectors. Public sector includes government (federal, state or/and local), development corporations and public corporations and private sector includes developers, financial institutions, industries and commerce, building societies, individual promoters and privatised companies. Researchers all over the world have highlighted the significance of teams in a general organizational perspective. Most organizations that seek to improve efficiency have embraced teams as a way to meet the demand of the turbulent and challenging market place (Fisher et al. 1997).

There are various disciplines and professionals within the industry; architects, quantity surveyors, engineers, builders who are more on the periphery of the industry, the planners, economists, lawyers, and accountants, the contractors, suppliers, and manufacturers, sub-contractors of various types and specialist firms who do highly skilled work, (Seeley, 1997).

The construction industry is bounded by an ever-increasing numbers of rules and regulations with different trades and professional organizations monitoring them intently and dealing

Alake, O.; Abiola-Falemu, J. O.; Folorunso, T. O. & Makanjuola, S. A. (2016). Effects of Work Attitudes of Design Team on the Service Delivery of Quantity Surveyors. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 544-551

with variety of problems which may affect or affecting the efficiency, reputation and work of the industry before the 'client'- the most important person to the industry.

The building sector is very important in the national economy and it's a very sensitive sector. To a good extent the fortunes of the Nigeria construction industry are closely related to the state of the Nigeria economy as a whole as postulated by (Ajanlekoko, 2002). He opined that the output of the construction industry has a significant impact on the country's Gross Domestic Product (GDP) and the Nations construction investment. Therefore, it is not the sole responsibility of the quantity surveyor to establish a successful cost solution and guarantee an effective project delivery in the terms of cost, time, safety and quality standard. All the professionals within the industry are responsible, most especially the design team, being the decision maker for all construction work in the construction industry.

Practicing quantity surveyors are been faced with numerous challenges erupting from his design team-mates in most project works, ranging from clients' attitudinal behaviours, design decisions, drawings provided by the architect/engineers to professional superiority complex that exist among the professionals. Every activity of each design team member has significant effect on one another's service(s). The quantity surveyor been the centre of attraction (cost expert), depends so much on the service products of the design/production team-mates. A close collaboration between the design team members and the quantity surveyor throughout the design stage for effective cost control will enable the production members to be kept fully informed of the cost implications of all the design decisions. Team should work together to represent the interest of the client by achieving his aim and objectives in terms of cost, time, quality and standard performance. A successful project is a justification of expertise and if otherwise, the purpose of professionalism and expertise is jeopardized and defeated. (Sepani and Akalaka 2009). When good team spirit is developed among team-mates in a construction design team, the quantity surveyors enjoys the joy of rendering quality service to his client or employer. To distribute generated design knowledge among design team members for the progress of design, they need to process their own specialist data before useful information can be delivered to others. Designers participate in various ways in the team and are depending on each other's output. Many participate as individuals, working alone for crucial periods and then return to the network process, (Dainty et al. 2006). These will in-turn boosts the good reputation of the design team and the construction industry as a whole. This will invariably contribute to the nation's economy and development.

RESEARCH METHODOLOGY

The descriptive survey method, (Leedy and Ormond 2005) was adopted for the study using structured questionnaires as the main tool for exploring the opinions and the individual experiences of quantity surveying practitioners in research area. The respondents were given statements to assess based on a five point Likert scale on a questionnaire designed comprising three (3) sections with relevant questions pertaining to the topic; section 1, personal data of respondents, section 2, design team features, design products and attitudes of design team members and section 3, services of the quantity surveyor at the design stage.

The population of respondents for data gathering was drawn from among practising professional quantity surveyors in the Nigerian construction industry resident in Akure and Ibadan cities respectively. The sample population of respondents was from registered and practising quantity surveyor only numbered 72 and 35 in Ibadan, Oyo and Akure, Ondo states respectively, who are well experienced in the profession and have being involved in building design team.

The Yamane (1967) formula used to determine the sample size is $\frac{N}{1+N(E^2)}$
Where N = Number of professionals and E = Degree of precision 10%

Applying the above formula, a total of 68 Quantity surveyors; 41.86 and 25.93 was sampled out from the 72 and 35 registered and practising quantity surveyors in the Ibadan, Oyo and Akure, Ondo state respectively.

From the formula used to derive the sample size for respondents, random selection was done on the list of the professionals particularly to Ibadan and Akure residents. This is simply due to the fact that most contracted building works happens more in these places. Primary data was fetched using a structured questionnaire for this research work. This is to enable perpetual disclosure of qualitative and relevant experiences of my respondents without any undue influence**.** The questionnaire covered the demographic background of the respondents and specific aspects that revealed their professional experiences in relation to work attitudes of professionals in the design team to how it affect the service delivered by the quantity surveyors.

Preliminary research approach comprising a qualitative method of data production from the target population was adopted. Data was retrieved through questionnaires by direct contact.. The addresses of practicing quantity surveyors were sourced for and were also used to locate them. Secondary data were sourced for this study from: journals, published/unpublished articles, conference scripts, textbooks and the World Wide Web (websites). Data collected were processed and analysed with the use of the Statistical Packaged for Social Science (SPSS) software version 17 Frequency distribution table, percentage and mean were used.

QUAESTIONNAIRE ANALYSIS

This section presents how the questionnaire is been administered in respect to distribution and collection expressed in percentage:

Table 1 Quaestionnaire Analysis

S/N	No. of questionnaire distributed	No. received	Percentage received	Percentage not returned	Total percentage
1	68	51	75.00	25.00	100.00

Table 1 above shows that a total of sixty-eight (68) questionnaires were distributed to respondents in person at Ibadan and Akure cities, Oyo and Ondo states respectively, only 51 were returned for analysis representing 75% proportion of the total number distributed.

Frequency Distribution Table for Demography Data

This section presents the frequency distribution tables and their respective percentage accruable.

From Table 2, above, two sectors (private and public) were reached out to with 22 private firms and 29 public organizations of respondents. Company/firm type, 22 consultant firm, 3 consortium, 23 client organization and 3 other firms/company of respondents. Organizations with more than 10 years working experience in building construction took the largest proportion (72.50%) and organization with less than 10 years' experience have a cumulative percentage of 27.50%. This is expected to make the finding of this work more reliable. 41 males (60.4%) and 10 (19.60%) female quantity surveyors professionals were my respondents. Age range 41 - 50 took the largest percentage while age under 25 took the lowest. This invariably will also enhance the reliability of the findings of this work. Educational highest qualification of the respondents are Diploma, Postgraduate Diploma, and

Bachelor's Degree each with over 20% proportion while Master's Degree holders took the largest (27.50%) percentage proportion. Respondents with less than 5 years personal working experience in the construction industry are 11.80%, 33.33% are have between 5-10 years' experience and 54.90% have more than 10 years working experience. This is a true justification of any outcome from this research work as this will have great influence on the response output. Positions of office of my respondents,19.60% principal quantity surveyors, 49.00% senior quantity surveyors, 17.60% assistant quantity surveyors and 13.70% others offices

Table 2 Demography data of respondents

		Frequency	Percentage	Total Percentage
Sector	Private	22	43.1	43.1
	Public	29	56.9	100.0
Company/Firm	Consulting firm	22	43. 1	43.1
	Consortium	3	5.9	49.0
	Client organization	23	45.1	94.1
	Others	3	5.9	100.0
Year of org. experience				
	Less than 5 years	8	15.7	15.7
	5 years - 10 years	6	11.8	27.5
	More than 10 years	37	72.5	100.0
Gender	Female	10	19.6	19.6
	Male	41	80.4	100.0
Age	Under 25 years	2	3.9	3.9
	25-30 years	8	15.7	19.6
	31-40 years	13	25.5	45.1
	41-50 years	18	35.3	80.4
	Over 50 years	10	19.6	100.0
Qualification	Diploma	11	21.6	21.6
	Postgraduate Diploma	13	25.5	47.1
	Bachelor's Degree	13	25.5	72.5
	Master's Degree	14	27.5	100.0
Personal years of experience				
	Less than 5 years	17	33.3	45.1
	5 years - 10 years	6	11.8	11.8
	More than 10 years	28	59.4	100.0
Office	Senior QS	25	49.0	68.6
	Assist. QS	9	17.6	86.3
	Principal	10	19 .6	19.6
	Others	7	13.7	100.0

Table 3 Characteristics of building design team

Design Team	Frequency					Mean	Rank
	5	4	3	2	1		
Quantity surveyors (QS) are introduced at the conceptual stage	19	20	6	6	0	4.02	1
Design team members come together to gain initial awareness about each other	20	15	10	6	0	3.96	2
Design team develops to maturity to attain effectiveness before production stage	10	29	10	2	0	3.92	3
High level of trust and flexibility exists among design team members	11	21	17	2	0	3.80	4
Ideas are discussed freely at design sessions especially with the QS	10	18	14	7	2	3.53	5
Qualitative and quantitative information are transmitted in clear and understandable language to the QS	11	18	9	12	1	3.51	6

From the table 3 above, it is clear that quantity surveyors are introduced at the conceptual stage of building construction projects; 4.02 mean value ranked as the first, members of design team comes together to gain awareness of one another; ranked second (mean value 3.96). Also design team develops to maturity to effectiveness before the production stage i.e. construction on site, 3.92 mean value. High level of trust and flexibility exists among design team members, 3.80 mean value. Only the 5th and 6th variables were rated little above neutral, (3.53 and 3.51 mean value) for "ideas are discussed freely at design sessions especially with the quantity surveyors and Qualitative and quantitative information are transmitted in clear and understandable language to the quantity surveyors respectively. On the average (3.79 mean score) it is seen that the design team is characterized as a well-structured and organized team for quantity surveyors to perform their professional obligations and services

Table 4 Characteristics of building design products

Design Products	Frequency					Mean	Rank
	5	4	3	2	1		
NTS – Not To Scale, wrong scale and mixed scaling are often design deficiencies	23	12	12	4	0	4.06	1
Advancement in designs and construction works has positive and significant effects on designer's work attitude	13	28	8	2	0	4.02	2
Design inadequacies are as a result of designer's negligence, inexperience and incompetence	18	18	10	4	1	3.94	3
Architects and engineers supply inadequate details	11	22	10	6	2	3.67	4
Designers supply coordinated information in designs, drawings and schedules	7	25	13	3	3	3.59	5
Designs are reviewed by team members many time before quantities are prepared by the QS	12	15	12	10	2	3.49	6
Complete drawings, specifications and schedules are provided for the QS to use for his estimate preparations	13	17	5	8	8	3.37	7
Drawings, specifications and schedules provided are clear and understandable	11	14	8	14	4	3.27	8
Designs are deficient in contents	5	20	11	11	4	3.22	9
Designs are inefficient	0	20	13	14	14	2.96	10

From the table 4 above shows that advancement in designs and construction works has positive and significant effects on designer's work attitude, is ranked second, designers supply coordinated information in designs, drawings and schedules (3.59), designs are reviewed by team members many time before quantities are prepared by the quantity surveyor (3.49) and complete drawings, specifications and schedules are provided for the quantity surveyor to use for his estimate preparations (3.37).

Despite the good characteristics of design products as characterized by the above result, there are reflections of some self-attitudes in these products; not to scale (NTS), wrong scale and mixed scaling have been identified as design deficiencies as it is ranked highest with mean score of 4.06, this implies that is often a major challenge in the design team. Design inadequacies are often as a result of designer's negligence, inexperience and incompetence, ranked third (3.94) this is intone with (Adefolalu, 2006) in his work, and a respondent in his personal opinion attributed this to laziness of the designers in doing their job. Architects and engineers supply inadequate details (3.67) is ranked forth which is buttressing the above facts.

It is clearly revealed that design products are not absolutely of professional standard. Deficiencies are pin-pointed especially in quantifiable product contents which are valuable and could enhance the quantity surveyors effective service delivery.

The table 5 above shows a mean average score of 3.94 also revealed that nature of client influences positively the output of quantity surveyors although, 3.43 mean score revealed that clients alter and/or delay the progress and estimate of the quantity surveyors .3.75 mean score

revealed that information are transmitted to the quantity surveyors through dialogues and meetings media by design team members, queries to architects and engineers are responded to promptly (3.16), (3.71) mean showed that architects and engineers corporate and contribute positively to the cost planning process of design and (3.45) and designers listen to the professional advice of quantity surveyors (3.67).

Table 5 Designers and their Work Attitudes in Design Team

Work Attitudes	Frequency					Mean	Rank
	5	4	3	2	1		
Specialists designer's organization influence their work attitudes positively	10	31	9	1	0	3.98	1
Nature of client influences positively the output of quantity surveyors	19	16	11	4	1	3.94	2
Information are transmitted to the QS through dialogues and meetings media	12	26	5	4	4	3.75	3
Architect and engineers corporate and contribute positively to the cost planning process of design	12	20	13	4	2	3.71	4
Architect makes excessive changes to design especially when estimates are prepared by the QS	10	25	7	8	1	3.69	5
Individual designer attitudes are reflected in their product drawings	6	28	13	2	2	3.67	6
Designers listen to the professional advice of quantity surveyors	10	15	16	8	2	3.45	7
Government rules and legislations influences designers work attitudes positively	4	23	16	8	0	3.45	7
Clients alter and/or delay the progress and estimate of the QS	5	24	12	8	2	3.43	9
Queries to architects and engineers are responded to promptly	4	16	16	14	1	3.16	10
Designers are unwilling to provide quantifiable and qualitative information	0	22	15	10	4	3.08	11
Designers exhibit hostile relationship with quantity surveyors	2	18	17	8	6	3.04	12
Quantity surveyors are seen unimportant by other design team members	4	14	9	12	12	2.73	13

A mean average score of 3.98 has revealed that specialist designer's organization also influences their work attitudes positively as well as government rules and legislations (3.45). But designers are still unwilling to provide quantifiable and qualitative information (3.08) necessary to enhance the quantity surveyor's work; the architects also make excessive changes to design especially when estimates are prepared by the quantity surveyors (3.69). Though 2.73 mean, opined in disagreement that quantity surveyors are seen unimportant by other design team members but designers exhibit hostile (unfriendly) relationship with the quantity surveyors (3.04) reflected in their individual self-attitudes and their products.

Table 6 Effects on the Quantity Surveyors

Effects	Frequency					Mean	Rank
	5	4	3	2	1		
Work pressure/stress increases for the QS at insufficient information	33	10	3	2	3	4.33	1
Wrong attitudes toward the quantity surveyor has brought constraints to the profession's awareness in Nigeria	21	14	10	6	0	3.98	2
Commission opportunities are loss by QS due to harsh attitude of team members especially the architect	18	13	10	6	4	3.69	3
Quantity surveyor's professional fee are delay or/and denied due to adversarial attitudes form team members (client)	3	8	19	8	13	2.61	4

The table 6 above revealed that hostility and unfriendly relationship exhibited by designers in design team as revealed in the above result, shows that work pressure/stress for the QS especially at insufficient information in the designer's products (4.33) is increased. This was ranked highest of the effects. Also, this wrong attitude toward the quantity surveyor has

brought constraints to the profession's awareness in Nigeria (3.98); ranked second, Even commissions opportunities at times are loss by quantity surveyors due to these harsh attitudes of team members especially the architect (3.69). The research has in disagreement revealed that (2.61) quantity surveyor's professional fee are delay or/and denied due to unfriendly attitudes of team members (such as the client).

Table 7 Effects on the Quantity Surveyors' products

Effects	Frequency					Mean	Rank
	5	4	3	2	1		
Bills of quantity (BOQ) preparation	27	20	4	0	0	4.45	1
Preliminary cost advice	26	19	4	2	0	4.35	2
Cost estimate	19	18	13	1	0	4.08	3
Cost planning	13	23	10	4	2	3.78	4
Contractual arrangement	13	23	10	1	4	3.78	4
Financial management	9	20	15	5	2	3.57	6

Table 7 shows the effects of these attitudes to the quantity surveyors have significant consequences on his products. These effects was rated highest on the Bills of quantities (4.45) provided by the quantity surveyors and preliminary cost advice (4.35) was rated second. Cost estimate (4.08) third, Cost planning 3.78 and Contractual arrangement 3.78 were rated fourth while Financial management 3.57 was rated least among all the services provided by the quantity surveyors it the design stage. On the average this research study/work revealed that the hostility exhibited by design team members exhibited in their work (products) and behavioural/self-attitudes (Abiola-Falemu, 2007) have significant (reducing) effects on the service offered by the quantity surveyors.

SUMMARY OF FINDINGS

The study revealed that the design team is a well-structured and organized team for quantity surveyors to perform their professional obligations, tasks or/and services but designers' work attitudes through their design products create a mundane and frustrating atmosphere for the quantity surveyors. Instead of providing production drawings which could be valuable and enhance the quantity surveyors effective and proficient service delivery (and invariably the design team), sketches are provided as working drawings.

The work attitudes revealed by this research work in building construction projects during the design stage include:

i. Personal attitude and individual way of designing without full consideration for the quantity surveyor.
ii. Hostile (unfriendly) relationships with the quantity surveyors (drawing wise).
iii. Unwillingness to provide quantifiable and qualitative information on drawings.
iv. Poor team spirit in team work as earlier stated by (Ajayi, 2004).
v. Provision of not to scale (NTS), wrong scale and mixed scaling drawings, these attributed to laziness of the designers
vi. Excessive changes to designs especially when an estimate has being prepared by quantity surveyors.

CONCLUSION

The study has been able to explore the various effects of work attitudes put on by design team and how it affects the service delivered by the quantity surveyors. These design inadequacies are often as a result of designer's negligence, inexperience and incompetence or unethical behaviours and self-attitude or work stress on them (Statt, 1994) but I perceive a drift from the standard of RIBA plan of work by these professionals' designers especially as apply to

design which is a reflection of the dominance of personal attitude over professional discipline.

This work has also revealed the following effects of these work attitudes of the design team on the services delivered by the quantity surveyors;

i. The hostile and unfriendly relationship exhibited by designers in a design team increases work pressure/stress for the quantity surveyors especially at insufficient information/details in the designer's products (working drawing)
ii. This wrong attitudes toward the quantity surveyors has brought constraints to the profession's awareness in Nigeria, even many do not see the need for the Quantity Surveyor.
iii. Commissions opportunities at times are loss by quantity surveyors due to these harsh attitudes of team members especially from the architect
iv. The hostility, unethical and poor team spirit exhibited by design team has efficient reducing effects on the service offered by the quantity surveyors.

ABSTRACT

Housing is a major necessity of man but its provision has remained a major challenge to most people especially in the developing countries like Nigeria due to huge capital it requires. While insurance firms constitute a major potential source of housing finance, it is not clear if they are contributing significantly to reducing the national housing deficit. This study therefore assesses the role of insurance firms in housing delivery in Nigeria. Both primary and secondary data are employed for analysis in this study. Structured questionnaires were employed to retrieve data from thirty-five (35) insurance firms and sixteen (16) real estate developers operating in Lagos metropolis. Data on investment engagements of insurance companies were also retrieved from the National Insurance Commission and Central Bank of Nigeria. The results of the analysis show that the contribution of insurance firms to housing finance either through direct investment or through loans and advances is very low. The study also revealed that most of the insurance firms do not grant long-term loans which are most suitable for real estate development. Lack of trust in real estate developers, risk associated with real property investment and low public patronage are found as the three most significant factors inhibiting the contribution of insurance firms to housing finance. It is recommended that government should provide an enabling environment that can foster a high level commitment of insurance firms to housing delivery in Nigeria.

Keywords: Challenge, Delivery, Finance, Housing, Insurance firm

INTRODUCTION

Housing constitutes one of the most important needs of man. It is recognized world-wide as one of the basic necessities of life and a pre-requisite to survival of man (Waziri & Roosli, 2013). Housing is also perceived as a measure of success and economic freedom (Ayoola, 2006). This accounts for the high aspiration for home ownership among eligible populace across the globe. Perhaps no aspiration is more deeply embedded in human mind than the desire to own a home(Maller, Horne, & Dalton, 2012).While the Nigerian real estate sector is growing fast and is now the sixth largest sector in the economy,the quality of housing stock in the country is poor and far below the national housing demand with abysmal low homeownership rate of 25% far behind Indonesia (84%), Kenya (73%), and South Africa (56%) (CAHF, 2015).

Whereas, housing provision is one of the preoccupations of the government, the ever increasing national housing deficitis a reflection of the fact that public housing programmes have failed to contribute meaningfully to housing provision(Waziri & Roosli, 2013).The ramification for households is the huge financial burden that comes with home ownership. According to Manda, Nkhoma and Mitlin (2011), finance remains a major hindrance to home ownership especially among the low and medium income earners in Malawi. Also, OmirinandNubi, (2007) note that as desirable as housing could be, its production regardless of the scale is bedevilled with the problem of inadequate access to funds. Therefore, in order private sector to be able to meet up with the huge capital requirement of housing provision, there is the need for a good source of finance.

Ezeokoli N.B. & Oyedokun T.B. (2016). Performance of Insurance Firms in Housing Deliveryin Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 552-562

The importance of finance in housing delivery cannot be over-emphasized. It is the economic power needed to mobilize materials and other resources required to actualize the goals of the various housing policies and schemes of any government (Odu, 1992). Provision of housing and other infrastructures depend on the financial sector which makes it the life-wire and engine of growth for all national economies (Ningi, 2013). Globally, the role of the financial sector in the growth and development of economic and social systems remains crucial. It plays an essential role in providing and channelling financing for investment as it serves as both source of short and long-term finance for investors (OECD, 2013).

According to the National Housing Policy of 1991, some financial institutions in Nigeria are expected to contribute to the housing finance system in a bid to help increase the number of housing units developed in the country. These include commercial banks, merchant banks and insurance companies (Agbola, 2005). The National Housing Funds (NHF) Act Decree No. 3 of 1992 states that a minimum of 20% of the non-life funds and 40% of the life funds should be contributed by insurance companies operating in Nigeria to real property development. Furthermore, the new Insurance Act of 2003 stipulates that not more than 35% of the general insurance business and life insurance business funds are to be invested in real estate and property. While this sounds odd to existing provisions, it implies insurance companies are allowed to invest up to 35% of their investible funds.

This study therefore assesses the performance of insurance industry in housing delivery in Nigeria. The main questions of focus in the study are (1) how significant is the contribution of insurance companies to housing finance in Nigeria? and (2) what are the factors responsible for such level of contribution? The rest of the paper is structured as follows. The second section presents a review of extant studies on Nigerian housing policies and sources of housing finance. The section reveals the position of insurance companies in the housing finance system. Research methodology is presented in the third section followed by results and findings. The fifth section is devoted to discussion of findings before the presentation of conclusion and policy implications in the final section.

LITERATURE REVIEW

One of the areas that have been heavily researched in the real property domain is housing. Core aspects that have been dealt with include housing supply, demand and affordability, housing finance, mortgage lending and default, roles of relevant stakeholders such government, financial institutions, property professionals and private sector, housing development policies and programmes among others (See Adewale, Siyanbola, & Siyanbola, 2014; Omirin & Nubi, 2007; Ukoje, State, & Kanu, 2014; Waziri & Roosli, 2013; Oyalowo & Nubi, 2013, etc). While all these studies were conducted in a bid to solve the national housing problem, the ever increasing national housing deficit is a reflection of the fact that housing programmes have not deliver the required respite (Waziri and Roosli, 2013). Availability and access to finance has been identified as a huge constraint to home ownership (Omirin and Nubi, 2007). Lemo (2007) observed that the production and supply of housing continues to be constrained due to lack of long-term finance for construction and mortgage finance. Also, Anota (2008) lamented the paucity of insurance industry in the building

market. It posited that the absence of sustainable long-term fund, which is required for construction, is the impediment of the insurance system.

Despite the challenge of housing finance, the role financial institutions has been clearly defined given their potential as funds mobilizers (Oyalowo & Nubi, 2013). Among the financial institutions, insurance firms have been rated high as possible source of housing finance given their relatively huge capital base and ability to issue long term funds (Oloke, Durodola, & Emeghe, 2015; Ubom, 2014).It has however been opined that the Nigerian insurance sector seems to be underperforming this role (Ubom, 2014). Consequently, the absence of thriving and sound insurance system has made Nigerians to have no other choice than to obtain loans from commercial banks (Akomolede, 2007), which ought to be short-term financiers with high interest rate. Despite the unattractiveness and non-suitability of such loans, stiff conditions still need to be met before advancement because banks are not ready to bear the risk of mismatching short-term deposit to fund mortgage concerns (Folorunso, Khan and Olowoyo, 2012). Ironically, the low income groups who occupy the largest segment of the Nigerian society are the most affected by this finance menace.According to section 5(2) of the National Housing Funds Act of 1992, a minimum of 20% of the non-life funds and 40% of the life funds should be contributed by insurance companies operating in Nigeria to real property development. Sub-section 3 further stated that nothing contained in the Insurance Act or relating to investment of insurance companies on real property shall affect the provision of this Act.

Housing problem is a global phenomenon confronting the developed and developing nations of the world. Accordingly, a combination of factors were identified as the bane of effective and sustainable housing among which are the problem of land accessibility, stunted financial and insurance system, exorbitant prices of building materials and disproportional capacity building in the sector in Lagos (Alufohai, 2013). In Nigeria, despite several housing policies in the past years, the housing deficit is ever increasing. The study of housing situation in Nigeria put existing housing stock at 23 per 1000 inhabitant. Housing deficit is put at 15 million houses (Mabogunje, 2007), while N12 trillion will be required to finance the deficit. This is about 4 times the annual national budget of Nigeria (FHA, 2007).

Insurance is a system under which individuals, businesses, and other organizations or entities, in exchange for payments of a certain sum of money known as premium, are guaranteed compensation for losses caused by certain perils and other specified conditions. The cost of purchasing insurance (Premiums) are not fixed arbitrarily; however, it depends on the level of risk involved. High risk usually attracts high premium (Kunreuther and Pauly, 2005). According to section 25 (3) of the Insurance Act of 2003, not more than 35% of the general insurance business and life business funds are to be invested in real estate and property. The Act stipulates that policy holder's funds shall be invested as loans to building societies by the Nigerian Insurance Commission, which can be made a veritable source of long term funding in real estate development. Since life funds of insurance companies are long term savings in form of annuities or endowment policies, which can only mature at the occurrence of certain known events, this can enable life assurance companies to invest primarily on long-term capital assets like real estate investment. Despite the various pronouncements, regulations and

deregulations, and all financial implementation policies of this country, the issue of accessing sufficient funds for an effective housing delivery system remain perpetually unsolved (Ozurumba, 2011). It averred thatthe loss of focus by some Primary Mortgage Institutions (PMIs) in favour of non-core activities such as trading as well as the slow disbursement of National Housing Funds (NHF) to the PMIs, made some of them to be competing with the banks in sourcing of funds for purposes other than mortgage financing coupled with the inability of the financial institutions to mobilize resources effectively for low-income housing.

METHODOLOGY

This study focuses on the performance of insurance firms in the provision of housing finance in Nigeria. The study is based on both primary and secondary data. Two different surveys were conducted to obtain (primary) data from the real estate developers as fund users and insurance companies as fund providers; while secondary data was obtained from the NAICOM annual report and CBN Statistical Bulletin. Likert-type scale structured questionnaire was adopted. The questionnaire for the real estate developers contains questions on (1) the forms of real estate development finance mostly used or easily assessable by them and (2) their desirability of finance from insurance companies. On the other hand, insurance companies were asked on the factors inhibiting their contribution to housing finance. While the study relates to Nigeria as a country, the city ofLagos has been selected as the study site. This is not in any way an attempt to localize the issue under consideration; rather it ismainly for the purpose of data collection. Being a former national capital city and currently the hub of the nation's commercial activities, Lagos houses more number of real estate establishments and insurance companies than any other city in Nigeria(NBS, 2015). Besides, it is one of the largest Nigerian cities in terms of population and has similar housing shortage asthe entire nation.Lagos alone accounts for 5 million housing deficit representing 31% of the estimated national housing deficit of 18 million (Oshodi, 2010).Thus, the authors believe that the data emanating from the city can be safely used to generate conclusions that are applicable nationally.

The real estate developers surveyed are those on the membership list of the Real Estate Developer's Association of Nigeria (REDAN). These are mainly corporate organizations involved in business related to the housing industry or commercial real estate development such as building of residential, commercial and industrial structures. According to the list provided on REDAN's website, there are only one hundred and six (126) financial members nationwide as at November 2015. However, as the list only contains names of companies and not details of their locations, the authors had to search manually for company addresses and locations. Eventually, only twenty-six (26) companies who are members of REDAN are traceable to Lagos metropolis. According to the NAICOM's website, there are fifty-four (54) licensed insurance companies as at November 2015 operating in Lagos. However, in the course of data collection, only fifty (50) of them were reachable. For both surveys, authors ensured that the data obtained satisfy relevant quality and reliability criteria (Creswell, 2009). This was achieved by ensuring that only the senior and experienced personnel were targeted among the companies and only their responses were considered for analysis. At the end,

thirty-five (35) insurance firms out of fifty (50) and sixteen(16) real estate developers out of twenty (26) operating in Lagos metropolis participated in the survey, which yields response rates of 70% and 62% for the two groups respectively. All the questionnaires that were returned were found suitable for analysis and the response rates are found satisfactory for the research design adopted (Nulty, 2008).Surveys were conducted between June and October 2014.

Secondary data on major investment engagements of insurance companies were also retrieved fromNAICOM. Due to data accessibility, the data which ought to cover the period 1996-2014 terminates at 2011. Data analysis is mainly through the weighted average estimated using Equation I. given the nature of data while presentations are done through the use of frequency tables and charts.

$$\bar{x}_w = \frac{\sum_{i=1}^{N} x_i w_i}{\sum_{i=1}^{N} w_i} - - - - \text{Equation I}$$

Where:$\bar{x}_w$ is the weighted item; x_i is value of ith item *x*;w_i is the weight of ith item *x.*

RESULTS AND FINDINGS

This section presents the results of data analysis starting with the background information of the respondents presented in Table 1. This is followed in Table 2 by real estate developers' response on the type of real property mostly developed by their firms in Lagos. On a 5-point rating scale, '5' is used to denote mostly developed property type, while '1' is used to denote the least developed.

Table 1:Years of Operation of Real Estate Developers and Insurance Firms

Years of Operation	Real Estate Developer's Firms		Insurance Firms	
	Frequency	(%)	Frequency	(%)
1-10 years	5	31.3	3	8.6
11-20 years	6	37.5	21	60
21-30 years	2	12.5	11	31.4
31-40 years	3	18.8		
Total	**16**	**100.0**	**35**	**100.0**

Table 1 shows the years of operation of Real Estate Developers Firm and insurance firms in Lagos. From the table, most of the real estate developers firms are below 20years. This indicates that the firms are recent phenomena as individual developers now find it very difficult to access funds for real estate development. But the coming of these firms has made development more feasible and achievable.

Table 2:Type of Property Developed by Real Estate Developers

Property Type	**Development Rating**					**Weighted**
	5	**4**	**3**	**2**	**1**	**Average**
Residential properties	12	4	0	0	0	4.75
Office accommodation	10	6	0	0	0	4.63
Shopping centres	8	7	1	0	0	4.44
Industrial properties	4	6	4	2	0	3.63
Recreational properties	3	2	5	2	4	2.88

Table 2 shows the various types of real property mostly developed by real estate developers in Lagos. From the table, residential property ranks highestwith a mean score of 4.75, while this is followed by office accommodation and shopping centres developments with mean

rankings of 4.62 and 4.44 respectively. This has rapidly improved the commercial sense of these areas, turning areas like Victoria Island into central business district (CBD) where the core of business emerges. The result shows that real estate developers do not go much into industrial and recreational properties as they ranked 4th and 5thwith mean score of 3.63 and 2.88 respectively. This is an indication that housing development is of high demand and this ought to be given utmost attention by all stakeholders.

In Table 3,real estate developers' responses were sought on the sources of finance mostly available for the developers. On a 5-point rating scale, '5' is used to denote highest level of availability, while '1' is used to denote the least available.

Table 3: Source of Finance for Housing Development

Source of finance	Availability rating					Weighted
	5	4	3	2	1	average
Mortgage institutions	9	3	2	0	2	4.06
Commercial Bank loans	8	3	2	3	0	4.00
Equity fund	5	6	2	3	0	3.81
Loans and advances from insurance company	4	7	2	1	2	3.63
Loan syndication	2	9	1	2	2	3.44
Real Estate Investment funds	1	9	1	2	3	3.19

As shown in the table, mortgage institutions and commercial banks are the two most significant sources of housing finance to real estate developers with weighted averages of 4.06 and 4.0 respectively. Equity ranks third with a weighted average of 3.81 followed by insurance sector which achieves weighted average of 3.63 to occupy the fourth position. The least rated sources of housing finance in terms of availability are syndication and real estate investment fund with weighted averages of 3.44 and 3.19 respectively. In order to identify if lack of interest in loans from the insurance sector is the reason for the low rating achieved by the sector as reported in Table 4, real estate developers were asked to rate their desirability of the various sources of housing finance. On a 5-point rating scale, '5' is used to denote highest degree of desirability while '1' is used to denote the least desirable. The responses of the real estate developers are presented in Table 4.

Table 4: Desirability of Real Estate Finance for Housing Development

Source of finance	Desirability rating					Weighted
	5	4	3	2	1	average
Mortgage institutions	7	5	1	2	1	3.94
Loans and advances from insurance company	5	6	3	0	2	3.75
Loan syndication	4	6	2	0	2	3.63
Commercial Bank loans	4	6	3	1	2	3.50
Real Estate Investment Funds	4	6	2	1	3	3.31

The table shows that mortgage institutions and insurance sector are the two most desired sources of housing finance with weighted averages of 3.94 and 3.75 respectively. With weighted averages of 3.63 and 3.50 respectively, syndication and commercial banks rank third and fourth as the most desired housing finance sources by the real estate developers. As shown in the table, the least desired source of housing finance is real estate investment fund with 3.31 weighted average. The performance of insurance companies is further examined through secondary data on their major investment commitments over the period 1996-2011 as presented on Table 5.

Table 5 shows that in terms of nominal value, the amount of money investedby insurance companies into the real estate and mortgage was in excess of ₦2.5 billion in 1996. The figure grew to ₦2.7 billion in the year 1997 followed by drastic decline and lower investments

between 1998 and 2004. Over this period of trough, investment in real estate and mortgage fell to ₦212 million in 1998 while the highest volume of investment was ₦960 million recorded in 2002. Things however changed remarkably in 2005 when the volume of investment climbed up again to ₦33.8 billion. Since then, investment volume has continued on the rising trend with 2011 figure at about ₦49.5 billion. In order to assess the commitment of insurance companies to mortgage and real estate investment, the proportions of investment in government securities and stocks are calculated. Fig. 1 presents the insurance companies' investment in the three selected investment media expressed as percentage of total investment.

Table 5: Major investments of insurance companies, 1996-2011

Year	Govt. Securities(₦' million)	Stock & Bond (₦' million)	Real Estate & Mortgage (₦' million)	Cash deposits (₦' million)	Bills of exchange (₦' million)	Others (₦' million)
1996	1,546	4,048	2,523	3,347	119	796
1997	2,012	4,095	2,684	3,816	164	842
1998	4,146	3,633	212	1,993	3,371	2,301
1999	2,987	4,174	333	4,184	5,781	4,124
2000	3,559	4,993	282	3,844	7,302	5,212
2001	3,843	6,886	359	4,285	10,178	6,706
2002	3,752	8,351	960	4,095	11,881	7,901
2003	3,559	4,993	282	3,844	7,302	5,212

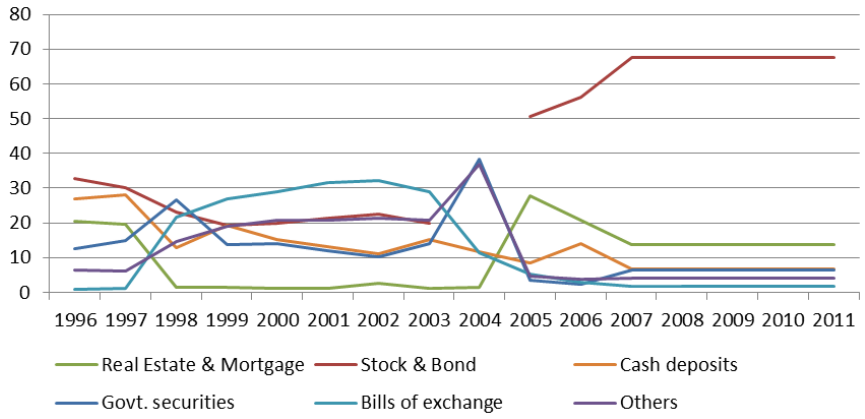

Fig. 1: Investments of insurance companies as percentage of total invested fund, 1996-2011

As shown in the figure, the percentage of investment of insurance firms in real estate and mortgage was about 20% in 1996 which was above investments in government securities, bills of exchange and 'others' but far below stock and cash deposits. There was a general fall in the period 1997 - 2002 except for bills of exchange during which investment in real estate and mortgage fell below other outlets. In fact, investment in real estate and mortgage did not pick up not until 2004 which was a year after the other outlets such stock and bond and government securities have experienced rise in investment volume. Since 2005, real estate and mortgage has maintained middle position similar to the pre-1996 period.

The chart also shows that investment in real estate and mortgage exhibits inverse relationship with bills of exchange as the former moves in opposite direction with the latter almost throughout the period under study. While investment in stock has increased remarkably from about 33% to 68%, investment in real estate and mortgages reduced to 14 per cent.

In order to identify the reasons for the low level of investment in real estate and mortgage, insurance firms were asked to rate a list of possible factors as reported in Table 6. On a 5-point rating scale, '5' is used to denote most severe, while '1' is used to denote the least severe factor inhibiting the contribution of insurance firms to housing finance.

Table 6: Factors Inhibiting the Contribution of Insurance Firms to Housing Finance

Factors	**Severity rating**					**WA**
	5	4	3	2	1	
Lack of Trust in real estate developers	17	16	2	0	0	4.43
Low patronage of insurance industry by the general public	14	16	3	0	2	4.14
Huge tax burden payable on profits realized	9	22	3	0	1	4.09
Ineffective disbursement of funds through mortgage	8	22	4	1	0	4.06
Stringent government counter policies	10	19	3	2	1	4.00
Uncertainty/risk in financing real estate	0	11	20	3	1	3.17

As shown in Table 6, lack of trust in real estate developers ranked 1st with 4.43 as mean, while low patronage of insurance industry by the general public ranked 2nd with a mean of 4.16. Other factors are huge tax burden payable on profits realized (4.09), ineffective disbursement of funds by mortgage institutions (4.06) and stringent government counter policies (4.00), while uncertainty involved in financing the housing development ranked least with a mean score of 3.17. In order not to lose its funds or investment to real estate development, the Insurance Act of 2003 has placed a maximum percentage of premiums investable in real property development at 35%. Though, this was to curb the menace of bankruptcy or foreclosure of insurance companies and loss of funds meant for policy holders should any unforeseen event occur, but it is a policy which has countered that of NHF Act of 1992 thereby encouraging insurance firms to contribute less to housing development in Nigeria.

DISCUSSION OF FINDINGS

In Nigeria, insurance companies are encouraged to contribute to funding of real estate development especially provision of affordable homes. This is because they Insurance firms forma major segment of the national financial system. The main preoccupation of insurance companies relates to financial intermediation, mobilization of financial resources and utilizationof such for economic development including provision of housing (Ubom, 2014).However, this study shows that the proportion of investment flowing into the real estate and mortgage from the insurance companies is very low. This agrees well with the study by Oloke, Durodola and Emeghe(2015)in which forty-six insurance firms (representing 96% of the total firms surveyed) only allocate 10% or less of their investable funds to real estate. In terms of availability for housing development purpose, finance from insurance sector ranks fourth behind mortgage institutions, commercial banks and equity (Table 3).While insurance companies are well-suited to provide ample housing finance due to their stable source of income and long-term nature of their liabilities, the result gives an indication that the insurance sector has not been a good source of finance for housing development.

The low finance contribution from the insurance sector is further unveiled by the sector's investment activities (Table 5 and Fig. 1). Throughout the period under consideration, investment into the real estate and mortgage was never in excess of 28% (recorded in 2005) of the total insurance companies' investment. In fact, between 1997 and 2002, investment in

real estate and mortgage was in melting pot after a drastic fall from 20% it enjoyed until 1997. It is worthy of note that all the investments outlets except bills of exchange suffered the downward trend due notably to the global financial crisis that rocked the decade. Whereas, real estate ought to have high risk-hedging capability than most other investment outlets, the fact that investment in real estate and mortgage went under might be a reflection of the insurance companies' lack of trust in this potential in line with a recent study by Oloke, et al. (2015) in which Nigerian insurance companies generally affirm they perceive real estate as risky asset. The second and perhaps the most important reason that may explain the dwindling investment in real estate and mortgage especially during the downturn is the relatively illiquid nature of real estate assets. Insurance companies rate illiquidity as one of the critical risk elements that are germane to their investment decision (Oloke, et al., 2015). This sounds reasonable as they need to guide against not being able to access fund to perform their primary function in the face of economic gloominess.

However after the crisis, one would expect investment in real estate and mortgage to shoot up again at least to 20% recorded in 1996 and 1997. While this has been the case for investment in stock which has increased drastically from 33% to 68%, investment in real estate and mortgages remained moderately low at 14 per cent since 2007 after a momentary period of spike between 2005 and 2006. In the absence of data on the total fund as well as insurance categories, it is difficult to ascertain whether this current level of investment in real estate by the insurance companies meets up with the minimum benchmark provided by NHF Act of 1992. While the law stipulates that 20% of the insurance companies' non-life funds should be committed to real property sector, it is not clear if the current 14% of total investment is big enough to meet benchmark. The provision of the Insurance Act of 2003 which stipulates (as interpreted)that insurance companies can invest in real estate to the tune of 35% of their funds seems to weaken the NHF Act. Based on these laws, the insurance sector can be exonerated from any potential blame for not doing more in housing finance as the functions of the lending institutions in the property market rests heavily on the policy environment in which they operate (Omirin and Nubi, 2007). While the governments have made series of interventions at solving the problem housing, presence of multiple policies with conflicting provisions can be blamed for the failure of such programmes (Waziri and Roosli, 2013).

There is evidence that the real estate developers would want loan from the insurance sector. Conversely to the level of availability where it ranks fourth (Table 3), insurance sector ranks second after mortgage institutions in terms of desirability as source of finance for housing (Table 4). While the real estate developers rely more on mortgage institutions, commercial banks and equity, this result shows that they still desire their funding from insurance companies. This can be adduced to the fact that insurance companies are potential long-term financiers. The preference for equity funding over loans from insurance companies no doubt is worrisome. Thus, finance has been and will continue to constitute major hindrance to effective production of affordable housing in Nigeria unless necessary actions are taken (Manda et al., 2011).The contribution of the insurance firms to the housing sector is low as found in this study. Earlier, Ubom (2014) concluded that insurance sector's contribution to national economic development as a whole seems very insignificant. All these point to the under-utilization of fund from a sector with good capacity to fuel economic growth and development.

There cannot but be reasons why insurance companies detest or seem to have little interest in financing real estate development especially housing. As reported, lack of trust in real estate developers constitutes a major factor preventing insurance companies. This may be the case given the level of non-performing loans and default in the country (Akinlo & Emmanuel, 2014).Furthermore, insurance firms have not been at the forefront of financing real property

development. This could be the reason for the low patronage received from the general public as this ranked second. Other factors are huge tax burden payable on profits realized (4.09), ineffective disbursement of funds by mortgage institutions (4.06) and stringent government counter policies (4.00). For instance, the National Housing Fund Act of 1992 stipulates that 20% of non-life insurance fund and 40% of life fund should be contributed to real property development. However, in order not to lose their funds or investment to real estate development, the Insurance Act of 2003 places a maximum percentage of premiums investable in real property development at 35%. Though, this was to curb the menace of bankruptcy or foreclosure of insurance companies and loss of funds meant for policy holders should any unforeseen event occur, but the policy has countered that of NHF Act of 1992 thereby encouraging insurance firms to contribute less to housing development in Nigeria.

CONCLUSION

It is evident that the insurance sector remains a key player in the financial services sector and a leading contributor to the sour-economic growth of the nation. But the fact still remains that its huge reserves and investible funds that are diverted into other forms of investments have been inadequately exploited to fund housing development, which remains crucial and indispensable to the existence of man. Insurance industry has remained relevant in the area of mortgage financing through loans and advances to mortgage institutions. These loans and advances to building societies and primary mortgage institutions could be a veritable source of long term funding for housing development. However, evidence shows that this has not been adequately exploited. This was basically due to lack of trust in real estate developers, low patronage by the general public, ineffective disbursement of mortgage loans and stringent policies from the government, which sometimes counter each other.

Government can help facilitate effective contractual agreements between developers and insurance companies to deal with issue of lack of trust. Since insurance companies would not commit to long-term investment as we found due to risk of liquidity, Government should put framework in place to always come to the rescues of insurance firms anytime they are short of fund for insurance cover due to their investment in real estate. Government can also develop aggressive motivational strategies, which give reward to insurance companies that invest well into housing provision.

ABSTRACT

Consideration for risk factors impacting on cash flow forecasts has been identified as a key issue affecting contractors' application of forecasting models. This research was conducted in order to assess the risk factors influencing the prediction of "cash-in" flow by contractors in the Nigeria construction industry. The perceptions of construction contractors were sought on a list of risk factors that influence cash-in flow forecasts. The research data were collected through an industry-wide questionnaire survey of contractors operating in the entire Nigerian construction industry. A list of 40 risk factors influencing "cash-in" flow was generated from literature review. Responses obtained from 157 contractors were used to analyse the major risk factors that are responsible for the impact on cash in forecasts. The research provides stakeholders with information on factors which, if properly understood, will make planning for "cash-in" for construction projects easier and thus render project delays less likely. Seventeen risk factors were found to significantly influence cash-in forecasts for projects executed in Nigeria. These include- "delay in receiving retention", "accuracy of estimates", "change in government officials", among others. The findings from this research have regional dimension. It is therefore suggested that contractors should apply the results with caution. For, the risk factors influencing cash-in forecasts is affected by individual culture, regulations and nature of the construction industry under consideration.

Keywords: Nigeria, Construction Industry, Risk factors, Cash Flow, "Cash-in", Forecasts

INTRODUCTION

The success of any construction company depends largely on the ability of its management to foresee and prepare for the future. One area of great challenge is that of managing present and future financial requirements. An essential component of financial management is that of forecasting cash flow. Cash flow in construction contracts is concerned with the timing of payments, receipts of payments and the consequent balance of cash remaining due to these transactions. Construction contractors know that there can be a significant lapse in contractual time from the point at which they are granted a project, incur labour, material and other costs ("cash-out"), to the time they are actually paid for completed work ("cash-in"). Cash flow in construction consists of the following important components (Kenley, 2003): goss cash flow- consisting of inward cash flow and outward cash flow; net cash flow- consisting of the balance between inward ("cash-in") and outward (cash-out) flow; organisational cash flow- consisting of the overlaying of the organisation's individual project net cash flows; and strategic management of cash flow- consisting of the policy and strategic framework for managing the cash flow for the entire organisation, including non-construction projects or investments.

Several factors affect cash flow to a contractor working on a project. These factors include (i) duration of the project (ii) retention conditions (iii) times for receiving payments from clients (iv) credit arrangement with suppliers, equipment rentals etc and (v) times of payment to subcontractors (Park, Han and Russell, 2005). Other factors affecting cash flow forecasting include the type of client, size of the project, the procurement route, type of the project, among others (Kaka and Khosrowshahi, 1996). Thus, the need for forecasting the cash requirement of a project at the right time, in order to determine when and where to borrow or redirect funds cannot be over emphasised.

Abdulrazaq, M.; Ibrahim, Y. M. & Ahmed D. I. (2016). An Assessment of Risk Factors Impacting on Construction Contractors' Cash-in Forecasts in the Nigerian Construction Industry. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 563-571

In an attempt to assist contractors and employers forecast their cash requirements, several researchers have made efforts to develop cash flow forecasting models. The approach of early studies may be characterised as nomothetic- the studies attempted to discover general laws and principles across categorised or none categorised groups of construction projects (Kenley, 2003). Some of the techniques used for modelling cash flow forecasts include polynomial regression (Balkau, 1975; Bromilow, 1978; Peer, 1982), Weibull-linear model (Tucker, 1986), Logit models (Kenley and Wilson, 1986, 1989), neural network (Boussabaine and Kaka, 1998; Boussabaine *et al.*, 1999) and fuzzy logic (Boussabaine and Elhag, 1999; Chen *et al.*, 2013). The nomothetic approach adopted by early researchers has gained fewer acceptances because of several shortcomings that resulted in the inability of the models to produce typical value curves. These short comings emanated as a result of the uniqueness of construction projects arising from difference in payment conditions (Chen *et al.*, 2005), time lag between billing and actual payment (Park *et al.*, 2005), type of project (Boussabaine *et al.*, 1999), procurement route (Kaka and Khosrowshahi, 1996; Kaka and Price, 1991), type of client and several other factors.

This paved way for the introduction of the idiographic approach- the search for specific laws pertaining to individual projects. Researchers have shown that models developed using the idiographic approach, are more accurate than the nomothetic models (Kenley and Wilson, 1986; Kaka and Price, 1991; Boussabaine *et al.*, 1999). Despite these improvements, forecasts by existing models continue to vary considerably with actual cash flow (Odeyinka *et al.*, 2002; Odeyinka *et al.*, 2008, Ross *et al.*, 2013, Zayed and Liu, 2014). According to recent researches (Ross *et al.*, 2013; Odeyinka *et al.*, 2013; Zayed and Liu, 2014) the variation between the forecasts and the actual is as a result of non-consideration of risk factors inherent in construction by the models developed. Hence more researchers are advocating for understanding and evaluation of the influence of risk factors on cash flows. Zayed and Liu (2014) in a comparative study of risk factors impacting on cash flow forecasts in North America and China showed that the risk factors had regional dimensions. Results from their study showed that the extent of impact of the risk factors is regionally endemic owing to geotechnical, cultural, attitudinal and other regional issues.
