In Nigeria, authors have linked project abandonment to delays associated with payments (Aibinu and Jagboro, 2002; Olawale and Ming, 2009; Lawal and Onohaebi 2010, Olusegun and Michael, 2011). These delays, according to the authors, were caused by cash flow management problems and other factors like procurement route, availability of credit facilities, interest rates, retention rates, time lags between billing and actual payment, project type, type of client (public or private), among others. The cash flow management issues that have been linked to project abandonment in Nigeria are mostly risk factors influencing cash flow forecasts-interest rates, availability of credit facilities, procurement route, project complexity and the likes. Despite these evidences from literature a comprehensive investigation of the risk factors impacting on cash flow forecasts in Nigeria has not been carried out. Similarly, existing researches on risk factors on cash flow forecasts available in literature have failed to consider some risk factors. Some of the risk factors not captured include charging of 'land dues' by locals (illegally), change in government officials, bureaucracy in processing payments (giving bribes to "speed up" payment), change in activities' start time, among others. The purpose of this study is to assess the impact of the risk factors on construction contractors' cash in forecasts, including the erstwhile neglected risk factors.

LITERATURE REVIEW

Financial management of the business of construction is as important as the management of the technical rudiments. This is especially as the competition in modern construction business has become very high. Contractors' financial successes have been attributed more to their background in business and finance rather than construction itself (Kaka, 1990). The number of projects that a firm is able to accommodate in the short-run in order to remain operational is determined by the skills and foresight of its management. The management decision is often propelled by the skills available to the firm. The effect of the failure of one project can be very damaging to the overall survival of a firm.

The effect of managerial decisions on the survival of individual firms and consequently a country's construction industry are numerous (Kenley, 2003). The relative content of labour and materials that must be decided by management varies from project to project. This necessitates the different ratios of labour and materials being used in the built-up cost index applied in a firm's financial planning. Such planning if appropriately executed ensures the survival of construction companies. The need to invoke strict financial management techniques has long become apparent especially for construction projects. During the periods of high inflation some large projects tend to double in cost.

Four major factors were identified as the reason for construction company failure generally; inadequate funding, underestimating costs, inadequate cost accounting, and poor management (Nunnally, 1998). The construction industry experienced a proportionately greater number of bankruptcies than other industries in recent years (Kenley, 2003). Compared to other industries, the construction industry is not capital intensive, because it is able to support a relatively high turnover in relation to capital employed. The traditional interim payments available to contractors and the delays of payment to subcontractors, suppliers and other creditors can reduce the required working capital to considerably low levels (Kaka, 1990). The low level of capital employed usually enables contractors to operate with very low profit margins on investment and high level of risk, since most of the finances required come in form of interim payments and credit facilities (Kaka, 1990).

Researchers and businessmen have long appreciated the prevalence of risk in businesses. Researchers in the construction industry have attempted to define risk and suggest management strategies for containing risks. Healey (1982) defined risk as "an exposure to economic loss or gain arising from involvement in the construction process". However, Moavanzadeh and Rossow (1976) regarded risk as "an exposure to loss" only. Perry and Hayes (1995) defined risk as "the chance of exposure to the adverse consequences of future events". It is generally recognised that participants within the construction industry are continually faced with a variety of situations involving many unknown, unexpected, frequently undesirable, and often unpredictable factors (Fong, 1987). Flanagan and Norman (1993) asserted that risks are associated with uncertainties but uncertainties, in contrast to risks, might be defined as situations in which there are no historic data or previous history relating to the situation being considered by the person making a decision. The more the thought that is given to risks and uncertainties, the more the inclination to accept risk as the more important term in the building industry (Flanagan and Norman ,1993). The aim of a construction firm should be to identify, analyse, evaluate, and operate on risks. Risk, if contained properly in businesses, can be used as an instrument for gaining advantages (Khosrowshahi, 2000).

Aibinu and Jagboro (2002) studied the effects of construction delays on project delivery in the Nigerian construction industry. The study revealed that shortage of material/manpower, variation orders, strikes, civil unrests and inclement weather were inimical to smooth project

delivery in the country. Subsequent researchers identified the same as risk factors affecting cash flow forecasts.

Odeyinka, Lowe and Kaka (2002) argued that despite several attempts by researchers to develop cash flow forecasting models for contractors and clients in the construction industry, many of the models failed to consider and analyse the risk factors responsible for the considerable variations in the modelled cash flow profiles. Consequently the researchers set out to identify and assess the risk factors responsible for variations in the construction cash flow profiles. The result of the analysis conducted revealed the major risk factors affecting cash flow forecasting relates to "changes in design or specifications", "contract conditions pertaining to cash flow", "interim valuations" and "certificates and construction programming" issues such as "inclement weather". However, the study was conducted in the UK where the researchers identified as having "a stable economy". The research further emphasised the geographic dimension of risk factors impacting on cash flows and cash flow forecasts.

Kaka, Lewis and Petros (2003) studied the effects of variability of project planning on cost commitment curves. One real project was used as a case study while employing four different planners independently to prepare work programme for the same project. The four programmes produced were analysed and converted to cost flow curves using a single data base of productivity and unit cost rates. The result showed a minimal variation in cost flow as a product of the difference in planning. Other factors were suggested to be of more effect in the variability - size of the project, duration of the project, experience of workers, availability of labour and plant.

Dantata (2007) in a study of the general overview of the Nigerian construction industry identified key factors affecting the growth of contractors in the Nigerian construction industry. The researcher identified skilled manpower shortage, high cost of materials, unstable prices of materials, delay in payment by clients, frequent social tensions and bureaucracy in processing payments (i.e. having to bribe officials) as key factors inhibiting contractors from growing. Dusai (2011) also identified bureaucracy in processing payments, change in government leadership and informal charging of "land dues" by locals as important factors affecting contractors' progress in the Nigerian construction industry. Although neither of the two researchers tagged the factors as "risk factors to cash flow forecasts", it is quite apparent that they are.

Enshassi, Al-najjar and Kumaraswamy (2009) carried out a study of Gaza strip (Palestinian authority) to determine delays and cost overruns in the construction projects. The study was prompted by the special conditions available in the region (Gaza strip frequently undergoes civil unrest as a result of dispute between Israel and Palestine). A combination of contractors, consultants and owners in the construction industry were randomly selected for the study. The findings from the research are that strikes and border closures, material related factors, lack of materials in markets, and delay in material delivery to site contribute majorly to time delays. While cost overruns are caused majorly by price fluctuations of construction materials, contractor delays in material and equipment delivery, and inflation. The factors identified by the study are direct risk factors influencing cash flow forecasts.

Buertey *et al.* (2010) developed a model for predicting construction cash flow in Ghana through a case study of a group of flats under construction by the government. Analysis of data gathered through a questionnaire survey of consultants, contractors and client's representatives 18 factors were identified as significantly affecting cash flow forecasts for contractors in Ghana. The factors include contractual specification for maximum amount valuation, availability of credit facility, advance payments, interval between two certificates,

period of honouring certificates by client, rate of retention, interest rates, front/back end loading, accuracy of measurements etc.

Mbachu (2011) investigated the sources of contractors' payment risks and cash flow problems in the New Zealand construction industry. Data was collected from project teams as to their perception of the risks contributing to payments in New Zealand. The result identified payment delays, high interest rates, inflation, government regulations, complexity of projects and claims as significantly affecting cash flows.

An analysis of the impact of negative cash flow on construction performance in Dubai carried out by Al-Jabouri *et al.* (2012) showed that there were negative cash flows for up to 70% of project duration. The study also revealed that adjustment of activities' start time and relationship between contractor and owner were major risks in forecasting cash flows.

Odeyinka *et al.* (2013) identified eleven significant risk factors impacting on cash forecasts for contractors in the UK. By studying 26 risk factors via a questionnaire survey of contractors, the researchers were able to conclude that the eleven factors impacted cash flow forecast more in UK's "stable" economy. The study revealed a regional dimension to risks in cash flow forecast. Ross *et al.* (2013) also revealed "activities' start time", "estimating errors", "dates of interim payment", and "retention percentage" as being crucial to expenditure forecasting practice by construction contractors.

McClain *et al.* (2014) discovered that poor communication, geotechnical issues and problems with foundation were prominent risk issues associated with cash flow forecasts. Also, delay in payment by employer, delay in honouring certificates, change orders and nominated subcontractors fault were identified as significant contributors to decisions to delay claims in construction contracts executed in India (Chaphalkar and Iyer, 2014).

Zayed and Liu (2014) emphasised on the impact of location on factors affecting cash flow forecasts. Data for the study was collected from North America and China. A total of 43 factors affecting cash flow forecasts were used for the study. 33 and 67 questionnaires were collected from North America and china respectively seeking respondents to rate the impact of each identified factor on cash flow forecasts. Result from the survey showed a significant difference in the impact of the following risk factors in the two locations- "contractor's personal relation with the consultant team", "contractor's personal relation with the owner", "lack of skilled labour", "change of progress payment duration", "change of labour and staff wages", "delay of making payments to suppliers", and "number of claims".

Evidently, several researchers have attempted to highlight the influence of risk factors to cash flows in different locations of the world. Hence, the current research seeks to explore, analyse and document these factors in the specific context of the Nigerian construction industry. An understanding of the factors will help contractors manage their finances properly and thus finish their projects on schedule.

RESEARCH METHOD

This research developed a list of 40 risk factors influencing "cash-in" forecasts from extant literature. The risk factors identified formed the focal point of the research. A questionnaire survey was conducted amongst responding contractors who were classified according to the types of projects they executed (Table 1), to assess risk factors that they deemed to have high level of occurrence in the Nigerian construction industry**.** The questionnaire was divided into two parts (sections A and B). This was done to make the questionnaire easy to understand and very clear to the respondents. Section "A" requested general information from the respondents. These include mainly information about the respondents such as name of

organisation, type of projects commonly executed, position of the respondent in the organisation, the average duration of projects executed, average value of project executed, the procurement route commonly adopted in projects executed, the annual turnover of the organisation and the nature of the client served. The provision of the 'other (please specify)' option was included to in each category of the questions to reduce rigidity which may artificially constrain the responses (Fellows and Liu, 1997). These pieces of information were to enable the grouping of the responses provided by the respondents.

In section B of the questionnaire, table 1 consisting of 40 risk factors derived from literature as potentially affecting "cash-in" flow forecasts were listed. Respondents were then requested to provide opinions regarding the likelihood of each factor occurring. Respondents were asked to score their opinion on a 0-5 Likert type scale, zero being included so as to accommodate the instances where the risk factor was not applicable (Holt, 1997). The highest likelihood of a risk factor occurring was assigned a score of 5.

Probability sampling technique was adopted for the study, owing to the fact that the size of the population was already known. Cochran's (1977) table for determining minimum returned sample size for a given population size for continuous and categorical data was used for determining the appropriate sample size for this study. A total sample size of 370 was identified to be sufficient for the study. A list of registered contractors was obtained from Corporate Affairs Commission (CAC), the government establishment saddled with the responsibility of registering and ensuring continuity of construction and other contractors in Nigeria.

The data obtained from the questionnaire survey were of numerical nature. The numerical data were compiled and entered into the Statistical Package for Socials (SPSS version 21) Software. The analysis of the data involved both descriptive and inferential statistical operations available in the SPSS software. The quantitative data were analysed and results of descriptive statistics obtained include frequency distributions, measures of central tendency (means) and standard deviation.

Table 1: Type of Projects Executed by Respondents

Types of Project	Frequency	Percent	Cumulative Percent
Commercial Buildings	64	40.8	40.8
Hospital Buildings	23	14.6	55.4
Residential Buildings	7	4.5	59.9
Public and Community Buildings	63	40.1	100.0
Total	**157**	**100.0**	

In spite of the provision for "others (please specify)" in the questionnaire, no other type of buildings was captured. The prevalence of commercial and public/community buildings can be explained by the fat that government pays more attention to these building types than any other. As government is the major client in the Nigerian construction industry, it is not surprising that residential buildings, mostly owned by individuals, had the least patronisation.

From table 2, the risk factor whith the highest occurence is Delay in Receiving Retention. This is followed by Accuracy of Estimates, Change in government Officials, Bureaucracy in Processing Payments (giving bribe to "speed up" payment files movement), and Increased Duration of the Project. These represent the top 5 risk factors that occur in construction projects in Nigeria. Client's Insolvency, Civil Disturbance, Large RetentionPercentage, Labour Strikes and Subcontractor's Insolvency were the last five amongst the 40 risk factors. The positions of the first five does not come as a surprise as corruption has become common-place in Nigerian Government coffers. Change in government Officials and Bureaucracy in Processing Payments (giving bribe to "speed up" payment files movement) are manifestations

of corrupt practices in Government parastatals saddled with the responsibility of paying contractors at the required time. Changes in officials handling government issues results mostly in the abandonment of an existing policy to give way for the selfish interest of the new officials.

The ressults obtained have variations with those obtained from previous studies. Zayed and Liu (2014) identified change of progress payment, payment duration, financial position of the contractor, project delays and poor planning as the most significant factors affecting congtractors' forecasts in North America and China. The similarities with that and those observed in this study appear only in project delays juxtaposing with increased duration of the project, while payment duration juxtaposes with Bureaucracy in Processing Payments (giving bribe to "speed up" payment files movement)/ Delay in Receiving Retention, although the reason for that in America and china was not related with corruption. Other factors like Accuracy of estimates and Change in government Officials do not seem to be as important in China and North America.

Table 2: Probability of Occurence of Risk Factors Affecting "cash-in" Forecasts

Risk Factors	Mean	Rank
Delay in Receiving Retention	4.72	1
Accuracy of Estimates	4.61	2
Change in Government Officials	4.57	3
Bureaucracy in Processing Payments (giving bribe to "speed up" payment)	4.36	4
Increase in duration of the Project	4.27	5
Delay in Payment from Client	4.25	6
Delay in Releasing Advance Payment	4.20	7
Withholding Tax	4.13	8
Discount on Materials Purchased	4.06	9
Delay in Paying Creditors	3.97	10
Dispute Between Contractor and Owner	3.84	11
Variations	3.68	12
Under Valuation	3.68	13
Changes in Activities' Start Time	3.50	14
Change in Interest Rates	3.38	15
Production Time Slippage	3.32	16
Changes to Initial Design	3.25	17
Geotechnical Issues	2.97	18
Inclement Weather	2.95	19
Long Interval Between Two Certificates	2.76	20
Overheads	2.66	21
Problems with Foundation	2.64	22
Replacement of Defective Work	2.48	23
Bad Relationship Between Contractor and Consulting Team	2.16	24
Compliance With New Regulations	1.99	25
Unavailability of credit facilities	1.75	26
Incompetent Consulting Team	1.72	27
Back/Front end Loading	1.54	28
Bad Relationship Between Main and Sub Contractor	1.52	29
Bad Relationship Between Contractor and Owner	1.50	30
Change Orders	1.43	31
Period of Honouring Certificates	1.23	32
Listed Buildings	1.23	33
Contractual Specification of Minimum Amount Valuation	1.16	34
Receiving Advance Payment	1.13	35
Client's Insolvency	1.10	36
Civil Disturbance	0.99	37
Large Retention Percentage	0.87	38
Labour Strikes	0.82	39
Subcontractor's Insolvency	0.46	40

In a study of risk factors affecting construction cash flow forecasting in the UK, Odeyinka et al. (2013) identified changes to initial design, inclement weather, variation to works, labour shortage and production time slippage as the 5 top-most risk factors occurring. The same factors ranked 17th, 19th, 12th, 39th and 16th in the present study. Incidentally, Client's insolvency, Labour Strikes, and Civil Disturbance ranked very low in both studies. This implies that the civil unrests and labour strikes rarely pose a great danger to construction contractors in both the UK and Nigeria. More importantly though is the fact that the most significant factors occuring in Nigeria are either rating low or totally absent in the UK construction industry (e.g. change in government officials). Another related study by Chaphalkar and Iyer (2014) in india indicated delay in payment from employer, delay in honouring claims, change order and nominated subcontractor's insolvency as being more critical. In comparison, the present study rated all but delay in payment by employer, low.

CONCLUSION

The importance of this research was based on the relevance of risk factors impacting on cash in forecasts to construction contractors. Previous researches on cash in forecasts had failed to capture some risk factors. This study conducted an industry-wide questionnaire survey of contractors operating in the Nigeria construction industry by capturing the identified risk factors impacting on cash in to contractors. The study reveals that different categories of contractors agree that the risk factors that have the highest occurrence in the industry are client (i.e. government) related- delay in receiving retention with a mean 4.72, followed by accuracy of estimates (4.61), change in government officials (4.57) and beauracracy in processing payments (giving bribe to 'speed up' payment) (4.36).

It can be concluded that the major risk factors impacting cash-in forecasts are client related. The major clients in the country are the federal and state governments. It then means that the government is responsible for most of the risk factors influencing "cash-in" forecasts. These risk factors, if properly addresed will likely enhance timely "cash-in" for construction contractors and thus eliminate project delays. Further studies need to be undertaken to determine the impact of these risk factors on the cash-out forecasts and to model the risk factors.

Assessment of Factors Affecting Buildability and Maintainability of Construction Projects in Abuja, Nigeria

Ijigah, Edoka Augustine[1*] & Abiola-Falemu, Joseph Ojo[2]

[1 & 2]Department of Building, School of Environmental Technology, Federal University of Technology, Akure, Ondo State

ABSTRACT

Buildability and maintainability also known as constructability is the optimum use of construction knowledge and experience in procurement, planning, engineering and field operations to achieve the overall project objectives. There is a need to understand its underlying importance because of frequent building collapse, high cost of maintenance, disputes arising from variation in material and specification of building projects in order to minimize their occurrences. This paper evaluates the factors that affect buildability of construction projects in Abuja. The study employed survey questionnaire generated through a systematic random sampling of one hundred and twenty (120) contractors, consultants and client, out of which ninety (90) was found valid and applicable for the study. This constitutes 75% of the sample size. The data collected were subjected to statistical analysis using simple percentage, Relative Important Index (RII) and Severity Index (SI). The results indicated that low budget at the pre-tender stage, wrong procurement method during contract administration, poor workmanship at the construction stage were major factors affecting buildability and maintainability of construction projects. Other factors were omission or faulty architectural design, poor contract planning and management, lack of motivation for staff and complexity of the project. The study concluded that for an enhanced performance of construction industry, complete working drawing, strict adherence to specification and other contract documents by construction professionals should be followed. It was recommended that professionals should harmonize the implementation of national building codes to enforce buildability and maintainability of construction projects.

Keywords: Buildability, Construction projects, Factors, Maintainability

INTRODUCTION

The construction industry in Nigeria is one of the biggest industries and any extra cost means huge losses to the contractor and higher expenses to the client (Achuenu & Kolawole, 1998 and Obiegbu, 2004). To avoid such losses in construction rework; cost overrun, time overrun and dispute, extensive research need to be carried out on factors that affect the performance of the construction project in Nigeria, and Abuja in particular. Also buildings should be constructed with least variation to design, cost and to give maximum satisfaction to all the stakeholders in the design and construction team. It is believed that the use of skilled construction knowledge from the conception stage to the completion stage of the project will provide benefits and solutions that will achieve the design intent in a cost effective and timely manner. But construction projects executed in Nigeria are faced with problems such as poor site accommodation, delay in construction work, poor workmanship, use of inferior material, formwork failure, idleness of mechanical plant on site, poor design and unplanned construction method during project execution (Bamisele, 2004, Kunya, 2006, Otti, 2012 and Otali & Adewuyi, 2015). Most of the construction projects were not completed as designed due to partial use of cost planning techniques, adaptation of engineering specifications, use of right procurement methods and field operations to achieve the overall project objectives. This leads to building abandonment, high cost of maintenance, disputes among the stakeholders, variation in material specification, escalation of cost and time of project and if care is not taken, building collapse when contractors are forced to complete the project.

Another factor recognized in the sector was lack of cohesion between designers and contractors and the ability of both parties to see the whole construction process as one (Aina

Ijigah, E. A. & Abiola-Falemu, J. O. (2016). Assessment of Factors Affecting Buildability and Maintainability of Construction Projects in Abuja, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 572-584

& Wahab, 2011). Contractors asserted it was the designers' fault and responsibility that the cost of buildings is high, and that the building designers were not enabling the clients to obtain the highest possible return/value on their investment. Designers equally blamed the contractors for not being able to realize their design objectives in the best economical way. Such a polemical argument has encouraged the research effort into approaches that will identified the root cause of the problem in order to bring design and construction professionals to work more closely together. Also the study into the Implementation of buildability and maintainability to meet client's satisfaction was a siege that will promote the performance of construction projects, especially in Nigeria (Obiegbu, 2004, Bamisele, 2004 and Aina & Wahab, 2011).

LITERATURE REVIEW

Buildability and Maintainability in the Construction Industry

In 1983, the Construction Industry Institute (CII) an association of owners, contractors, academic institutions, and other construction professionals was officially established at the University of Texas at Austin (Construction Industry Research and Information Association (CIRIA, 1983). The mission of the CII is to improve construction industry cost-ineffectiveness, and provide continuing research in construction. One area of research funded by the CII is the interface between design and construction practices, for which it has designated a Buildability Task Force. Two primary objectives of the buildability task force are to promote the benefits of buildability to industry professionals, and to provide a package of concepts for improving the construction industry in general (Russell, Gugel & Radke, 1992, Arditi, Elhanssan & Toklu, 2002, Pulaski Horman & Riley, 2006 and Mohd et al., 2009).

Buildability in the United Kingdom, is the extent to which the design of a building facilitates ease of construction subject to the overall requirements for the completed building (CIRIA, 1983). According to Jergas & Van (2001), buildability is a relationship between designers and contractors. In the United State of America, Buildability is known as constructability, is defined as the optimum use of construction knowledge and experience in planning, engineering, procurement and field operations to achieve overall project objectives (CII, 1983). Maintainability on the other hand is defined as the design characteristic which incorporates functional accessibility, reliability, ease of services and repair into all active and passive system components to maximize cost benefits of the expected life cycle value of the facility (Ahmad, 2003, Lavy & Shohet, 2004, Daling, Cloete & Horak, 2006, and Flores, Colen & Brito, 2010). Buildability and maintainability attribute is the term used to describe buildability characteristics in optimizing integration of construction knowledge in the building process (Gray, 1990).

According to this research, buildability and maintainability is the optimum use of construction skill, experience and knowledge in planning, engineering, procurement and in construction to achieve the overall project objectives of cost, quality, function accessibility, reliability and ease of services or repair of the completed building component to maximize cost benefit of the expected life cycle value of the facility.

On this note, a framework for buildability and maintainability analysis have extensively been developed and applied in some countries such as the United State of America(USA), United Kingdom(UK), Malaysia, Australia and later in Hong Kong. The studies in these countries have demonstrated that improved buildability and maintainability leads to significant savings in both cost and time required to complete construction projects and also improved project performance (Russel, Gugel & Radke, 1992). Some of these countries have reached the advanced stage of the framework for the implementation of buildability and maintainability

with the enforcement of the application of Building Information Modeling (BIM) which was implemented and enforced in Australia, USA and UK from January 2016. These developments in the construction industry highlight the importance and relevance of buildability and maintainability analysis if adequately carried out during the design stage of the project. Also proper and timely consideration of buildability and maintainability of building project enhance the final design outcome to meet all the performance criteria. It is on this note that Trigunarsyah, Bakti, & Majid, (2011) stated that early implementation of buildability and maintainability can oblige the builder and engineer to finish construction projects on time and within the budget. Also in view of this, several other authors have buttress the usefulness of buildability and maintainability studies in their research. This include works by Russell, Gugel & Radke, (1992), Salau, (1996); Oyekan (1996), Arditi, Elhanssan & Toklu, (2002), Obiegbu, (2004), Pulaski, Horman & Riley, (2006), Bamisele (2004), Mohd et al.,(2009), Aina, & Wahab, (2011) and Bakti, & Majid, (2011).

Russell, Gugel & Radke, (1992) and Shen, (1997), claimed that the implementation of buildability management can lead to significance quantifiable improvements in project performance in terms of time, cost and quality. In addition to the quantifiable measures, buildability management can also lead to qualitative improvements in the project process as well as the building project.

Achuenu & kolawole, (1999) and Obiegbu (2004), stated that proper implementation of buildability and maintainability of construction work at the early stage of the project will avoid loses in construction rework; cost overrun, time overrun and dispute.

Aina & Wahab (2011) carried out a research work on buildability problems in the Nigerian construction industry. The research report that complexity of project, faulty and defective working drawings, resistance of client to buildability programmes, budgetary limitation and non-standardization of design are the major problem of buildability in Nigeria. The study concludes that working drawings, specifications and other contract documents must be prepared by construction professionals. They also added that construction professionals should be aware of the likely impacts of buildability problems on their finished projects. They summarized by promoting communication skills among construction stakeholders at all stages of construction projects.

A seminar paper presented on structural failure: causes, effects and remedies for structural stability of building and civil engineering structures in Nigeria pointed out that poor technical knowledge of designer, construction error and the use of sub-standard materials are the major cause of building failures (Oyekan, 1996). All this can be corrected with proper implementation of buildability and maintainability during the design and conception stage of the project.

In a related view, Salau (1996) stressed that structural failures in buildings are as a result of non- adherence to good construction practice, codes and specifications. Among the building indentified to have failed due to this factor includes skyline mega apartment building in Fair Fax County, Virgina and United State of America (USA) in July, 1983; Quebec Bridge in the United State of America (USA), a multi-storey building in Madrid, Spain, the collapse of Rhein Bridge in Germany and the failure of the Bedford Town Hall in the United State of America (USA) (Russell, Gugel & Radke, 1992 and Pulaski, Horman & Riley, 2006). In Nigeria the collapse of the Synagogue church of All Nation (SCOAN) church building in 12th September, 2014 was credited to non- adherence to good construction practice, codes and specifications as reported by Leadership Newspaper of 15th September 2014. Structural failures in buildings are in four stages of the building life, namely, at the planning, design,

construction and service stages which can be reduced with the introduction of enabling laws to back the implementation of buildability and maintainability in Nigeria.

Some construction stakeholder in Nigeria use incompetent hands, in a bid to cut cost of construction management or supervision (Bamisele 2004 and Aina & Wahab, 2011). Most clients make use of bricklayers in the place of professionally trained Builders to manage the construction production process while Decree 45 of 1989 constitution spelt out clearly who should manage the physical construction process on site as inscribed in Act CAP B13 of 2004 LFN. It is only those who are registered by the Council of Registered Builders of Nigeria (CORBON) that are qualified to be engaged as builders. They are the ones that have been trained in the act of construction management. And they will adhere to the construction practice as spell out in the national building code. They know how building materials work and are skilled in construction management. Most of the building that have failed in Nigeria in particular did not engage a resisted CORBON builder to carry out the oversight function of supervising the actual construction on site (Chucks, 2014).

The concepts for improving buildability and maintainability of projects vary from one country to another and it depends on the nature of the construction projects to be carried out. However in the Nigerian construction industry, research into buildability and maintainability assessment is not well developed. There is lack of available sources and reliable documentation that explain buildability and maintainability concepts and guide their application in Nigeria context. Nigerian Builders, Architect and Engineers and other professionals engaged in building production have a disadvantage by not knowing, when and how they should enhance the project buildability and maintainability compared with the engineers in more developed countries (Bamisele, 2004). These motivate the research into the factors that affect the implementation of buildability and maintainability of construction project in Nigeria.

Importance of Buildability and Maintainability Analysis of Construction Projects

Encourage innovative/efficient construction

Buildability and maintainability encourages the use of efficient and innovative construction methods like the use of modular coordination in prefabricated buildings, tube in tube for high rise buildings, visualization and simulation of building component before actual construction, use of graphical design like revit, google sketch, archCAD to produce 3Dimensions (3D), 4D and 5D models (Koo & Fischer, 2000 and Kaner et al., 2008). It also aids the practice of lean construction and cost/value engineering to assess building cost. Softwares to est*i*mate project cost and duration are not left out as all this improve the quality and safety program of construction projects (Trigunarsyah, Bakti & Majid, 2011).

Clear and complete design information

Buildability and maintainability consider the co-ordinating of drawings and specifications to remove ambiguities or misunderstandings that may occur during the planning stage of the project. Information on the topography of the soil, soil characteristics, weather condition, hydrological data, geographical site analysis and material test must be accurate and readily available during the design stage of the project to ease construction. All these information are important as no two construction site or project have the same characteristics.

Prefabrication and standardization

Precast or prefabricated buildings with standardized units facilitate a better management of resources and reduce the amount of activities on site (Ting, et al., 2007). Since prefabricated building components are produced under a controlled factory environment, pollution and adverse weather condition are usually eliminated. In the similar view, standardization is manifested in repeated grids, components sizing and connections. It enhanced ease of

construction by increasing project performance and reduces project cost (Griffith & Sidwell, 1995). Site personnel find it easier to acquaint themselves with the repeated working logistics, as it reduces learning time (Griffith, 1989). Standard components size like columns, doors and windows saves time and efforts because of less variation in formwork based on common dimensions which are important of buildability and maintainability assessment of building during the planning stage of construction projects.

Abridge detail and installation

Buildability and maintainability encourages details to be kept as simple as possible to reduce the learning curve effect of site tradesmen and reasonable tolerances as specified (Arditi, Elhassan & Toklu, 2002). In the case of innovative design or composite construction, adequate text is carried out on the material to ascertain their compatibility. It is also good to create a simulation models or erect prototypes of buildings to study the installation process and possible pitfalls before full scale production. Irregular shapes, complex geometrical profiles, complicated installation details and multi-disciplinary designs could burden contractors with additional resources for coordination and site assembly. As such, building designs with simple configurations that will enable works to be executed in a straight forward manner and facilitate ease of construction should be encouraged (Ting, et al., 2007). However, this aspect must be balanced with the aesthetic requirements of clients and artistic aspiration of designers. If complexity is necessarily required, the design process should be coordinated properly to ensure that minimum cross-referencing of documents is required, otherwise expensive errors are prone to occur on site.

Allow construction flexibility and sequence

High adaptability of building elements to buildability saves resources and increase the flexibility for change and comply with the actual site conditions during construction. Buildability and maintainability encourages interchangeable components with vast orientation and universal assemblies that can fit into any positions other than that designated by the design. Also the sequence of installation should not be dictated in design document but left for the contractor to decide. For example, ground floor slabs can be constructed before or after superstructure construction to allow flexibility in the timing of underground drainage works.

Employ visualization tools

The rapid development of information technology has enabled advanced software to be used for preparing design that integrates visualization features (Mahalingam, Kashyap, & Mahajan, 2010). Visualization improves the collaboration between the construction and design teams in solving buildability problems that may arise during the physical construction. It also irons out difficulties that may occur before actual construction commences on site.

Optimum use of labour/skills, materials plant and equipment

Labour and skills requirements vary between one projects and locality. Design must include a realistic assessment of the level of skill likely to be available from appropriately chosen contractors and specialists. Products and materials to be specified during design should be selected with care particularly, when such material have not been accepted within the industry. It is advised that selected products and materials, which have been tested and certified fit for the project is used. In addition, more economical benefit can be gained if local materials are used as they are cheaper and are readily available. Designing for optimum use of plant and equipment and having the knowledge of them and also designing for temporary plant and equipment anchorage in permanent structures are some of the important issues which are addressed with the implementation of buildability and maintainability analysis.

Effective site layout and management
The environment around the construction site has significant influence on the whole development process. The smoothness of construction is susceptible to traffic conditions, especially when pedestrian pavements and vehicular routes are noticed. Temporal fence, stores, site offices, material procurement, material storage, equipment control, equipment transportation model, inventory control, Security, water, services provision, trades men management and waste management are the general project management functions that buildability and maintainability analysis will solve.

Adequate health and safety for workers
Buildability assists the designers in looking at the impact of the design solution on health and safety of workers during the construction process. The use of safety protective aids and early warning signs to control accident on site and the use of charts and direction signs placed at strategic points to control traffic in the workplace is important. In addition, machines, tools and equipments are encouraged to be arranged to allow easy accessibility of use and disposal of its waste like the concrete testing machine (crushing machine) in building workshops.

Encourage sustainable construction
With heightened awareness of environmental pollution, natural resource depletion and accompanying social problems, sustainable development and sustainable construction have become a growing concern throughout the world (Pulaski, Horman, & Riley, 2006). Buildings are one of the heaviest consumers of natural resources and account for a significant portion of the greenhouse gas emissions. Conventional on-site construction methods have long been criticized for low productivity, poor quality and safety records, long construction time, and large quantities of waste in the industry. The implementation of buildability and maintainability assessment of any building structure will reduce the negative environmental impacts of the projects and enhance its sustainability.

Factors Affecting the Implementation of Buildability and Maintainability
Technical factors
Technical factors affect buildability and maintainability during planning / condition survey, design stage, construction and maintenance phases of the projects (Lateef, 2009). Building condition survey provide information on the building age, building/green area ratio, information on nearby structures, structural condition of the building, height, location, proposed use of the building, current building performance, available services, structural type of the building, energy use in the building and the pre determined life span. Design related factors are faulty architectural design, consultant experience to scrutinize the design and simulation of the design approach. While construction related factors include staff competency, tradesmen training, re-training of staffs, level of supervision, allowable tolerance and test carried out to determine the standard of work been carried out. Lastly maintenance factors include provision of adequate maintenance check list, maintenance policy, recruitment and training of maintenance staff, motivation of maintenance personnel and feedback for further buildability and maintainability analysis.

Building characteristics and design defects mostly arise due to the need for extension of initial three principles of integration, construction knowledge and team skills (El-Haram, 2002). Construction and maintenance related issues occur when buildability and maintainability knowledge and methodologies are not incorporated in the design and construction phase of the project (Souponitski et al., 2001 and Kalamese, 2002). Also getting to know corporate objectives of clients will improve better maintenance and its implementation on facilities and having a realistic buildability and maintainability analysis

for the entire project will reduce the amount of reworks that will result from fast technological advances on construction projects (El-Haram, 2002 and Williams & Clark, 2010).

Managerial factors

Managerial factors are grouped into three categories of project management factors, economical and financial factors and resource management factors. Project management factors includes, incomplete construction documents, conflict among stakeholders, late sustainability issues consideration, organizational policy constraints, poor relationship and communication with worker, site management, unclear decision making process and well developed construction program. Economical and financial factors includes inadequate budget, high cost of material, plants and equipment, high cost of labour, high cost of capital, high rate of inflation and inadequate cost planning and control (El-Haram, 2002 and Lam, 2007). Resource management factors includes, equipment and materials procurement and control, poor workmanship, lack of motivation, lack of supervision and manpower training (Lam, 2007 and Lateef, 2009). Having efficient and a well developed project specifications will enhance economical and financial aspects of buildability, operability and maintainability implementation.

Political and legal factors

Political and legal factors occur when government restricts the use of standards, and contract agreement to executed projects. Political and legal factors are caused by political inconsistency, adaptation of ambiguous legislation framework, variety of standards, and delay in Legal implementation and political manipulations of procurement acts turning all contract to turnkey model in Nigeria (Lateef, 2009). All this result in an inefficient and ineffective project management process that hinder planning and programming of the projects and restricting the use of buildability and maintainability (Lavy & Shohet, 2009).

Environmental and biological factors

Environmental and biological factors are also source of problem during buildability and maintainability phases of infrastructure projects. These factors include control of climatic change, environmental degradation, environmental pollution, deforestation, Indoor and outdoor environmental changes and erosion. Review of buildability and maintainability analysis on environmental factors of a project is a good way of resolving negative impact of environmental factors on total project objectives. It also facilitates successful delivery of construction projects.

Health and safety factors

This includes safety and security of end-users, health and safety issues, faulty use of facility, unclear current or future usage, distractions from neighbouring users and high expectations from the facility that affect the implementation of buildability and maintainability of construction projects. Having an effective health and safety plan incorporated into the planning stage of construction project will go a long way to achieve the corporate objectives and project aim of the entire stakeholder involved without ambiguity or compromise.

METHODOLOGY

In order to adequately capture respondents perception on existing factors militating against the implementation of buildability and maintainability analysis within Nigerian construction industry, a case study of Abuja, one hundred and twenty (120) structured questionnaire were randomly distributed to contractors, consultants and client, out of which ninety (90) was found valid and applicable for the study. Among the respondents are Architects, Builders,

Engineers and Quantity Surveyors selected across small, medium and large scaled construction firms. Questionnaire response rate amounted to 75% which was adequate for the sample size.

The data derived was subjected to descriptive statistical analysis using simple percentage, Relative Important Index (RII) and Severity Index (SI). The framework for this study is as presented in Figure 1.

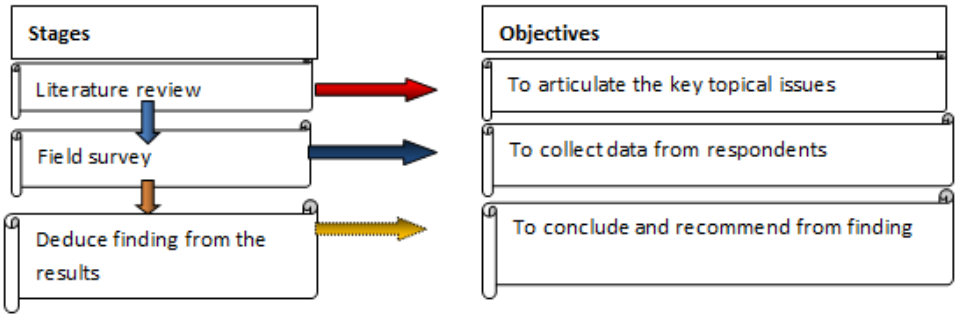

Figure 1 Research Framework

FINDINGS AND DISCUSSIONS

From table 1, the majority of the respondents are builders with 34.4% and was closely followed by 31.1% quota, represented by the engineers and the least was estate surveyors with 07.8%. The professional membership status of the respondents shows that 44.4% are corporate members, 22.2% are graduate members while 12.2% of them are associate members of their respective professional bodies. As for the years of working experience of the respondents, it can be seen that 25.6% fall within 6-10 years of experience, 24.4% of the respondent are within 1-5 years of experience while 23.3% falls within 11-15 years of experience. The last category of 21 years and above accounted for only 5.0% of the respondent. Also analyses in table 1 revealed that majority of the respondents are B.Sc. / B.Tech. holders with 55.5% and this is followed by respondents with M.Sc./ M. Tech. qualification representing 20.0% while PGD came third, representing 17.8% of the respondents. Six of the respondents have a Ph.D as their highest qualification and it translate to 06.7%. Table 1 also shows that 46.7% of the respondents are working in a building construction company, 33.3% are working in real estate development companies while 20% are working at civil engineering companies. Also in addition, 51.1% of the respondents' works in a small construction firm, 35.6% worked in a medium construction firm while only 12.3% worked in a large construction firm. Information supplied by these categories of respondents are considered to be adequate and reliable for this study as this set of respondents have executed and commissioned several construction projects in their organization.

Table 2 shows the level of occurrence of factors affecting the implementation of buildability and maintainability of construction projects in Abuja Nigeria. Low budget at pre tender stage was ranked first with mean score of 4.2778, Use of wrong procurement method during contract administration with mean score of 4.1889 was ranked second while poor workmanship at the construction stage was ranked third with mean score of 4.1778. Others are faulty or omission in architectural design, poor contract planning and management and recruitment, training and motivation of personnel's during construction stage.

The result is in agreement with Aina & Wahab (2011) findings that stated that Use of wrong procurement method during contract administration normally brought about buildability factors in the construction stage. The report is also in agreement with the work by Bamisele (2004) which says that stakeholders in the Nigeria Construction Industry should pay more

attention on poor workmanship at the construction stage of projects to mitigate the occurrence of buildability and maintainability problem. In the same vein, the findings concurred with Shen, (1997) work that stated that faulty architectural design normally have serious difficulty in carrying out maintenance work on a structure. Also when a design is very complex; there is likely hood of buildability factors. Therefore unqualified staff should not be used as consultant as the engagement of quacks as consultants normally hinder the implementation of buildability and maintainability of construction project. When a site cannot be managed properly there is likely hood of buildability problems which will eventually lead to maintainability problem. Also when they is poor planning on the part of the consultant or contractor implementation of buildability and maintainability analysis becomes a problem. From the result also, the use of wrong procurement method at the management level hinders the implementation of buildability and maintainability. Unqualified contractors should not be given contact, either due to favoritism or corruption in the system. Lastly when there is shortage of trained manpower and inadequate plants, equipment and material in the Industry many work will move in a slow pace which will hinder the implementation of buildability and maintainability analysis.

Table 1: Demographic Information of the Respondent

Background Information	*Freg.*	*%*	*Cum. %*	*Background Information*	*Freg.*	*%*	*Cum. %*
Profession of respondent				*Nature of Company*			
Architects	13	14.4	14.4	Building construction	42	46.7	46.7
Builders	31	34.4	48.8	Civil engineering	18	20.0	66.7
Estate surveyors	7	07.8	56,6	Real estate development	30	33.3	100
Engineers(Structural, Mechanical and Electrical)	28	31.1	87.7				
Quantity surveyors	11	12.2	99.9				
Total	*90*	*100*	*100*	*Total*	*90*	*100*	*100*
Highest Qualification				*Company size*			
OND	9	10.0	10.0	Small	46	51.1	51.1
HND	11	12.2	22.2	Medium	32	35.6	86.7
B.Sc. / B.Tech.	30	33.3	55.5	large	12	13.3	100
PGD	16	17.8	73.3				
M.Sc/ M. Tech	18	20.0	93.3				
Ph.D	6	06.7	100				
Total	*90*	*100*	*100*	*Total*	*100*	*100*	*100*
Years of Experience				*Professional membership*			
1-5	22	24.4	24.4	Trade membership	9	10.0	10.0
6-10	23	25.6	50.0	Associate	11	12.2	22.2
11-15	21	23.3	73.3	Graduate	20	22.2	44.4
16-20	19	21.1	94.4	Corporate	40	44.4	88.8
21 and above	5	05.6	100	Fellow	10	11.1	99.9
Total	90	100	100	Total	90	100	100

From Table 3, high cost of construction project ranked first with mean score of 4.3556 and building collapse ranked second on the table with mean score of 4.2889 while abandonment of project ranked third with mean score of 4.0667. Project tends to be abandon when it is perceived to be complex with inadequate construction methodology. Extension of construction duration ranked last among the ten (10) listed problems caused by the non-implementation of buildability and maintainability with mean score of 2.8422. Though insignificance as it may be, it is a problem that must be given proper attention if buildability and maintainability of construction project is to be minimized on construction projects in

Nigeria. Sick building, litigation among stakeholder, material shortage during construction, unemployment/layoff of construction workers, valuation and fluctuation of materials and equipments are all factors that need adequate attention to reduce the current malice.

Table 2 Factors Affecting the Implementation of Buildability and Maintainability of Building Construction Projects

	Mean	*SI*	*%SI*	*Rank*
Low budget at pre tender stage	4.2778	0.8556	85.56	1
Use of wrong procurement method during contract administration	4.1889	0.8378	83.79	2
Poor workmanship at the construction stage	4.1778	0.8356	83.56	3
Faulty or omission in architectural design	4.1333	0.8267	82.67	4
Poor contract planning and management	4.1111	0.8222	82.22	5
Recruitment, training and motivation of personnel	4.1000	0.8200	82.00	5
Complexity of the project	4.0889	0.8178	81.78	7
Non implementation of standards and codes	4.0778	0.8156	81.56	8
Incomplete construction contract document	3.9667	0.7933	79.33	9
Conflict among stakeholders	3.9444	0.7889	78.89	10
Lack of construction program	3.9000	0.7800	78.00	11
Inadequate cost planning and control	3.8444	0.7689	76.89	12
High cost of material plants and equipments	3.7778	0.7556	75.56	13.5
High cost of labour	3.7778	0.7556	75.56	13.5
Staff incompetency	3.7667	0.7533	75.33	15
Poor supervision	3.7556	0.7511	75.11	16
Poor communication or relationship with workers	3.7444	0.7489	74.89	17
Poor site management	3.7333	0.7467	74.67	18.5

Extend Construction Duration	2.8422	0.5684	56.84	10

Table 4 shows the various ways of improving the use of buildability and maintainability among the ninety (90) respondents surveyed in the cause of carrying out this study. Full implementation of National Building Code (NBC) was ranked first with mean score of

4.5889, coordination of design and construction team was ranked second with mean score of 4.4778 while engagement of professionals at all stages of the project rank third with mean score of 4.4111. Minimization of complex construction projects was ranked least among the fourteen (14) listed precaution to full implementation of buildability and maintainability on building projects with mean score of 3.1111. Other important precautions are complete preparation of detail drawings and specification at the planning stage, preparation of complete contract documents before award of contract and provision of sufficient budgetary allocation for building construction projects. These subjections and opinions will go a long way in enhancing the implementation of buildability and maintainability of building construction projects.

Table 4: *Precaution factor for the implementation of buildability and maintainability*

	Mean	*SI*	*%SI*	*Rank*
Full Implementation of the National Building Code(NBC)	4.5889	0.9176	91.7600	1
Coordination of design and construction team	4.4778	0.8954	89.5400	2
Engagement of Professionals at all stages of the project	4.4111	0.8822	88.2200	3
Encourage complete preparation of detail drawings and specification at the planning stage of the project	4.3778	0.8754	87.5400	4
Preparation of complete contract documents before award of contract	4.3667	0.8732	87.3200	5
Sufficient budgetary allocation	4.3444	0.8688	86.8800	6
Introduce effective communication skill among the various stakeholders	4.3333	0.8666	86.6600	7
Encourage accurate Design and supervision of Building projects	4.3222	0.8644	86.4400	8

Minimize complexity of construction projects	3.1111	0.6200	62.0000	14

CONCLUSION, RECOMMENDATION AND CONTRIBUTION TO KNOWLEDGE

Assessment of factors affecting the implementation of buildability and maintainability analysis is an important issue that needs to be tackled in the construction industry to enhance the performance of building project. This phenomenon will continue to reoccur unless construction stakeholders takes vital action to control the factors that lead to implementation of buildability and maintainability right from the design stage to construction stage and finally to the maintenance stage of building projects. The study was carried out on stakeholder of construction projects in Abuja, Nigeria. Low budget at pre tender stage, use of wrong procurement method during contract administration, poor workmanship at the construction stage, faulty or omission in architectural design, poor contract planning and motivation of personnel's during construction stage are the major factors affecting the implementation of buildability and maintainability of building construction projects in the study area. Also the study revealed that high cost of construction projects, building collapse, abandonment of project, unhealthy building, litigation among stakeholder, material shortage during construction and layoff of construction workers are all problems caused by non-implementation of buildability and maintainability of building construction projects during the design and planning stage. The study concluded by making the following recommendations:

i. Government at all levels should approve the implementation of National Building Code;
ii. Design and construction team should be coordinated to work together in harmony;

iii. Professionals should be engagement at all stages of building construction projects;
iv. Consultants should be encouraged to prepare complete set of detail drawings and specification at the planning stage of the project;
v. All contract documents should be available before awarding construction contracts;
vi. Sufficient budgetary allocation should be made for construction projects;
vii. Effective communication skill should be encouraged among the various stakeholders;
viii. Training and development of productive construction workers should be encouraged;
ix. Client should be encouraged to use buildability and maintainability assessment programs;
x. Maintenance policy of building projects should be simple, straight forward and non-ambiguous.
xi. All stakeholders in the construction industry should take the responsibility of making use of the preferred solutions to mitigate the effect of buildability and maintainability on construction projects.

Contribution to Knowledge

i. The implementation of this research work will significantly benefit design and construction of future projects by reducing the total cost of the project from design through operation and maintenance.
ii. From the research, it was deduced that failure to implement buildability and maintainability during the design and construction stages of building projects produce facilities that are difficult to maintenance therefore increasing the cost in use.

ABSTRACT

Scenario analysis has been used over the years to provide forecasts of possible outcomes of changes in multiple input variables. The use os spreadsheet packages have since facilitated the efficient construction of scenarios. Although the deterministic application of spreadsheet-driven scenarios has been adopted over the years for quantitative investment decisions, there has been a knowledge gap on the techniques for the application of this artifact to the domain of property portfolio performance measurement. Approached from the perspective of design research method, hypothetical data and formula audits for measurement of property portfolio performance were used to construct scenarios of Time Weighted Rate of Return (TWRR), Money Weighted Rate of Return (MWRR), Internal Rate of Return (IRR), and income yields of a property portfolio. Results from the application of "What-If Analysis" tool of Microsoft® Excel® indicated that the purchase or sale of underlying properties would lead to a marginal increase in the IRR above the base case. The study further unraveled one of the main strengths of spreadsheet-driven scenario analysis to include proactive timing of acquisition and disposal of underlying property assets for optimal portfolio returns. The value of this article is anchored on the scenario construction as an entry-level analytical tool for Monte Carlo simulation of property portfolio returns which have not been addressed in literature from the forecast perspective.

Keywords: Formula audit, Performance measurement, Property portfolio, Scenario analysis, Spreadsheet

INTRODUCTION

Over the years, scenarios have been used to improve the analysis of investment and capital budgeting decisions (Dayananda, Irons, Harrison et al., 2002; Park & Tippett, 1999). Facilitating this process is the application of spreadsheet packages (Bodie, Kane, & Marcus, 2003; Feibel, 2003). Scholars have argued that the process of real estate portfolio construction and management is indeed continuous and draws upon relative improvements in theories, methodologies, and analytical decision making techniques used in appraising alternative investment media (Banfield, 2005; Brown & Matysiak, 2000; Hall & Hargitay, 1984; Hargitay & Yu, 1993; Hoesli & MacGregor, 2000). Consequently, a number of early texts on the subject provided an evolution of measures for the assessment of property portfolio returns comprising Time Weighted Rate of Return (TWRR), Money Weighted Rate of Return (MWRR), and a portfolio's Internal Rate of Return (IRR). (Hall & Hargitay, 1984; Hall, 1983). Furthermore, the demand for computerization of property portfolio management led to the closing of knowledge gaps in the application of spreadsheets to measure property portfolio returns (Dixon, 1986; Dixon, Hargitay, & Bevan, 1991), as well as property portfolio selection (Byrne & Lee, 1994) which were fraught with some limitations at that time because most spreadsheets were not built to handle sophisticated tasks. Although spreadsheet software has been used over the years for computing the performance of property portfolios, very little is known about its utility in the construction of scenarios for TWRR, MWRR, and IRR. The question now is: How can scenario analysis of property portfolio performance be constructed using spreadsheet tools?

Ataguba, J. O.; Olukolajo, M. A. & Nwugo, G. E. (2016). Techniques for Spreadsheet-driven Scenario Analysis in the Measurement of Property Portfolio Performance. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 585-596

This paper aims to unravel the techniques for the application of spreadsheets in constructing scenarios of performance measures that could assist portfolio managers in making rational timing decisions for the sale or purchase of underlying property assets. Specific objectives of this paper include to:

i. identify the input data for the measurement of a typical property portfolio performance;
ii. examine the techniques for constructing scenarios of property portfolio performance measures in a spreadsheet environment; and
iii. evaluate the likely outcomes of the scenario analysis.

A cursory examination of related studies and texts comprising Brown and Matysiak (2000); Hall and Hargitay (1984); Hall (1983); Hargitay and Yu (1993); Hoesli and MacGregor (2000) indicates that the techniques for measuring portfolio performance which were originally developed from the field of investment and finance have been successfully adapted to the analysis of property portfolio performance leaving behind a gap on how scenario construction (which has hitherto been applied to capital budgeting) can be deployed in analysis of measures of property portfolio returns. Hence, it is imperative to examine scenario construction process within the context of property portfolio performance measurement and analyze the impacts arising from the acquisition and disposal of underlying property assets. The value/originality of this article is anchored on the scenario construction as an entry-level analytical tool for Monte Carlo simulation of property portfolio returns which have not been addressed in any existing literature from the forecast perspective.

LITERATURE REVIEW

The concept of property portfolio

A portfolio is a pool of multiple investments designed to diversify risk across each investment class and provide the investor with returns (Hargitay & Yu, 1993). Specifically, property portfolio is a collection of property investments held and let by an investor in expectation of regular returns on capital invested and capital appreciation (Banfield, 2005). For a property portfolio, it is pertinent to say that a two-asset scenario comprising property and cash is usually the norm. In other words, some properties within the portfolio can be disposed and the proceeds of the sale is held as cash, which can be deposited in a bank account to generate interest pending the allocation to properties that might likely enhance portfolio returns and at a minimal risk profile.

Purpose of property portfolio performance measurement

Institutional investors are interested in the financial stewardship of their property portfolios for the purpose of asset-liability matching or profit optimization. Hargitay and Yu (1993) identified four purposes for the appraisal of property portfolio performance to include monitoring the direction of invested capital, monitoring of relative performance (herd instinct of portfolio investors), analysis of past performance for future decision-making, and evaluating the performance of portfolio managers (attribution analysis). First, performance measurement is deployed to unveil the temporal appreciation and depreciation in the portfolio's capital value. Secondly, it might be used to sustain an investor's desire to maintain the lead on the league table of vibrant performing portfolios. Thirdly, it provides a basis for forecasting ex-ante acquisitions and disposals of underlying property assets, while availing portfolio managers with data for optimizing portfolio returns. Finally, it is applicable towards evaluating sources of returns and competence of the portfolio manager on the other hand.

Importance of benchmarks and iterations

Portfolio benchmarks are reference points used by portfolio managers to judge the performance of their portfolios, thus enabling them to track the extent to which the portfolio under-performed or outperformed the various indices (Banfield, 2005; McIntosh, 1997). When constructed, benchmark portfolio should produce an efficient frontier of risk and return. However, with an emphasis on measures of return, scenario analysis could be used to construct a base case performance measure that meets the investor's objectives. Iterations can be run on this base case scenario to show the implication of changes in input variables, on the overall portfolio returns.

Measures of portfolio performance

Performance implies achievement relative to benchmarks and objectives (Banfield, 2005). In quantitative terms, the measurement of portfolio performances reveals the degree of convergence/divergence of a portfolio with/from the benchmark (Banfield, 2005; Hargitay & Yu, 1993). The emphasis of this paper includes total return measures comprising Time Weighted Rate of Return (TWRR), Money Weighted Rate of Return (MWRR), and Internal Rate of Return (IRR). Notwithstanding, income yields of a property portfolio shall be considered given its role as a fundamental analytical tool for assessing portfolio returns at a glance.

Income yield of a property portfolio

Income yield of a property portfolio is the ratio of the net earnings of the portfolio to the capital value (Ajayi, 1998; Wyatt, 2007). Within the context of this paper, there are two categories of this measure of return. The first is the income yield on cost which is the ratio of initial net income of the portfolio to the initial capital value of the portfolio (expressed as a percentage), and named as "Yield 1-Jan." The second is the income yield on value indicated in this paper as "Yield 31-Dec" which is the ratio of current net income of the portfolio to the capital value of the portfolio at the end of the measurement period (expressed as a percentage) (Ajayi, 1998). According to Hoesli and MacGregor (2000), increase (decrease) in income yield of a portfolio is an indication of increase (decrease) in portfolio risk as well as capital value depreciation (appreciation). In other words, income yield is an indicator of expected market risk, value growth and depreciation (Hoesli & MacGregor, 2000; Ifediora, 2005).

Time Weighted Rate of Return (TWRR)

Although Feibel (2003) defines TWRR within the context of an investment fund, its definition within the context of a property portfolio reflects performance of a portfolio which takes into cognizance the portfolio capital value, value changes (appreciation/depreciation), and portfolio income over the entire period that underlying property assets are held (Hall & Hargitay, 1984; Hargitay & Yu, 1993). The calculation of TWRR commences with the calculation of sub-period returns (Feibel, 2003). In other words, the sub-period return, t_i which is a function of capital appreciation and the portfolio income is expressed as the ratio of the capital value of the portfolio at the beginning of the sub-period as indicated in equation 1 below:

$$t_i = \frac{CV_t - CV_{t-1} + I_t}{CV_{t-1}} \qquad (1)$$

Furthermore, the TWRR (expressed as a percentage), is the geometric mean of all the sub-period returns of a portfolio (Ajayi, 1998; Brown & Matysiak, 2000; Hargitay & Yu, 1993; Hoesli & MacGregor, 2000; Ifediora, 2005). It is numerically expressed as:

$$\text{TWRR} = \sqrt[n]{\{(1+t_1)(1+t_2)(1+t_3)\cdots\cdots(1+t_n)\}} - 1 \quad (2)$$

With reference to equations 1 and 2, CV_t is the capital value of the portfolio at the end of a sub-period, CV_{t-1} is the capital value of the portfolio at the beginning of a sub-period, I_t is the net income of the portfolio at the end of the sub-period, t_1, t_2, t_3, and t_n represent the various sub-period returns. Hargitay and Yu (1993) adjudged the appropriateness of this measure of total return for inter-portfolio comparisons because of the inability of portfolio managers to control the timing of a portfolio's cash inflow and outflow.

TWRR provides the basis for comparing returns earned on a portfolio as well as the success or otherwise of portfolio manager's decisions in a given measurement period (Brown & Matysiak, 2000; Feibel, 2003). In other words, an increase (decrease) in TWRR during a given period relative to a benchmark is an indication that:

i. the underlying property assets are (not) performing optimally; and
ii. the decision-making process of the portfolio manager is (not) yielding optimal results.

Money Weighted Rate of Return (MWRR)

MWRR is a performance measure which expresses the sum of capital value appreciation/depreciation and portfolio incomes as a quotient of capital invested in the portfolio (Ajayi, 1998; Ifediora, 2005). The equation for MWRR is expressed as:

$$\text{MWRR} = \frac{Total\ net\ income\ received + Change\ in\ Capital\ value}{CV_{t-1} + (CE_t \times t_e)} \quad (3)$$

Where CV_{t-1} is the capital value of the portfolio at the beginning of the measurement period, CE_t is the capital expenditure during the measurement period, and t_e is the proportion of time for the spread of the capital expenditure, which is pegged at 0.5 on the assumption that funds injected into the portfolio would be distributed symmetrically throughout the period for a bi-annual performance measurement period (Newell, 1986).

Contrary to the opinion of Brown and Matysiak (2000); Hargitay and Yu (1993); Kalu (2001), it would be erroneous to conclude that MWRR is identical to internal rate of return (IRR). This is because MWRR and IRR equates when the underlying assets in the portfolio are held for a single period without any capital expenditure (Ifediora, 2005). Hence, MWRR (expressed as a percentage) is only an approximation of the IRR. According to Feibel (2003), the injection of more capital into the portfolio prior to value appreciation (depreciation), would lead to appreciation (depreciation) of MWRR at the end of the measurement period. On the other hand, Feibel (2003) reiterated that capital withdrawal from the portfolio prior to value appreciation (depreciation), would deflate (inflate) MWRR at the end of the measurement period. In this context, the injection (withdrawal) of capital implies the purchase (sale) of underlying properties in a portfolio. According to Brown and Matysiak (2000), the timing of purchase/sale of underlying property assets is adjudged to be optimal if MWRR > TWRR; otherwise it would not be optimal if MWRR < TWRR.

Internal Rate of Return (IRR)

The IRR is the rate (expressed as a percentage) at which the discounted cash inflow equates to the discounted cash outflow (Ajayi, 1998; Brown & Matysiak, 2000; Ifediora, 2005), such that the net present value of the portfolio equals zero. Similarly, Crean (2005) reiterated that IRR is the calculated discount rate that equates value with price. For the purpose of financial decisions, IRR is the highest cost of capital for which an investor can afford pay for a loan borrowed to finance the purchase of an income yielding investment (portfolio) such that incomes earned from that investment (portfolio) can adequately service the periodic tranches of principal and interest arising from the said loan (Bierman & Smidt, 1975). The framework for calculation of IRR is given as:

$$\sum_{t\geq 1}^{t=n} \frac{\text{Cash outflow}}{(1+IRR)^t} = \sum_{t\geq 1}^{t=n} \frac{\text{Cash inflow}}{(1+IRR)^t} \quad (4)$$

Where *t* in equation 4 represents the tenor for the measurement of portfolio performance. According to Ifediora (2005), IRR is the most favoured measure of portfolio performance because it precisely reflects the size and timing of cash flows; and considers cash flow realized as opposed to expected cash flow.

Fundamental data inputs for measurement of property portfolio performance

Hargitay and Yu (1993) outlined the fundamental data inputs for the measurement of performance to include market capital value and net income of the portfolio at the beginning and end of the period of analysis; net income, capital expenditure of the portfolio (including purchase price of additional properties), and income appreciation/depreciation during the period of analysis, and details of lease structure of underlying property assets. Save for the exclusion of income projections, all these input variables have been captured in this study. In addition, this study gave credence to the treatment of market capital value and net incomes of underlying property assets purchase/sold during the period of analysis.

Application of scenario analysis

Fundamental to the application of scenario analysis is the concept of sensitivity analysis, which is an experiment performed with the intent of determining the effect of a change in individual variables on a single outcome of an appraisal while freezing input variables in the same appraisal at their deterministic values (Ajayi, 1998; Dayananda et al., 2002). Taking sensitivity analysis a step further, scenario analysis entails establishing an array of result of numerous dependent variables arising from changes in numerous input variables of an appraisal at their deterministic values (Park & Tippett, 1999). Notwithstanding these authors' bias for capital budgeting applications, scenarios might be applicable towards forecasting property portfolio performance. It is common practice to see the outcomes of scenario analysis to be expressed in three-folds as base case-, worst case-, and best case scenarios. While base case scenarios represent the current outcome which the investor intends to evaluate, indices and results for worst case-, and best case scenarios in the context of this study may depend on the portfolio benchmarks and expectation of an investor.

Application of spreadsheet software

Morley and Parker (2011) define spreadsheet software as application software typically organized as ledger sheets with rows and columns, which can be used to perform calculations and other alphanumeric operations. Within the context of this paper, Microsoft® Excel® 2007, which is famous among investment analysts, was used to prepare scenarios of property portfolio measurement. Facilitating this analysis within the Excel® environment is the "What-If Analysis" function which ushers the user into the scenario analysis dialogue box (Dixon, 2007; Harvey, 2006). This dialogue box enables an analyst to generate scenarios from multiple input variables for onward comparison. Therefore, questions put forward to address gaps identified in this study are:

i. How can Excel® be used to construct scenarios of property portfolio performance measures?
ii. With reference to a hypothetical base case scenario and given different instances of net income and initial capital value of a portfolio, what would be the outcome of TWRR, MWRR, and IRR (per annum) when:
    a. additional properties are purchased?
    b. some existing properties in the portfolio are sold?

METHODOLOGY

This study is approached from the perspective of the design research methodology, which is directed towards the development and testing of an artifact that solves specific problems (Çağdaş & Stubkjær, 2011). The artifact in this study is a system of scenarios for the analysis of property portfolio performance. Like any other artifact, the development of scenarios draws upon the theories and knowledge from cognate fields of design science, investment/finance, and statistics (Dayananda et al., 2002; Hevner, March, Park et al., 2004; Lee & Lee, 2006). Notwithstanding, scenario construction in this context is anchored on underlying constructs/vocabulary within the domain of portfolio management and spreadsheet analyses. Specifically, the *What-If Analysis* tool of Microsoft® Excel® 2007 was used to facilitate scenario construction for the selected measures of property portfolio performance. This tool generally produces multiple outcomes arising from an array of multiple decisions which an analyst might likely take pertaining to the input variables (Dixon, 2007). In this context, the Philosophy behind *What-If Analysis* is that it unveils an array of likely performance of a property portfolio when input variables assume an array of values arising from the portfolio manager's decision to purchase or sell underlying properties as well as value changes during a performance assessment period.

According to Peffers, Tuunanen, Rothenberger et al. (2008), the six steps involved in a design research include motivation and problem identification, study objectives, artifact design and development, testing, evaluation, and reporting. The design and development of scenarios summarized in the flowchart (Appendix 1) was drawn from these six steps. Four input variable data tables were created. These input variables comprise capital value of portfolio at the beginning, net income of existing properties, capital value of properties sold/purchased and net rent of properties sold/purchased. The development of scenarios in this paper was facilitated by hypothetical data inputs and formula audits for these tables (see Appendix 1). Within the Microsoft® Excel® 2007 environment, the application of scenario analysis begins by clicking the Data menu button as follows: Data > What-If Analysis > Scenario Manager. The Scenario Manager box was populated with changing input variables as follows: Click "Add" > Enter scenario name in the dialogue box > Select the changing input variable(s) > Check the prevent changes box > Click OK to return to the Scenario Manager dialogue box. The process was repeated until the desired numbers of scenarios were created. Ten different scenarios were created using varying initial capital values and the net incomes respectively. In order to view changes in the results, a specific scenario name was selected and the button labeled "show" was clicked afterwards.

The scenario summary for the varying initial capital values and the net incomes was created using the following steps: Within the Scenario Manager dialogue box, click Summary > Check the summary circle > Enter the result cells by selecting the cells where the formula audit of portfolio performance measures were originally prepared and computed in the Worksheet > Click OK. With the copy and paste tool, these results can be used to populate the blank scenario summary that was initially created in the worksheet. The scenario results were saved in different Worksheets to facilitate further analysis and comparisons. Analysis of results was principally based on the difference between returns from each scenario and the base case portfolio returns.

FINDINGS AND DISCUSSIONS

Analysis of the Base case scenario

The data input used in connection with the scenario building process is presented in Appendix 2. With reference to these inputs, a performance analysis table was prepared in the same Appendix 2 on the premise that properties in the portfolio are valued bi-annually.

Results of base cases (Table 1) were generated from Appendix 2; such that the shaded returns in Table 1 can still be traced to the bi-annual portfolio valuation in the same Appendix.

Table 1 Base case of portfolio returns

Parameters	Capital value of portfolio (in ₦ 'million) at the beginning									
	500	**550**	**600**	**650**	**700**	**750**	**800**	**850**	**900**	**950**
Net income of existing	56	56	56	56	56	56	56	56	56	56
Yield 1- Jan	11.20	10.18	9.33	8.62	8.00	7.47	7.00	6.59	6.22	5.89
Yield 31-Dec	11.50	10.43	9.54	8.79	8.15	7.60	7.12	6.69	6.31	5.98
TWRR	8.51	7.74	7.10	6.56	6.09	5.69	5.34	5.03	4.75	4.50
MWRR	8.60	7.81	7.16	6.61	6.14	5.73	5.37	5.06	4.78	4.52
IRR	8.84	8.01	7.33	6.76	6.26	5.84	5.47	5.14	4.85	4.59

Scenario 1: When additional properties are purchased

For each case of initial capital value and net income, portfolio returns in Table 2 indicate that IRR increases as initial capital value increases, while income yield on value would be higher than income yield on cost.

Table 2 Portfolio returns when additional properties are purchased

Parameters	Capital value of portfolio (in ₦ 'million) at the beginning									
	500	**550**	**600**	**650**	**700**	**750**	**800**	**850**	**900**	**950**
Net income of existing	28.5	30.5	38.4	42.1	47.5	52.5	56	62	68	71
Capital expenditure	86.6	93.1	110.4	125.5	145.0	162.3	166.7	173.	188.3	216.
rent (additional	10.4	11.4	12.16	12.35	12.92	13.3	14.25	14.8	16.15	19
Yield 1- Jan	5.70	5.55	6.40	6.48	6.79	7.00	7.00	7.29	7.56	7.47
Yield 31-Dec	6.79	6.65	7.25	7.14	7.26	7.32	7.37	7.60	7.83	7.80
TWRR	4.54	4.54	5.47	5.60	5.97	6.21	6.28	6.60	6.91	6.96
MWRR	3.81	3.89	4.80	4.95	5.30	5.55	5.67	6.02	6.34	6.38
IRR	4.20	4.27	5.33	5.51	5.95	6.26	6.37	6.76	7.14	7.24

Suffice to say that the purchase of additional properties would not alter the income yield on cost (Table 3). However, income yield on value appreciated marginally when additional properties were added to the portfolio, which is an indicator of increased portfolio risk and capital value depreciation as postulated by Hoesli and MacGregor (2000). Hence, the portfolio would be exposed to additional risks if more properties are purchased.

Table 3 Difference between scenario 1 results and the base case scenario

Parameters	Capital value of portfolio (in ₦ 'million) at the beginning									
	500	**550**	**600**	**650**	**700**	**750**	**800**	**850**	**900**	**950**
Net income of existing	28.5	30.5	38.4	42.1	47.5	52.5	56	62	68	71
Capital expenditure	86.6	93.1	110.	125.	145.	162.	166.	173.	188.	216.
rent (additional	10.4	11.4	12.1	12.3	12.9	13.3	14.2	14.8	16.1	19
Yield 1- Jan	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00
Yield 31-Dec	0.94	0.97	0.71	0.53	0.35	0.20	0.25	0.19	0.16	0.22
TWRR	1.56	1.46	1.33	1.20	1.10	0.99	0.94	0.86	0.81	0.86
MWRR	0.71	0.71	0.57	0.48	0.37	0.29	0.30	0.26	0.23	0.28
IRR	1.06	1.05	1.03	0.96	0.94	0.90	0.90	0.89	0.92	1.02

TWRR increases within the range of 1.56% and 0.86% for lower and higher bands of portfolio capital values when additional properties are purchased (Table 3); implying that the underlying property assets are performing optimally or that the decision of the portfolio manager would contribute towards optimal portfolio performance relative to the base case scenario as postulated by Brown and Matysiak (2000) and Feibel (2003). Furthermore, MWRR in Table 3 increased within the range of 0.71% and 0.28% for lower and higher bands of portfolio capital values thereby violating the principle put forward by Feibel (2003) that the injection of more capital (purchase of more underlying assets) prior to value

depreciation would lead to depreciation of MWRR. In practice therefore, asset allocation decision within these bands of input values in Table 2 would not warrant MWRR to fall below a benchmark or a base case scenario.

In view of the decision rule for the comparison of TWRR and MWRR put forward by Brown and Matysiak (2000), all cases of value inputs examined under this scenario (Table 2) indicates that MWRR < TWRR; implying non-optimal timing for the sale of the underlying properties. Drawing from the postulations of Brown and Matysiak (2000) and Feibel (2003) that increase in TWRR (as captured in this scenario) indicates optimally performing underlying property assets, the timing of purchases would not be optimal considering the situation where portfolio capital value would have depreciated by ₦36.17 million.

Scenario 2: When some properties in the portfolio are sold

For each case of initial capital value and net income, portfolio returns in Table 4 indicate that increase in the initial capital values corresponds with increases in IRR when some properties in the portfolio are sold. Notwithstanding, this scenario reveals that income yield on cost would be higher than income yield on value.

Table 4. Portfolio returns when some properties are sold

Parameters	Capital value of portfolio (in ₦ 'million) at the beginning									
	500	**550**	**600**	**650**	**700**	**750**	**800**	**850**	**900**	**950**
Net income of existing	28.5	30.5	38.4	42.1	47.5	52.5	56	62	68	71
Capital value of	86.6	93.1	110.	125.	145.	162.	166.	173.	188.	216.
Net income of properties	10.4	11.4	12.1	12.3	12.9	13.3	14.2	14.8	16.1	19
Yield 1- Jan	5.70	5.55	6.40	6.48	6.79	7.00	7.00	7.29	7.56	7.47
Yield 31-Dec	4.51	4.30	5.51	5.82	6.38	6.82	6.73	7.11	7.42	7.22
TWRR	0.80	1.05	2.25	2.65	3.22	3.70	3.91	4.46	4.87	4.75
MWRR	2.05	2.14	3.22	3.52	4.00	4.38	4.48	4.89	5.21	5.10
IRR	4.20	4.27	5.33	5.51	5.95	6.26	6.37	6.76	7.14	7.24

While the sale of additional properties would not alter the income yield on cost (Table 5), income yield on value depreciates marginally when some existing properties in the portfolio are sold. This marginal decrease in the income yield on value (Yield 31-Dec) indicates a decrease in portfolio risk as well as capital value appreciation which aligns with the fundamental concept of income yield as an indicator of portfolio performance (Hoesli & MacGregor, 2000; Ifediora, 2005). In other words, the portfolio risk is minimized when the appropriate properties are selected and sold. The cash proceed from such sales can be deposited in bank account and channeled into the purchase of properties that would offer enhanced diversification benefits.

With reference to the base case scenario, it can observed in Table 5 that the sale of some properties (at specific prices for each case of sales) would lead to decline in TWRR in the range of 2.18% and 1.35% for lower and higher bands of portfolio capital values respectively. In consonance with the decision rule postulated by Brown and Matysiak (2000) and Feibel (2003), decrease in TWRR either implies that the underlying property assets are not performing optimally or that the decision of the portfolio manager would not contribute towards enhancing portfolio performance relative to the base case scenario (benchmark).

Furthermore, MWRR decreased within the range of 1.05% and 1% for lower and higher bands of portfolio capital values respectively. This finding is contrary to the principle put forward by Feibel (2003) that the further withdrawal of capital (through sale of underlying assets) from a portfolio prior to value depreciation would lead to appreciation of MWRR at the end of the measurement period. In practice therefore, asset allocation decision within these bands of input values in Table 6 would warrant MWRR to drop below a benchmark/base case.

Table 5. Difference between scenario 2 results and the base case scenario

Parameters	Capital value of portfolio (in ₦ 'million) at the beginning									
	500	**550**	**600**	**650**	**700**	**750**	**800**	**850**	**900**	**950**
Net income of existing	28.5	30.5	38.4	42.1	47.5	52.5	56	62	68	71
Capital value of	86.6	93.1	110.4	125.5	145.0	162.3	166.7	173.2	188.3	216.5
Net income of properties	10.45	11.4	12.16	12.35	12.92	13.3	14.25	14.82	16.15	19
Yield 1- Jan	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00	0.00
Yield 31-Dec	-	-	-	-	-	-	-	-	-	-
TWRR	-	-	-	-	-	-	-	-	-	-
MWRR	-	-	-	-	-	-	-	-	-	-
IRR	1.06	1.05	1.03	0.96	0.94	0.90	0.90	0.89	0.92	1.02

In view of the decision rule for the comparison of TWRR and MWRR as postulated by Brown and Matysiak (2000), all cases of value inputs examined under this scenario (Table 4) indicates that MWRR > TWRR; implying an optimal timing for the sale of the underlying properties. Based on the assertions of Brown and Matysiak (2000) and Feibel (2003) that a decrease in TWRR relative to a benchmark indicates under-performing properties or ineffective portfolio management, the timing of sales would still be optimal notwithstanding the ₦36.17 million depreciation in portfolio capital value. The divergence in choice of decision criterion might be settled in favour of MWRR if an investor intends to optimize portfolio risk by selling those underlying property assets that do not offer enhanced diversification benefits.

For both scenarios, it is generally observed that the purchase or sale of underlying properties would lead to a marginal increase in the IRR. This implies that a portfolio investor could borrow money at a rate higher than the base case (initial) IRR if the re-structure of underlying property assets in the portfolio becomes imperative. When compared with the base case, the sale of existing properties coupled with a depreciation in the capital value of underlying properties would reduce TWRR, MWRR and income yield on value unless capital value appreciates beyond a threshold necessary to compensate for loss of initial portfolio returns.

DISCUSSION OF RESULTS

Findings of this study have been isolated and discussed here on the basis of the study objectives. For the first objective, it has been identified that the input data for the measurement of property portfolio performance include market capital value and net incomes of underlying property assets sold or purchased during the period of analysis, allocations for capital improvements, income changes during the period, details of lease structure and the capital value and net income of the portfolio at the beginning and end of the measurement period, which are consistent with the specifications outlined by Hargitay and Yu (1993). These data are further required as inputs for the construction of scenarios within the spreadsheet environment.

In consonance with the second objective of this research, the technique for constructing scenarios of property portfolio performance measures in a spreadsheet environment is anchored on six system design steps among which are problem definition, design specification, data definition and entry, and the deployment of the scenario manager box in the "What-If" Menu of Microsoft® Excel® to the testing, evaluation, and reporting of the scenarios of portfolio performance measures when underlying properties assets are sold or purchased. Specifically, the essential tools required for constructing spreadsheet-embedded scenarios of portfolio performance measures is the synergy between system design algorithm (Peffers et al., 2008), and the process for "What-If" analysis within the Microsoft® Excel® environment as adapted from Dixon (2007) and Harvey (2006).

Turning attention to the third objective, which is to evaluate the likely outcomes of the scenario analysis; it was found that income yield on value would increase following the purchase of additional underlying property assets. The implication is that such addition of new properties would expose the portfolio to higher degree of risks. Secondly, the sale of some existing properties would reduce the income yield on value of the portfolio to warrant exposure of the portfolio to lesser degree of risk especially when the properties that do not contribute significantly to portfolio returns/diversification are appropriately selected and sold. These results align with the notion that an increase (decrease) in income yield at the portfolio level is an indication of an increase (a decrease) in portfolio risk as well as capital value depreciation (appreciation) (Hoesli & MacGregor, 2000).

In consonance with the decision rule for the comparison of MWRR and TWRR (Brown & Matysiak, 2000), and the reporting of results from the analysis of TWRR (Feibel, 2003), the scenario analysis indicates that the purchase of additional properties into the portfolio would place TWRR ahead of MWRR to warrant enhanced performance of underlying assets in the portfolio but with an attendant problem of wrong timing of the purchase of these additional properties. On the other hand, results from the scenario analysis indicates that the sale of existing properties would place MWRR ahead of TWRR to warrant under-performance of underlying property assets in the portfolio; notwithstanding the optimal timing of sale indicated by virtue of this result.

The scenario analysis for property portfolio performance measures in this paper further indicates that the IRR of a portfolio would increase irrespective of whether the decision of sales or purchase of underlying property assets is taken by the portfolio manager; implication of which is the possibility of the investor to accommodate optimal borrowing rates for capital within the limits of the higher IRR arising from the portfolio re-structuring plan.

Lastly, scenario analysis has revealed that the withdrawal of capital from a portfolio (sale of underlying property assets) prior to value depreciation, would lead to depreciation of MWRR at the end of the measurement period, while the injection of more capital into the portfolio (purchase of additional properties) prior to value depreciation, would lead to appreciation of MWRR at the end of the same measurement period. This result is found to be contrary to the assertion of Feibel (2003) concerning portfolio transactions in the context of value appreciation/depreciation.

RECOMMENDATIONS

The following recommendations are put forward in support of scenario construction process for property portfolio performance measurement:

i. In the absence of sophisticated simulation software packages, the portfolio manager can avail himself/herself with scenario analysis in order to examine an array of ballpark measures of portfolio returns arising from possible acquisition and/or disposal of underlying property assets; and
ii. Portfolio managers should attempt generating scenarios for a portfolio's Internal Rates of Return when they intend to know their threshold of borrowing rates for the funding of more property acquisitions.

CONCLUSION

Spreadsheets are software packages that facilitate efficient application of quantitative tools for investment decisions. It may be recalled that this article sought to find answers to the question of how scenario analysis of property portfolio performance can be developed using spreadsheet tools. Within the context of this paper, the construction of scenarios for property portfolio performance measures in a spreadsheet environment was anchored on the synergy

between system design procedure and the deployment of "What-If" analysis tools within the Microsoft® Excel® environment. It was found that portfolios with TWRR higher (lower) than MWRR are characterized with underlying property assets that are (not) performing optimally but with a snag (an advantage) of non-optimal (optimal) timing of capital injection/withdrawal. Although the scenario building technique examined in this paper might be used to facilitate proactive monitoring of portfolio performance in relation to the timing of acquisition and disposal of underlying property assets, further research on this topical area might scale up the methodology towards Monte Carlo simulations with a view to provide a robust dimension to the results obtained in this study. Finally, this paper has shown that the portfolio manager can translate intuition into scenarios of portfolio performance measures that portray potential benefits derivable from rational investment decisions.

ABSTRACT

Acquisition process usually leaves in its trail a number of unresolved problems after its completion. This is often complicated through political interference leading to compensatory problems, inability to take successful possession of the acquired land and consequent delay in project executions. This paper assesses the process of acquisition in Ondo State in order to identify gaps between the set standards and the existing practice. To achieve this, the actual output of the process in some selected acquisitions vis-a-vis set standards in the acquisition process was gotten from the Ondo State Land Records Bureau. The result of the analysis revealed that 60 working days is the average time required for processing an acquisition for land of less or equal to 30 hectares. The least possible time for proper acquisition is 33 working days with an average of 62 official table exchanges from the least officer to the State Governor. Nine Acquisition projects were considered between 2010 and 2014. It was observed that only three of the projects were concluded which is inconsistent with the set standard. On the general assessment; site identification, perimeter survey, release of funds, title clearance and payment of compensation were identified as possible policy targets to improve on to enhance effective public land acquisition process in the study area. Inflation of the cost of acquisition projects, increase in hostility from the affected community, increase costs and stifling of Government remedy projects due to unresolved appeals were implications of the deficiencies in acquisition process. The paper recommends a critical attention to the procedures of public acquisition aimed at achieving the level of efficiency required by the masses to derive optimum benefits from government investments and minimizing waste of time and money.

Keywords: Acquisition, Acquisition Process, Ondo State Nigeria, Processing Time, Public Land

INTRODUCTION

Land acquisition is a legal and bureaucratic procedure which the government uses in acquiring any land without the willing consent of its owner or occupant in order to benefit the public (Kakulu, Bryne and Viitanen, 2009). This power is often necessary for social and economic development (Nuhu, 2008). The incidence of rapid urbanization in many parts of Ondo State has led to many urban problems such as road congestions, poor quality environment and inadequate social amenities. The State government therefore requires the provision of housing, widening of roads, hospitals, institutions of higher learning and other infrastructure in its urban areas. In order to generate employment large agricultural projects is also developed in many non-urban areas.

Preceding the provision of such infrastructural facilities, public works and development is the acquisition of appropriate land by government (Food and Agricultural Organization, 2008). Like any other part of the country, land acquisition in Ondo State is plagued with so many problems which have hindered its successful implementation. Ineffectiveness and lack of transparency in the processes of public acquisition could also attract enormous economic, social and political costs as it usually takes time-consuming. According to Larbi (2008), weeks or sometimes years elapse before the Acquisition process is completed and ready for development. From the time the notice of acquisition was duly served to the time the compensation was paid, anything can happen to prolong an already projected time for the whole acquisition process (Huggins, Roach and Jessemy 2009). The risk of not meeting the purpose for public acquisition becomes high when the acquisition time cost is high (Cernea,

Ige, V. O. & Akinlabi, A. J. (2016). Assessment of Public Land Acquisition Process in Ondo State, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 597-605

2000). Incidence of price inflation on project may result in postponement or abandonment of government project, thus tying down the acquisition (Observer Research Foundation, 2010). Change of Government or political instability usually associated with governance in developing countries also makes the acquisition process to linger, sometimes proving very costly to all parties (Anthony, 2011).

Hence, this study assesses acquisition process in Ondo State, Nigeria with a view to identifying the gap between the set standards and the existing practice with a view to recommending means of cutting down costs in acquisition projects and at the same time increasing dividends of government's investment to the people.

LITERATURE REVIEW

General Overview of Public Land Acquisition Process

The procedure of land acquisition is based and driven by the provisions of country specific acts, decrees and other relevant statutory enactments guiding the process (Nuhu, 2009). For instance, in Nigeria it is a statutory process under the Land Use Act 1990 (Sections 28 (1); 2 (a), (b), (c); 3(a), (b), (c), (d) and (4)). This framework usually dictates the basis and methods of assessment, as well as the procedures (Nuhu, 2009). Land acquisition and compensation matters are therefore entirely products of statute (Xavier, 2001). The basic principles and processes in compulsory acquisition and compensation are perceived to be quite similar even though the practice may vary in different nations (Viitanen and Kakulu, 2008). Procedure of compulsory acquisition is critical if government's exercise of acquisition power is to be efficient, fair and legitimate. However, according to Nuhu (2008), the Land Use Act No. 6 of 1978 on compensation for compulsory acquisition has generated feeling of dissatisfaction and resentment which has discredited the compensation procedure in compulsory acquisition of Land.

The Land Acquisition process at times can be very long and drawn out. Most times individuals are unaware of their role and function in the process (Huggins, Roach and Jessemy, 2009). Certain activities of Ministries and State agencies in Acquisition process often lead to compensatory problems for the affected property-owners later in the process. In many cases the acquiring authority has acquired and utilized private properties long before compensating the land owner. Claimants have to wait for decades before they are compensated while others still await compensation (Huggins, Roach and Jessemy 2009). A well-defined procedure for expropriations should therefore provide clarity, transparency, and predictability (Asian Development Bank, 2007). Where the process is designed or implemented poorly, the economic, social and political costs may be enormous.

Factors Affecting Processing Time

Land acquisition always involves the passing of time. Weeks or sometimes years elapse before the Acquisition process is completed (Dundas and Evans, 2001; Azuela and Herrera, 2007 and Omar & Ismail, 2009). According to Observer Research Foundation (2010), a large number of projects are held up because of procedural delays relating to land acquisition. This is also the root cause of cost overruns, mass resistance and sometimes violent protests. And further creates an anti-developmental attitude in the society. The following however are often the main obstacles:

Physical Factor

Location identification seems to be the most sensitive aspect of the process as it is usually the early step in the process of providing facilities and infrastructures. In some cases, several locations could be suitable for a project but not feasible due to physical terrain. Accidents of Land officers and Land Surveyors in difficult terrains may result in delays or slowing down

of the whole process (Food and Agricultural Organization, 2008; Huggins, Roach and Jessemy, 2009; German, Schoneveld and Mwangi, 2011).

Technological factor

Where there is shortage of land surveyors, there are undue delays in the completion of survey plans and at times the survey order has to be contracted (Huggins, Roach and Jessemy, 2009). This is often due to absence of modern or advanced equipment like Unmanned Aerial Vehicles (UAV) for data capturing during enumeration. This could prolong the processing time of acquisition assignments. Lack of these instruments may prolong the period of field work which is also subject to all kinds of manipulations and dangers as some places remain inaccessible to the enumerators.

National Economy/Inflation

Dwindling or unpredictable national economy may affect eventual compensation sum arrived at for a particular acquisition. Government may become jittery when the cost of acquisition is too much or almost outweighs the proposed cost of the public projects.

Legal Factor

Most people are unaware of their correct role and function and the law as it pertains to the Land Use Act. These have caused delays, even from the onset in an acquisition process (Ojikutu, Bennett, and Groenendijk, 2012). If notices are not well served, affected land owners are entitled to go to Court to obtain injunctions against the Government (Larbi, 2008). This can halt the whole process.

Administrative Factor

Acquisition as a project involves the institutional managers in the acquiring Ministry. The acquisition project manager is the Estate Surveyor who is usually the Director of Lands Services. The success of the project depends on his managerial skills. Any incompetency from the acquisition manager could therefore disrupt the acquisition process. Huggins, Roach and Jessemy, (2009) also confirmed lack of synergistic cooperation amongst personnel to cause inadequate delays in the acquisition process and untimely compensation of affected land owners. Availability and adequacy of the personnel, materials and funds that would be used in carrying out the project can eliminate bureaucratic bottle necks that can affect process time. Effective supervision and commitment of persons are required for civil service performance.

Social Factor

The level of mobilization and the prevailing political conditions can affect the efficiency and effectiveness of the machinery put in motion for acquisition. Though, the issue of prompt social mobilization is always the same, motivations can be varied. Lack of communication between Government and the people may lead to breakdown of law order during acquisition exercise (Larbi, 2008).

Political Factor

Setting of goals for public acquisition; choosing of location; issuing of warrant to release funds; and approval of compensation of values are often subject to political manipulations. Furthermore, change of government or political instability usually associated with governance in developing countries also makes the acquisition process to linger sometimes proving very costly to all parties (Observer Research Foundation, 2010).

Climatic Factor

Different Vegetation belts in Ondo State have different people, culture and climatic conditions that can affect acquisition process time differently. The coastal regions during the

raining seasons presents unpredictable conditions that require the experience of the acquisition officer when budgeting for enumeration project.

METHODOLOGY

In assessing each stage of land acquisition certain parameters such as the specific definition of the task(s) involved, its measurability and time limits will enable the acquiring managers to know the efficiency and the effectiveness of their operations. Also jobs or tasks required in each stage which includes field work and verification of claims must be accurate and realistic. Quality implementation strategies in the process must also minimise waste of time or money. To investigate this, 13 land officers of the Ondo State Land Records Bureau were purposively selected for an in-depth interview. They were purposively selected because of their professional qualifications and year of experience as senior officers. The interview session was part of the qualitative data targeted at capturing actual output of the public land acquisition process vis a vis the set standards in the Ondo State Land Records Bureau, the government agencies involved in land administration; so as to deduce the level of realisation of a wanted result in respect of public set goals and also examine whether implementation strategies are qualitative in terms of minimizations of waste of time or money. Structured questionnaires which was closed ended in nature was also administered to the 13 purposively selected land officers to explore their perspectives on factors affecting the effectiveness and efficiency of acquisition process *(see appendix I)* and the implications of the deficiencies regarding land acquisition implementations in Ondo State, Nigeria.

FINDINGS AND DISCUSSIONS

Table 1: Summary of average required time and personnel at different acquisition stages

Acquisition Stages	Required time < 30 Ha (t days)		Personnel		Average time required (< 30Ha)	Average required personnel
	Min.	Max	Min.	Max.		
Choice of Site	3.0	10.0	3.0	5.0	6.5	4.0
			3.0T	4.0T		3.5T
Sensitization (I)	1.0	3.0	3.0	5.0	2.0	4.0

	33.8	88.6	50T	74T	61.225	62T

Table 1, shows the Acquisition procedures, minimum and maximum time required per hectares in days and the minimum and maximum number of personnel involved in public acquisition in the Ondo State Land Records Bureau (the Acquiring agency). From the table, **t** represents number of working days required while, **T** represents number of officials involved in a given task. The average time required for processing an acquisition for land of less or equal to 30 hectares of land was about 60 working days. The least possible time for proper acquisition is 33 working days. This required an average of 62 official table exchanges from the least officer to the State Governor. The time lines for personnel and material deployment and meetings is as shown in appendix I.

Table 2: Selected acquisition projects (2010-2014)

Project	Purpose of Acquisition	Location	Area (ha)	Acquisition	
				Begin	End
1	Wealth Creation Agency WECA (Millennium Agric. Village)	Auga-Akoko	444.788	2011	Not completed
2	PHCN 2KV Transmission Station	Oba-Ile	22.15	2010	2012
3	Trauma Centre (TC), Gani Fawehinmi- Extension	Ondo	63.12	2011	2012
4	Film village (FV)	Ikota	60.09	2010	Not completed
5	Forward Operational Base (FOB)	Agadagba Obon	4.634	2011	Not completed
6	Beach Sport Complex (BSC)	Igbokoda	0.3719	2011	Not completed
7	Gboluji Grammar School Ext.(GGS)	Ita-Olodo, Ile-Oluji	51.511	2012	Not completed
8	Millennium Park (MP)	Akure	4.03	2010	2012
9	Cultural Village (CV)	Aponmu	2.191	2010	Not completed

Source: Ondo State Land Records Bureau, 2014

Table 2, shows nine Acquisition projects in Ondo State between 2010 and 2014. It further highlighted the purpose of acquisition, location, area in hectares, commencement and status of completion of acquisition projects as at 2014. It was observed from the Table that only three of the projects were concluded in 2012. This is inconsistent with the set standard of the 33 working days as the least possible time for acquisition in the study area. Hence, the findings is in consonance with the findings of Larbi (2008) that the entire process of acquisition is often very long and winding.

Table 3: Comparison of actual output with expected standards of output

Project	Site identification	Perimeter survey	Publication	Service of notice	Field work	Computation	Release of funds	Title clearance	Payment of compensation	Assessment
WECA	<	=	=	=	<	=	>	=	0	B
PHCN	>	<	=	=	>	=	>	=	>	G
TC	=	<	>	>	=	=	>	<	=	F
FV	<	<	=	=	=	>	0	0	0	F
FOB	<	=	=	0	0	0	0	0	0	B
BSS	<	=	=	=	=	>	0	0	0	B
GGS	>	>	>	>	>	>	0	0	0	F
MP	>	>	>	>	>	>	>	>	>	G
CV	<	=	0	0	0	0	0	0	0	B
General Assessment	F	F	G	G	G	G	F	B	B	

From Table 3, >, < and = signs represents 'average time limit', 'below average time limit' and 'average time limit' respectively while G, F, B represents 'good', 'fair' and 'bad' respectively. The Table compared actual output with expected standards of output for each of the projects via acquisition stages. From the Table only two of the acquisition projects was

rated good. On the general assessment; site identification, perimeter survey, release of funds, title clearance and payment of compensation were identified as possible policy targets to improve on to enhance effective public land acquisition process in the study area. This also corroborates the findings of Dundas and Evans (2001) that compulsory acquisition is often associated with persistent widespread dissatisfaction with the process and compensation extending over long number of years.

Table 4: Implications of Deficiencies in Acquisition Process

S/N		Mean	Ranking
1.	Inflation of the cost of acquisition projects	3.46	1
2.	Increase in hostility from the affected community	3.38	2
3.	Increase costs and stifling of Government remedy projects due to unresolved appeals	3.38	2
4.	Undermining of Government's legitimacy	3.15	4
5.	Disaffection between government and the affected community	3.31	5
6.	Institutional hoarding due to abandonment of government project	3.00	6
7.	Tenure insecurity and reduced acceptability of land as collateral	2.62	7
8.	Precarious situation of the affected urban poor remain unabated	2.54	8
9.	Housing deficit problem compounded in the affected urban area	2.38	9
10.	Causes psychological imbalances to impoverished claimants	2.23	10
11.	Loss of lives arising from disappointments of under-compensation	2.00	11

Table 4, shows the implications of deficiencies in acquisition process. 'Inflation of the cost of acquisition projects was the most important consequence of deficiencies in acquisition processes. This was evident from its mean score of 3.46, while 'increase in hostility from the affected community' and 'increase costs and stifling of Government remedy projects due to unresolved appeals' ranked second with the mean scores of 3.38. 'Loss of lives arising from disappointments of under-compensation' is least popular although it remains as one of the implications of deficiencies in acquisition process. Observer Research Foundation (2010) noted that delays and cost overruns in public land acquisition projects is a direct consequence of flawed acquisition procedure.

CONCLUSION

This study has established various processes in land acquisition. Generally an established work flow pattern that guarantees a fair acquisition process is in place in Ondo State when there is no undue meddling from the political class. It has equally revealed that where the process is executed poorly, the economic, social and political costs may be enormous. Attention to the procedures of public acquisition is therefore critical at achieving the level of efficiency required to making sure that the masses derive optimum benefits from government investments. Therefore, procedures that meet acquisition demands must ensure that processes are not delayed. In view of this, the study recommends the following:

i. Time is crucial. Hence, everyone should have a proper understanding of their role and function in the Land acquisition process so that things would move faster.
ii. To ensure that all affected landowners are aware of the project, timely notice should be publicised as widely as possible.
iii. A clear time-limit should be placed to ensure that acquisition process is not unduly long.
iv. There is need to achieve increasing organizational effectiveness through heightened structural capacities. The Directors in the Lands Services department should be given maximum freedom and flexibility to operate.
v. The Land Services department should adopt management principles and techniques that bring effective results and build the personnel in the course of their operations.

vi. The State Government should always set expected standards of output before commencing an acquisition process. To make it effective, a system of costing the inputs and outputs of any acquisition job and prompt funding should be devised as it is in the case of the private sector.

vii. The State Government should adopt ICT at different stages of the Acquisition process. Technology has bolt from the stable and the State need to keep abreast. Each personnel should be able to interact via the use of the web or some government portal operating data sheets to assist in a timelier management of the process.

A Study of Developers Speculative Activities in Lagos Urban Fringe

Thontteh, Esther O.

Department of Estate Management, Faculty of Environmental Science, University of Lagos, Akoka, Lagos, Nigeria
estherthontteh@yahoo.com

ABSTRACT

The use and misuse of land resources in and around urban fringe is one of the principal issues that call for urgent attention particularly in rapidly growing areas where there are land use shifts, market distortions and increase in land acquisition. This study investigated developers' activities in Lagos-Ibadan Express way and implication in the study location. The study is purposive in nature, employed both qualitative and quantitative techniques. Population for the study was the 128 registered members of Real Estate Developers Association of Nigeria (REDAN) out of which the sample size was systematically drawn. The selection of the study area allowed for an understanding of the roles of developers in Lagos urban fringe. Mean Item Score (MIS) and factor analysis was used to isolate critical factors germane to developers' activities in relation to land speculation. The study established that there is a significant relationship between developers' activities and land speculation as the bulk of land acquired was subdivided for on-ward sale. Furthermore, analysis showed that finished products (housing) of most of the developers are often times beyond the reach of the common man (low class). Based on the finding, further investigation needs to be conducted to establish the nature of developers' speculative activities as well as institutionalizing systematic and prompt approach such as Land Value Tax (LVT). It is further expected that this study would draw the attention of the appropriate authority to the dysfunctional activities of developers in the urban fringe areas for land control.

Keywords: Agricultural land, Developer, Lagos, Speculation, Urban fringe

INTRODUCTION

Speculative demand and pressure force changes in the property market due to some inevitable external forces that simultaneously shape urban fringe areas besides government policies. Moreover, Problems of urban fringe in developing countries are quite similar according to Masum (2009). Furthermore, land use change from predominant agricultural use to residential development is common across the world as noted by Holtslag-Broekhof, Beunen, van Marwijk and Wiskerke (2014) as one million hectares of agricultural land are converted and developed for residential use annually in Europe. The urban fringe is viewed as a multifunctional environment, but often characterized by essential service functions; a dynamic environment characterized by adaptation and conversion between uses; a low density economic activity including retail, industry as well as an untidy development pattern, (Scott et al., 2013). Kombe (2005) further noted that an unprecedented growth of informal settlements as well as land speculation in most sub-Saharan countries has continued to generate fears about imminent haphazard development including lack of basic infrastructure services in the rapidly densifying urban fringe settlements. Moreover, problem stemming from institutional decadence, conventional tools inherited from the colonial masters such as master plans and structure plans for regulating and directing urban land use development are no longer potent instruments for promoting planned land use development especially in the urban fringe areas of sub-Saharan countries. The outcome is daunting and seen in cases of unregulated land subdivision and transactions. Some authors including Monkkonen, 2013; Ding and Zhao, 2014; Kombe, 2005; Holtslag-Broekhof, Beunen, van Marwijk and Wiskerke (2014) noted that speculation is common to every investor as they embark on it as a means of attaining profit under conditions of uncertainty. This is as a result of lack of ineffective

Thontteh, E. O. (2016). A Study of Developers Speculative Activities in Lagos Urban Fringe. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 606-615

government intervention in land markets, the patterns of ownership and uncertainty. In addition, Triantafyllopoulos (2010) and Ding and Zhao (2014) suggests that land speculation may be regarded as a socially embedded action which follows a particular social behavior and consequently leads to an overall inefficient land market. As such, speculation is said to be a fundamental cause of both micro-economic and macro-economic disturbances due to delay in development or best use for future anticipated price increase and in order to earn profit.

Oftentimes speculation in the property market is termed to be almost synonymous with investment in the equities and capital market where investor expectations are sometimes shaped in an inaccurate way. Although, speculation could be encouraged in the stock and commodity market where a speculator renders a public service by increasing production where it is needed but not with land because the stock of land is fixed. However, it is considered to be a destructive and destabilizing force in progressive economies as such, when purchased land is kept vacant without improvement, thus realizing "unearned increment" or delay development until the uncertainty about the most profitable use is clear. The latter clearly shows the weakness of planning and development control.

Speculation is essentially referred to as social epidemics and it is associated with economic bubbles (Bogle, 2012). This occurs when the price of landed properties exceed its intrinsic value by a significant margin. Speculative bubbles are characterized by rapid market expansion driven by word-of-mouth. This brings about initial rise in price, attraction of new buyers and subsequently generates further inflation.

Some of the negative implications of speculation include the following: (1) restriction of access to immediate land use; (2) reduction in housing stocks with less supply, high demand and high price for the quantity available; (3) limiting land tax revenues when the land acquired remain undeveloped; (4) speculation is associated with market manipulation; (5) speculation push prices higher than reasonable levels. That is price moves are often exaggerated; (6) acquisition of asset exclusively for sale motivated solely by anticipation of capital appreciation and gain; lastly, speculators play on market psychology rather than productive enterprise.

Speculation is not caused by a shift in demand due to change in taste and fashion, a shift in consumption demand, a change in supply or a shift in certain fundamentals (Knittel & Pindyck, 2013). However, a shift in fundamentals can certainly cause a change in price but not a determinant for land market speculation.

The high rate of increase in land prices in metropolitan centres in most sub-Saharan countries is an indication that the supply of land does not correspond to the increase demand for land (Rukwaro & Olima 2003). Accordingly Ezenagu (2000) affirmed, the major housing problem confronting Nigeria as a nation is the inadequacy of housing stock to meet the high demand of her teeming population. This has placed the urban fringe areas under intense pressure to meet the ever increasing need for shelter provision, Nigeria included. Nigeria has been faced with the challenges of planning and development of its urban neighbourhoods most especially the urban fringes (Oduwaye, 2009). Moreover, housing strategies geared towards the provision of complete housing units for the ever increasing population have not achieved the expected results due to lack of adequate funding (Nubi, 2015). Due to the inability of government to meet the high demand for housing provision, the emergence of land developers ensue which has attempted to sporadically increase residential landscape. This process involves the purchase of land parcels sub-division of plots as well as carrying out residential developments.

However, close observation of the developments in urban fringes reveal predominant haphazard development which could be as a result of non adherence to residential development guidelines on the part of the developers (Wrenn & Irwin, 2015). Furthermore, Wrenn and Irwin (2015) affirmed that non adherence to control is as a result of delay in residential sub-division approval and profit loss to developers. Several authors including Rukwaro and Olima (2003); Kombe (2005); Lawanson et al., (2012) explicitly observes that causes of haphazard development is clearly a case of ineptitude and negligence of government authorities entrusted with responsibilities of planning order and control as well as developers having disregard for building codes and guidelines during the development stages, especially for areas such as road networks, building setbacks, sewerage systems as well as recommended building materials for health and safety of occupiers. Participants involved in speculative practices have been grouped into three levels by Triantafyllopoulos (2010) as informed speculators- these are informed speculators with both public and private information. They are otherwise known as public officials in charge of land plot allocation. Secondly; un-informed speculators- these are individuals who only have public information, they are otherwise known as either investors or developers and thirdly; private purchasers who are individuals who are not information driven. However, bought land but could not develop within 2-5 years of purchase.

Land use ought to be subject to government control but such regulation seems not evident in most of the urban fringe areas where sprawl-like development and completely undeveloped or partially developed land abound. This may be due to inadequate infrastructure provision or susceptibility of land itself to speculative activities of traditional land owners, investors and sometimes government agencies. Accordingly, the land hunger emanating from housing shortage and the efforts of developers and investors to meet the shortfall is seen as one of the possible drivers of speculation in the fringes coupled with the surge in demand for land and home ownership which is now prompting land subdivision and sale by installments in the area, remains an issue of concern. Moreover, the motivation behind the ownership patterns of private individuals is yet unknown, probably representing mixture of reasons and associated with speculation, business expansion or family ties. However, hardly are there any studies on land speculation, its effects and responses to controls if any. Yet, urban fringes are places of strategic importance for formal expansion, growth control, land use transition, infrastructure development and agricultural stability (Kombe, 2010 & Potsiou, 2007).

This study aims at investigating developers' speculative activity in Lagos urban fringe, as such, a number of wide ranging questions arise in the mind of the researcher. These include the following: - Does speculation exist in urban fringes of Lagos; what is the motivation behind the land acquisition patterns in Lagos urban fringe? And what are the factors responsible for land speculation in the study area? The quest for improved knowledge and empirical understanding of land speculation has become more necessary given its multifunctional and dynamic environment characterized by adaptation and conversion between uses. As such, this study will broaden an understanding of underlying motives and effects of land speculation. Moreover, urban fringes are seen to be the raw material for housing subdivisions, industrial estates and mobile home parks in the UK Scott et al., (2013). However, this needs to be regulated for effective use and reduction of conflicts.

Urban Fringe Growth

Urban fringe has many different expressions in the literature in terms of its meaning, features and delimitation. As such the area of transition from agricultural zone to urban area, rural urban fringe, urban fringe, pre-urban fringe, rural fringe of the city, pre-urban areas and metropolitan fringe are used sometimes with recognized gap but usually in synonymous way overlap each other strongly suggesting similar connotations (Masum, 2009). However, the

apparent simplicity of the phrase ”Urban fringe” belies the complexity of processes and actors involved in what essentially is a zone of physical interface and human – environment. As such, it is a zone of transition with potential for disruption, uncertainty of tenure; boundary conflict and other opportunity that transition entails. Furthermore, same definition was ascribed to urban peripheries and fringes of the cities affirming that there is no precise definition of urban fringe, there is however, a common understanding that fringe is an area of transition where urban and rural land uses intermix. Urban fringe is therefore dynamic as it continuously shifts outward from the city. Moreover, it is not only a transition of land from rural to urban use but also complex in nature as it involves change in land ownership pattern, land transfer, regulatory measures, enforcement mechanisms and types of development.

With increasing improved transportation and communication, urban fringe areas have undergone diverse structural changes. The simultaneous changes in socio-economic structure and high land value systems in urban centres' affected the location preference of urban fringe areas. Moreover, the demographic and structural changes of the city have serious implications on the quality of life in urban settlement as such the low income earner and sometimes middle workforce tends moving outward. This pattern of outward movement is not homogeneous in nature and is determined by various pull and push factors in various countries (Masum, 2009).

Consequently, location choices of different sectors in the urban centre inevitably changed and urban fringe development areas have spread out into rural areas. Government planning policies and regulation are expected to control this new pattern of development to prevent land speculation and haphazard development. These problems vary from spontaneous development of land with inadequate services and facilities as well as non formalization of land titles.

In addition, urban fringe is the leading edge of urban growth and often implies weak planning control on land sub division which often times may be due to lack of effective laws and regulations supporting planning, the good will and determination of government officials. Ozge Balta and Eke (2011) affirms that the following factors propel spontaneous development of urban fringes; they include macro economic factors, micro economics factors, demographic factors, housing/ location preferences, inner city problems, transportation and regulatory frame works.

Furthermore, Ozge Balta and Eke (2011) affirmed that haphazard development in urban fringes has many effects such as increased traffic congestion, negative environmental effects such as reduced air and water quality, loss of open space and other natural resources and agricultural land, higher public costs for new facilities and services for the newly developed areas (e.g. road constructions, sewer, water systems), more expensive infrastructural services, priority given to personal gain rather than public/ community benefit and of course land speculation. With this, speculation is a valid investment view from the perspective of the investor but the effect on the public is what matters which need urgent attention.

The Property Developers

Developers are investors that initiate and carry out land development projects. They play an active and leading role in the development of urban fringes. Thus, they are perceived as the prime sculptors of spatial structure in any open space (Maruani & Amit-Cohen 2011). Furthermore, Jonas and Wilson (1999) refer developers to growth machine as well as other auxiliary players such as the media, university, banks and professional groups. As such, the combination of activities of this groups increase the value of land and revenue stream for

growth. This has often times been the case for urban fringe foundation, its processes of growth and development.

A variety of tactics and methods are used including placement of advertisements in news papers and property journals, sponsorship of jingles and other efforts that may raise the profile of the urban fringes to property purchasers. However, often time, activities of the various developers suggest "propaganda projects" since most of the infrastructural improvement earmarked and listed may not be achieved for years afterwards. Scott et al., (2013) noted that many agencies and developers do not have a particular view on the fringe space except when it is part of an actual project. This is exacerbated by the prevalence of the quest for securing economic growth outcomes and prosperity which is seemingly taking precedence over physical and environmental concerns.

Developers' have further been referred to as the key decision makers in the residential development process, most times in relation to private sector development. Furthermore, a property developer is one who transforms certain element of production, notably labour, capital, materials and land into some form of development such as commercial, residential or industrial. This function can be undertaken by private individuals, multi-national construction companies, local builders and contractors, cooperatives or local housing associations e.g REDAN amongst others.

Focusing solely on residential development activities, the role of the property developer is to produce or supply new housing. In practice; these encompasses variety of roles which includes: initiator of development, coordinator of factor of production, builder and salesman. Moreover, when operating in the private sector, he is largely a free agent.

The property developers overriding motive often times is profit motivated. Whether operating in the private or public sector since residential development is regarded as a commercial venture. The profit motive is waived only in very special circumstances e.g. in a crisis where avoidance of risk is essential to ensure the survival of the firm or where a decision is taken to forego profit in a goodwill gesture designed to enhance the firm's reputation or relationship with government authority.

Moreover, emphasis on the profit motive prompts comment on the developer's speculative activities. But in real sense, a speculator can be anyone engaged in a commercial operation which incorporates the possibilities of risk and profit. Yet when applied to developers, it often becomes an emotive term conjuring up images of "self interested"; passion for low income housing". Awareness of this general criticism may explain the defensive stance often adopted by developers. Although, they are always quick to express their "social welfare" motivation which may reflect the honest personal response of the individual respondent. However, the desire to be (or at least appear to be) socially responsible is primarily a cosmetic or promotional screen behind which commercialism remains the driving force. For the developers, land represents both a source of financial gain and a means of ensuring continuity of production source (Abdul- Aziz et al., 2014). A developer's profitability and survival is often determined by: his foresight and astuteness in identifying the promising localities and groups of potential consumers, the accuracy of his chosen method as well as his ability to "follow through" with decisive action.

THEORETICAL FRAMEWORK

Land transaction during Land use change has also been studied by Holtslag-Broekhof et at., (2014) and Zhang and Skitmore (2015) using game theory. It was affirmed that the theory builds on the assumption that decision-making is an interaction process which relies on three basic concepts to describe decision making; the players, referring to the developers making a

decision; strategies referring to developers actions; and pay offs, referring to the value that the result of a decision gives. In addition there are three agents which determine the development decision model which include (i) the developers who initiate development plans (ii) the government institution saddled with approval of such plans and (iii) the public, whose demand for residential and occupational areas drives development (Mruani and Amit-Cohen 2011). Subsequently, the outcomes of the interaction between the three agents will eventually determine the attributes of the urban fringe areas as well as spatial pattern of developed areas.

The role of each agent in this model may be characterized by its contribution to the process, in terms of leadership, strategies and dominance. Developers play a leading active and dominant role in urban fringe development decision making most of the times they are the first player on site. This is not suppose to be, as government agency are suppose to be the first player on site to plan, design and subdivide the area for take-off of building development.

Developers start up the process by initiating development plans taking active steps to promote the plans towards approval by the planning authority, using among others political and economic influential connections. Developers are dominant in the Lagos urban fringe in the sense that they often stir up formulation of the propose project attributes such as opening up accessible route as well as striving for maximum financial profit. They have also established mechanism of land transaction in which potential buyers pay in instalments. The price is paid over few years, mostly by monthly instalments; sometimes potential buyers make a one-off payment. The land title instrument often times is general in nature that is a global C of O as such, legal ownership is granted after full payment. However most of the developers promise to be responsible for the provision of utility services which are part of the advertisement and profit making strategies of the developers are left unfulfilled. Whereas, such land use plans are required to conform to the planning requirement as well as control haphazard development. Most of the times, illegality of land conversion, violation of the design standard tenure insecurity and the current spatial pattern development that do not follow land use regulations of urban fringe areas poses critical challenge for government and her agencies (Morshed, 2014).

Government institution (Town Planning Authority) tends to be more reactive Oduwaye (2009) that is, responding to developers planning initiatives than being active. This seems to be a major setback for adequate spatial planning as well as control mechanism for larger acquisition of land in the urban fringe area. Out of the three agents, the public is the least active as they often times have access to land sold to them by developers through subdivision of parcel of land for development purpose.

METHODOLOGY

Lagos State remains the industrial and commercial nerve centre of the country with a population of 9,113,605 in 2006 census and total land area of 3671km^2. The projected population in 2015 is 12,427,000; 14,162,000 and 15,810,000 in 2020 and 2025 respectively (UN-Habitat, 2010). Thus, it is one of the world's megacities (Lawanson et al., 2012; Oduwaye, 2015). It has an estimated growth rate of 3.2% and population density of 2725/km^2 (Lagos State Government, 2013). The implication of these increasing population pressure arising partly from continuous migration not only increases the demand for land derivatives but also indirectly increases the need for effective regulatory framework to avoid squatter settlement, haphazard development and enforcement of sustainable building codes and control.

The case study area is the Lagos Ibadan Expressway comprising of Isheri, Opic, Magboro, Arepo, Warewa, Mowe, Ibafo, Shimawa and Shagamu interchange area respectively. The study area was selected because of its rapid growth and diverse built forms that are being erected. It is low, middle class and a fast developing estates that is being developed by plot purchasers who bought land from developers as well as Omo-Onile (family Heads) in the various urban fringe.

Data Collection Technique

Data was collected through a combination of methods including survey, questionnaires, direct observation and in depth interviews. The REDAN membership strength of Lagos (southwest zone) was made available comprising of 128 members who have duly paid their dues. This therefore, forms the population from which the sample size was systematically drawn. Sample size for the study is 43 while 36 developers granted interview as well as filled the questionnaire, representing 83.72% responses. Semi structured interview guide and questionnaires was used to collect data from developers. The selection of the study area allowed for an understanding of the roles of developers in the Lagos-Ibadan Express way axis. The study employed descriptive statistics, mean item score and factor analysis to isolate critical factors germane to developers' activities in relation to land speculation in the study area.

Data Analysis and Presentation

This section examines the characteristics of the respondents, motivations as well as implication of developers' activities in the Lagos urban fringe.

Table 4.1 motivational factors

Motivational factors	Motivate	Do not motivate
Profit seeking	26(65.0)	14(35.0)
Achieve orientation	24(60.0)	16(40.0)
Desire for power	3(7.5)	37(92.5)
Ideological motivations	9(22.5)	31(77.5)
Preference for proximity to urban land uses	25(62.5)	15(37.5)

Respondents were asked to tick their motivational factors and the outcome is presented by table 4.1. The table shows that the major factors that motivate the respondents were profit and preference for proximity to urban land uses. Other factors were indicated not to have been major motivational factors at least for 92.5% (for desire for power) and 77.5% (for ideological motivations) It can be deduced from this outcome that developers develop in areas where they perceive to get optimum return from investment.

Table 4.2 reason why large land is acquired

	Std. Deviation	Mean	Rank
Investment seeking	.7457	4.51	1
Future sales	1.08542	4.08	2
Quality life impacts	1.05267	4.05	3
Cheaper land	1.07537	3.85	4
Planning rules	1.02736	3.84	5
Bequest/inheritance motive	1.19773	3.39	6

Table 4.2 presents reasons respondents felt that large land should be acquired. Investment seeking is top of the list with a mean ranking 4.51. Significant also are future sales, 4.08; quality life impacts, 4.05; others are cheaper lands, 3.85; planning rules, 3.84. Bequest/inheritance motive with 3.39 is the least of the reasons for large land acquisition.

Land Acquisitions

The respondents were asked to rate factors that determine the acquisition of their land within Lagos urban fringe. According to the result obtained from the study, there are three major factors that developers considered in acquiring land: proximity to the CBD; availability of large land for development; and availability of infrastructures. This implies that large land closer to CBD is liable to speculative activities of developers.

Source of Finance and Prospective Targets

Finance is a major driver of property development and the research examines the source of the respondents finance and their outcome is presented in table 4.3. It can be deduced from the outcome that despite the availability of C of O on land, few developers used borrowed funds either from friends, families, and financial institution (local and foreign) to erect their building. The most surprising is majority (about 65%) of the respondents gets their finance from equity.

The study went further to examine the prospective targets for subdivision of plot by the property developers. Evaluating the targets by earning power, the study finds out that targets for developers are high income earners, workers earning above 200,000 naira monthly. As this was applicable to subdivision of plots as well as finished products when available

Table 4.3 Source of finance and target respondents

		Frequency	Percentage
Source of finance			
	Savings/equity	24	64.9
	Borrowed from friends	5	13.5
	Nigeria financial institution	6	16.2
	Foreign banks	1	2.7
	Others	1	2.7
	Total	**37**	**100**
Targets after subdivision of plot			
	Workers below 50,000	3	7.9
	between 50,000-100,000	12	31.6
	101,000-150,000	8	21.1
	151,000-200,000	2	5.3
	Above 200,000 monthly	13	34.2
	Total	**38**	**100**
Targets after construction of houses			
	Workers who earn below 50,000	3	7.1
	Between 50,000-100,000	10	28.6
	101,000-150,000	5	14.3
	151,000-200,000	7	20.0
	Above 200,000	10	28.6
	Total	**35**	**100.0**

DISCUSSION OF FINDINGS

This study verifies the earlier assumption of the researcher that several other persons are involved in development activities in the urban fringe other than professionals in the built industry. Over 40% of the developers' affirmed they were lawyer, accountant or economist and business administrations. The supporting factors show that they have either worked in a construction company, have former experience, relevant knowledge and skills, acquaintance with other developers as well as connection within the relevant institutional system.

This study has also confirmed empirically that developers perceive housing to be a normal market good which could be compared with other commodities in the market. However, this is not true. A higher percentage of developers surveyed (65%) affirmed profit seeking is a major motivation for land acquisition in the urban fringes followed by the preference for

proximity to urban land uses. Alexander (2014) noted that landed property are not normal market goods as they often do not share the defining characteristics of the goods and services that are the object of competitive market transactions. Since housing is said to be a "merit good", there is need to control developers' activities in the Lagos urban fringes.

Furthermore, some of the identified drivers of land acquisition as affirmed by the respondents is the "desire to own my business (investment purpose); future sales, availability of cheaper land as well as inheritance motive. Some others affirmed "job loss" while others affirmed it s a passion and ideological motivation that man should have access to adequate housing. However, the original motivation to provide housing is not often achieved. Hence land sub-division. Subsequently, developers were asked to rate factors determining acquisition of land in Lagos urban fringe. Response shows that proximity to the CBD (Central Business District); availability of large land for development as well as availability of infrastructure. This implies that large land closer to the CBD is susceptible to speculative activities by developers.

This study further established the speculative activities of developers by asking the year of land purchase and the year allocation of title was actually granted. This study shows that 5 (five) years after allocation of title construction has still not commenced, rather land subdivision. This is sometimes carried out even before title processing. In addition, some developers who affirmed to have completed title processing since 1987 still have the land vacant. Majority of the respondents acquired the land in the early ninety's but still have the land vacant while some have divided for on-ward sale to ensure profit maximization. However, developers in the study area affirmed that several challenges were encountered after land purchase from local land agents such as lack of integrity of the local land agents leading to re-sale of land, frequent interference by land thugs popularly called "omo-onile" and dispute within members of the land owning families. While lackadaisical attitude of government officials towards perfection of land document is sometimes encountered during title processing as such impede the process and time elongation which may affect further development on site

Prospective Targets

In evaluating the target market through their earning power, the study revealed that target market for land sub-division as well as housing unit purchase are workers earning above 200,000 Naira monthly ($1000) using 200 Naira to a dollar. Very few developers affirm their target markets are those earning below 50,000 Naira to 100,000 Naira. This calls for urgent attention as the minimum wage in Nigeria is 18, 000 Naira monthly ($90). As such, the low income earner would hardly have access to land let alone adequate housing.

Development Control and Planning

This study largely adduced the uncontrollable acquisition of urban fringe land to weak government control in the fringes resulting in negative environmental effects such as reduced air and water quality, loss of open space and other natural resources as well as traffic congestion and haphazard development. In addition, the lack of political will of government to tax vacant land is also an issue of concern. However, none of the developers surveyed agreed to land value tax (LVT) as a form of control. Where the difference between the prices at which the investor sells his undeveloped land and the sum of his acquisition and holding cost accrues to the government and community as a whole, not to private individuals. Since the enhanced value of urban fringe land are largely due to government infrastructure and works and services.

CONCLUSION

The property developers' overriding motive is profit oriented; whether operating in the private or public sector. However, emphasis on the profit motive with urban fringe land

portends a major risk factor. As such, coordination of diverse existing planning and development control rules with new development areas need to be encouraged as a way of overcoming negative effects of weak control in the Lagos urban fringe.

This study therefore recommends LVT; joint venture of real estate development between public and private investors; the use of available technologies for prompt dissemination of land information to avoid a particular group taking advantage over individuals and community at large. In addition, state decentralization is encouraged to ease complex system of both policies and regulation of urban fringe land management. As such, a systematic and prompt approach should be institutionalized for ease of land formalization. Lastly, Participatory planning between public and private sector should be encourage as well as creating environmental consciousness of developers' activities and implication on the fringes to the general public.

ABSTRACT

This study reflects the view of clients, consultants and contractors about the relationship between contractor's selection criteria and cost performance of civil engineering project. Data collected through questionnaire were analyzed using regression method. Results show that positive relationship exists between contractor's selection criteria and cost performance of civil engineering project. However, criteria for contractor selection influence cost performance of civil engineering project at varying degree. The impact of contractor's selection criteria on cost performance of civil engineering project is also at varying degree. It concludes that contractor's background, reputation, environmental, socio-political and financial ability impact greatly on cost performance of civil engineering project while the entire criteria for contractor selection impact on cost performance of civil engineering project at most, more and less significant impact levels. Hence, cost performance of civil engineering project depends mainly on these criteria for contractor selection. In addition, these criteria for contractor selection are the driving force for cost performance of civil engineering project. It is therefore recommended that clients and consultants, supposedly saddled with the responsibility of determining the cost performance of civil engineering project, should concentrate on non-financial criteria while selecting the contractor to handle the delivery of civil engineering project.

Keywords: Civil Engineering Project, Contractor, Cost, Criteria, Performance, Project, Relationship

INTRODUCTION

Infrastructural facilities are provided in other to meeting man's needs for shelter and convenience (Zavadskas, Vulitiene, Turskis and Tamosaitiene, 2010). It comprises building, civil engineering, and heavy/industrial engineering (Akinmusire and Ariyo, 2010). Consequently, Civil engineering can be defined as a broad field containing many subdivisions. These divisions include transportation engineering, environmental engineering, geotechnical engineering and construction engineering with different kinds of civil engineering projects emanating from them. The civil engineering projects include roads, buildings, airports, dams, bridges, water supply, and sewage systems. However, civil engineering projects is a professional engineering discipline that deals with the design, construction and maintenance of physical and natural built environment. Despite this, civil engineering projects are distinct and differ from other construction project categories in terms of type, nature, complexity and resource requirements (Barbara, 2004; Oforeh, 2006 and Lake, 2008). Oforeh (2006) further opines that civil engineering works are complex in nature. Evidently, contractors to handle these aspects of construction are usually screened and selected based on a number of selection criteria (Ogunsemi & Aje, 2005; Salama, Abd, EL & EI, 2006; Puoy, 2011). This is done by investigating contractors in terms of past performance, business location, technical capability, financial soundness, resources, quality assurance among others (Ogunsemi and Aje 2005; Zavadskas, Vilutiene, Turskis Tamosaitiene 2010 and Puoy 2011). This is absolutely aimed at prejudging contractors' capability and competence towards ensuring that selected contractor is suitable and capable in all ramifications to successfully execute projects regardless of its nature and magnitude (Aje, 2012).

Adedokun, O. A.; Akinmusire, A. O. & Aje, I.O. (2016). Effect of Contractor's Selection Criteria on Cost Performance of Civil Engineering Projects. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 616-625

Managaveni and Zunzhi (2001) argue that there can be no successful realization of construction works without achieving reasonable success, most importantly, at design and construction stages of the project. Oyegoke (2008) submits that construction projects are successful when completed within predetermined cost. Corroborating this view, Ng and Aminah (2006), Tran (2009) and Azian and Ismail (2010) believe that construction project is adjudged successful if completed within estimated cost, reasonable time and required quality. Therefore, choosing a contractor to undertake the construction of a project require diligence and must be carefully thought out since a wrongly chosen contractor posses a lot of danger to successful project completion (Ramus, Birchall and Griffiths, 2006). Ogunsemi and Aje (2005) reveal that the selected contractor is expected to be capable to successfully deliver project within a predetermined cost. Failure to achieve this has been identified as the principal cause of the low performance rating ascribed to Nigerian construction industry (Oyegoke, 2008). Research results show that a lot of efforts have been made to modify the present contractor selection process which has not yielded the expected positive result (Ogunsemi and Aje 2005). Furthermore, contractor selection process is costly to both client and contractor. According to Ng and Skitmore (2001), money is spent by clients on defining the standard for assessment, preparing and printing of prequalification documents. They reveal other cost components to include, obtaining information, storing the information, interpreting the information, finding and summarizing useful information. In addition, applying the information to the assessment model, analyzing and assessing information, and making decisions also contribute to the cost of contractor selection process. On the part of the contractor, the cost aspects of contractor selection process include collecting the required information, reorganizing information to required format, planning, checking, typing, presenting, printing, submitting and explaining the information to the client. These can be summarized into bid documentation, collection, submission, evaluation, reporting and final selection.

The Nigerian construction industry still performs below expectation despite its contribution of about 70% to the nation's fixed capital formation (Arazi & Mahmoud, 2011). However, Tran (2009) admits that cost overrun is peculiar and often occurs in construction projects even in the global world. The study carried out by Ng and Aminah (2006), Rathsayam (2009), and Azian and Ismail (2010) indicate that construction projects, building and civil engineering, often fail to meet cost target. Supporting this view, Le (2011) agrees that initial and final construction project cost rarely tally. The study carried out on cost, time and quality performance of construction projects by Ng and Aminah (2006), Azian and Ismail (2010) and Puoy (2011) show that cost is central to judging the performance of construction projects. Sloboan (2006) admit the complex nature of civil engineering projects and that civil engineering projects are affected by a number of factors that render their completion within predetermined cost difficult. According to Othman, Torrance and Hamid (2006), performance of civil engineering project in terms of cost is affected by delays and project characteristics. These often lead to delivery of civil engineering projects out of budget. Therefore, the study assessed the effect of contractor's selection criteria on cost performance of civil engineering projects.

LITERATURE REVIEW

The Nigerian construction industry, like any other construction industry in the world, is crucial to the development of the nation by contributing significantly to her economic growth (Arazi and Mahmoud, 2011). Arazi and Mahmoud (2011) opine that the construction industry contribute about 70% to the fixed capital formation of Nigeria. This shows the immense contribution of the construction industry to the gross domestic product of the nation. According to Civil Contractors Federation (2010), civil engineering industry produces civil

engineering projects that play crucial role in meeting infrastructural needs of the people. Consequently, the economy of a nation relies on the contribution from the construction industry for growth. Ogunsemi and Aje (2005), and Zavadskas *et al* (2010) stress the strong relationship between the construction industry and the economy of a nation to the extent of revealing that there can be no meaningful economic development in any nation without active participation of the construction industry. The task of construction product delivery within budgeted cost is that of project stakeholders (client, consultants and contractor). Ng and Aminah (2006) posit that most construction projects are bedeviled with unexpected additional cost due to faulty designs and poor contract administration in addition to the uncertainties that are peculiar to construction projects. Moreover, Rathsayam (2009) and Le (2011) agree that construction projects are hardly completed within the cost predetermined by client and consultants. The reason for this is attributable to peculiar uncertainties that may positively or negatively affect construction cost (Sameh 2008). The study conducted by Rathsayam (2009) trace the reasons for construction project cost overrun to poor project conception, planning, construction and closing phase, and wrong choice of contractor. The factors responsible for poor cost performance of construction projects include economic problem, politics, legal problems, design, contractual, inflation, change in government regulations, technical problems, delay and contractor incapability (Lee, 2011).

Consequently, cost is one of the three essential project success/performance measurement criteria (Adnan; Sherif, and Saleh, 2009; Ogunsemi and Aje, 2005; Barbara, 2004; Roshana and Akintola, 2002; Azian and Ismail, 2009; Puoy, 2011 and Aje 2012). Part of the primary objectives of construction projects, according to Tran (2009) and Rathsayam (2009), is to be completed within cost based on the standard and specifications. According to Doan (2011), the only way to make clients happy is to deliver products that meet cost target. This implies that clients expect projects to be completed without paying extra money (Nguyen, 2012 and Aje, 2012). Construction projects vary in type and complexity and depends on the purpose for which it is needed (Barbara, 2004). In Barbara (2004) and Oforeh (2006), civil engineering projects are generally complex requiring vast resources and usually take longer time to put them in place. Lake (2008) opine that civil engineering projects encompasses roads/highways, railways, canals, airports, harbours, docks, water supply, drainage, flood and erosion control, bridges, tunnels, pipelines, dams, irrigation systems, among others. According to Sloboan (2006), the success of civil engineering projects require adequate knowledge of civil engineering production, its complexity and project specifics. Moreover, civil engineering project specifics are portrayed in the uniqueness, character of work and inseparability of the product from its location (Sloboan, 2006). Construction project developmental stages include design, tendering, tender evaluation and reporting, contractual arrangement, and award of the contract. Hence, these stages of project development process are unique, sequential and require unique team to design and construct. According to Pierre (2003), civil engineering projects are to be planned, designed and constructed/realized. These project phases involve different tasks with corresponding skills to be performed by different professionals. Consequently, planning of civil engineering projects is rendered difficult by their complexity and their production that involves a lot of participants (Sloboan, 2006).

Ajayi and Ogunsanmi (2012) opine that most client prefer adoption of selective tendering in the selection of contractors for their construction projects. The reasons ascribed to this are prevention of default from contractors including associated contractors' overhead costs, easy assessment of contractors' liability, competence and potential contractors' capability and minimization of potential project risks. Arazi *et al*. (2011) and Xiaohong (2011) consider the process of selecting the most suitable contractor to handle the delivery of construction project as an uneasy task. They opine that contractor selection is vital to the overall construction

project success. On the other hand, construction involves putting resources together with resultant costly product according to Zavadskas *et al*. (2010). They further opine that selecting a contractor is an important part of construction process that should be handled with great care. This is as a result of the dangers of extra financial burden inherent in erroneous choice of contractor (Ng and Skitmore, 2001; and Ogunsemi and Aje, 2005). This usually lead to waste of resources and hostility between the client and the contractor which can lead to litigation or arbitration that can prevent the project from seeing the light of the day (Ogunsemi and Aje, 2005). Customarily, the aim of contractor selection process is to ensure the emergence of the most suitable contractor and making the choice of same successful contractor (Ajayi and Ogunsanmi, 2011). As a result of the sensitivity of contractor selection process, Salama *et al*. (2006) consider this to be very important to the client and his advisers/representatives. The result of the study conducted by Banaitiene and Banaitis (2006), revealed in Ajayi and Ogunsanmi (2011), identify unsuitable criteria, inappropriate importance attached to the criteria, wrong contractor evaluation and selection as the principal cause of erroneous choice of contractors. Nonetheless, incompetent contractor pose a lot of threat to both the project and all stakeholders. Contractor selection process is incomplete without tender/bid evaluation. The study carried out by Khamidi; Khan, and Idrus (2011) and Capital Works Management Framework (2011) indicates that contractors are evaluated based on price and non-price criteria. As far as price criteria is concerned, emphasis is on the tender price submitted by the contractors and other documents such as evidence of financial stability turn over, profit, obligations, amount due and owned financial funds, meant to appropriately evaluate the financial stability of the bidders (Xiaohong, 2011). However, Xiaohong (2011) agree that the price offered by the bidders is the most paramount criteria considered during bid evaluation and forms the basis for the award of the contract. However, Queensland (2007) believes that cost is one of the principal project objectives that determine the choice of the criteria for contractor selection.

In view of this, Khamidi *et al*. (2011) and Arazi *et al.* (2011) posit that cost is a crucial instrument for measuring the performance of construction project as well as major determinant of client's satisfaction. They describe construction cost as the total amount of money expended on a construction project from inception to completion including costs arising from variations, modification and all legal claims. Furthermore, Khamidi *et al.* (2011) categorizes construction project cost into direct, indirect and overhead costs. According to (Khamidi et al., 2011) construction cost is a cumulative of these costs which eventually becomes the cost baseline for the project. The cost of any construction project is usually predicted and established through an estimate which is to be targeted and controlled to ensure that the project is completed within the estimate (Barbara, 2004). In the construction industry, the cost of a particular construction project is usually agreed by both the client and the contractor early enough in the life of the project. This constitutes the budget and it is expected to be sufficient to execute the project from start to finish. In Le (2011), construction projects are hardly completed at or within the agreed cost despite client's and consultants' efforts towards this. The circumstances surrounding the difficulty in achieving construction project of same initial and final cost, according to Ali and Kamaruzzaman (2010) and Le (2011), is basically the risky nature of construction projects. This is particularly the result of wrong estimate, design changes, inflation, site condition, poor contractor's technical, managerial and financial capability, poor site management as well as poor financial capability by the client. Construction project cost performance is affected by project manager's competence, top management support, project manager's coordinating and leadership skills (Iyer & Jha, 2005). Other factors are monitoring and feedback by participants, decision making, coordinating among project participants, owner's competence, social condition, economic condition and climatic conditions.

Rathsayam (2009) and Arazi *et al*. (2011) admit that several projects experience unexpected cost overruns despite the fact that factors contributing to this are avoidable. This problem is traced to faulty project conception, planning and controlling/monitoring. Arazi *et al*. (2011) further show that cost overrun occurs when the total amount of money expended on construction project exceeds the initial estimated cost of the project. The cost of a project needs careful determination bearing in mind that it must be sufficient to completely execute the project without subjecting the client to extra financial burden (Barbara, 2004). The effect of cost overrun as revealed in Khamidi *et al*. (2011) includes financial loss to client and contractor as well as disputes, unpleasant project progress and remarkable increase in construction project cost. According to Azian and Ismail (2009), construction project cost goes beyond the tender sum. It is the overall cost incurred on the project. This includes cost of variations and any other claims due to the contractor in addition to the tender sum. A comparison between the overall cost and the initial cost of a project will show how much the project is over or under budget. Hence, Salter and Torbett (2003) and Azian and Ismail (2009) opine that cost variance is a vital factor that determines project performance. Khamidi *et al*. (2011) argue that cost overrun brings unpalatable situation to client, contractor and the project itself. Therefore, they suggest cost monitoring of construction projects by consultants so as to keep the cost within the initial estimate. While noting that larger part of construction project cost is spent during construction, Khamidi *et al*. (2011) submit that monitoring of construction project cost as the prime duty of client's consultants. They ascribe construction project performance to the efficiency of the consultants to control the cost so as to ensure completion within the budget. Additionally, comparing the amount expended on construction project with the estimated cost is a better tool for monitoring construction project cost (Khamidi *et al*. 2011). Khamidi *et al*. 2011 therefore believe that construction project is successful if completed within the initial estimated cost. Moreover, before the cost performance of a construction project can be judged; certain factors have to be considered. These factors, according to Adnan *et al*. (2009) include uninterrupted cashflow, completion within budget, material and equipment cost required for the project, labour cost required for the project, amount expended on workers' motivation, cost of variation orders and amount of overhead expended on the project. Other factors are amount of profit realized from the project, cost incurred as a result of material wastage, amount expended on overtime charges and cost incurred as a result of labour resource wastage.

In line with standard practice, construction contractors are chosen based on some selection criteria. These selection criteria are identified in Ng and Skitmore (2001) and revealed in Ogunsemi and Aje (2005). They include past performance, contractors experience, workmanship ability, tender sum, plant and equipment, contractor's reputation, management capability, quality assurance, contract period, health and safety policy, financial standing, project size, location, project type, contractors' current work load, competition, length of time in business relationship with client, and amount of subcontract work. This shows the result of previous researches where it is revealed that contractors can be selected based on financial soundness, technical ability, management capability, safety performance and reputation (Ng and Skitmore, 2001). This list is expanded to include method statement, percentage of advanced payment, schedule of payments, past failures, disputes and claims records and arbitration records (Salama *et al.*, 2006). However, exceptional situation may arise in case of civil engineering projects because of the peculiar characteristics of civil engineering works. Sequel to this, Salama *et al*. (2006), which reveal the contractors prequalification criteria adopted for the parallel runway for Kingsford Smith Airport, indicate additional criteria to those mentioned in the previous researches. They include relevance of experience, size of firm, relationships (industrial relations, occupational health and safety, and claims and dispute history), past failures among others. Moreover, general information or contractor's

background, financial, managerial, technical and safety abilities are common contractors prequalification criteria as indicated in Ng and Skitmore (2001); Puoy (2011); Nguyen (2012); Aje (2012); and Salama *et al*. (2006).

The research conducted by Puoy (2011) and Aje (2012) show that construction project cost performance is affected by contractor selection criteria. Investigation reveals past performance, technical ability and management capability as dominant prequalification criteria affecting cost performance of construction projects (Puoy, 2011). However, emphasis has been on both price-related selection criteria and non-price-related contractors prequalification criteria. Contrarily, Queensland (2011) argues that the price at which a contract is awarded may not offer best value for money. Thus, contractor carrying out work under the supervision of client's representatives is expected to deliver the project within the budgeted cost (Oyegoke, 2008). In addition, how much each contractor intends to execute the project together with consultant's estimate is uncovered during bid evaluation. The pre-estimated budgeted cost is used as reference to judge contractors' bid performance according to Salama *et al*. (2006). Investigations show that contractors are, in most cases, selected based on bid price or tender sum only at the expense of other crucial contractor's financial soundness criteria (Salama *et al.,* 2006). As a result of this, the lowest bidder usually emerges victorious. Admitting this view, Xiaohong (2011) argue that contracts are often awarded to the lowest bidder who usually finds it difficult to successfully execute such contract because of the attendant problem of financial bottleneck the contractor would eventually face. Aje (2012) consider this as a major contributory factor to construction project failure because such contractor is prone to financial difficulty, which may lead to additional financial burden on the client and/or poor quality product in the long run.

RESEARCH METHODOLOGY

This study was carried out by sampling the opinion of construction professionals in both public and private organizations in Ondo and Lagos states. These include Quantity Surveyors, Civil/Structural Engineers, Clients and Civil Engineering Contractors. According to Puoy (2011), Quantity Surveyors and Civil/Structural Engineers play significant role towards making the choice of competent civil engineering contractor as well as administration of civil engineering projects. Therefore, the population comprises registered financial professionals and organisations totaling 636 respondents. The figure was scientifically reduced to a sizeable portion of 246, using Yamane's formula. The data were collected from Ondo and Lagos states, Nigeria, through questionnaire survey administered on 246 respondents including Quantity Surveyors, Civil/Structural Engineers, Government ministries and parastatals (dealing in civil engineering projects) and Civil Engineering Contractors. Convenience sampling technique was adopted. This is a non-probability sampling method involving collecting data from easily accessible and willing respondents (Charles and Fen, 2007). Out of 246 questionnaires, 156 were retrieved and found suitable for analysis using regression method. In this case, the independent variable (contractor's selection criteria) with the highest standardized coefficient beta value, t-value and significance level, less than or equal to 5% (0.05) is taken to have significant impact on the dependent variable (cost). The degree of association between the dependent variable (cost) and independent variables (contractor's selection criteria) as well as the causal relationship between the independent variables is shown by the Karl Pearson correlation generated by the regression model.

RESULTS

Table 1 illustrates the correlation between criteria for contractor selection and cost performance of civil engineering project as well as the interrelationship between the criteria

for contractor selection. From the table, a positive relationship exists between cost performance of civil engineering project and contractor's general/background, technical ability, financial ability, management ability, reputation, past performance, health and safety, and environmental, social and political criteria with $r<0.5$. Despite this, contractor's general/background recorded highest correlation ($r=0.456$) with cost performance of civil engineering project. This implies that contractor's general/background have higher tendency to influence the cost performance of civil engineering project relative to other criteria for contractor selection. Contractor's technical ability, financial ability, and reputation also register a remarkable positive relationship with cost performance of civil engineering project ($r>0.3$). This means that they have considerable positive influence on cost performance of civil engineering project. Apart from this, contractor's management ability, past performance, health and safety, relationship, and environmental, social and political criteria recorded noticeable positive relationship with cost performance of civil engineering project ($r>0.2$). This shows that they have noticeable influence on cost performance of civil engineering project. Table 1 further shows that positive interrelationship exists between criteria for contractor selection and cost performance of civil engineering project with $r>0.5$ and $r<0.5$ respectively. This indicates that criteria for civil engineering contractor selection positively related with one another while influencing the cost performance of civil engineering project. However, table 2 reflects the impact and predicting power of criteria for selecting contractors on cost performance of civil engineering project. It is revealed that contractor's general/background have the highest standardized coefficient beta value and t-value of 0.408 and 3.858 respectively. The standardized coefficient beta value of this criterion for contractor selection is substantially high, meaning that it makes most significant impact on cost performance of civil engineering project. This indicates that contractor's general/background have the strongest cost predicting power for civil engineering project over other criteria for selecting contractors. Table 2 further shows that contractor's general/background makes statistically significant unique contribution in predicting the cost performance of civil engineering project at $p\leq0.05$. Moreover, contractor's reputation, environmental, social and political, and financial ability, has standardized coefficient beta value in 0.1 range. Thus, they make more significant impact on cost performance of civil engineering project. Majority of the criteria for contractor selection, representing about 56%, fall below 0.1 standardized coefficient beta values. This comprises technical ability, past performance, health and safety, management ability, and relationship with $p<0.05$. This means that they make less significant impact on the cost performance of civil engineering project. The adjusted R^2 value is 0.206, meaning that about 21% of cost performance of civil engineering project is impacted upon by criteria for selecting civil engineering contractors.

Table 1 - Relationship between contractors' prequalification criteria and cost performance of civil engineering project

	Cost									
Cost	1.000									
General/Background	.456	1.000								
Technical ability	.325	.630	1.000							
Financial ability	.371	.560	.501	1.000						
Management ability	.288	.457	.742	.500	1.000					
Reputation	.349	.443	.678	.616	.715	1.000				
Past performance	.274	.443	.722	.498	.659	.713	1.000

DISCUSSION OF FINDINGS

The findings in this research indicate that a significant positive relationship exists between criteria for contractor selection and cost performance of civil engineering project. The entire criteria for contractor selection listed in this study positively correlated with one another at varying degree of interrelationship. Also, criteria for contractor selection impact significantly on cost performance of civil engineering project at varying degree. It can be advanced that the resultant effect of inadequate criteria for contractor selection is completion of civil engineering project out of budget. This study shows that contractor's background, reputation, environmental, social and political and financial ability impacts significantly on cost performance of civil engineering projects. It is found that financial ability came last in this group. This shows that cost performance of civil engineering project depends mainly on non-financial selection criteria for contractor selection. However, this result negates the result in Aje: Odusami, and Ogunsemi (2009) and Puoy (2011), which focuses on building and housing construction projects. Here past performance, technical ability, and management capability were found to impact on project cost performance. In view of this, it can be deduced that civil engineering project stakeholders' opinion about the effect of criteria for contractor selection on cost performance differs from those of building project. This can be attributed to the characteristics as well as resource requirement difference that exist between civil engineering and building projects.

Table 2 - Impact of contractor selection criteria on cost performance of civil engineering project

Variables	Standardized Coefficients Beta	t-value	p-value	Adjusted R^2
(Constant)		6.035	.000	.206
General/Background	.408	3.858	.000

Dependent variable – Cost
P is Significant at 5% ($p \leq 0.05$)

CONCLUSION

Criteria for contractor selection affect cost performance of civil engineering project. The degree of the impact of the criteria for contractor selection on cost performance of civil engineering project is remarkable. This indicates that no choice of competent civil engineering contractor can be made at the expense of any of the contractor selection criteria. There is significantly positive relationship between criteria for contractor selection and cost, performance of civil engineering project. Thus criteria for contractor selection contribute significantly to cost performance of civil engineering project. Therefore, when the criteria for contractor selection sneeze, cost performance of civil engineering project catches cold. Thus, criteria for contractor selection are critical to cost performance of civil engineering project. Despite this, there is different degree of severity of the criteria for contractor selection on cost performance of civil engineering project. However, non-financial criteria for contractor selection, such as general/background, reputation, and environmental, social and political criteria are more critical to cost performance of civil engineering project than financial criteria. Hence, it can be advanced that they are causal driving force for cost performance of civil engineering project. However, technical ability, past performance, health and safety,

management ability, and relationship criteria impact less on cost performance of civil engineering project. Consequently, cost performance of civil engineering project depend less on these criteria for contractor selection.

RECOMMENDATIONS

Based on the conclusion drawn from the findings of this research, it is imperative to recommend that the choice of the criteria for selecting the contractor for civil engineering project should be based on the importance attached to meeting cost target. Civil engineering project clients and consultants should concentrate on non-financial criteria, such as general/background, reputation, and environmental, social and political criteria for contractor selection rather than financial criteria. Hence, prioritizing the criteria for selecting civil engineering contractor should be in the order of general/background, reputation, environmental, social and political, financial ability, technical ability, past performance, health and safety, management ability, and relationship. Consequently, all clients' and consultants' efforts should be geared towards full implementation of these criteria for contractor selection while making the choice of the contractor to handle the delivery of civil engineering project.

ABSTRACT

This paper assessed the state of construction change management practices in tertiary educational building projects in order to ascertain the practitioners awareness and adoption of the practice while taking into consideration the possibility of challenges facing the practice. 131 questionnaires were administered to key construction stakeholders. 87 questionnaires were returned and found suitable for analysis which represents 66.41% of the total sent out. Percentile and mean item score (MIS) were employed to analyze the data collected via questionnaire survey drawn on a 5-point likert scale. 15 factors, which were rated by the respondents, were significant after analysis with MIS. Kruskal Wallis H test was adopted in testing opinions of the respondents and Cronbach alpha test was also carried out to establish the reliability of the research instrument used for collecting data. The respondents had a convergent view i.e. statistically significant agreement regarding the level of awareness and adoption of construction change management practices while there were divergent views in relation to the challenges facing adoption of the practice. This is not unconnected to uniqueness and peculiarities possessed by each construction projects. The most highly significant challenges facing full adoption of CCM practices in its entirety include resistance to change current practice for a new approach and lack of continuing professional development (CPD) due to insufficient resources. It is recommended that construction practitioners be encouraged to undergo training while professional bodies should organize seminars for their members as this will reorient them in adopting new approach for existing current practice of doing things.

Keywords: Change, Construction, Changes, Management, Practices, Projects

INTRODUCTION

The propensity, at which changes on construction projects are transmogrifying, is alarming, as arithmetical progression is an understatement to quantify it, be it in form of scales, types, quantity and even magnitude (Zhuoyuan, Benson, & Imriyas, 2005). The performance of construction industry in terms of meeting its objectives or goals has been invariably affected by construction changes, thereby making it vulnerable to what has been broadly categorized as time and cost overruns as well as lack of quality products that hardly stand the test of time (Adedokun, Ogunsemi, Aje, Awodele & Dairo, 2013). Based on this, it is highly desirable but hardly feasible to eliminate construction changes completely on projects due to multi-layered contracting nature, which calls for an effective change management for firms' sustained survival (Zhuoyuan et al., 2005). A severe risk contributing to project failure could be ameliorated if changes are resolved through a formalized change management process (Anees, Mohamed & Abdel Rasek, 2013). Changes are to be classified adequately in order to effectively manage them and classifications of changes in general terms apply to changes in construction domain (Hao et al., 2008). Motawa et al (2007) classified changes based on parameters of time, need and effect. In summary, "*based on time, change could be anticipated or emergent, proactive or reactive, or pre-fixity or post-fixity. Based on need, change could be elective or required, discretionary or non-discretionary, or preferential or regulatory. Based on effect, change could be beneficial, neutral or disruptive."* (Motawa et al., 2007).

LITERATURE REVIEW

Construction Change Management Practices

Construction change management is the application of integrated solutions to coordinate the process, e.g. documentation, drawing, process, flow, information, cost, schedule and personnel of a project from inception to completion by ensuring that disputes; cost and time overruns are managed (Hao et al., 2008). Effectively managing changes on a project can substantially bring about reduction in risk of cost and time overruns, which often times result in disputes and claims (Egan et al, 2012). Despite the fact that implementation of change management processes can aid in the effective management of change, currently, there are no widely accepted industry standards pertaining to change management processes (Bolin, 2013; Egan et al, 2012). Hao et al (2008) suggest that unlike small reworks with minor impacts which do not need to go through a formal change process, changes with noticeable impacts, either reworks or change orders, require the following formal process in change management. The process according Hao et al (2008) is a generic change process model considered to have five stages including (i) identify, (ii) evaluate and propose (iii) approve (iv) implement and (v) review.

Having reviewed the works of several authors such as project change management by the Construction Industry Institute (CII), AACE international's Professional Practice Guide to Contracts and Claims, which includes a number of AACE International transaction papers like Project Trends and Change Control, Change Management for Today's Project-A Process Approach, and Effective Management of Project Change Orders and host of others, Egan et al (2012) summarized some of the practices from these various approaches and outlines the steps that can be taken to effectively manage change on a construction project as follows: (i) Address potential changes in the contract documents. (ii) identify the potential change (iii) create a proposed change order and document the proposed change (iv) review and evaluate the proposed change order timely (v) execute the change order and (vi) document the executed change.

Other guidelines on managing construction changes based on the principles of effective change management model by CII (1994) in Egan et al (2012) are as follows: (i) promote a balanced change culture (ii) recognize change (iii) evaluate change (iv) implement change (v) continuous improvement from lessons learned. Northwestern University Information Technology, NUIT (2011) put forward seven (7) processes involved in change management as (i) Change logging(ii) Change Review (iii) Change Assessment and Plannig(iv) Change Approval (v) Coordinate Change Implementation (vi) Change Evaluation and Closure and (vii) Emergency Change Handling Facilities Operations and Development (2008) suggested (i) identify the change (ii)assess the impacts of the change (iii) develop an action plan to address the impacts of the change (iv) gain acceptance of the action plan and (v) revise the six-year capital plan, (if applicable) on their university projects as change management process.

The works of myriad of authors aforementioned indicated that there is no "one size fits all" process or set of procedures for change management on projects (Bolin, 2013; Egan et al, 2012). Therefore, owner's, contractor's and project specific requirements, contract types, management preferences, and logistical issues are a few of the many factors that may influence the structure of the change management process for a given project (Bolin, 2013). Although there are expected differences in the change process between projects (Bolin, 2013), the following diagram in figure 1 defines the basic elements and processes that are typically expected during the construction phase of the project.

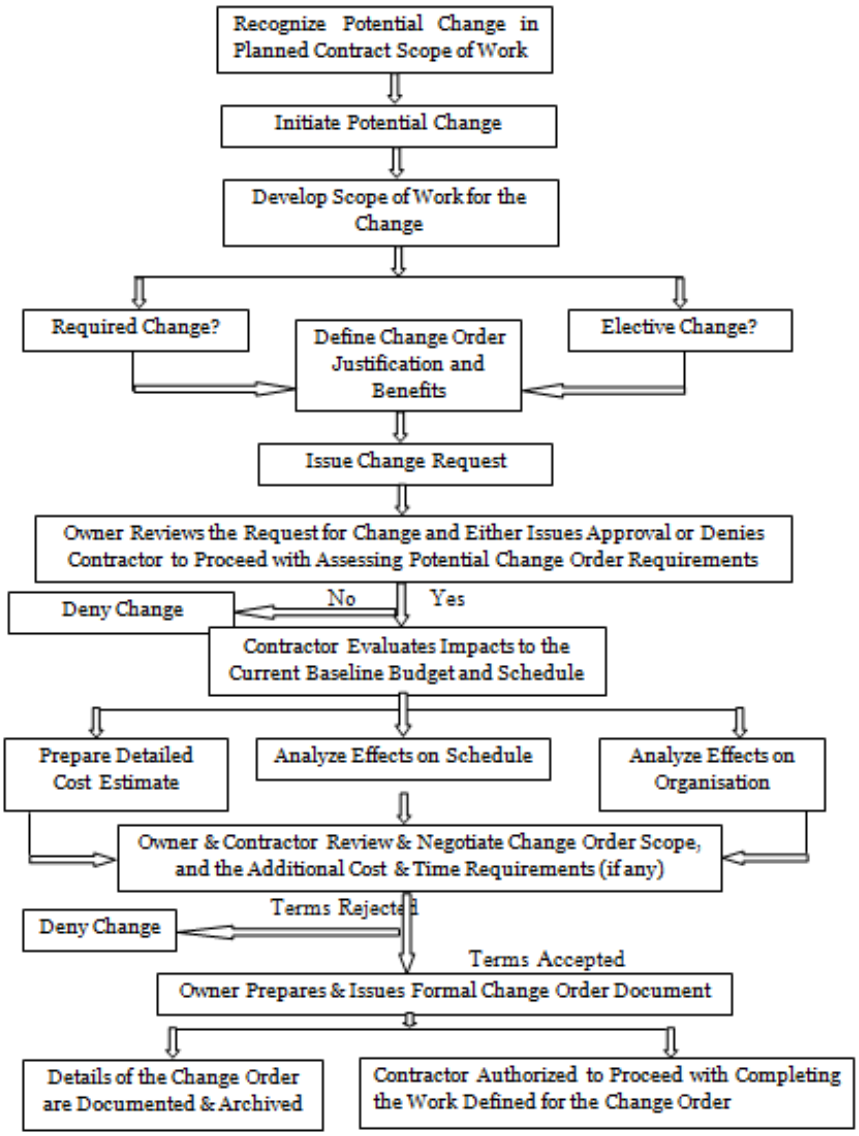

Fig 1: Change Management Process (Bolin, 2013)

Challenges facing Construction Change Management Practices

Hao et al. (2008) opined that developing an effective construction change management process is a challenging task because it requires an integrated solution for coordinating everything involved for the purpose of the change management in question according to Figure 2. Change management is a topic that one can hardly get through any resources unlike project management or construction enterprise management software that are readily available on the market.

Hence, the following are some of the challenges facing construction change management practices (Hao et al., 2008):

i. Unacceptability of new ideas by professionals
ii. Inadequate encouragement as regards learning within the firm
iii. Unavailability of change management unit
iv. Unavailability of time to exchange ideas
v. Insufficient time for after action review
vi. Difficulty in transferring change management knowledge
vii. Unwillingness of staff to share knowledge

viii. Excessive time associated with construction change management
ix. Uniqueness associated with projects which makes knowledge gotten from a project a waste to other projects
x. Variation on nature of projects
xi. Lack of organizing training/ seminars due to insufficient resources
xii. Too much work preventing evaluation of previous work
xiii. Overbearing workload which prevents cross project learning
xiv. Unwillingness to learn by professionals
xv. Resistance to change current practice and adopt new approach

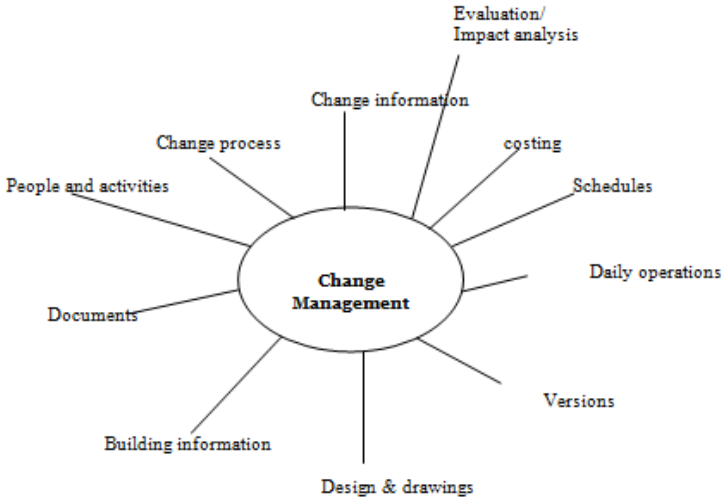

Fig 2: Requirements of an integrated change management system (Hao et al., 2008)

RESEARCH METHODOLOGY

This research employed a qualitative research design in the conduct of the study which involved the use of questionnaire survey administered to key construction stakeholders. The population for this work includes 131 key construction stakeholders comprising 44 Contractors/ representatives, 32 Quantity Surveyors, 28 Architects and 27 Structural Engineers, in the tertiary educational institutions in Ondo state, Nigeria (Tables 1and 2). The construction professionals used are both in-house professionals within the client organisation and the consultants outside the client's organisation but working on client's projects and the contractors executing the projects for clients. The targeted respondents were involved in the completed tertiary educational building projects from 2010 – 2014. The choice of the duration is to enable the respondents to quickly remember the activities that transpired during the course of the projects, knowing too well that records are seldom kept in a retrievable manner (Tarr and Car, 2000), hence considering too long duration is tantamount to guess work.

Table 1: Population breakdown of the respondents

S/N	Institutions	CLIENTS REPRESENTATIVES						Nr. of Ktors/Rep	**Total**
		In-House Professionals			External Consultants				
		QS	Arch	S/Eng	QS	Arch	S/Eng		
1	Tert. Ins. 1	2	2	4	5	4	4	10	31
2	Tert. Ins. 2	3	1	2	4	3	3	5	21
3	Tert. Ins. 3	0	0	0	1	2	2	5	10
4	Tert. Ins. 4	2	2	2	9	7	6	10	38
5	Tert. Ins. 5	0	0	0	0	0	0	0	0
6	Tert. Ins. 6	0	0	0	4	4	3	8	19
7	Tert. Ins. 7	2	3	1	0	0	0	6	12
Total		9	8	9	23	20	18	44	**131**

Key: Tert. Ins. – Tertiary Institution; Nr. of Ktors/ Rep – Number of Contractors/ Representatives; QS – Quantity Surveyors; Arch – Architects; S/Eng – Structural Engineers

The adequacy of a sample is assessed by how well such sample represent the whole population of participants from which the sample is drawn (Kothari, 2009). In order to achieve this, the lists of relevant construction professionals were collected from Physical Planning Unit (PPU)/ Works and Services Department of their respective Tertiary Educational Institutions. Since the target population, as obtained from the Physical Planning Unit (PPU)/ Works and Services Department of their respective Tertiary Educational Institutions, is just 131, it was found to be manageable thus census method was employed which involved the use of the entire population rather than picking a sample which might introduce some level of bias in the study.

Table 2: Population of the respondents

S/N	Respondents	Population
1	Quantity Surveyors	32
2	Architects	28
3	Structural/Civil Engineers	27
4	Contractors/ Representatives	44
Total		**131**

Data Collection Instruments

The research instrument that was used for collecting data from the respondents included a structured questionnaire that was administered using a set of predetermined questions. The questions designed for this research were such that first section dwelt on the background information of the respondents while the other section focused on matters relating to the research study. Questions inherent in the structured questionnaire were multiple-choice type with different checkboxes and tables posed on a 5-point Likert scale for ease and uniformity of response. Its application implies that most part of the data analysis was based on a scoring system.

ANALYSIS AND DISCUSSIONS

Tables were employed in this paper for data presentations while the analyses of the collected data were carried out using percentile, mean item score, factor analysis, Cronbach alpha test and Kruskal Wallis test. The results of the analyses were presented as follows under the various headings

Demographic Information of Respondents

Out of the 131 questionnaires administered, 87 were completed, returned and found suitable for the analysis. The analyzed questionnaires represent 66.41% of the total questionnaires sent out. This is considered sufficient for the study base on the assertion of Aje, Adedokun and Ibironke (2015) that the result of a survey could be considered as biased and of little significance if the return rate was lower than 20-30%.

From Table 3, it can be seen that majority of the respondents in this case are Quantity Surveyors with 43.7% and was followed by 29.9% quota, represented by the Structural/Civil Engineers and least was Architects with 26.4%. The professional membership status of the respondents shows that 41 are graduate members, 44 are corporate/ associate members while 2 of them are fellow of their respective professional bodies with 47.1%, 50.6% and 2.3% respectively.

As for the years of working experience possessed by the respondents, it can be seen that 26.4% falls within 1 - 5, 54% of the respondents are within 6 – 15 years of experience, while 8% falls within 16 - 20. On the average, the respondents have 10 years of working experience and the information supplied by this category of professionals is considered adequate and can

be relied upon. These set of respondents have their establishment in existence for an average of 13 years.

Analysis in Table 3 reveals that majority of the respondents are Postgraduate diploma holder with 40.2% and this is followed by respondents with BSc/ BTech qualification representing 20.7% followed by 19.5% and 18.4% representing HND and MSc/ MTech. Only one of the respondents has a PhD as the highest qualification and this translated to 1.2%.

Having analyzed the demographics of the respondents, it is evident that the respondents had sufficient knowledge and experience to participate in the research. Hence, the data collected from these respondents can be relied upon

Table 3: Demographic information of the respondents

Background Information	*Frequency*	*Percentage*	*Cum. Percentage*

Reliability of the research instrument

Reliability according to Kothari (2009) is an important aspect of research instrument and must be considered to ensure that accurate results are obtained. One of the most commonly used reliability coefficients according to Kothari is Cronbach's alpha test (α). Cronbach alpha test was employed in this paper to test the reliability of the questionnaire administered to the respondents during the survey carried out.

Table 4: Test of reliability for measuring scale

Scale of measure	Cronbach ∝-value
frequency of undertaking CCM practice activities	0.961
challenges facing implementation / adoption of CCM	0.800

Table 4 shows that the Cronbach's α value for scale of measures of the research instruments ranges from 0.800 to 0.961. Since the degree of reliability of the instrument is more perfect as the value tends towards 1.0 (Kothari, 2009), it can then be concluded that the instrument used for this research is significantly reliable.

Table 5: State of construction change management practices

	Mean	Remark
Level of Awareness	4.22	Awareness > Adoption
Level of Adoption	3.64	

Table 5 showcases the state of construction change management practices on project in terms of awareness and adoption level. From table 6, respondents are of the opinion that their level of awareness of the practice is high (**Mean Score = 4.22**). It can be seen that the level of adoption is also significant with mean score value of **3.64** but the level of awareness of the practice is far greater than the rate at which CCM practice is adopted on construction projects. The implication of this is that there exist certain factors impeding the full adoption of the practice despite its wide degree of awareness.

Table 6: Test of significance on the level of awareness of CCM on project

	Profession	Group	Mean
Chi-square	86.000	Quantity Surveyors	19.50
Df	2	Architects	50.00
Asymp. Sig	0.000	Structural/ Civil Engineers	74.50

From table 6, Kruskal Wallis test carried out shows that the p value is < 0.05, being 0.000, then null hypothesis which says that there is no significant agreement in the opinions of the respondents, is rejected and the alternate hypothesis is accepted that there is statistically significant agreement in the opinions of the respondents on the level of awareness of construction change management practices. The implication of this is that the respondents have convergent views as to the existence of the practice.

Table 7: Test of significance on the level of adoption of CCM practices

	Profession	Group	Mean
Chi-square	86.000	Quantity Surveyors	42.50
Df	2	Architects	12.00
Asymp. Sig	0.000	Structural/ Civil Engineers	74.50

From table 7, Kruskal Wallis test carried out shows that the p value is < 0.05, being 0.000, then null hypothesis which says that there is no significant agreement in the opinions of the respondents, is rejected and the alternate hypothesis is accepted that there is statistically significant agreement in the opinions of the respondents on the level of adoption of

construction change management practices. The implication of this is that the respondents have convergent views as to the adoption of the practice on projects.

Table 8: State of the activities inherent in CCM practices

Activities/ Tasks	Mean
Addressing potential change in the contract document	3.84
Documentation of the executed change	3.80
Identification of the potential change	3.72
Executing the change order	3.72
Review and evaluate the proposed change order timely	3.70
Creation of a proposed change order and documentation of the proposed change	3.69

Table 8 shows that the respondents are carrying out various tasks under construction change management practices. All of the activities have a high significant mean score values with the least recording 3.69. As a rider to table 5, the implication of these two tables is that the respondents are not only aware of the CCM as terminology but they are also undertaking the activities inherent in the practice during their day-to-day construction exercise.

Table 9: Test of significance on the activities inherent in CCM practices

	Profession	Group	Mean
Chi-square	9.741	Quantity Surveyors	4.17
Df	2	Architects	10.83
Asymp. Sig	0.008	Structural/ Civil Engineers	13.50

From table 9, Kruskal Wallis test carried out shows that the p value is < 0.05, being 0.008, then null hypothesis which says that there is no significant agreement in the opinions of the respondents, is rejected and the alternate hypothesis is accepted that there is statistically significant agreement in the opinions of the respondents on the practice of activities inherent in the construction change management practices. The implication of this is that the respondents have convergent views and not only are the respondents aware of the terminology but actually practicing it in their day-to-day construction works.

Table 10: Challenges facing construction change management practices

Challenges	Mean	Rank
Resistance to change current practice and adopt new approach	3.78	1
Lack of organizing training/ seminars due to insufficient resources	3.78	1
Unwillingness of professionals to share knowledge	3.76	3
Variation on nature of projects	3.72	4
Unavailability of change management unit	3.68	5
Unacceptability of new ideas by professionals	3.64	6
Insufficient time for after action review	3.60	7
Unavailability of time to exchange ideas	3.54	8
Inadequate encouragement as regard learning within the firm	3.48	9
Difficulty in transferring change management knowledge	4.47	10
Uniqueness associated with projects which makes knowledge gotten from a project a waste to other projects	3.45	11
Excessive time associated with construction change management	3.41	12
Unwillingness to learn by professionals	3.34	13
Too much workload preventing evaluation of previous work	3.32	14
Overbearing workload which prevents cross project learning	3.31	15

Of all the numerous significant challenges facing implementation of construction change management practices on projects, table 10 shows that resistance to change current practice and adopt new approach ranked 1st and tied with lack of organizing training / seminars due to insufficient resources (Mean Score = 3.78), this is closely followed by unwillingness of the

professionals to share knowledge and variation on the nature of projects that ranked **3rd** and **4th** with mean score values of **3.76** and **3.72** respectively.

Table 11: Test of significance on the challenges facing CCM practices

	Profession	Group	Mean
Chi-square	2.805	Quantity Surveyors	27.63
Df	2	Architects	20.77
Asymp. Sig	0.246	Structural/ Civil Engineers	20.60

Table 11 reveals that the respondents have divergent opinions on the challenges facing implementation of CCM on projects. The result of Kruskal-Wallis test carried out shows a low chi-square value of 2.805, P value is > 0.05 i.e. **0.246**, hence there is no significant agreement in the opinions of respondents on the challenges facing implementation and this may be due to the fact that each construction project is unique on its own, hence the challenges of one project may require management measure that is quite different from others.

DISCUSSION OF FINDINGS

State of construction change management practices

It is evident from the analysis carried out that construction practitioners (Quantity Surveyors, Architects and Structural/ Civil Engineers) are not only aware of the existence of construction change management practices in the industry but are also adopting the practice on construction projects. This is actually in support of Harrison (2012) and Hao et al. (2008) that need to consciously manage construction changes is now recognized as important practice to improving innovation, construction project performance and client's satisfaction. It is also evident from the analysis carried out that the respondents are significantly carrying out activities inherent in construction change management practices during the discharge of their professional obligation in relation to executing construction projects. Without prejudice, mention must be made that the level at which construction change management practices was adopted was found to be lower than its wide level of awareness. By extension, the implication of this is that the practice still suffers some challenges which is preventing its full adoption on projects.

Challenges facing construction change management practices

Adoption of construction change management practices on projects in its entirety still suffers challenges. Some out of the challenges that are impeding full adoption of construction change management practice and thereby making it lower in level than its awareness include resistance to change current practice and adopt a new approach, lack of organizing training/ seminars as a result of insufficient resources and unwillingness on the part of the experienced professionals to share their knowledge. All these are contrary to the findings that lingering factors are incomplete information, assumptions and the personal experience of the construction professionals, upon which decisions relating to the construction projects are based (Hao et al., 2008) culminated with little understanding of construction change management in practice. Despite the fact that all respondents differ on the challenges facing construction change management practice, yet all factors listed are significant challenges when analyzed.

CONCLUSIONS

The paper explored the state of the art on construction change management practices based on vertical tertiary educational building projects in Ondo state, Nigeria in a bit to enhancing the performance of these projects. Consequent to the forgoing analysis carried out, it can be inferred that;

i. the level of adoption of construction change management practices is significant on projects, yet it is lower than the rate at which construction practitioners are aware of the practice.
ii. resistance to change current practice for a new approach coupled with lack of training/ seminars as a result of insufficient resources are some of the challenges impeding full adoption of construction change management practices in its entirety among others.

RECOMMENDATIONS

In order to accomplish the purpose for which this research was carried out, bearing in mind the magnitude of fund committed into construction projects, the following recommendations are proposed for stakeholders in the construction industry so as to achieve hitch free construction process that ensure minimal construction changes;

i. construction practitioners are enjoined to fully adopt construction change management practices on projects in order to enhance construction performance.
ii. construction practitioners should be encouraged to undergo training; professional bodies should organize seminars for their members as this will change their orientation in order to adopt new approach for existing current practice of doing things.

ABSTRACT

This study provides evidence on the value capitalization effect of public infrastructure in Minna. It employs rental transactions and datasets constructed from various secondary sources to provide information on geometric and spatial distribution of 4 groups of public infrastructure. Due to aggregation bias in these data sets, we utilize the quartile procedure to construct aggregate indices which capture the effect of the different infrastructure stock component but not infrastructure quality. The quartiles were used to compute location quotients for 12 a priori neighbourhoods, hence providing the basis for grouping and classifying neighbourhoods into low and high infrastructure neighbourhoods. A tenable statistical justification for this neighbourhood split by infrastructure is the Hodges-Lehman point estimate of shift (Δ) at 95.89 confidence level which is (−3.234,−11.072,−0.339) which revealed that the two classified neighbourhoods (low and high) are different . Findings revealed that geometric and spatial distribution of infrastructure is reasonably uneven across the study area. In addition, marked variability exists in quality of infrastructure between low and high-infrastructure neighbourhoods based on respondents' perceptual rating. The conjecture that high-infrastructure neighbourhoods have higher residential property values in contrast with that associated with low-infrastructure neighbourhoods was also found to be plausible. The capitalization effect of public infrastructure is evident in a falling market: high-infrastructure neighbourhoods significantly outperformed low-infrastructure neighbourhoods by N 14470, while in period of soaring property value, high-infrastructure neighbourhoods command N 57305.60 more than the low-infrastructure neighbourhoods. These findings have substantial implications for optimal location of public infrastructure and its capitalization into urban residential property value. To maximize this capitalization effect, policy makers and planners must efficiently allocate public infrastructure across space.

Keywords: Infrastructure Stock, Location Quotient, Neighbourhoods, Property Values, Rents

INTRODUCTION

Public goods such as infrastructure are location-specific and by extension not easily traded across space (Venables, 2009). Against this backdrop, infrastructure has continued to be spatially but disproportionately distributed. Beyond that, urban bias and primate city favouritism due to policy distortions (Henderson and Becker, 2000; Henderson, 2002a, Henderson, 2002b; Saiz, 2006) have further resulted in highly unbalanced infrastructure distribution and quality between urban centres and even within urban neighbourhoods. Majority of research in public economics has however long recognized the connection between public infrastructure investment and economic development. For example, the adequacy of Infrastructure affects quality of life, confers agglomeration benefits and impact on a nation's productivity outcomes and economic competitiveness (See, Röller and Waverman, 2001; Ling and Archer, 2005; Dechant and Finkenzeller, 2013). Globally, infrastructure requirements have been estimated at US$3 trillion per annum, with countries only able to meet one-third (US$1 trillion) of this sum in terms of current spending on infrastructure investment (OECD, 2010; UNCTAD, 2014). Various estimates (AFD and World Bank, 2010; UNDP, 2014) have however shown that, in contrast to the rest of the world, Africa currently has the largest infrastructure deficiency; and would need to invest between US$90-$120 billion annually until 2025 to fill this infrastructure gap. In sub-sahara Africa, expansion of infrastructure stock raises growth rate by 1.20% on annual basis, though reverse causation of infrastructure deterioration concurrently reduces annual net contribution

Ayoola, A. B.; Ojetunde, I.; Kemiki, O. A. & Popoola, N. (2016). An Assessment of the Impact of Public Infrastructure on Residential Property Values in Minna. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 636-649

to growth rates by 0.50% per year (Calderon and Serven, 2008). Nigeria a country within the sub-sahara region of Africa is not without its fair share of the problem.

Over a long term, passive commitment of public sector to infrastructure investment in Nigeria has precipitated a sharp decline in infrastructure growth in the economy. Further accentuation of this decline is the decrepit condition and benign neglect of existing urban infrastructure (Rioja 2003; Kalaitzidakis and Kalyvitis 2004; Banerjee et al. 2007) with such situations further deteriorating the insalubrious living and housing conditions in most urban centres. Infrastructure however is easily capitalized into house prices. This capitalization phenomenon according to Brueckner (2011) comes from a compensating differential such that increased property value is the resultant effect of urban infrastructure in urban areas where they are adequately provided and efficiently managed.

Against this background, we provide evidence in this paper of the residential property value impact of infrastructure stock and quality in Minna, North-Central Nigeria. In passing, we provide explanations for four (4) fundamental research questions: Is there inequality in the distribution of infrastructure stock across neighbourhoods? Suppose the presence of inequality, can neighbourhoods be classified into low-infrastructure neighbourhoods and high-infrastructure neighbourhoods? Perceptually, does infrastructure quality vary between low and high-infrastructure neighbourhoods based on residents' opinion? How do residential property values differ between high-infrastructure neighbourhoods and low- infrastructure neighbourhoods? Prior studies which used data on stock and quality of infrastructure have employed either principal component analysis (Calderon and Serven, 2004; Calderon and Serven, 2008; Seneviratne and Sun, 2013) or quartile approach (Hulten, 1996; Chong and Calderon, 2001) to construct aggregate indices which capture the effect of such infrastructure. Our paper utilize the quartile approach proposed by Hulten (1996) for only infrastructure stock component, due to paucity of robust data on infrastructure quality. This quartile approach avoids any aggregation bias and non-linear problem as it allows aggregate index to be constructed from data of different infrastructure. Previous studies in this area (Van de Walle, 2002; Duflo and Pande, 2007; Gonzalez-Navarro and Quintana-Domeque, 2010) have shown that selection bias may arise in infrastructure placement, as simple comparison of places with and without infrastructure in observational data might be misleading. Unlike those prior studies, we adopt a simple but intuitively plausible approach by employing location quotient to group and classify infrastructure into high-infrastructure neighbourhoods and low-infrastructure neighbourhoods. The Wilcoxon-Manny-Whitney rank sum test for inequality of samples is then used to compare whether the two groups of neighbourhoods are different. With this result we further conjecture that the distribution of residential property values should vary between high-infrastructure and low- infrastructure neighbourhoods.

LITERATURE REVIEW

Determinants of Urban Location and Property Values

A starting point in assessing the residential property value impact of public infrastructure is the theoretical construct of some underlying theories of urban dynamics. Central to theoretical discussions on location of urban infrastructure is the development of urban residential location choice theory. A useful insight into urban location theory, for instance, was the integration by Hurd in 1903 of Von Thunen theory of agricultural land use with the theory of land rent as formulated by David Ricardo for the analysis urban location activities. The highpoint of Hurd (1903) work was the application of the theory of economic competition to provide explanation for spatial variation in land value across urban landscape. Hypothetically, Hurd surmised that "since value depends on economic rent, and rent on location and location on convenience(infrastructure), and convenience on nearness.....by eliminating the

intermediate steps it can be concluded that value depends on infrastructure and nearness'' Given the assumption of market equilibrium, the optimal location of individual enterprise lies where the net profit is greatest (Losch, 1954). Intuitively, this implies therefore that location is the engine that drives real estate activities and values.

An understanding of the central role of neighbourhood location preference for public infrastructure comes from space-access (bid-rent) theory as postulation by Alonso. The standard access-space model formulated by Alonso (1964) for the analysis of urban land and property markets posits that housing and accessibility are jointly purchased and that it is only abstracting location specific activities, that households would lower their bid price for housing as commuting cost increases from the city centre. A simple modification of the standard access-space model to incorporate infrastructure is to define neighbourhood as the immediate area at any given distance to the centre (Straszheim, 1987). Suppose public infrastructure is exogenous at all locations and available without any charge, the hypothesis that rent gradients decline away from the centre may no longer hold. In such case, the utility function yields equilibrium rents, such that households are indifferent to locations. With better public infrastructure at more distant locations, the infrastructure effect may exceed the cost of friction and by extension the land rent gradient will be positive. This implies that urban residents may value distant locations with better infrastructure higher inspite higher commuting costs. The variation in rents and prices for such sites relative to similar sites is offset by the compensating differential in infrastructure.

A large theoretical body of hedonic literature on residential property market has pointed to the determinants of house prices. Several empirical contributions from this literature are deeply rooted in Rosen (1974) work. Studies by Can (1992), Basu and Thibodeau, (1998) and Paetz et al. (2008) suggest that house price is a function of packages of structural (dwelling size and age), neighbourhood and location (accessibility to service and other attractive points) neighbourhood (public utilities, sea view and school quality) attributes of the dwelling. However, quality location and neighbourhood amenities as aptly indicated by Tse (2002) induce better quality properties to be constructed and contribute to variation in price. The relationship between house price and location factors is the result of unobservable variation in shared infrastructure across properties. In his study, Tse further argued that house prices tend to be spatially autocorrelated because neighbourhood residential properties share public infrastructure and amenities. Such neighbourhood effects will be capitalised into the nearby house price in the house price determination process (Can, 1992; Goodman and Thibodeau, 1998; Kestens et al. 2006; Tu et al., 2007; Paetz et al., 2008).

Conceptual Issues in Public Infrastructure

Infrastructure has been variously defined as the collection of social, economic and physical facilities necessary for productivity and well being of economic units (governments, firms and individuals) of a nation (American Heritage Dictionary Editors, 2000; Nubi, 2002). According to Jerome (2006) infrastructure includes all public services as varied as education and public health to transportation, communication, power and water supply, as well as such agricultural overheads in irrigation and drainage systems. Against the background of this inexhaustible list, infrastructure has been classified under different thematic areas. For instance, unlike Obateru (2005) who grouped infrastructure into physical and social infrastructure, RREEF (2005) and Jerome (2006) classified infrastructure purely into economic (utilities, airports, power stations and pipelines) and social (healthcare facilities, education facilities and correction facilities) components.

In view of the fact that infrastructure is a congestible and non-excludable capital good that produces services for its users (Laan et al., 2000) public involvement in urban infrastructure

provision and management becomes a necessity. In theory, the need for public sector regulation in infrastructure provision is due to the divergence between marginal social benefit and marginal social cost of infrastructure which must not be dictated wholly by the market (Canning, 2006). In the past, governments have employed a traditional approach to infrastructure development by promoting public sector infrastructure monopolies. With this approach, urban infrastructure development has not kept pace with urban population, resulting in infrastructure deficits in most urban settlements (Yan, 2000 and Fay, 2005). Consequently, governments' decision to cut expenditure on public infrastructure in recent times and engage in control of critical infrastructure through variants of privatization schemes has been termed as the contemporary approach to infrastructure development (Canadian Union of Public Employees, 2004).

In spite, the attended level of involvement of government, it is clear that satisfactory solutions have not been found to the deficit of infrastructure services as the governance of infrastructure service features high on the agenda policymakers and economists (Laan et al, 2000). In Nigeria and other developing countries, infrastructure provision and quality have remained a major challenge as a result of government's poor financing and insufficient political will to pull private participation (Otegbulu, 2014). In quest for solution, user groups, workers and the general public have been agitating for renewal and re-investment as public infrastructure crumbles. Most studies have therefore unearthed how communities have been renewing and or improving the dearth and decaying situation of public infrastructure. Jack and Morris (2005) for instance have stressed the concept of community-based networks or organisations; depicting how communities have organized themselves and developed capacity to tackle the complex issues of housing and infrastructure.

METHODOLOGY

The analysis in this study draws on various data sources from Minna Urban. The first is the Niger State Primary Health Care Development Agency, which provides a comprehensive list of public health facilities (hospitals, maternity clinics, primary health care centres and dispensary) and their spread across Local Government Areas (LGAs), political wards and neighbourhoods. The data comprise a sample of 16 health facilities currently owned and managed by the government in Minna. Secondly, Niger State Universal Basic Education Board records data on student enrolment by gender and the number of public primary and secondary schools in Niger State. From this record, an aggregation of 16 primary schools located within the study area was extracted. The data from Parks and Gardens Department of Ministry of Environment and Abuja Electricity Distribution Plc comprise a respective sample of 5 recreation centres and 142 electricity step-down transformers, geographically located across different neighbourhoods. Generally, the data constructed from these sources provide information on geometric and spatial distribution of 4 groups of public infrastructure: primary schools, health facilities, fire service stations and electricity transformers (proxy for electricity distribution capacity) in this study. Finally these datasets, which are mainly secondary in nature, were augmented with 2006 neighbourhood population and household data from National Population Commission. Projection at an annual growth rate of 3.80% (NPC, 2006) was subsequently made for the 9 year time lag covering 2006 to 2015.

Aside the secondary data, a survey based technique involving a designed 11 item structured questionnaire, was employed to obtain primary data on infrastructure quality from household heads (respondents) who are renters in the study area. By adopting cluster random sampling, the study area (consisting of 12 neighbourhoods) for the questionnaire administration was drawn from the *a priori* 25 neighbourhoods in Minna Urban. The selected 12 *a priori* neighbourhoods comprise: Bosso Estate, Tunga Low Cost, Barkin Saleh, Jikpan, GRA,

Limawa, Minna Central, Shango, Tudun Wada South, Agwandaji and Dutsekura. The choice of these neighbourhoods for the study was further premised on the availability of robust data on public infrastructure stock in the Minna Urban. The number of questionnaire to be administered was based on 33871 households in the study area as at 2015. 3372 (10.99%) households were initially drawn from the total households in Minna in 2015. Of these, 1 out of every single household of 5 persons (NPC, 2006) is a household head. In passing, 745 household heads represent the active sample size in the study area.

Subsequently, we controlled for bias in the sample size and concluded that we are 95% confident that this estimate from the total population will be ±10.99% the margin of error (in this case, between 6.99% and 14.99% for a 4% margin of error). However, only 463 of the administered questionnaire were retrieved from the 745 household heads. This proportion of questionnaire retrieved gives an approximate total response rate of 62%. This response rate concurred with those reported by Willimack et al. (2002) for primary data collection. Table 1 shows the breakdown of the questionnaire administered, retrieved and the response rate.

The resulting survey, in addition to sourcing data on rental transactions (proxy for house price) for different residential property types (tenement, bungalow, flat and duplex) as well as demographic characteristics of the respondents, provided a perceptual rating of infrastructural quality in their immediate neighbourhoods. Respondents were requested to rate quality on a 5 point scale (with very poor assigned a score of 1; poor rated as 2; fair as 3; good as 4 and very good rated as 5). Table 2 provides a summary statistics which describe the characteristics of these 643 respondents for the study.

Table 1: Questionnaire Distribution to Household heads in the Study Area

S/No	Neighbourhoods	Household size (2015)	Sample size	Proportion of Household Heads	Questionnaire Retrieved	Response Rate (%)
1	Bosso Estate	447	207	42	42	100
2	Shango	747	254	51	38	74.80

11	Minna Central	6,560	353	71	46	65.16
12	Tundun Fulani	2,609	335	67	43	64.18
	TOTAL	**33871**	**3372**	**745**	**643**	**62.18**

A starting point in the methodology employed for data analysis in this paper involves the estimation of location quotients on neighbourhood basis for the 4 groups of infrastructure stock. Location Quotient (LQ) is a quantitative measure of the relative allocation or the degree of concentration of a particular activity in a city and in a region as a whole. An infrastructure's LQ for neighbourhood i is given as:

$$LQ_i = \frac{Q_i}{Q_a} / \frac{Pi}{P} \qquad (1)$$

Where Q_i is the quantity of infrastructure in neighbourhood i

Q_a is the total quantity of infrastructure in all neighbourhoods

P_i is the population in neighbourhood in i

P is the total population in all neighbourhoods

A $LQ > 1$ indicates that the local area is more heavily concentrated in that activity relative to its average across region. If $LQ = 1$, it means that the local area has its faire share in a

particular activity. Although Morenikeji (1995) is one of the few authors in Nigeria, who have empirically demonstrated its application in the study of spatial distribution of social facilities, location quotient has been applied elsewhere in most regional economic base studies (See, Richardson, 1985; Brown et al., 1992; Coulson, 2006).

Before estimating the location quotients, we observe non-linearity and aggregation bias across the measures of infrastructure stock and dealt with this problem by grouping individual measure separately into quartiles. The 1st quartile is ranked 0.25, the 2nd quartile, 0.50 while the 3rd and 4th quartile is ranked 0.75 and 1.00 respectively. With these quartiles, we compute the neighbourhood location quotients for each of the 4 groups of infrastructure stock. In addition, the aggregate index of all infrastructure for a neighborhood is determined by simply averaging the location quotients. This quartile procedure is identical to that employed in Hulten (1996) study, which allows aggregate index to be constructed from data of different infrastructure.

Table 2: Descriptive Summary of Demographic and Socio-Economic Characteristics of Respondents

Variables	Variable Type	Mean	Standard Deviation
PANEL A (Continuous Variable)

Furthermore, it is plausible to estimate the infrastructure share of neighbourhood i that is excessive (E), since that is the only part of the infrastructure that brings the quotient above 1. This can be expressed as:

$$E = LQ - 1/LQ \qquad (2)$$

Following the logic of the LQ in equation 2, we classify and group the 12 neighbourhoods into low-infrastructure neighbourhoods and high-infrastructure neighbourhoods. With this, we explore further the possibility of whether the neighbourhoods so classified are different because they have different location quotient patterns or that such observed differences are due to random sampling errors in our observations. The Wilcoxon- Mann-Whitney statistic tests the null hypothesis that the shift in location between the distributions of the populations is equal to zero. In other words, do the classified low and high infrastructure neighbourhoods come from population having identical distribution? A rejection of the null hypothesis would suggest that neighborhoods classified as low-infrastructure neighborhoods have more in common with one another relative to those classified as high-infrastructure neighborhoods.

On the basis of this classification, we examine the conjecture that infrastructure quality should vary between low and high-infrastructure neighbourhoods across the study area. Taking a cue from previous studies by Galster and Hesser (1981) and Ame'rigo (2002) that place users satisfaction at the heart of evaluation of quality of urban environment, respondents were asked to respond on the perceptual quality of their respective neighbourhood infrastructure using a five point likert scale ranging from 1 (very poor) to 5(very good). The frequency of responses for the classified low and high-infrastructure neighbourhoods were then weighted for each infrastructure to arrive at the composite(sum) quality score and subsequently, the weighted mean quality score for each infrastructure. Chi-square (χ^2) test was used to determine the relationship between respondents' responses on infrastructural quality across the classified neighbourhoods.

Finally, we applied one-way Analysis of Variance (ANOVA) with post-hoc comparison to test our expectation that high-infrastructure neighbourhoods are associated with higher house prices (proxy by house rents) than that associated with low-infrastructure neighbourhoods. As homogeneity of variance is one of the stringent assumptions underlying ANOVA, we hypothesized that the population variance for house prices would not hold due to the heterogeneity of the property type employed for the analysis. Brown-Forsythe's test for equality of group variance was therefore conducted to determine whether the house price mean for the classified neighbourhoods are approximately equal. On this basis, we applied Dunnett two tailed t-test to examine the individual comparison in residential property values between high and low-infrastructure neighbourhoods after conducting a standard analysis of variance test.

All analyses were estimated using Analyse-it version 4.20 and SPSS version 20 statistical packages.

FINDINGS AND DISCUSSIONS

Neighbourhood Location Quotients of Infrastructure Stock

The results of location quotients for all the 12 neighbourhoods arranged by infrastructure stock are shown in Table 3. These location quotient patterns have spatial manifestations. The first striking observation is that at a disaggregated level, the wide disparity in location quotients for the 4 groups of infrastructure across neighbourhoods did suggest a close relationship between infrastructure allocation and neighbourhood population. Unlike high-populated neighbourhoods, high location quotients are associated with low- populated neighbourhoods. For instance, with regards to the allocation of primary school, Bosso Estate (4.20), Agwandaji (12.01) and Tudun Fulani (16.81) which are less populated exhibit similar quotient pattern compared to densely populated neighbourhoods like Tunga Lowcost (0.38), Barkin Saleh (0.84), Jikpan (0.74) and Minna Central (0.25). Apparently, the geometric and spatial distribution of infrastructure is reasonably uneven across the study area with severe implications for sustainable urban growth. Unplanned residential location patterns,

decentralised urban density and sporadic urban development are some of the spatial dimension to inequality issue in infrastructure distribution

Table 3: Neighbourhoods' Location Quotients for Infrastructure Stock in the Study Area

S/N	Neighbourhoods	Population	Primary School	Health Facilities	Fire Service Station	Electricity Supply	Mean LQ	(E)	Classification
1	Bosso Estate	816	4.20	5.40	16.81	4.54	7.74	0.87	High
2	Tunga Lowcost	9084	0.38	0.97	0.38	1.22	0.74	-0.36	Low
3	Barkin Saleh	8200	0.84	0.54	0.42	0.45	0.56	-0.78	Low
4	Jikpan	9238	0.74	1.43	0.37	1.20	0.94	-0.07	Low
5	GRA	5979	1.15	0.74	0.57	1.24	0.92	-0.08	Low
6	Limawa	5979	1.15	1.47	0.57	1.86	1.26	0.21	High
7	Minna Central	27272	0.25	0.16	0.50	0.41	0.33	-2.02	Low
8	Sango	9084	0.75	1.94	1.51	0.41	1.15	0.13	High
9	Tudun wada south	5979	1.15	1.47	0.57	0.62	0.95	-0.05	Low
10	Agwadaji	856	12.01	5.15	4.00	4.32	6.37	0.84	High
11	Dutsen Kura	9238	1.48	0.95	1.48	1.60	1.38	0.28	High
12	Tundun Fulani	816	16.81	5.40	16.81	9.08	12.03	0.92	High

Secondly, at an aggregated index level, the LQ patterns (third to the last column in Table 3) are nearly identical to the disaggregation. From this, the difference between neighbourhoods with over-concentration and those with less than fair share of infrastructure is straightforward to discern. With this bifurcation, neighbourhoods such as Bosso Estate, Limawa, Sango, Agwandaji, Dutsenkura and Tudun Fulani are tentatively classified as high-infrastructure neighbourhoods. Conversely, Tunga Low Cost, Barkin Saleh, Jikpan, GRA, Minna Central and Tundun Wada South are grouped as low-infrastructure neighbourhoods.

Table 4: Wilcoxon/Manny-Whitney Test of Equality of Means for Location Quotient of Low and High Infrastructure Neighbourhoods

Neighbourhoods	Wilcoxon Statistic	Hodges-Lehman Point Shift	P-Value
Low-High	21.000	-3.234 95.89CL (-11.072 to -0.339)	0.0022

The actual sign of the excess (E) as seen in the second to the last column in Table 3 further provides a tentative support for the classification of neighbourhoods by quotient patterns. However, the results of the Wilcoxon- Mann-Whitney test in Table 4 provide a consistent justification for this neighbourhood split by infrastructure. The Wilcoxon-Mann-Whitney statistic (21.000) with correction for ties indicates that the distributions of location quotients are statistically different between low and high infrastructure neighbourhoods at 5% significance level (P value < 0.05). Since the null hypothesis that the shift in location between the distributions of the populations is equal to zero (H_0: $\Delta = 0$) has been rejected, we extend the Wilcoxon- Mann-Whitney test by estimating the Hodges-Lehman point estimate of shift (Δ median $_{Low}$ - Δ median $_{high}$) to determine the direction and magnitude of such difference. The Hodges-Lehman point estimate of shift (Δ) at 95.89 confidence level which is (−3.234,−11.072,−0.339) further reveals that the median location quotient for low-infrastructure neighbourhoods is stochastically lower than those of high-infrastructure neighbourhoods. Implicitly, the result implies that significant difference in location quotients exist between the two classified neighbourhoods, and by extension, low infrastructure neighbourhoods appears to have considerably low location quotients. This portrays that the two classified neighbourhoods (low and high) are different and therefore their observed LQ differences are not due to any unsystematic oddity in the data. This result sets the stage for the analysis of infrastructure quality as provided in Table 5.

Infrastructure Quality for Classified Low and High-Infrastructure Neighbourhoods

Table 5 shows the frequency of responses on infrastructure quality by neighbourhood class. Aside the evident high response (ranging from 96.33% to 99.57%) in opinion of the 463 respondents, the preponderance of respondents' responses on infrastructure quality oscillate between poor, fair and good perceptual rating.

Table 5: Frequency of Responses on Quality of Infrastructure in Low and High Infrastructure Neighbourhoods

Quality	Very Poor	Poor	Fair	Good	Very Good	Valid Responses	Percentage of Responses
				N=463			
Electricity:							
Low	39	56	95	37	5	232	50.11

With these divergent rating in responses, the weighted means imputed from respondents weighted responses for the classified low and high-infrastructure neighbourhoods, however provide a clear-cut interpretation of respondents' opinion on infrastructure quality as seen in Table 6.

Table 6: Relatedness of Opinion on Quality between Low and High Infrastructure Neighbourhoods

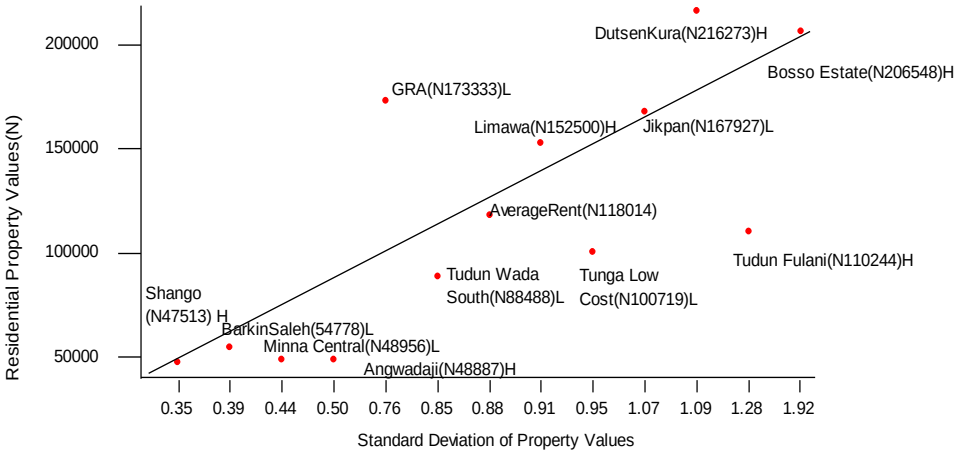
* The weighted responses are derived from the frequency of responses (with very poor assigned a score of 1; poor rated as 2; fair as 3; good as 4 and very good rated as 5).

A cursory look at the weighted mean of respondents' opinion apparently indicates marked variability in quality of infrastructure between low and high-infrastructure neighbourhoods. For instance, while relatively large weighted mean values are confirmed in high-infrastructure

neighbourhoods, all of the weighted means observed in low-infrastructure neighbourhoods are much smaller. We explore whether consensus ratings of these infrastructure as depict by weighted means of the classified neighbourhoods are related in terms of the frequency of responses from the respondents. As evident from Table 6, the reported chi-square (χ^2) values of 15.74, 20.89, 26.92 and 20.92 for electricity supply, fire service, health facilities and primary school have corresponding p-values of 0.733, 0.699, 0.360 and 0.182. Since the p-values in all cases exceed the 5% rejection level, we confidently conclude that there are no significant differences in the respondents' opinion towards infrastructure quality and that respondents in the classified neighbourhoods are largely decided on this issue. Against this background, it can be concluded that infrastructure quality vary between low and high-infrastructure neighbourhoods based on residents percept in Minna.

Distribution and Variability in Residential Property Values for Classified Neighbourhoods

The historical performance of residential property values relative to the average rent and standard deviation across the 12 neighbourhoods is graphically presented in Fig. 1. During 2015 period, property values in 5 residential neighbourhoods (GRA, Limawa, Dutsenkura, Jikpan and Bosso Estate) outperformed the average residential property value (rent) in the 12 neighbourhoods. On the other hand, the average residential property value (₦118014) for all neighbourhoods is far more than the average returns for Shango (₦ 47513), BarkinSaleh (₦ 54778), Minna Central(₦ 48956), Angwadaji (₦ 48887), Tudun Wada South(₦ 88488), Tunga Low Cost(₦ 100719) and Tudun Fulani(₦ 110244).



*Property Values are presented in parenthesis. While L and H signify Low and High-Infrastructure Neighbourhoods

Fig.1: Distribution of Residential Property Values, 2015

Apparently, while residential property values in Shango, Barkin Saleh, Minna Central and Agwadaji are low and subdued, property returns in GRA, Limawa, Jikpan, DutsenKura and Bosso Estate are relatively high and exhibit much more pronounced volatility. This disparity however did not suggest any general pattern or close relationship between property value levels in low and high-infrastructure neighbourhoods. Furthermore, these general observations on property value performance are overly simplistic but can however be given some less hypothetical explanation by employing an empirical test for variability in residential property value across the study area.

The significance of the variability level in property values between the classified low and high-infrastructure neighbourhoods is tested by one-way Analysis of Variance (ANOVA). However, before turning to the ANOVA result, the Brown-Forsythe robust test for null hypothesis of equality of variance shows that the assumption of homogeneity of variance has

been grossly violated. This implies that residential property values for the classified low and high-infrastructure neighbourhoods do not have identical population variance as the F-test statistic of 5.79 is greater when compared with a 5%, F(11,440).

The ANOVA result for variation in residential property values is shown in Table 7. Since the F-statistic of 18.48 is highly significant at 5% level of significance, this implies that high-infrastructure neighbourhoods have higher residential property values in contrast with that associated with low-infrastructure neighbourhoods. The strength of this contrast can be observed from the confidence interval of the mean difference in residential property value. The mean difference in residential property value which is ₦ 35887.80 (95% CL: 14470 to 57305.60) indicates that the true mean difference is between the lower limit of ₦ 14470 and the upper limit of ₦ 57305.60. Suppose a falling residential property market, high-infrastructure neighbourhoods significantly outperformed low-infrastructure neighbourhoods by ₦ 14470 while in period of soaring property value, high-infrastructure neighbourhoods command ₦ 57305.60 more than the low-infrastructure neighbourhoods.

Table 7: Variation in Residential Property Values in Minna

Contrast	Mean Difference	F-Statistic	Simultaneous 95%CL	P-value
High - Low	35887.80	18.48	14470 to 57305.60	0.0011

Neighbourhoods with strikingly differences in mean property values are revealed by the Dunnett 3T post-hoc test for pairwise comparison of residential property values between high and low-infrastructure neighbourhoods in Table 8.

Table 8: Dunnett Two Tailed T- Test for Individual Comparison of Residential Property Values

High Infrastructure Neighbourhood (I)	Low Infrastructure Neighbourhood (J)	Mean Difference (I-J)	Sig.	95% Confidence Interval	
				Lower Bound	Upper Bound
Angwadaji	GRA	-133012.5*	.000	-199295	-66730
Angwadaji	Jikpan	-124197.87*	.000	-188148	-60248
Bosso Estate	Tudun Wada South	122479.09*	.021	9390	235569
Bosso Estate	Minna Central	156509.32*	.000	47678	265340
Bosso Estate	Barkin Saleh	151912.70*	.001	43455	260370
Shango	GRA	-132075.68*	.000	-196595	-67557
Shango	Jikpan	-123261.04*	.000	-185170	-61352
Dutsenkura	Tunga Low Cost	113656.25*	.000	35262	192050
Dutsenkura	Tudun Wada South	133996.95*	.000	69915	198078
Dutsenkura	Minna Central	168027.17*	.000	113000	223054
Dutsenkura	Barkin Saleh	163430.56*	.000	109227	217634

*Mean Difference is significant at 5% level of significance

Out of the 36 possible contrast cases between high and low infrastructure neighbourhoods, only 11 neighbourhoods showed marked significant differences in their residential property values. From the mean difference of the Dunnett 3T test (column 3) in Table 8, it is evident that property values in high-infrastructure neighbourhoods like Angwadaji and Shango vary from those passing in GRA and Jikpan- which are low infrastructure neighbourhoods. Similarly, property values for such high-infrastructure neighbourhoods like Bosso Estate and DutsenKura differ from low infrastructure neighbourhoods of Tudun Wada South, Minna Central and Barkin Saleh. Property value in Dutsen Kura is also markedly different from that of Tunga Low Cost- a low infrastructure neighbourhood. On the other hand, there are no significant variations in property returns for Limawa and Tudun Fulani when compared with all the 6 low-infrastructure neighbourhoods (Result of the non-significant cases is available from the authors upon request).

CONCLUSION

This study has provided evidence on the residential property value impact of infrastructure by employing location quotient to group and classify infrastructure into high-infrastructure neighbourhoods and low-infrastructure neighbourhoods. Infrastructure provision tends to be unequally distributed across the study area. On the basis of this bifurcation of neighbourhoods, perceptual rating of respondents' opinion equally showed marked variability in quality of infrastructure between low and high-infrastructure neighbourhoods. Relatively large weighted mean quality values for instance are associated with high-infrastructure neighbourhoods compared with low-infrastructure neighbourhoods. Furthermore, property values tend to differ between the classified neighbourhoods: high-infrastructure neighbourhoods have higher residential property values in contrast with that associated with low-infrastructure neighbourhoods. Interestingly, these findings have substantial implications for optimal location of public infrastructure and its capitalization into urban residential property value. It is possible to argue for the existence of capitalization effect of public infrastructure in the study area as renter households tend to exhibit the willing to pay (WTP) higher property values in neighbourhoods with high public infrastructure level than neighbourhoods with low level of infrastructure provision. Although there are exceptions to this capitalization effect across residential space, a tenable justification as aptly stated by Duranton and Puga (2004) is the inefficient sharing of indivisible facilities such as local infrastructure.

Claimants' Classification of Heads of Claims for Oil Spill Damage Assessment in Ondo State, Nigeria

Mustapha Oyewole Bello & Michael Ayodele Olukolajo

Department of Estate Management, Federal University of Technology Akure, Nigeria
maolukolajo@futa.edu.ng

ABSTRACT

Oil spillage is one of the major causes of environmental pollution and degradation in Nigeria; the impact of which is untold hardship on the residents as evident in substantial loss of means of livelihood. An important step towards awarding equitable compensation for oil spill damage is proper definition of 'heads of claim'. This study assessed the oil spill victims' definition of heads of claim based on Total Economic Value concept in Abereke community of Ilaje Local Government of Ondo State. Out of 368 questionnaires distributed, 247(64%) of the retrieved were found adequate for data analysis. This study employed Relative Impact Index (RII) – an example of descriptive statistics in analyzing data elicited from potential claimants. The results indicate that compensation for loss of fish harvest, other aquatic life, source of drinking water and food/crop production ranked high among the direct use of land and environmental resources. Flood control, biodiversity maintenance and shoreline protection are least among the potential head of claims among the private claimants. The study recommended among others that there is need to redefine heads of claim considered in awarding compensation to oil spill victims to mitigate the effect of oil spill on the claimants and promote peace in oil producing communities.

Keywords: Oil Spill, Compensation, Heads of claim, Claimants, Total Economic Value

INTRODUCTION

Oil exploration and production is an all-important activity in Nigeria upon which the economy of the country rests. Oil exploration in Nigeria dated back to 1938, when Shell D'Archy was granted an exploration license. Since then Nigeria shore has been subjected to various oil activities leading to the influx of many oil companies in the country. Crude oil was first discovered at Oloibiri by Shell British Petroleum (now Royal Dutch Shell); however, the oil exploration activities have spread out to cover nearly all states within Niger Delta Region (**NDR**) of the country. About 90% of Nigeria's foreign earnings are derived from sale of crude oil (Odularu 2008).

Much of the world depends on the production or the trade of oil to drive their economy (Fagbohun 2010). However, its exploration, production and transportation are not without associated mishaps. Prior to the influx of multinational oil companies in Nigeria, the inhabitants of oil rich areas (Niger Delta) depend largely on the ecosystem provisioning services of wetland (Adekola, 2011) for their livelihood; these have been eroded. Oil spills does not only impact negatively the physical but also psychosocial environment; as there is evidence of psychiatric disorder associated with oil spill (Palinkas, Petterson, Russel, & Downs, 1993). The impact of oil pollution include deforestation, ecosystem destruction and loss of pristine habitats, degradation and chemical contamination of land, air and water; long harm to flora and fauna, acute and chronic health problems for human beings; safety risks for host communities and oil industry workers and immediate to medium term threat to indigenous communities (Fagbohun 2010).

Oil spills when it leaves the place of its confinement to an undesired place, capable of causing harm or injury. A number of reasons have been adduced for oil spillage especially in NDR. These include corrosion of pipelines, corrosion of oil storage tanks, sabotage, equipment/machine failure, bunkering, loading/discharging error, oil theft/illegal fuel

Bello, M. O. & Olukolajo, M. O. (2016). Claimants' classification of Heads of Claims for Oil Spill Damage Assessment in Ondo State, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 650-659

siphoning as a result of the thriving black market for fuel products, spills due to engineering drills, human error, accident from third party, illegal refining, deliberate damage of oil installations during protests, natural causes such as rain and flood, well head blowout, refinery process, marine transportation accident and unknown causes (Aprioku, 1999; Onyepe, 2002; Nwilo, & Badejo, 2006; Nwilo & Badejo, 2008; Imosemi & Abagwu, 2013). The unknown categories of oil pollution is referred to as an act of God under Section 1001(1) of United States Oil Pollution Act 1990 which include any "unanticipated grave natural disaster or other natural phenomenon of an exceptional, inevitable, and irresistible character the effects of which could not have been prevented or avoided by the exercise of due care or foresight". Also oil spills can be natural seepage from ground.

A standard practice is that oil pollution victim is compensated for loss suffered especially when the polluter is identifiable. This is entrenched under the polluter pay principle (PPP) and in tandem with equity, justice and fairness. Bleeker (2009) based on judgments of the European Court of Justice stressed that the application of the PPP must be proportional; that is, a polluter can only be asked to bear the burden of paying for pollution based on the proportion of his contribution to it. For polluter to actually pay for damage caused in oil spill situation and to ensure a standard compensation practice, the first step in the process is to properly and objectively identify claims made by oil spill victims. Such items of claims are also referred to as heads of claim (HOC). In Nigeria, studies such as Nuhu (2008), Otegbulu (2009), Famuyiwa and Omirin (2011) and, Udo and Egbenta (2011) on compensation valuation indicate that the exercise is bedevilled with inadequacies. The definition of what constitute HOC has always been controversial subject especially between oil companies and claimant/claim agents in Nigeria. Babawale (2013) observed that the law relating to compensation for oil spillage in Nigeria leaves opened a number of crucial issues including the exact 'heads of claim' as well as the basis and the method of valuation applicable; all these to the discretion of valuers, and of course, the court, which is the final arbiter.

This study is an attempt to define what oil spill victims have in mind when heads of claims are being contemplated; a reflection of what they possibly consider as necessary to launch them back to pre-pollution state. Although compensation claimants may be private individuals, partnerships, companies, private organizations or public bodies, including states or local authorities (International Oil Pollution Compensation Fund, 1992), the scope of this study is limited to private claims only. Such claims exclude properties which no individual can lay personal claim on in term of ownership and are naturally considered as community claims and no individual has ownership right to the exclusion of others. The rest of this paper is structured as follows: the next (section two) reviewed relevant literature; Section three is the description of procedure for data collection and method of data analysis. The fourth section presents the results and discussion of findings form the research. Finally, the closing section contains the recommendation, statement on the policy implications of the study and conclusions.

LITERATURE REVIEW

The purpose of compensation is to restore an injured party to the previous position he was prior the act that caused harm or damage. The purpose is neither to make him richer nor poorer but the universal principle underlying valuation for compensation is to obtain a cash payment that would reasonably restore the claimant to status quo (Babawale, 2013). In general, the word "compensation" means balancing one action (or its effects) with another action. In relation to oil spill damage, Thébaud, Bailly, Hay, and Pérez, (2005). stressed that the primary reason for assessing the cost of oil spill in monetary term is at least to establish the level of compensation that would make the victims whole. Ibrahima (2006), classified

damage resulting from oil spills into four and these are personal or health damage, material damage, loss of profit or pure economic losses sustained consequent upon damage to the environment, and damage to the ecosystem and living components of the environment.

Dick (2006) posited that the underlying principle of compensation which is to restore claimants to the same financial position as they would have been without the oil spill, poses a great challenge to Natural Resources Damage (NRD) valuation, because there are no commercial transaction on them; and this has led to some groups resorting to a kind of abstract calculations yielding value which are not defensible. Although the purpose of compensation valuation is unambiguous, the extent of environmental damage resulting from oil spill may be difficult to extrapolate because of many factors that interact leading to different levels of damage. For instance, the type of oil spilt, the time of the year of occurrence, weather condition as well as the effectiveness of clean-up, all combine to determine its environmental consequence. Therefore, over-simplifying such a complex changing situation may lead to adoption of a formula which is neither scientific nor reflecting the true effect oil spill has on the people and environment. Dick (2006) warned that any attempt to attach monetary value to distorted image of reality will lead to injustices, inconsistencies and the impression that polluter is penalised rather than compensating damage caused.

In Nigeria, there appears to be no comprehensive legislation that addresses issues of compensation and liability for oil spill and environmental damage (Oluduro, 2012). Schopp and Pendergrass (2003) observed that a majority of the statutes and regulations in Nigeria do not confer any right of private action for the victims of oil pollution. Thus, claims have generally been brought as common law tort claims under the theories of negligence, nuisance, and strict liability. Apart from Oil Pipeline Act Cap 145, LFN, 1990 that contains direct provision relating to compensation arising from oil spillage, other statutes - Land Use Act (1978), Minerals Act Cap 121 of 1946, and Petroleum Act No. 51 of 1969 now Cap 350 LFN 1990, Mining Act No 24 of 1990, Oil in Navigational Water Act, Cap 337 LFN 1990- deal primarily with property acquisition rather than injurious affection (Imosemi & Abangwu, 2013). Otegbulu (2009) described the Nigerian legal framework for compensation as either not designed to capture the total economic value of the impaired interests, or misinterpreted by the practitioners. Kakulu, Byrne, and Viitanen (2009) argued that Nigeria Constitution does not allow a fair play in compensation assessment of non-market goods; while NOSDRA (2014) concluded that the Land Use Act was not designed for the oil industry at all. Apart from the application of Land Use Act in the valuation of structures on land, Valuers depend largely on a pre- determined rates commonly called the OPTS (Oil Producers Trade Section of Lagos State Chamber of Commerce and Industry) rates.

Babawale (2014) examined the contents of compensation valuation reports prepared by Nigerian valuers and highlighted the reported heads of claim to include injurious affection, ecological degradation, health hazards, loss of fishing rights, loss/damage of fishing of trap/ponds/hooks, loss of shrine, and general claims. Although, this study regarded some of the claims as frivolous, lack adequate and convincing explanatory data, they are indeed a reflection of pains that victim of oil spill suffer in Nigeria. Akujuru and Ruddock (2014) opined that heads of claims for compensation purpose should incorporate socio-cultural values especially in oil producing communities of Niger Delta Region (NDR), Nigeria. The losses suffered by these communities included desecration of shrine or traditional worship sites, contamination of fish ponds and fishing channels, contamination of the mangrove forest resulting in the loss of mangrove and other economic trees, non-timber forest resources like crabs, periwinkles, crayfish and other seafoods which are usually gathered freely from the mangrove vegetation, and contamination of water sources and fishing gear.

Studies such as Akujuru (2005), Otegbulu (2005), Udo and Egbenta (2011), Ajibola (2012), Akujuru and Ruddock (2014), among others advocated for the application of Total Economic Value (TEV) framework as the basis of determining compensation payable for wetlands degradation and oil spill damage assessment. Total Economic Value (TEV) comprises both use values (direct and indirect use) and non-use values (Option, bequest and existence values) (Dixon, 2008). Grafton, Pendleton and Nelson (2002) broke TEV of an environmental goods and services into those values which people can exploit through direct use of the resource (called use values) and those that consumers do not put into direct use (non-use or passive use values). Based on TEV concept attempts have been made by scholars to classify various attributes and services of wetland that are germane to the wellbeing of the local communities especially in Niger Delta region of Nigeria. For example Adekola and Mitchel (2011) compiled the beneficial attributes of wetland to Niger delta communities as shown in Table 1.

Table 1: Major ecosystem services provided by or derived from Niger Delta wetlands

General Ecosystem Services	Niger Delta Ecosystem Services
Provisioning	
Food	Fish and other aquatic food such as barnacles, crabs and other invertebrates (Nwadiaro 1984; Fentiman 1996; Davies *et al*. 2009)
Fresh water	Agricultural and tree crops: cassava, yam, cocoyam, rice, maize, ogbono, cocoa, etc. (World Bank 1995; Umoh 2008; Omofonmwan, & Odia 2009)
Fibre and fuel	Timber products: saw logs, transmission poles, bamboo, building poles, fuelwood and chewing sticks (World Bank 1995; NDDC 2006; Alogoa 2005; McGinley 2008)
Biochemical	Aquatic insects (Arimoro, & Ikomi 2009)
Genetic materials	Medicinal species (Ndukwu, & Ben-Nwadibia (2005)
Other products	Bush meat (Luiselli 2003; Luiselli *et al*. 2006)
	Other products including raffia, snail, spices, mangrove salts, reeds and sedge (World Bank 1995; UNDP 2006)
Regulatory	
Climate regulation	Provides a good sink for greenhouse gases of CO_2 and CH_4 (Brooks *et al*. 2000)
Water regulation (hydrological flows)	Provides buffer against natural disaster including coastal erosion and regulates flood (Cugusi, & Piccarozzi 2009; Sanford 2009)
Water purification and waste treatment	Regulates water movement, quality and volume (Abam 2001; Uluocha, & Okeke 2004)
Erosion regulation	Habitat for pollinators (Dupont *et al*. 2000)
Natural hazard regulation	Natural attenuation (Benka-Coker, & Ekundayo 1995; Abu, & Dike 2008)
Pollination	
Salinity control	
Cultural	
Spiritual and inspirational	Source of spiritual inspiration (Isichei 1982)
Recreational and tourism	Site for fishing festivals (Jonathan 2006)
Aesthetic	Spiritual and sacred sites (Anderson, & Peek 2002; Bisina 2006)
Educational	Vast biodiversity (indicative of tourism) (World Bank 1995; Ebeku 2004)
Supporting	
Soil formation	Supports delta's biodiversity (Ejechi 2003)
Nutrient cycling	Soils support nitrogen mineralization (Iwegbue *et al*. 2006)
	Supports transportation (inland ports) that link places (Wolf *et al*. 2002; NDDC 2006; Egbagbe 2009)

Adapted from Adekola (2011)

METHODOLOGY

Ondo state is one of the oil producing states in Niger Delta Region of Nigeria. The oil production activities are particularly found in Abereke, Ilaje Local Government Area of the State (Department of Research and Statistics, 2010). Data used for this study was elicited from residents of Abereke – an oil rich community with an estimated population of 17,500 residents based on community records. A sample of 392 was selected following Israel (2013)

equation used for determining a representative sample proportion when dealing with large population. The study achieved 64% response rate (i.e. 247 retrieved questionnaire) and found the retrieved questionnaire useful for data analysis. Respondents were asked to rank the importance of various components of TEV based claims which they considered relevant to determining fair compensation payable to private claimants in event of oil spill damage using a five-point. Likert scale.

The relevance of each of the feature of wetland was examined and ranking of the nature of injury suffered during oil spill was carried out by use of Relative Importance Index (RII). RII was computed using equation (1) as follows:

$$\sum_{i=1}^{5} W_i X_i / \sum_{i=1}^{5} X_i \quad (1 \leq RII \leq 5) \tag{1}$$

Where:

W = the weight assigned to each factor by the respondents. This ranges from 1to 5 (i.e. where "5" means "extremely important" and "1" means "Not Relevant")

Xi = the number of respondents with the i^{th} rating of which i ranges from 1 - 5

FINDINGS AND DISCUSSIONS

Demographic Characteristics of Respondents

Data obtained on respondents' characteristics as shown in table 2 indicate that the male constituted 64% of the respondents while the female gender is 36%. The respondents' age distributions indicate that 98% are above age 20, and have lived in the community for nothing less than 10 years minimum. Apart from about 11% who are engaged in civil service, other respondents are self-employed in farming, fishing, trading and other businesses. Out of these, crop and fish farming constitute 60.8%.

Table 2 Respondents Characteristics

Category	Classification	Frequency	Percentage
Sex of respondent.	Male	158	64.0
	Female	89	36.0
	Total	**247**	**100**
Age of Respondents	20 years & Below	5	2.0
	21 - 29	41	16.6
	31 - 40	53	21.5
	41 - 50	75	30.4
	51 - 60	32	13.0
	Above 60 years	41	16.6
	Total	**247**	**100**
Number of years already spent in the Community	Below 10 years	6	2.4
	10 – 20 years	32	13.0
	21 – 30 years	38	15.4
	31 – 40 years	71	28.7
	41 – 50 years	49	19.8
	51 – 60 years	44	17.8
	Above 60	7	2.8

	Others	14	5.7
	Total	**247**	**100**

Ranking of Total Economic Value based Heads of Claim by Oil Producing Community Residents

Residents of the oil producing communities as potential victims of oil spill damage were asked the relevance of the identified wetland features (functions and services) to determining the compensation for damage they suffered due to oil spill. Questions inherent in structured questionnaire meant to elicit information on the relevance were asked on a five-point Likert scale type and it was chosen for ease and uniformity of response. Their expressed opinions are as presented in table 3 based on aspects of total economic value concept.

Table 3: Abereke Community Residents Opinion of TEV based head of claims for compensation

Wetland Function/Services		SUM	RII	RANK
Extractive Use Value				
1	Fish harvesting	1190	4.82	1
2	Other aquatic life	1144	4.63	2
3	Source of drinking water	1100	4.45	3
4	Fibers and Fuel	1088	4.40	4
5	Food/Crop production	982	3.98	5
6	Spiritual inspiration	958	3.88	6
7	Recreational use	879	3.56	9
8	Timber production	763	3.09	15
9	Medicinal Herbs and Roots	835	3.38	12
10	Grazing	814	3.30	13
11	Game Hunt	876	3.55	10
12	Building Materials	925	3.74	8
13	Water Transportation	645	2.61	18
Non-Extractive Use Value				
14	Tourism	554	2.24	24
15	Education	600	2.43	22
16	Research	527	2.13	25
17	Aesthetic	518	2.10	26
Indirect –Use Value Attributes				
18	Flood control	505	2.04	28
19	Groundwater recharge	670	2.71	17
20	Toxics retention	567	2.30	23
21	Biodiversity maintenance	501	2.03	29
22	Shoreline protection	447	1.81	30
23	Micro climate stabilization	509	2.06	27
24	Groundwater purification	814	3.30	13
25	Carbon sequestration	641	2.60	19
26	External support for fish habitat	864	3.50	11
Non Use Values				
27	Biological diversity	691	2.80	16
28	Cultural Heritage	938	3.80	7
29	Wetland Uniqueness	642	2.60	19
30	Option Use/Bequest/Existence	608	2.46	21

The significance of aspects of TEV based potential heads of claim for compensation in the event of oil spill damage were expressed by the oil producing community in this riverine area. In all, the identified claim through literature search and classified under different TEV aspects are 30 in number. Table 3 indicate that fish harvesting in the community is the worst-hit of oil spill effect in the riverine area. This has RII of 4.82 and ranked 1st. The 2nd in rank was non-fish aquatic life with RII of 4.63. These are scarcely included in valuation for compensation purposes; whereas Kadafa (2012) had highlighted that a large number of local population of the Niger Delta survive on harvesting crabs, periwinkles, shrimps fish, cockles, mollusks, birds, and animals. 3rd and 4th in rank are pollution of source of drinking water, and fiber and fuel with RII of 4.45 and 4.40 respectively. Otegbulu (2009) had decried non-

recognition of non-timber forest products "NTFPs" in the natural resource damage valuation in Nigeria; this he claimed has led to impoverishment of the people.

It is noteworthy that oil spill affect the respondents mostly in the extractive use of wetland resource. Among the 13 identified extractive use of wetland in the study area, respondents expressed that the first six items (i.e. Fish harvesting, Non-fish aquatic life, Source of drinking water, Fiber and fuel, and Crop/food Production) have the 6th positions in the RII. 7th in rank is the cultural heritage of the people among the non-use values. This corroborates the findings of Akujuru and Ruddock (2014) canvassing for the incorporation of socio-cultural values in terms of sacred sites and traditional religion when valuating of contaminated lands in Niger Delta, Nigeria.

The 8th (RII= 3.74) ranked value to the respondents is the extractive use of building materials such as bamboos, rattans etc. They claimed that when oil spills affect the source for raw material for building purpose, the cost of buildings increases. Private recreational use and Game hunt ranked 9th and 10th among the extractive use of wetlands in the community. The flow of oil into rivers in the community hinders swimming and other recreational fishing activities. Also oil spills were claimed to repel game hunt. These have RII=3.56 and 3.55 respectively.

Item that ranked 11th is found under the indirect use value of wetland. This is External support for fish habitat which has a RII of 3.50. The importance of this factor stems from the fact that fish production/farming is a major occupation among the people in this region generally. Use of wetlands for medicinal herb ranked 12th in order of importance for compensation claims among the people. Use of some medicinal herb is hampered when they are affected by oil spill. Babawale (2014) reported that some valuers make claims for hospital bill incurred by persons affected by oil spill. Over the years the local communities have discovered ways of helping themselves with these herbs especially with the high cost of accessing hospitals and private clinics. It is not unusual that oil spill can affect human health. Institute of Medicine (2010) confirmed that oil spill have both short and long term physical and psychological effect on people. Both grazing and ground water purification activities in wetland were both ranked 13th in position with RII = 3.30. Timber production ranked 15th with RII=3.09.

Top from the bottom is shoreline protection, biodiversity maintenance, and flood control functions of wetland with RII of 1.81, 2.03 and 2.04 respectively. Whereas studies such as Otegbulu, (2005, 2007, 2009), Udo and Egbenta, (2011) have advocated for Total Economic Value as an acceptable basis for compensation valuation especially when the contaminated land is wetland; it is noticeable that disaggregating TEV into specific component reveals that when the impaired interest which are privately owned is the subject of valuation, it is doubtful if all aspect of potential heads of claim are relevant. Thus the reason why many items are ranked low by the respondents could be that they are not considered relevant to private claimants. These appear to be public goods and no one can lay claims on them to the exclusion of others. A careful look at table 3 paints a picture that private claimants' concerns are basically items (heads of claims) found within "Extractive Use Value" of wetland; only cultural heritage ranked high under 'Non-Use Values". The work of Ibagere (2002) corroborates the importance of cultural heritage to compensation claimants. The study reported that compensation claims presented in respect of desecration of Inyosa family Juju shrine, and Ikhimwin-no-zokpa shrine at the bank of Ikpoba River in Edo state were upheld by the High Court and the clients got the total claims as presented by the valuer. Akujuru and Yalaju (2015) argued that TEV as a basis for determining compensation is impracticable in Nigeria owing to the existing legal framework for compensation practice.

CONCLUSION AND RECOMMENDATION

The study has highlighted the definition of total economic value based claims within compensation for oil spill damage assessment for private claimants. The oil producing community residents have expressed dissatisfaction towards compensation paid for oil spill damage over the years, and many parts of Niger Delta have expressed their displeasure in riots, disruption of oil productions, destruction of oil and gas installations, and the new dimension of kidnap of expatriates and key oil company employees. Huge sum of money and man-hour have been lost to this unwholesome development. Although there are many dimensions to their displeasures, it is expedient that the government and oil companies should consider the local communities as a major stakeholder in compensation matter. Therefore it is hereby recommended that instead of relying on OPTS rate which has been described as illegal and inconsistent with any known legislation in Nigeria, valuers who have been trained in the valuation of impaired interests should be given freehand to determine the compensation sum due to their clients without undue interruption of the polluters. Valuers should in turn ensure that compensation claims on items that are not privately owned should be considered under community claims for the common benefit of all. Such fund should be well managed by the trusted members of the community and should not end in individuals' pockets. Also, there is need to redefine various heads of claim to reflect the actual loss people suffered in the event of oil spill. The intent of compensation practice is to and must indeed be seen to restore the claimants back to the position they were prior the unfortunate event.

ABSTRACT

The problem associated with design errors and incomplete drawings is an old but recurring problem in the Nigerian construction industry. This study, therefore examined the effect of design errors and incomplete drawings on construction project delivery in Nigeria. Primary and secondary data were used for the study via questionnaire and literature survey respectively. The study population comprised Architects, Quantity Surveyors, Engineers, and selected building contractors within Edo State. Out of the 110 questionnaires administered, 45 were retrieved and considered fit for analysis. Purposive sampling technique and random sampling technique were adopted. Frequencies, percentages and relative importance index were adopted in analyzing and ranking the results. The study revealed that consultants, contractors and clients were the major stakeholders mostly implicated in design errors and incomplete drawings. The results indicated that late or inadequate instructions from client, regular interference by client, inadequate site investigation by design consultants, inadequate and unclear documentation by design team, hurry to meet-up with client unrealistic deadline, and lack of constructability reviews in design, lack of clarity in design were ranked most as the causes of design errors and incomplete drawings. Findings also revealed that delays, cost overrun, rework, accidents, disputes, loss of life were ranked most as the impact of design errors and incomplete drawings on construction project. The study concluded that comprehensive site investigation should be carried out at the design phase of the project. Also, there is need for construction design to pass through constructability reviews and encourage the use building information modeling during design.

Keywords: Keywords: Constructability, Construction, Design Errors, Incomplete Drawings, Project Delivery

INTRODUCTION

The construction industry is an important sector for the development and economic growth of Nigeria, which is a developing country (Ebekozien, 2012). In Nigeria, it is very rare case that most construction project is completed on the time and cost specified or agreed upon. Construction projects are mainly multi-disciplinary and involve several consultants and contractors. Therefore, project success is mainly propelled by essential understanding of the design principles and construction methods by various team players (Love & Smith, 2003). Construction designers (Architects and Engineers) are expected to use reasonable and ordinary care in the practice of their profession, and their responsibilities are in part defined by social provenance. Among professions, this legal perspective is well known, but conversely clients are not always aware or informed about it. Perhaps construction designers cannot guarantee the results of their service, their liability for errors and omissions (incomplete drawings) can be determined by whether they have performed their services with the standard of care consistent with other professional designers within their community (Guckert & King's study as cited in Love, Lopez, Kim, & Kim, 2014). There are cases where clients understand their designer's obligation but find it difficult to comprehend what is meant by standard of care. Clarity is expected to be provided by a court of law or panel of experts once a breach of the standard of care is identified.

Design errors and incomplete drawings are the major cause of construction project delay (Dosumu & Adenuga, 2013; Kikwasi, 2012; British Columbia Construction Association,

Ebekozien A.; Uwadia, F. E. & Usman, D. A. (2016). Impact of Design Errors and Incomplete Drawings on Construction Project Delivery in Edo State, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 660-667

2011). The problem associated with design errors and incomplete drawings is an old but recurring problem in the Nigerian construction industry. Design error entails different meanings and usages depending on how it is conceptualized. Busby (2001) defined design error 'as the occurrence which were unexpected, involve surprise and which could not be attributed entirely to chance or circumstance'. While Reason (2006) see design error as an error that relate to those occasions in which a planned activities fails to achieve its intended outcome, and when these failures cannot be attributed to the intervention of some chance agency. Love and Smith (2003) defined design error 'as unintended deviations from correct and acceptable practice that are avoidable'. British Columbia Construction Association (2011) opined that different researchers have conducted studies to identify the common causes of significant claims on construction contracts and the results seem to be consistent. On average, claims amounted to 30% of the construction value. Four of the major causes for claims were: inadequate site and/or subsurface investigation prior to starting the design; starting design efforts too late and/or unduly limiting the cost of engineering and design; calling for bids with an incomplete set of drawings; and endeavouring to complete the design through shop drawing review. The common feature of all these projects was hurriedly and incompletely prepared bid documents, giving rise to design changes. Project changes and/or adjustments are inevitable as they are a fact-of-life at all stages of design and construction. These changes are not resolved through a formalized change management process; it can become the major source of contract disputes, which can pose severe risk that can hamper project performance (Hao, Shen, Neelamkavil, & Thomas, 2008).

All errors are human error, because it is the people who decide what to do; how it should be done; and it is the people who have to do it (Blockley's study as cited in Love *et al.*, 2014). Human errors are among the leading causes for defects, rework and wastages in construction projects (Love & Jasephson, 2004). Perhaps, errors in construction projects can be costly and even become a social problem due to future repairs, inconveniences, and other perils including safety (Rimer's study as cited in Ekambaram, Muthukaruppan & Chi-Ming, 2007). Research undertaken by the Construction Industry Institute (1987) and National Research Council (1994) reveals that design error and omission rate is in the range of 2-3% of construction cost and is deemed to be an acceptable threshold level. There have been several studies in this direction, Atkinson (1998); Love *et al*. (2014); Chapman (1991), identified types of design errors; while factors responsible for design errors were identified by Ren, Atout and Jones (2008), Palaneeswaran, Ramanathan and Tam (2007), Endsley (1999), Barkow (1995). The impacts of delays were identified by Oyewobi, Ibironke, Ganiyu and Ola-Awo (2011). Most of these studies were conducted outside Nigeria. For the few ones that were conducted in Nigeria, emphases were on the causes of construction delay and not within Edo State. Detail studies have not been conducted in the area of the major causes of construction delays in Nigeria. However, this subject area appears to be new in spite of the problem associated with poor construction project performance experienced in the country as a result of design errors and incomplete drawings; which are the major cause of construction delay (Dosumu & Adenuga, 2013). While design errors and incomplete drawings are deemed prevalent, most design and construction firms do not measure the number of errors they create, thereby having initial knowledge regarding their mechanism to undermine project performance even when it is obvious and recurring problem in the Nigerian construction industry.

Against this background therefore, the objectives of the study are to identify the stakeholders that are mostly implicated in design errors and incomplete drawings causation in construction projects, identify the prevalent causes of design errors and incomplete drawings, identify the effects of design errors and incomplete drawings on construction project delivery and proffer

measures to be taken in order to reduce the occurrence of design errors and incomplete drawings in construction documents. With the identification of the causes and impacts of design errors and incomplete drawings in construction projects, there will be a basis for design error minimization in construction projects with a view to better the professional image of firms. This will lead to resultant effect for more effective design management and improve the profitability and competitiveness of consulting and contracting firms.

LITERATURE REVIEW

The construction process can be divided into three important phases, i.e. project conception, project design and project construction (Ebekozien, 2012). Although the vast majority of project delays occur during the construction phase, theses cause could be traced to either project conception phase or design phase but only manifest during construction phase. Ramanathan, Narayanan and Idrus (2012) defined construction delay 'as the time overrun either beyond completion date specified in a contract or beyond the date that the parties agreed upon for the delivery of a project'. It is a project slipping over its planned scheduled and this is a common problem in construction projects. It is in the design stage where the requirements of the client are identified and the constructive aspects and the standards of quality are defined through procedures, drawings and technical specifications. However, the work within the design stage is split into several temporary sequences, and it is delivered to different specialists for its execution. In building projects, first the owner selects the Architects who prepare the architectural designs and specifications, and then the structural design and other specialty designs are developed (Luis & Daniel, 1998).

Norman (1988) defined error as 'something that has gone wrong in the production of a design'. Mistakes are errors in choosing an objective or specifying a method of achieving it whereas slips are errors in carrying out an intended method for reaching on objective. The division occurs at the level of the intention. Center for Universal Design (2014) developed seven principles for professionals in the built environment. The principles are to guide the design process and educate both designers and clients about the characteristics of more usable products and environments. They are: equitable use; flexibility in use; simple and intuitive use; perceptible information; tolerance for error; low physical effort; and size and space for approach and use.

Common Causes of Design Errors and Incomplete Drawings

Records have it that design errors and incomplete drawings are the major causes of construction delay. However, it has been widely studied by researchers from different countries (Ren, Atout, & Jones, 2008; Rajendran, Seow, & Goh, 2014; Dosumu & Adenuga, 2011; Hao *et al.*, 2008; Luis & Daniel, 1998; Kikwasi, 2012; Baloyi & Bekker, 2011; British Columbia Construction Association, 2011; National Society of Professional Engineers, n.d.; Ekambaram *et al.* (2007); Ramanatham *et al*., 2012; Love *et al*., 2014; Alia, Emad, Ashraf & Mahmoud, 2014; National Research Council, 1994; Construction Industry Institute, 1987; Acharya, Lee & Kim, 2006). With this in mind, the following basic categories developed in Antill and Woodhead's study as cited in Baloyi and Bekker (2011) was adopted. Client related causes; consultant related causes and contractor related causes.

Past Studies

Kikwasi (2012) investigated the causes and effects of delays and disruptions in construction projects in Tanzania. The study revealed 'design changes' as the most significant cause of delays and disruptions in the order of severity. Also, time overrun and cost overrun were highly ranked 1st and 2nd respectively as effects on construction projects. These findings agreed with Ren and Jones (2008), which investigated the root causes of construction project delays in Dubai. The only slight difference is that the causes were categories into three

categories: client; consultant; and contractor. The survey by Baloyi and Bekker (2011) in finding the causes of construction cost and time overruns: the 2010 FIFA World Cup stadia in South Africa shows that design errors and incomplete drawings were ranked highly as major causes of construction cost and time overruns. Although advanced software tools and techniques, such as three-dimensional modeling, automated material take-offs and change reference control had been developed to improve the productivity of design outputs, these aspects remain some of the most significant contributors to time delays on construction projects.

Dosumu and Adenuga (2013) examined the causes, effects and remedies of errors in Nigerian construction documents. Lack of documentation, poor communication between professionals and clients, incomplete and incorrect drawings, changes to specification were among highly ranked factors identified as causes of errors in Nigerian construction documents. Others were: professionals' inexperience, non availability of information, lack of quality management, and negligence. The suggestion provided by the study in order to prevent errors in Nigerian construction documents includes: comprehensive information for the design of construction documents, good communication among project participants, effective project management, constructability, design reviews management, electronic document management system and use of building information modeling. Ekambaram *et al.* (2007) findings revealed three interesting cases of design and construction errors which frequently occurred in recent projects. The study also agreed that these errors if not properly checked, could lead to serious concerns as the resulting rework and wastages will affect project performance and productivity aspects. Ramanathan *et al.* (2012) studied construction delays causing risks on time and cost – a critical review. Findings revealed that 18nos categories of causes were identified from the various related studies reported in the literature. Among them: design-related, consultant and owner/client were significantly ranked high as major causes of delays causing risks on time and cost of the project.

Love *et al.* (2014) provided the initial platform to examine the probability of design error costs. The study identified direct and indirect costs as the components of design error costs. The study agreed that the probabilities for both components need to be derived to establish a realistic estimate of design errors. Alia, Emad, Ashraf and Mahmoud (2014) investigated the change orders in construction projects in Kuwait. A field survey was conducted to identify the major causes of change orders, their effects on projects and control measures. The findings revealed agreed with Dosumu and Adenuga (2013). The study most significant control measures were: checking and reviewing the contract documents, reviewing design before change approval and change order should be negotiated by knowledgeable persons. Steven (2011) discussed the incomplete or abandoned construction project. The study concluded that client should overlook trivial negotiations and focus on those provisions that address the biggest areas of liability for the owner, or those provisions that allow the owner some degree of control in limiting liability and exposure during the project. By so doing, the owner will be perceived as a fair and trustworthy participant in the project by the contractor, but will not be subject to unwanted and unnecessary liability.

METHODOLOGY

This study is descriptive, designed to obtain views from clients, consulting firms, and construction firms respectively in regard to causes, impact and proffer measures to design errors and incomplete drawings on construction projects. Descriptive was adopted because it is used to describe characteristics of a population or phenomenon being studied, such as this study. Also, descriptive research involves collecting data to answer questions concerning the current status of the subject of the study. The sample size of 110 respondents was estimated

comprising of 10 construction firms top management staff, 20 Quantity Surveyors, 25 Architects, 35 Engineers, 10 Builders and 10 selected clients within Edo State, Nigeria. Two sampling techniques were adopted due to the nature of respondents to be involved in the study. Random sampling was adopted to select consultants and contractors. Clients were selected using purposive sampling technique, a type of non probability sampling technique. According to Walliman's study as cited in Kikwasi (2012), purposive sampling is a useful sampling method which allows a researcher to get information from a sample of the population that one thinks knows most about the subject matter.

For the purpose of this study, literature review and structured close ended questionnaires were methods adopted among the available methods in collecting data. These were adopted because of the nature of the topic, respondents and data for the analysis. The study assumed that all respondents have been involved directly of indirectly in construction project that suffered as a result of design errors or incomplete drawings. Fifty out of 110 questionnaires administered were returned, 45 were found fairly filled for the analysis. Out of these 45 responses, 3 responses received from clients, 39 responses received from consultants and 3 responses received from contractors. Majority of respondents (80%) have years of experience between 10 and 25years. The results of the study was computed through the use of statistical package for social sciences (SPSS17) using frequencies, percentages and relative importance index (RII) as used in Kometa, Olomolaiye & Haris; Faridi & Sayegh; Aibinu & Bekker's study as cited in Baloyi and Bekker (2011).

$$RII = \sum W/(A \times N), (0 \leq index \leq 1)$$

Where W = weight given to each factor by respondents and ranges from 1 to 5, A is the highest weight (that is 5 in this case) and N = total number of respondents (also, that is 45 in this case).

FINDINGS AND DISCUSSION

Table 1: Stakeholders Mostly Implicated in Design Errors and Incomplete Drawings

Identified Stakeholders	Frequency	Percentage
Consultants	45	100
Clients	35	77.8
Contractors	25	55.6

Table 1 shows major stakeholders that are mostly implicated in design errors and incomplete drawings causation in construction projects. The results obtained from the respondents shows that consultants, clients and contractors are the major stakeholders that are mostly implicated in design errors and incomplete drawings causation in construction projects. Table 1 reveals that at least 55.6% of the respondents agree that consultants, clients and contractors are the major stakeholders. However, all the respondents agree that in addition to contribution from other stakeholders, consultants are the key stakeholders in respect to design errors and incomplete drawings. This finding agrees with Ren, Atout and Jones (2008) that categorized the causes of project delays under three sub-heading: client, consultant and contractor respectively.

Table 2, 3 and 4 shows the respondents ranking of causes of design errors and incomplete drawings. Table 2 reveals consultants contribution, Table 3 reveals clients contribution and Table 4 reveals contractors contribution respectively to design errors and incomplete drawings in construction projects. Based on the ranking of causes, the five most important factors that could cause design errors and incomplete drawings as perceived by consultants are: unclear documentations, inadequate documentation, inadequate site investigation, incomplete design consultant staff and hurry to meet up with unrealistic deadline with

relative important index (RII) of 0.843, 0.836, 0.793, 0.786, and 0.767 respectively. Similarly, based on the ranking of causes, the five most important factors that could cause design errors and incomplete drawings as perceived by clients are: poor communication and coordination, regular interference, site's topography is changed after design, late or inadequate instructions, and unrealistic control duration set-up by client with a RII of 0.901, 0.890, 0.867, 0.810 and 0.791 respectively. Also based on the ranking of causes, the five most important factors that could cause design errors and incomplete drawings as perceived by contractors are: lack of clarity, inadequate organization management, incompetent contractor staff, lack of technical professional in the organization and shorter time to verify consultants' drawings with RII of 0.817, 0.801, 0.769, 0.737, and 0.731 respectively.

Table 2: Respondents Ranking of Causes of Design Errors and Incomplete Drawings: Consultants Contribution

Identified Consultants Contribution	RII	Rank
Unclear documentation	0.843	1
Inadequate documentation	0.836	2
Inadequate site investigation	0.793	3
Incompetent design consultant staff	0.786	4
Hurry to meet up with unrealistic deadline	0.767	5
Poor design management	0.757	6
Inaccurate project feasibility study	0.745	7
Poor communication between consultant staff	0.736	8
Lack of design coordination to eliminate design conflict	0.707	9
Lack of constructability reviews on design	0.701	10
Conflicts appear between drawings from different disciplines	0.693	11
Fees paid not accurate	0.681	12
Slow responses	0.679	13

Table 3: Respondents Ranking of Causes of Design Errors and Incomplete Drawings: Clients Contribution

Identified Clients Contribution	RII	Rank
Poor communication and coordination	0.901	1
Regular interference	0.890	2
Sites topography is changed after design	0.867	3
Late or inadequate instructions	0.810	4
Unrealistic control duration set up by client	0.791	5
Change orders	0.754	6
Lack of a capable representative	0.716	7
Unquantifiable items in bill of quantities	0.567	8

Table 4: Respondents Ranking of Causes of Design Errors and Incomplete Drawings: Contractors Contribution

Identified Contractor Contribution	RII	Rank
Lack of clarity	0.817	1
Inappropriate organization management	0.801	2
Incompetent Contractor staff	0.769	3
Lack of technical professional professional in the organization	0.737	4
Shorter time to verify consultants drawing for deficiencies or completeness	0.731	5
Obsolete technology	0.517	6

Table 5 reveals the impact of design errors and incomplete drawings while Table 6 reveals the measures to mitigate design error and incomplete drawings. The impact of design errors and incomplete drawings on construction project delivery were found to be construction cost overrun with relative important index (RII) of 0.934 followed by construction time overrun and rework with RII of 0.911 and 0.905 respectively. Others include: lost of labour, materials and equipment; Contract failure; arbitration; litigation; accident, loss of life as revealed in Table 5. This result is similar to that of Kikwasi, (2012) with a little deviation. For this study, construction cost overrun ranked 1st while in Kikwasi's study, it was ranked 2nd. From Table

6, the remedies suggested by this study were found to be consistent with the ones provided by Dosumu and Adenuga (2013). However, the remedies were found to vary in the area of training of stakeholders on how to manage change in design. Also since change is inevitable in design, the study suggested that designers should prepare their mind towards change.

Table 5: Respondents Ranking of Impacts of Design Errors and Incomplete Drawings

Effects	RII	Rank
Construction cost overrun	0.934	1
Construction time overrun	0.911	2
Rework (both in design and construction)	0.905	3
Loss of labour, materials and equipment	0.817	4
Contract dispute	0.801	5
Contract failure	0.787	6
Arbitration	0.765	7
Litigation	0.756	8
Accidents	0.615	9
Loss of life	0.613	10
Total abandonment	0.609	11
Poor quality of work done to hurry	0.603	12
Delaying in getting profit by clients	0.601	13

Table 6: Respondents Ranking of Measures to Mitigate Design Errors and Incomplete Drawings Impact on Construction Project Delivery

Remedies	RII	Rank
Provision of detailed and comprehensive information among key stakeholders	0.901	1
Good communication among key stakeholders	0.886	2
Constructability reviews on design	0.867	3
Design drawings should be in 3 dimension building information modeling (3D BIM)	0.858	4
Effective and efficient project management	0.847	5
Stakeholders should prepare their mind for change	0.830	6
Construction professionals should be trained on how to manage change in design.	0.770	7

CONCLUSION

The conclusion of this study is that three major categories could be implicated in design errors and incomplete drawings causation in construction project. They are: consultants, clients and contractors. The causes of design errors and incomplete drawings are: unclear and inadequate documentations/ instruction, inadequate site investigation, incompetent construction professionals, unrealistic deadline set by client, lack of constructability, poor communication and coordination, regular interference by client, lack of clarity by contractors among others. In order to prevent or mitigate design errors and incomplete drawings, there is need to make detailed and comprehensive information available among the key stakeholders, constructability and design reviews management in three dimensions BIM and stakeholders being trained on how to manage changes. It is therefore recommended among others that stakeholders should allow adequate time for the preparation of design drawings, timely issuing of detailed and comprehensive information to stakeholders. Also, constructability reviews on design should be encouraged in addition to use of three dimension building information modeling with construction practitioners in Nigeria.

ABSTRACT

Unethical practices hinder economic development, reduce social services, divert investments in infrastructure and encourage inefficiency in the procurement process. This study, therefore examined the effect of unethical practices on procurement performance of public building projects with a view to proffer ways to mitigating unethical practices during procurement of public building projects. Primary and secondary data were used for the study via questionnaire and literature survey respectively. The study population comprised governmental institutions, selected contracting firms and private consultancy firms within Edo State. Ninety questionnaire were distributed, 79 were returned and 72 (12 from governmental institutions, 18 from contracting firms and 42 from private consultancy firms) were found suitable for analysis. The method used in presenting and analyzing the obtained data includes tables, percentage and mean item score. The results indicated that culture of impunity, weak law enforcing institutions, cabal and political interference, fear of the unknown, absence of reward system, lack of leadership by example, absence of ethical training programs, and lack of consequences when caught were ranked most as the causes of unethical practices during procurement of public building projects. Findings also revealed that inflated contract sum, shoddy construction, fraud, unfair competition, dispute, litigation, and project abandonment were ranked most as the effects of unethical practices on procurement performance of public building projects. The study therefore recommended among others that policy makers and concerned authorities should practice what they preach. In conclusion, laws and regulations are no substitute for the presence of leaders who support and model ethical behaviour.

INTRODUCTION

Construction Industry plays a substantial role in a country's economy irrespective of the country's level of economic development (In Zantanidos and Tsiotras work as cited in Hanizah, Abdul-Rahman, & Xiang, 2010). Abdul-Rashid and Hussain's study as cited in Alex (2014) stated that between 2 to 10 percent of the total work-force is employed in the construction industry and the second largest industry next to agriculture. The Nigerian government had given a much needed boost to the country's construction industry between 1999-2011 where a total of 650 projects were constructed and commissioned (Ebekozien, 2012). This is the sector that produces public building projects.

However, much had been reported about the performance of the construction industry in terms of quality, productivity, safety and procurement in Nigeria. Contract procurement is the process that is used to deliver construction projects (Ebekozien, 2014). The execution of a construction project requires both design work and the carrying out of construction operation. According to Alex (2014), it has reported in 2011 by transparency international, Bribe Payers Index that out of the entire prominent sector in the world, public work construct and construction scored the lowest. Also, it has been estimated that unless adequate measures are taken a sum of $1.2 trillion risks been lost to corruption as a result of unethical practice on an annual basis. This figure could double when considering management and execution inefficiencies. This is definitely a highly worrying matter. Nigeria is perceived as one of the most corrupt nation in the World (Transparency International, 2013). In the Transparency

Ebekozien A.; Uwadia, F. E. & Usman, D. A. (2016). Effect of Unethical Practices on Procurement Performance of Public Building Projects in Edo State, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 668-675

International (T.I) corruption perception index (C.P.I), Nigeria ranked 33rd most corrupt nation in the world in the year 2007 and 2013. This point to the fact that any positive development towards the reduction in corruption in the public procurement process would have a direct and positive significant impact on the overall construction industry in Nigeria.

There is a perception that majority of unethical practices on procurement performance are caused by human factor. Therefore, the issue of professional ethics within the construction industry affects a wide spectrum of population. The ministries, departments, agencies and parastatals at federal, state and local government level respectively, consultants, private client organisations, supplies, contractors and users of public infrastructure are all within the scope of professional ethics. Previous studies such as Vee and Skitmore (2003), Haminah, Narfashiha, Norazian and Norizan (2011), Alfred and Sealza (2008) noted that unethical practices hinders economic development, reduce social services, divert investments in infrastructure and encourage inefficiency in the procurement process.

Perhaps, for public project delivery to be efficient and effective, the procurement process should be ethical. In any given day, professionals in the construction industry would face numerous ethical dilemmas. In the construction business, they will come in fields of procurements estimating, management, accounting, financial, customer relations, sub-contractors, vendors and suppliers and more (Alfred & Sealza, 2008). However, for the purpose of this study, the study is restricted to unethical practices on procurement performance of public building project in Edo State, Nigeria. This study, therefore evaluate the causes of unethical practices and its effect on procurement performance of public building projects. Also, the study proffer ways to mitigate unethical practices during procurements of public building projects with a resultant effect of time, cost, and quality of public building project delivery.

LITERATURE REVIEW

The Construction Industry

The Nigerian construction industry is a unique, complex and often fragmented industry. The industry is important in all countries of the world since it helps to add to the quality of life both through its architecture and also through the facilities it provides to users, both internally and externally (Ebekozien, 2014). National Bureau of Statistics (2011) refers to the industry as Building and Construction Sector in their sectoral classification of economy. The construction industry is essentially an assembling industry, assembling on site the product of other industries. Ebekozien (2014) stated that in the developed world, the construction industry is the highest employer of labour. While, in the developing world such as Nigeria, the construction industry is expected to be the second largest employer of labour after the agricultural industry. The construction industry is therefore a critical factor or variable in the drive for economic advancement of nations especially the less developed countries (LDCs) such as Nigeria. A survey of households by World Bank (2013) revealed that:

i. In urban areas, there is lack of pipe borne water, irregular electricity supply and lack of good roads.
ii. The vast majority of Nigerians have little access to basic public services.

This is worrisome even with the huge amount of money that has gone into the sector for the past 15 years. Out of all sectors of the World economy, the construction industry was found to be the most corrupt economic sector as per the findings of the survey for investigation of corruption by Transparency International (T.I) (Alex, 2014). It was further revealed that in the year 2004, 10 percent of the total value of construction was lost due to corruption in construction globally due to corruption in infrastructure procurement. Vee and Skitmore

(2003) lamented the unhealthy nature of some professionals in the construction industry. The authors identified some the unethical behaviour of these professional to be:

i. Concealing of construction errors and stealing of someone else drawing.
ii. Exaggerating experience and academic achievements in resumes and applications for commissions.
iii. Charging clients for work not done, costs not incurred or overstated.
iv. False promises of advancement as practiced by some consultants.
v. Misleading clients in project management.
vi. Involvement in conflict of interest.

Ethics

Ethics is used in determining what is right in a given situation and then following through with actions to implement what is right. Alfred and Sealza (2008) defined ethics as: "(i) A system of moral principles, by which human action and proposal may be judged good or bad, right or wrong. (ii) The rules of conduct recognised in respect of a particular class of human actions. (iii) Moral principles, as of an individual".

They evolved initially from religion by many thinkers in the Judeo-Christian tradition. Their study involves the activity of examining one's more standards of society and asking how these standards apply to our lives and whether these standards are reasonable or unreasonable. Perhaps, ethics cannot be arbitrarily created but discovered through argument and persuasion (Johnson study's as cited in Vee & Skitmore, 2003). Remember, an organisation is judged by its reputation which is a result of its integrity to the business world and its employees. The ethics of both the organisation leaders and employees make up how the organisation is perceived and whether they are seen as ethical or not. The set of moral standard that we use to guide our decision making are our ethics (Alfred & Sealza 2008). Collins Dictionary (1991) defined morality as "conforming to a conventional standard of moral conduct ". A moral refers to a distinction between good and bad or right and wrong. Perhaps ethical conduct in simplest is doing the right thing when no one is looking (McCarthy, 2012). There are three primary ethical directives: loyalty, honesty and responsibility. We will be called upon to be loyal to friend, family, organisation, profession et al. and being loyal to one may mean being disloyal to another. Honesty is telling the truth as you see it but it really much more. Responsibility requires taking ownership of the consequences of our action and insuring no harm comes to someone because of those consequences (Alfred & Sealza, 2008).

McCarthy (2012) noted that ethical conduct is the compliance with the following seven ethical principles:

i. Honesty- act with honesty and avoid conduct likely to result, directly or indirectly, in the deception of others
ii. Fairness- does not seek to obtain a benefit which arises directly or indirectly from the unfair treatment of other people.
iii. Fair reward- avoid act which are likely to result in another party being deprived of fair reward of their work.
iv. Reliability- maintains up to date skills and provide services only within your area of competence.
v. Integrity- have regard for the interests of the public, particularly people who will make use of or obtain an interest in the project in the future.
vi. Objectivity- identify any potential conflict of interest and disclose the conflict to any person who would be adversely affected by it.

vii. Accountability- provide information and warning of matters within your knowledge which are of potential detriment to others may be adversely affected by them.

Alex (2014) lamented that the unethical practices among players of construction industry is on the increase. The lack of professional ethics, as evidenced by the high rate uncompleted and delayed projects with huge time and cost over-run, poor and substandard quality of work due to non-adherence to contractual design and specification leading to shedding and uneconomical constructions and collapse of structures during construction or thereafter may be viewed by international business organization as less easy, possible and likely, to do business in comparison to other developing nations due to corruption and lack of professional ethics. Hamimah *et al*. (2011) highlighted many reasons why professionals are involved in unethical practices. This may be due to insufficient legislative enforcement, fierce competition, the economic downturn, insufficient ethical education from schools and professional institutions, cultural changes and high complexity of construction works. The Nigeria construction industry is no exception. Vee and Skimore (2003) noted that one of the most frequently reported unethical practices in business is bribery. Other frequently reported unethical practices are related to fraud, breach of confidence and negligence, deceit, trickery, sharp practice, or breach of confidence by which it is sought to gain some unfair or dishonest advantage.

Procurement

Based on the aide spread corruption, conducting government business degenerated so much in Nigeria in the early 2000. In an attempt to stop the ”business as usual syndrome”, Budget Monitoring and Price Intelligence Unit (BMPIU) was established. This unit was given the mandate to ensure fiscal transparency, strict compliance with Federal Government guidelines on due process certification as it concerns budgeting for and procurement of facilities/services/contracts at appropriate costs (Ezekwesili, 2005). This facilitated the enactment of Procurement Act 2007. However, even with the existence of procurement Act, the level of corruption in relation to procurement is still high. Ayoola (2008) lamented that some of the common techniques employed by these parties in corrupting the procurement process include failure to meet quality standards, colliding to fix bidding prices, promotion discrimination, discriminatory technical standard, claiming urgency as an excuse toward to a single contractor without competition, demanding private benefits, and diverting delivered goods for resale or for private use.

Oshiogbele (2010) stated that there are eleven principles which govern the administration of public procurement as provided in construction procurement guide 2008. They are as follows; accountability, competitive supply, consistency, effectiveness, efficiency, integration, integrity, informed decision making legality, responsiveness and transparency. Ebekozien (2014) noted that contract procurement is the process that is used to deliver construction project. There are a number of alternative procurement methods a client may use to acquire these services. These procurement methods give the client a choice of various management structure, different contractual managements and varying degrees of client risk. Ashworth, Hogg and Higgs (2013), Ebekozien (2014), classified the method into two major methods. The first is the traditional methods; this is one of the oldest methods of building procurement and conformed to straight forward and well-tried procedure. Examples are: based on bill of firm quantities, based on bill of approximate quantities, based on drawing and specification, based on schedule of rates (measured contract or measurement contract), based on cost reimbursements (prime cost or cost plus). The second is the alternative methods-since construction activities are dynamic, various alternative ways of promoting and carrying out construction project have been devised with varying degrees of success. Examples are; design

and building (design and construct or package deal), management fee, government procurement routes, project management, partnering, and joint venture.

METHODOLOGY

The study adopted a survey research technique and was limited to Edo State, Nigeria. Survey research was adopted because is often used to assess thoughts, opinions, and feelings. It is a method of collecting information by asking questions of respondents. Also, since it was a quantitative research, survey research was adopted. The target populations for this study comprised governmental institutions, selected contracting firms and private consultancy firms within Edo State, Nigeria. The study made use of data and information collected from both primary and secondary sources via questionnaire and literature survey respectively. Purposive sampling technique was adopted in administering the questionnaire to those respondents directly involved in procurement of public building projects in the study area. Ninety questionnaire were distributed, 79 questionnaire were returned and 72 (12 from government institutions, 18 from contracting firms and 42 from private consultancy firms respectively) were found suitable for analysis. This gave a response rate of 80% of the total. Secondary data includes relevant information from related studies. The method used in presenting and analyzing the obtained data includes tables, percentages and mean score rank. This was adopted because it is the simplest way to present and analyze the data for easy interpretation.

FINDINGS AND DISCUSSIONS

Table 1: Summary of Background Information on Respondents

Category	Classification	Frequency (N) (%)	Percentage
Organization types	Govt Institutions	12	17
	Contracting Firms	18	25
	Consultancy Firms	42	58
	Total	**72**	**100.0**
Respondents Designation	MD/CEO	5	7
	Director/Management staff	7	10
	Principal Partner	20	28
	Partner	18	25
	Operational Staff	22	30
	Total	**72**	**100.0**
Higher Academic Qualification	HND/B.Sc/B.Tech	42	58
	M.Tech/M.Sc/M.Phi	30	42

Years of Professional Experience	0-5 years	3	4
	6-10 years	5	7
	11-15 years	30	42
	16-20 years	20	28
	Above 20 years	14	19
	Total	**72**	**100.0**
Numbers of Public Building Projects Involved in the last 10 years (2005-2014)	0-5	3	4
	6-10	24	33
	11-15	20	28
	16-20	10	14
	About 20	15	21
	Total	**72**	**100**

Table 1 shows the summary of the background information of respondents. It is observable from Table 1 that 58% of the respondents are from consultancy firms, comprises of: Quantity Surveying, Architectural, and Civil Engineering Consultancy Firms respective. Also, Table 1 shows that the minimum academic qualification of the respondents was HND/BSc/B.Tech in

their various fields of study. Also, it shows that more than 79% respondents have a minimum of 11years and above experience in the construction industry and respondents cut a cross stakeholders to the study area. Similarly, it shows that more than 63% of the respondents have been involved in public building projects of not less than 11 projects within the last 10 years (2005 – 2014).

Table 2: Identified Causes of Unethical Practices

Identified Causes	Govt Institutions		Contracting Firms		Consultancy Firms		Overall	
	Mean	Rank	Mean	Rank	Mean	Rank	Mean	Rank
Lack of leadership by example	4.40	3	4.58	2	4.80	1	4.59	1
Fear of unknown	4.50	1	4.61	1	4.55	3	4.55	2
Culture of impunity	4.48	2	4.50	3	4.65	2	4.54	3
Weak law enforcing institution	3.75	5	4.55	4	4.11	4	4.14	4
Absence of reward system	3.90	4	4.40	5	3.90	5	4.07	5
Absence of ethical training programs	3.40	7	4.30	6	3.80	6	3.83	6
Lack of consequences when caught	3.60	6	4.20	7	3.50	7	3.77	7
Working in a diminished environment	3.10	8	3.60	8	3.20	8	3.30	8

Table 3: Identified Effects of Unethical Practices

Identified Effects	Govt Institutions		Contracting Firms		Consultancy Firms		Overall	
	Mean	Rank	Mean	Rank	Mean	Rank	Mean	Rank
Inflated contract sum	4.20	1	4.40	1	4.51	1	4.37	1
Encourages bribery and corruption	4.05	3	4.33	2	4.40	2	4.26	2
Encourages Fraud, unfair and dishonest conduct	4.15	2	4.05	3	4.28	3	4.13	3
Collusion tendering	3.91	4	3.59	5	4.15	4	3.88	4
Negligence and shoddy construction	3.44	6	3.80	4	3.80	5	3.68	5
Unjustified claims	3.65	5	3.33	7	3.71	6	3.56	6
Conflict of interest, dispute litigation	3.19	7	3.41	6	3.55	7	3.38	7

Reworks	2.85	10	2.91	10	2.88	10	2.91	10
Low inflow of foreign direct investment	2.76	11	2.75	11	2.88	10	2.80	11
Few and weak infrastructural facilities	2.69	12	2.65	12	2.77	12	2.70	12

Table4: Identified Ways to Mitigate Unethical Practices

Identified Ways	Govt Institutions		Contracting Firms		Consultancy Firms		Overall	
	Mean	Rank	Mean	Rank	Mean	Rank	Mean	Rank
Leaders as role model	4.30	1	4.57	1	4.69	1	4.52	1
Reinforcement and Upholding the rule of law	4.17	3	4.45	2	4.51	2	4.38	2
Strengthening institutions	4.25	2	4.34	3	4.35	3	4.31	3
Building a culture of transparency	4.02	4	4.22	4	4.10	4	4.11	4
Create standard code of ethics	3.81	5	4.05	5	3.85	5	3.80	5
Make training and retraining on ethical matters compulsory	3.59	6	3.85	6	3.29	6	3.58	6
Openness and communication	3.25	7	3.49	7	3.01	7	3.25	7
Ethical awareness	3.01	8	3.19	8	2.85	8	3.02	8
Show employee appreciation	2.77	9	3.01	9	2.75	9	2.84	9

Table 2 presents that the ranking by the government institutions and contracting firms deviated slightly from that given by Consultant. While fear of unknown and culture of impunity was ranked first and second by the government institutions with a mean score of 4.50 and 4.48 respectively, contracting firms ranked fear of unknown and lack of leadership

by example first and second with a mean score of 4.61 and 4.58 respectively consultants ranked lack of leadership by example and culture of impunity first and second with a mean score of 4.80 and 4.65 respectively. On the average, lack of leadership by example was ranked first, followed by fear unknown while lack of consequences when caught and working in a diminished environment as the last. This deviate slightly with Hamimah *et al*. (2011). In the findings of Hamimah et al. (2011) stakeholders involvement in unethical practices may be due to insufficient legislative enforcement, fierce competition, the economic downturn, insufficient ethical education from schools and professional institutions, cultural changes and high complexity of construction works.

Table 3 reveals the ranking of the identified effects of unethical practices on procurement performance of public building projects in Nigeria from the respondents view points. The analysis reveals that inflated contract sum, encourages bribery and corruption, fraud, unfair and dishonest conduct, collusion agreement, and negligence and shoddy construction are the most significant impacts of unethical practices on procurement performance. While reworks, low inflow of foreign direct and portfolio investment, and few and weak infrastructural facilities as the least impact. The study recognised that these impacts are not good for Edo State and Nigeria as a country at large, which is trying to become among the best 20 countries in the year 2020. These identified impact touch on all facet of the economy which also agrees with Alfred and Sealza (2008). Alfred and Sealza (2008) findings reveals that unethical practices hinders economic development, reduce social services, divert investment in infrastructure, and encourage inefficiency in the procurement process. This findings slightly agrees with Vee as Skirtmore (2003).

Table 4 reveals major identified ways to mitigate unethical practices in procurement performance of public building projects. It shows that on the overall mean score, leaders as role model with mean score of 4.52 was ranked first as the most important way to mitigate unethical practices. Moreover, Table 4 reveals that reinforcement and upholding the rule of law was ranked second with a mean score of 4.38, followed by strengthening institution with a mean score of 4.31. The uniqueness of Table 4 is that all the respondents irrespective of the background agree and ranked leaders as role models as first in their respective segment. While openness and communication ethical awareness, and show employees appreciation, as the least way to mitigate unethical practices. This deviate with McCarthy (2012). McCarthy (2012) findings reveal that the only major way to mitigate unethical practices is expected that stakeholders should be doing the right thing even when no one is looking.

CONCLUSION

The study succeeds to examine the effect of unethical practices on procurement performance of public building projects with a view to proffer ways to mitigate unethical practice during procurement of public building projects. The study show that causes of unethical practice is not necessary the individual's lack of moral standards. It is therefore hoped that unethical practice can therefore be prevented or limited by implementing certain measures and recommended among others that government should strengthening institutions, improving sanction, and enforcement and upholding the rule of law, and leaders should be ready to set examples of ethical practices.

ABSTRACT

The nature of commercial properties makes it susceptible to various management problems such as rent default, non-challant attitude among tenants in carrying out their obligations which have been attributed to inadequate / lack of tenant selection. This research work analyzed tenant selection and occupancy rate of office properties located along Oyemekun /Oba-Adesida road, Akure. Structured questionnaires were used in collecting data from the Estate Surveyors and Valuers in Akure as well as the occupants of office properties in the study area. Twenty-five(25) questionnaires was administered on practicing Estate Surveying and Valuation firms in Akure and a total of ninety-six(96) questionnaires were administered on occupants of office properties along Oyemekun /Oba-Adesida road. Data were analyzed using Descriptive statistics (weighted mean score) and Mann Whitney U-test. Results obtained from the data revealed that most of the Estate Surveyors and Valuers made use of the ability to pay rent and willingness to meet term of lease as basic selection criterion. It was also gathered that high rents have been the major determinant of occupancy rate of office properties in the study area with little impact from other factors such as adequate facilities, security, pollution, location, tenant selection amongst others. The research recommends that Estate Surveyors and Valuers should consider basic selection criterion such as ability to pay rent; meet lease obligations and ensure proper maintenance in other to keep the property in a tenantable condition, which if not done may lead to void in the long run.

Keywords: Occupancy Rate, Office Properties, Tenant Selection

Introduction

Commercial office properties comprise a large portion of the nation's wealth (DiPasquale and Wheaton, 1992) and provide the working environment that allows many businesses to operate efficiently (Clapp, 1993). Hough and Kratz (1983) also affirmed commercial properties as important component of the urban landscape. Commercial property which could come in form of office space, malls, retail stores, shopping centers, banks amongst others have an important role in real estate markets; which is related to three different factors such as factor of production, financial asset and as investment medium (Ustaoglu, 2003).

Oni, Bello and Oni (2011) asserted that there is an increased demand for commercial properties as a result of the increased population which has attracted a wide range of investors and developers in the provision of office spaces. Office properties generally provide environments conducive to the performance of management and administrative activities and other professional services (National Association for Industrial and Office Parks, 2012). These grandiose attributes of commercial properties offer have resulted to a plethora of such investment as office spaces in the study areas: Oyemekun and Oba Adesida Road, Akure which was hitherto a sprawl with residential structures.

The occupation of office spaces is initiated by a tenant selection process which is a very critical part of the property management process. Lawal (1991) noted that tenant selection requires personal knowledge of every prospective tenant and that Estate Surveyors and Valuers should ensure this by assessing the circumstances and needs of such prospective tenant. Agagu (2007) noted that the process ensures best-qualified tenants are selected while applicants with bad or no credit history are rejected. This process invariably affects the occupancy rate of such properties. Marrett and Swith (1989) also affirmed that tenant

Nwosu, A. E.; Ajani, U. Y. & Olofa, S. A. (2016). Tenant Selection and Occupancy Rate of Office Properties in Akure. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 676-683

selection and occupancy period affect every type of real estate although in varying degrees. Ustaoglu (2003) further accentuated that tenant selection and occupancy rates are more evident in commercial properties which perhaps are due to the fact that these properties are majorly built for business transactions.

Agagu (2007) stated the problem faced in office properties are traceable to wrong tenants' selection and where unmitigated may affect the occupancy rate of such properties. According to Ayo-Ojo (2014), high vacancy rates are usually viewed as a sign that the market is struggling while high occupancy rate is desirable for major property investors. The level of the natural occupancy rate has direct implications for the return on property investment. In the long-run equilibrium, the higher the natural occupancy rate, the greater the amount of rent generated by a given rental property, everything else held constant and this can be achieved through a concise tenant selection.

Various criteria such as ability and willingness to pay rent; suitability of the tenant; ability and willingness to meet the terms of lease; provision of suitable referees; client's preference; tenant's personal data and credit worthiness are considered during the tenant selection process (Wheaton, 1997; Nwankwo, 2005; Agagu, 2007 and Bello, 2008). Wheaton (1991) and Agagu (2007) further assessed effect of tenant selection on office properties which leads to non-surrender of properties, subletting, alteration and unauthorized installation, non-payment of rent and fulfilment of lease term and obligations.

Based on the above discussions, this paper tends to discover it the mode of tenant selection by Estate Surveyors and Valuers have any effect on the occupancy rate of office properties in Akure.

LITERATURE REVIEW

According to Corgel (2006), office property is the most common of all the commercial property and is definitely the first type of property that springs to mind when the term commercial property is mentioned. Office properties have different categories which include: high rise office complexes and low rise office building. Relative to office space occupation and property management is the tenant selection process. Agagu (2007) emphasized that the concept of tenant selection revolves round a well-documented and adequate enforcement of the term 'lease'. As opined by Wheaton (1988) and Agagu (2007) one of the basic and most common problems that Estate Surveyors and Valuers or landlords face in their property is the adequate selection of tenant and adequate return on investment through rental collection. The selection of tenants and the occupancy of properties are strongly correlated (Nwuba, 1994; McAllister, 1994 and Ustaoglu, 2003).

There has been a dearth of literatures on tenant selection and occupancy rate. In the developed countries, a number of studies have tested the relationship between vacancy rates and rent levels in the housing and commercial office market. These studies include Eubanks and Sirmans, 1979; Rosen and Smith, 1983; Rosen, 1984; Voith and Crans, 1988; Wheaton and Torto, 1994; Belsky and Goodman, 1996; Sivitanides, 1997; Gabriel and Nothaft, 2001, Hagen and Hansen, 2010.

Wang (2009) carried out a research on evaluating office users' requirements and occupiers' preferences in changing business environment. The study mainly focused on identifying office users' and occupiers' requirements and preferences from physical, virtual, social and financial perspectives. The study however revealed that from the physical perspective, organizations prefer to adopt open-plan office, aiming to efficiently use their space and enhancing the communication ability among the employees

Zhao (2011) also examined how office property investors address the changes in office tenants' space and lease requirements and preferences in their office investments. The study reflected the property investors' attitudes to tenants as they are recognized as service providers rather than only physical place provider. The investors also aim to offer an efficient platform for tenants to conduct their business, thus, the offering of office space is as tenants demanded. The investors ensures high occupancy rate and income stream to overcome the market challenge.

Yasmin and Daud (2010) also carried out a research on Identification of Important Factors for Office Space Decision by Tenants in Kuala Lumpur city centre, Malaysia – Experts' View. The research adopted the importance index to examine the factors influencing the tenant office occupation decision. The findings show that there is mixture of factors that have achieved high important consideration by the experts.

In Nigeria, several authors such as; Agagu, 2007; Olabisi, 2010; Ezeokoli 2012; Odusote, 2014 and Bello and Ezeokoli, 2015 amongst others have embarked on various researches related to commercial properties and occupancy rates; voids, rents and its investment returns. Agagu (2007) assessed tenant selection and void period which is important factor in property management. The research examined the property market major players, method/procedure used in selecting prospective tenant and the effect of void period on properties and its mitigation. The study revealed that the Estate Surveyors and Valuers opined that through proper and adequate tenant selection, there should not be problem of tenant selection and the level of void period in properties can also be reduced by proper and adequate maintenance. Also, Olabisi (2010) investigated into the problems of office void which is limited to Lagos Island area. The research examined the types of property prone to void, causes of office property void, the disparity between actual and natural void and the effects of void on office properties. Akinwande, (2010) also examined the effects of tenant selection on property management and stated that rent affordability of low-income earners and the risk involved in private rental investment as basic factors affecting property management.

Odusote (2014) analyzed the vacancy rate and rent level in the commercial office market, with effect to four major areas of Akure. The results from the analysis showed that vacancy rate and rent level are directly related to supply of commercial properties' spaces and inversely related to the demand for shopping paces and that vacancy rates has no significant effect on commercial property returns. Bello and Ezeokoli (2015) examined the effect of vacancy on shopping center investment returns in six major areas of Akure using descriptive statistics, one-sample t-test and simple linear regression analysis. The research revealed that the average rate of vacancy in shopping centres in Akure is 13.67%. The result also, shows that centres in Oba Adesida, Oyemekun and FUTA experienced low vacancy rate. Furthermore, the research revealed that Vacancy rate has a negative effect on the rental values of shopping centres in Akure indicating that an increase in vacancy rate will cause a decrease in the expected rental value.

The above literatures none have been able address tenant selection and occupancy rate of office properties in Akure, Nigeria. Hence, this paper tends to address it.

STUDY AREA

The study areas Oba Adesida road and Oyemekun road are in Akure the capital city of Ondo state, the Oyemekun road is an integral part of Ondo state majorly accessed from Ilesha Road. Oba Adesida Road Metropolis is one of the major roads in Akure and a major road along the Central Business District (C.B.D) of Akure having its link to the ancient town and the ancient Palace of the King; Deji's Palace which automatically links it to one of the busiest

market in Akure; Oja-Oba. It is also characterized by the presence of major commercial properties including office spaces such as shopping complexes, banking halls, office spaces, and shopping malls.

METHODOLOGY

The population of this study comprises the occupants of office properties and practicing Registered Estate Surveyors and Valuers in Akure. There are 25 registered and practicing Estate Surveyors and Valuers in Akure as derived from Ondo State Branch secretariat record of registered Estate Surveyors and Valuers 2015. The office properties taken into consideration in this research are those located along Oba-Adesida and Oyemekun road, Akure. The total number of office properties along this study area as observed in the study areas from field survey is ninety-seven (97). Two sets of structured questionnaires were administered on the target population (Occupants of office Properties and Registered Practicing Estate Surveyors and Valuers in Akure) to elicit information on tenant selection and occupancy rates of office properties in Akure. A total of ninety-five (95) were completed and retrieved seventy nine (79) from occupiers of office spaces and sixteen (16) from Estate Surveyours and Valuers which were used for the analysis.

Descriptive statistics, weighted mean score and Mann-Whittney U test was carried out to ascertain the relationship between the responses of the target population regarding the study. Mann-Whitney U-test is a non parametric statistical method that is used in measuring the difference between two groups of responses. Fellows and Liu (2008) noted that Mann-Whitney u-test is one of the statistics that is used in testing hypotheses related to differences in metric and non-metric scales.

$$U=n\_1-n\_2 \ +(n\_1\ (n\_1+1))/2-R\_1$$

Where n1 and n2 are the sample sizes and R1 is the sum of the ranks assigned to the values of the first sample. In decision making using P-value, Lucko and Rojas (2010) noted that if the p-Value is less than 0.05 then the null hypotheses is rejected and vice versa.

FINDINGS AND DISCUSSIONS

Table 1: Firms' Year of Establishment

Year	Frequency	Percentage (%)
1-5	1	6.3
6-10	5	31.3
11-15	2	12.5
16-20	4	25.0
20 and above	4	25.0
Total	***16***	***100.0***

Table 1 reveals that, 31.3% of the firms have been established between 6-10 years ago, 25% between 16-20 years and those between 20 years and above, 12.5% were established between 11-15 years ago. This shows that the firms have enough years of experience and gave good judgment to the questionnaires administered.

Table 2: Professional Qualification of Respondents

Professional qualification	Frequency	Percentage (%)
ANIVS	6	37.5
RSV	1	6.3
FNIVS	3	18.8
Others	6	37.5
Total	***16***	***100.0***

Table 2 reveals that 37.5% are associate members of NIESV (ANIVS) while 18.8% are fellows (FNIVS) 6.3% are RSV while 6 of them have other qualifications at 37.5%. This implies that most of the respondents are competent professionals who are members of the Nigerian Institution of Estate Surveyors and Valuers and have registered to practice as practicing Estate Surveyors and Valuers. In view of this, their opinion and response can be adequately relied upon.

Table 3: Number of Office Properties Managed by Firms in the study area

Number	**Frequency**	**Percentage (%)**
1-5	9	56.3
6-10	7	43.8
11 – 15	-	-
16 and above	-	-
Total	***16***	***100.0***

Table 3 result shows that 56.3% of the firms have between 1-5 office properties been managed by their firms' while 43.8% of the firms have between 6-10 office properties been managed in the study area. This shows that majority of the respondents do manage one or more office properties in the study area.

Table 4: Type of Office Properties

Type	Frequency	Percentage (%)
Multi-tenanted office building	6	37.5
Converted residential building	8	50.0
Single tenant Office building	2	12.5
Total	*16*	*100*

This table reveals that most of the office properties managed by the Estate Firms located in the study areas are converted residential office properties which have the highest frequency of 8 representing 50.0% of the total number of firms. This result is in conformity with Oni et al (2011) which study reveals that multi-tenanted office properties which are usually purpose built but built with the intention of creating spaces for more than one tenant to use and usually built to generate more return and create more spaces. The single tenant office properties on the other hand are relatively small compared to the other two types with a frequency of 2 representing 12.5%.

Table 5: Tenant Selection Criteria employed by Estate Surveyors and Valuers

Criteria	**MU**	**U**	**LU**	**NU**	**Mean**	**Rank**
Ability to pay rent	14(75.5)	2(12.5)	-	--	3.88	1st
Ability and willingness to meet term of lease	-	11(68.8)	4(25.0)	1(6.3)	3.63	2nd
Provision of suitable referees	-	4(25.0)	8(50.0)	4(25.0)	3.44	3rd
Use of acquaintance request form	-	8(50.0)	5(31.3)	3(18.8)	3.31	4th
Conducting interview	-	3(18.8)	8(50.0)	5(31.3)	3.25	5th
Suitability of the tenant to the property	-	8(50.0)	7(43.8)	1(6.3)	3.06	6th
Client's preference	4 (25.0)	1(6.3)	10(62.5)	1(6.3)	3.00	7th
Credit worthiness	-	4(25.0)	4(25.0)	8(50.0)	2.88	8th

MU=Mostly Used, U=Used, LU=Less Used, NU=Not Used

Table 5 assesses the criteria employed by the Estate Surveyors and Valuers in selecting tenants for office properties in the study area. The result shows that ability to pay rent is a criterion that is mostly used by the Estate Surveyors and Valuers in selecting tenants which represents a mean score of 3.88 and ranked 1st. This is also in line with the findings of Ayinde, (2008) that the ability to pay rent is the most considered factor for selecting tenants to properties. Credit worthiness is the least used or employed as criteria for most of the Estate

Surveyors and Valuers with a mean score of 2.88 and ranked as 8th. Agagu (2007), though considered ability to pay rent as a significant factor, he also based it on the income earned by such tenant that is, ability to earn high income.

Table 6: The average time needed to affirm tenants' information before selection

Average time	Frequency	Percentage (%)
Immediately	10	62.5
1-3 weeks	4	25.0
1-3 months	1	6.3
Others	1	6.3
Total	***16***	***100.0***

Table 6 depicts the average time needed for the Estate Surveyor and Valuer to affirm tenants' background information before finally selecting as tenants. It shows that a tenant can be taken almost immediately after showing interest in the lease of such property as it has the highest number chosen by 10 representing 62.5%.

Table 7: Respondents Opinion on the occurrence of void, rate of vacancy and the level of demand for office properties

	Frequency	Percentage (%)
Vacant Spaces / occurrence of Void		
No	11	68.8
Yes	5	31.3
Total	***16***	***100.0***
Rate of Vacancy		
Very frequently	--	--
Frequently	3	18.7
Less frequent	5	31.3
Not at all	8	50.0
Total	***16***	***100.0***
Rate of Demand for Office Properties		
Very High	9	56.3
High	4	25.0
Low	2	12.5
Very Low	1	6.3
Total	***16***	***100.0***

Table 7 assesses the respondent's opinion on the occurrence of void, rate of vacancy and the level of demand for office properties in the study area. As presented in the table, the research revealed that most of the office properties are fully let with no vacancy representing 68.8% while 31.2% of office properties have some vacancies. The occurrence of void in relation to the rate of vacancy shows 50% of the respondents opine to lack of vacancy while 31.3% opine that rate of vacancies are less frequent. The rate of demand for office properties on the other hand in the study areas shows that the rate of demand is very high at 56.3%. These findings are in agreement with the findings of Agagu (2007) that the occurrence of void in office properties in Akure is less frequent and the occurrence of void period in office properties in the study area is very low; hence there is a high occupancy rate.

Table 8: Vacant Rate of Office Properties in the Selected Area

Selected Areas	Number of Office Properties	Number of spaces in the Office Properties	Vacant spaces
Oba Adesida	6	283	2
Oyemekun	7	185	7
TOTAL	***13***	***478***	***9***

The vacancy rate of some office properties within the study area are presented in table 8. The research revealed a total of four hundred and seventy-eight office spaces in the study area and about nine are vacant. The shows a high occupancy rate of 98.12% of office properties in the study area.

Table 9: Determinants of occupancy rate in Office Properties

Cause of void in Office Properties	Asymptotic Significance
High rent	.026**
Location	.000**
Condition of the property	.001**
Accessibility to the property	.000**
Quality of property	.953
Lack of security of life and property	.021**
Rent of similar or neighbouring office property	.220
Renovation of property	.128
Pollution	.270
Lack of adequate facilities i.e water, security, electricity e.t.c	.001**
Termination of lease	.002**

The result revealed that the asymptotic significance of the measured values for the causes of void/ low occupancy rate in office spaces in responses of respondents, seven variables which are high rent, location of the property, condition of the property, accessibility of the property, lack of security of life and property, lack of adequate facilities and termination of lease shows a significant difference in responses of the respondents at a significant level of less than 0.05. This implies that there is significant difference in response of the respondents. However, four variables quality of property, rent of similar or neighbouring office property, renovation of property and pollution reveals that there is no significant difference in responses of the respondents. This implies that there is no significant difference in responses of the respondents

CONCLUSION

The research has been able to show that most of the Estate Surveyors and Valuers make use of the ability to pay rent and willingness to meet term of lease as basic selection criterion. It was also gathered that high rent have been the major determinant of occupancy rate of office properties in the study area with little impact from other factors or causes such as adequate facilities available, security, pollution, location, tenant selection amongst others. The research recommends that Estate Surveyors and Valuers should consider basic selection criterion such as ability to pay rent and ability to meet lease obligations and ensure proper maintenance in other to keep the property in a tenantable condition which if not done may lead to deterioration and cause void in the long run.

ABSTRACT

Housing is universally acknowledged as the second most essential human need after food and is a major economic asset in every nation. The study assessed the importance End-Users attach to their housing needs with a view to satisfying End-Users preference in housing delivery in Kaduna state, Nigeria. The research adopted a questionnaire survey to investigate a sample of occupants of the public housing units in Kaduna State. The population from which the samples were obtained is a 600 unit public housing scheme constructed in 2005 by Kaduna Sate Government. The housing scheme comprises three bedroom, two bedroom, two bedroom semi-detached and one bedroom units. A simple random sampling method, where each building type was given a number between 1 and 400, and the questionnaires were self-administered. Responses were requested on 5-point Linkert scale on factors obtained through an exploratory study and literature review. Four hundred questionnaires were distributed to respondents out of which 209 were completed and returned representing 52.25% returned rate and 47.75% were not returned. The data collected was analysed using Statistical Package for Social Sciences (SPSS) version 17.0. The results of the study were expressed in descriptive statistics namely: mean, frequencies, and percentages. The findings of the study suggest that the housing providers should meet the different segment of end-users. It is recommended that Housing providers should be aware of the important attributes of end-users' housing needs and expectations including incorporating them into design and housing provision(s).

Keywords: End-users, Expectations, Housing, Needs, Value profiling

INTRODUCTION

Housing represents one of the basic human needs and has profound impact on health, social interaction and general wellbeing of individuals and groups in any society (Mabogunje et al, 1978; Onibukun, 1998; Bayode, 2008). To most groups of people housing means shelter but to others it means more as it serves as one of the best indicators of a people's standard of living and their place in the society (Nubi, 2008). Housing is recognized world-wide as one of the basic necessities of life and a pre-requisite to the survival of man (Onibukun, 1983; Salau, 1990; United Nations, 1992; Ademuliyi, 2010).

According to a UNDP report in 2010, housing is a universal basic need and a key component of any nation's economy. Lack of it indicates one of the worst forms of poverty. Apart from its role in contributing to the Gross Domestic Product, it is an important contributor to the generation of employment, poverty reduction and promotion of social being. Despite numerous government intervention, policies and programmes towards remedying the worsening housing problem in Nigeria the dearth of housing has persisted unabated (Anunike, 2011).

Ogunsemi (2002) observed that housing shortages have been a recurring problem to the general public in Nigeria. This has been attributed to failure of various government efforts to adequately gauge the needs of those who end up using the products. Daramola (2004) made

Fadason, R. T.; Musa-Haddary, Y. G. & Ahmed, D. I. (2016). Value Profiling of End-Users' Housing Needs in Selected Housing Scheme in Kaduna State. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 684-692

similar observation to the effect that design of government houses start and ends only with the Federal/State agencies and with little or no involvement of end-users. The end-users' habits, tradition and requirements are hardly captured or reflected in the briefing during the design development process. This reflects in the end products that do not adequately meet end-users' needs and expectations (Othman, 2008; Adellatif and Othman, 2006; Carroll, 2007). The result of which is the lack of interest or outright rejection of the products by the end users thus sustaining the dire need for the right housing types. Othman (2008) found that users who accept the facility usually rent out or sell it. Those who use the products often adopt/adapt them to meet their needs and to accommodate their activities. While selling or renting out the unsatisfactory products sustain housing needs in a country, adapting them constitute economic waste. The process of adaptation involve removing unwanted or replacing undesired items; it may include expansion or contraction of spaces by demolition or rebuilding certain areas. All these waste can be saved by reflecting/capturing user value requirements in the design and construction.

In line with this, the following questions are asked:

i. What are the housing needs and expectations of end-users in selected housing scheme in Kaduna?
ii. What importance do end-users attach to their various housing needs and expectations?
iii. How satisfied are end-users with the housing products made available by the providers?
iv. Do they have their preferences in terms of what should be provided?

These questions pose problems in defining end-users needs and expectations at the design stage of housing schemes.

Statement of the Problem

The dearth of adequate housing in Nigeria has persisted despite efforts by the Government and developers. The generic problem is the neglect to put users' needs into consideration in the design and construction of housing projects. Users therefore often fail to use the product for the purpose of which they are constructed. This has led to persistent need for housing in Nigeria. If design will meet the expectation of users, the product will be put to right use and the need for housing will be solved. It is unclear what the end-users' needs and requirements from housing are in Nigeria.

Aim and Objectives

Aim

This research aims to assess the importance end-users attach to their housing needs with a view to satisfy End-User preference in housing delivery in Nigeria using the housing schemes in Kaduna State.

Objectives

i. To identify End-Users' housing needs and expectations prior to implementation of housing projects in selected housing schemes in Kaduna State.
ii. To assess End-Users' needs and expectations in selected housing schemes in Kaduna State.
iii. To evaluate the importance housing End-Users' attached to their housing needs and expectations in selected housing schemes in Kaduna State.

LITERATURE REVIEW

Housing

Housing has been described by Boarne (1981) and Daramola (2004) as a package of bundle of services which include the consumption of neighbourhood services (parks, school(s), a location (accessibility to jobs and amenities) and the proximity of certain types of neighbours (a social environment). Olotuah (2005), and Isa and Jusan (2012) define housing as building structure that accommodate people and that meets their shelter and social needs. These definitions imply that beyond the physical structure, housing encompasses the immediate environment, sanitation, drainage, recreational facilities and all other economic and social activities that make life worthwhile.

Value Profiling

Calder et al (1999) observed that Value Profiling is a less-developed concept, which has started to attract the attention of research community. The study's approach to value profiling is described as defined by Dallas (2006), "Method articulating a Client's value expectations" Adopting this definition this study attempts to articulate the End-Users' Valued expectations regarding their housing needs.

According to Wandhal *et al,* (2007) value is a central component for participants in building projects. To the client, value is what he receives in terms of design, usability and quality commensurate with the amount of money he spends. To the contractor, the architect and other consultants value is to contribute to the fulfillment of the client's requirement in such an efficient manner.

End User Satisfaction Evaluation Criteria

Using value management evaluation criteria can help to improve building performance while contributing to user satisfaction. Post-occupancy Evaluation (POE), a well established building performance evaluation approach, attempts to provide a link between building production and use by employing the use of occupants' feedback mechanism (Ilesanmi 2010, Hendrickson and Wittman 2010). Hence end-user satisfaction although subjective, must be brought to bear in order to harmonise values of all stakeholders in housing production and use. In developed countries this provision is made, through regulatory frameworks requiring housing producers to establish user requirement by incorporating them at decision making stages, thereby producing tenant involvement statement to the appropriate regulatory agency as a means of verifying their commitment in ensuring user satisfaction in product delivery (HouseMark Report, 2010)

End-user' satisfaction is a subjective and multidimensional concept. Studies on end-user' satisfaction evaluation of public housing programmes, emphasize the need to identify what works well and what does not; as well as consequent impact of such programmes on the life of beneficiaries and surrounding. For the end- users, evaluation is essential in determining their environment against an image of what they would like it to be. The evaluative pattern is primarily influenced by objective and subjective factors (Ilesanmi 2010, Ibem and Amole, 2010). Studies carried out end-users satisfaction in housing indicate that user satisfaction had little impact on improvement in design and implementation input. Desired value in the construction industry is derived from different stakeholders by identifying opportunities and exploring them to attain housing delivery objective considering every stakeholder's role in the process (Kowaltowski and Granja 2011). However, there seems to be lack of effective integration of client value system and end user satisfaction generally. Although both aspects of value contain objective and subjective elements, their evaluation criteria differ and are measured by differing parameters hence achieving client value system cannot automatically translate to achieving user satisfaction. Evaluation by actual building users is important for

design improvement therefore if innovations must be achieved in housing projects, user contribution must be sought from conception of any (Ilesanmi 2010). Liu (1999) recommended that residential buildings should not only be fit for the purpose of the users but must be able to perform functions relative to resident's satisfaction.

Mass Housing Development for Kaduna State Civil Servants

Mass housing is aimed at providing large quantity of houses for the populace who do not own a house and majority of the mass housing schemes are located within the state capitals in Nigeria. Mass housing is often viewed as the only way through which low income earning population of an urban centre can own a house by installment payments. It has been observed that the houses oftentimes do not get to the proposed house owner because the housing process did not start by identifying them (Adedayo, 2012). According to Kabir and Bustani (2008), the 3rd National Development plan of 1975-1980 showed how government tried to provide houses in large quantities throughout the country regardless of location, climate and culture. This same practice according to Arbigbola (2008) was continued in National Housing Policies of 2002. The practice of providing same house type around the country has been suggested as a major reason for the failure of the policies. It can be assumed that the realization of the failure of the policies led the government to call for the private sector to play active role in mass housing provision (Adedayo, 2012).

METHODOLOGY

The research adopted questionnaire survey to investigate a sample of occupants of the public housing units in Kaduna State. The questionnaire was designed to seek information from the occupants of housing units who for the purpose of this research are considered as the End-Users.

The population from which the samples were obtained is a 600 unit public housing scheme constructed in 2005 by the Kaduna Sate government. The housing scheme comprises three bedroom, two bedroom, two bedroom semi-detached and one bedroom units located in Malali, Narayi, Unguwar Baro, Kurmin Mashi, Kawo, Unguwar Mu'azu areas within Kaduna Metropolis, Kafanchan and Zaria. A simple random sampling method where each building type was given a number between 1 and 400. The questionnaires were self-administered.

Responses were requested on 5-point Linkert scale (5-Very important; 1-Not Important) on factors obtained through an exploratory study, and literature review. Four hundred questionnaires were distributed to respondents out of which 209 were completed and returned representing 52.25% returned rate and 47.75% were not returned. The questionnaires were in two parts: Part A is general information about the location of the respondents and Part B is assessing Users' needs and satisfactions. According to Burns and Grove (2007) data analysis is a technique used to reduce, organize, and to give meaning to the data. The data collected was analysed using Statistical Package for Social Sciences (SPSS) version 17.0. The results of this study were expressed in descriptive statistics namely: mean, frequencies, and percentages.

The main focus of this study is to collate the value profiling of end-users housing needs in selected housing scheme of Kaduna State with a view to improving housing delivery for medium income public servants from Grade Levels 08- Grade Levels 12 in Kaduna state. The Housing schemes were occupied by low income Gl. 01-Gl.07, medium income from Gl.08-Gl.12 and high income form Gl.13 and above. However, Gl.08 -Gl.12 was the most prevalent in the houses occupied. Dwelling features preferences were examined by analysing the

distribution of responses to the questions eliciting the respondents' preferences for the housing profiles included in the surveys.

FINDINGS AND DISCUSSIONS

Four hundred questionnaires were distributed to respondents out of which 209 were completed and returned representing 52.25% returned rate and percentage used in analysis. The essence of the analysis was to provide answers to the questions raised in this study and to enable the research draw inferences on the population of the study.

Analysis of Demographic Data of Respondents

Table 1 Respondents' Residence

Location	Frequency	Percent
Narayi H/cost	23	11.0
Unguwar baro	19	9.1
Kurmin mashi	118	56.5
Kawo	49	23.4
Total	209	100.0

The above table shows that more than half (i.e., 118 respondents representing 56.5%) of the respondents who participated in this study were from Kurmin Mashi. 49 respondents representing 23.4% of the total number of participants were from Kawo. Narayi and Unguwar Baro had 23 (11%) and 19 (9.1%) respectively.

Analysis of Research Questions

Four research questions were asked in this study and the essence of these questions were to give this study a direction and guide. Therefore, in this section, answers to those questions were provided and the results presented below in tabular form.

Table 2 Housing Needs of End-Users

S/n	Housing & expectations	Mean	Std. Dev.	Rank
1	3bedroom	4.82	.407	1
2	4bedroom	4.61	.543	2
3	4bedroom semi-detached	4.55	.777	3
4	3bedroom semi-detached	4.39	.546	4
5	2bedroom semi-detached	3.73	1.237	5
6	1bedroom semi-detached	3.11	1.159	6
7	2bedroom self-contained	2.94	1.277	7
8	1bedroom self-contained	2.05	1.316	8

The above table shows descriptive analysis which was carried out to find out the type of End-Users housing needs and expectations. The result revealed the mean response of the items in order of most prevalent expectations and needs of End-Users are as follows: 3 bedroom, 4 bedroom, 4 bedroom semi-detached, 3 bedroom semi-detached, and 2 bedroom semi-detached, 1 bedroom semi-detached, 2 bedroom self-contained, and 1 bedroom self-contained. This indicates also the consideration of the size of the family. Those with large family size will prefer the 3-bedroom and 4-bedrooms.

The above table shows a descriptive analysis which was carried out to find out the level of importance End-Users attach to their housing needs with regards to the dwelling unit features, ventilation of house, and finishes. The analysis shows the ranking of the items in order of importance. It was found that end-users attached high level of importance Dwelling Unit Features. To the End-Users, Living area with a mean of 4.82 and rank 1 is very important. Closely followed is Children's bedroom and wall tiles (toilet/bathrooms) with a mean of 4.65 and rank 1 and 3 respectively, Master bedroom with a mean of 4.64. Next is Dining space 4.56, Ceiling 4.55, Kitchen/store 4.50, Floor tiles 4.46, Shower/bathtub 4.37, Visitors' bedroom 4.26, Aluminium sliding windows 4.24, Toilet in every room 4.20, Plaster/painted walls 4.19, Aluminium projected windows 4.08, open courtyard 4.00, Sliding doors 3.89,

steel doors 3.85, aluminium casement windows 3.85, Steel projected windows 3.79, Tropical steel windows 3.72, Kitchen 3.76, casement doors 3.64, entrance verandah 3.61, Visitors convenience 3.598, steel casement windows 3.547, were found to be significantly important to end-user. While the result shows also that cement floor only 3.38, shower only 3.04, bathtub only 2.98, other dependents bedroom 2.95, Small Zaure (ante-room) 2.86 which has cultural and religious values of the respondents and toilet shared by some rooms 2.70 are least important to the End-Users.

Table 3 Importance rating of end-users' various housing needs and expectation

MEDIUM INCOME EARNERS			
	Mean	Std Deviation	Rank
Living Area	4.83	.378	1
Wall Tiles (Toilet/Bathrooms)	4.65	.922	2
Children's Bedroom	4.65	.530	3
Master Bedroom	4.64	.499	4
Dining Space	4.56	.674	5
Ceiling	4.55	.579	6
Kitchen/Store	4.50	.783	7
Floor Tiles	4.46	.924	8
Shower/Bath Tube	4.37	.868	9
Visitors Bedroom	4.26	.986	10
Aluminum Sliding Windows	4.25	1.024	11
Toilet In Every Room	4.21	.969	12
Plaster/Painted Walls	4.20	1.205	13
Aluminum Projected Windows	4.09	.856	14
Open Courtyard	4.01	1.199	15
Sliding Doors	3.89	1.271	16
Steel Doors	3.85	1.116	17
Aluminum Casement Windows	3.85	.924	18
Steel Projected Windows	3.77	.740	19
Kitchen	3.76	1.149	20
Tropical Steel Windows	3.72	.972	21
Casement Doors	3.64	1.199	22
Entrance Verandah	3.61	1.265	23
Visitors Convenience (Toilet)	3.59	1.468	24
Steel Casement Windows	3.55	.995	25
Cement Floor Only	3.38	1.292	26
Shower Only	3.04	1.328	27
Bath Tub Only	2.98	1.408	28
Other Dependents Bedroom	2.95	1.680	29
Small Zaure (Ante-Room)	2.86	1.541	30
Toilet Shared By Some Rooms	2.70	1.593	31

Table 4: Importance rating of end-users' various housing needs and expectation

MEDIUM INCOME EARNERS			
Variable	**Mean**	**Std Deviation**	**Rank**
Passage	4.79	.41	1
Water supply	4.77	.42	2
Parking space	4.74	.43	3
Distance to market	4.71	.55	4
Distance to work place	4.70	.59	5
Refuse collection point	4.69	.64	6
Security control	4.65	.57	7
Rain water	4.61	.62	8
Electricity supply	4.60	.50	9
Sewage chambers	4.59	.49	10
Noise level (quite)	4.56	.81	11
Distance to school	4.56	.95	12
Landscaping	4.54	.56	13
Perimeter road	4.53	.74	14
Distance to hospital	4.25	1.33	15
Distance to worship places	2.68	1.65	16

The above table shows descriptive analyses which was carried out to find out the how much importance end-users attach to their housing needs with regards to the dwelling unit features, drainages, social environment, and services. The analysis shows the mean response of the items in order of importance as perceived by respondents. It was found that end-users attached high level of importance to household features. To the end-users medium income earners, dwelling unit features such as passage, parking space, refuse collection points; perimeter road and lastly landscaping are of utmost importance to them. On drainages, the respondents considered rain water and sewage chambers as very important to them. Of most important to the respondents on social environment is distance to market and work place followed by the noise level, security and distance to school. Of least importance to the end user on social environment is distance to places of worship. Respondents also reported that social services such as water supply and electricity are very important. Generally, out of all the 16 features listed, respondents attached higher value to passage, distance to market and workplace, and water supply.

Table 5 Satisfaction Rating of End-Users' Housing Product

MEDIUM INCOME EARNERS			
Variable	**Mean**	**Std. Deviation**	**Rank**
Painting and decorating	2.52	1.21	1
Type of doors	2.41	1.28	2
Type of windows	2.36	1.18	3
Drainages/parking	2.11	.79	4
No of bathrooms	2.10	1.25	5
Size of toilets	1.87	.87	6
No of rooms	1.85	1.14	7
Size of rooms	1.79	1.09	8
Ceiling	1.79	.72	9

The table above is a descriptive analysis carried out to assess the level of end-users satisfaction with regards to housing products made available by the provider. The result revealed that end-users were not very satisfied with virtually all the housing products made available by the provider. In order of dissatisfaction, the end-users appear highly displeased with the number and size of rooms, size of toilets and the ceiling. They also reported that they are dissatisfied with type of door, number of bathrooms, type of windows, drainages/parking and even the painting and decoration. By this outcome, it appears much work still need to be done to improve the housing products made available to the end users by the providers in Kaduna state.

Table 6 Preferences of end-users' of housing provision

Variable	**Rank**
Increase in no rooms	1
Increase in size of rooms	2
Consider building location	3
Type of Doors	4
Increase in no of bathrooms/toilets	5
Consider family size	6
Increase in size of Toilets	7
Types of Windows	8
Consider Grade level	9
Drainage/parking etc.	10

The above table shows the mean scores of end-users preferences in term of what should be provided by providers. In order of preference, the result revealed that end-users preferred the number of rooms, followed by the size of the rooms, building location, Type of doors,

increase in number of bathroom/toilets. In general, the end users reveal higher preference to number and size of rooms and less preference drainage/parking space and grade level. This therefore implies that in order to improve end users satisfactions, the needs such as number and size of room must be met.

CONCLUSION/RECOMMENDATION

The result reveals that end-users most prevalent expectations and housing needs are the 3 bedroom and 4 bedrooms.

The end-users attached high level of importance to household features such as living areas, children's bedroom and of least importance is distance to worship place.

The end-users were not satisfied with virtually all the housing products made available by the provider. They were also highly dissatisfied with the number and sizes of rooms.

They also reported that they are dissatisfied with type of door, number of bathrooms, type of windows, drainages/parking and even the painting and decoration

In general, the end users reveal higher preference to number and size of rooms and less preference drainage/parking space and grade level. This therefore implies that in order to improve end users satisfactions, the needs such as number and size of room must be met.

The study bring to fore the need for housing providers to be aware of the important attributes of End-Users' housing needs and expectations including incorporating them into design and housing provision(s)

ABSTRACT

The passing of the bill on land use charge into law in the mid- year 2014 has diverse reactions from the professionals in the built environment as well as the property owners within the state capital where its implementation is to take-off. The new law tagged: Ondo State Land Use Charge Law, 2014 has combined all the land based rates and charges previously in the State. A number of issues were identified at the point of implementation of the land use charge law. Hence, this study analyzes the perception of the property managers within the city on the contents of the law, the composition of the members to execute it and the method of assessing the chargeable value on the properties. This is a survey which elicits data from the practicing Estate Surveyors and Valuers through a structured questionnaire on the Land Use Charge and descriptive statistics is employed to present the findings. The result reveals among others that the composition of membership is grossly inadequate and the basis of assessment of chargeable tax under the stipulated law is faulty. The study recommends the inclusion of all stakeholders (practicing Estate surveyors and Valuers, Land surveyors and the Property owners) in the implementation of the law. This will go a long way to have an agreed and appropriate basis of assessment thereby ensuring a problem free property tax administration in Ondo State, Nigeria.

Keywords: Estate Surveyors and Valuers, Land Use Charge, Law, Ondo State, Perception

INTRODUCTION

The dwindling revenue allocation from the Federal government has made various state governments seek an alternative means of improving state internally generated revenues through property tax in order to face the challenge of providing infrastructural facilities (Oni and Ajayi, 2011). According to Tesfay (2008) the responsibility of providing infrastructure at all levels rest on Government. This has however posed a great challenge to Governments. The attempt to resolve this gave birth to the advent of Land Use Charge in Nigeria. The first in its series was the enactment of Land Use Charge Law by the Lagos state government on 22nd June, 2001. The justification for this as pointed out by Oserogho (2002) was to generate further revenue required to develop the state as it is faced with increasing population without corresponding increase and developments. Provision of basic facilities will according to Tesfay (2008) afford cities an effective requirement for national development. Though the initiation of the Land Use Charge meant well as it was anticipated to assist rapid provision of infrastructures, harmonize some property tax and ease the problem of multiple taxes. However, the implementation of the tax law in spite of its significance was faced with myriad of challenges as avowed by Oni (2009).

Similarly, in the context of Ondo state, on 14th March, 2014 the Land Charges Bill was passed into law. The objective is to model a consolidated land charges reasonable and affordable to the citizens in order to enable the state government discharge its responsibility of providing basic facilities and make life more meaningful to the citizens. In spite of the importance of the main aim of the enactment of the Ondo State Land Use Charge law, a number of issues arise at the peak of the implementation of the provisions of the law just as experienced in Lagos as affirmed by Oni (2010). This among many others include non-

Oladapo, R. A. & Ige, V. O. (2016). Property Manager's Perceptions on the Ondo State Land Use Charge Law, 2014. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 693-698

involvement of professionals on land matters, non-sensitization of property owners, non-clarification on method of assessment, determination of taxable property, reasonable approach of levying the tax and the view that local government constitutional role was eroded. To tackle these issues, this paper examined the perceptions of estate surveyors and valuers who are core professionals on land related issues.

LITERATURE REVIEW

Concept of Taxation

Tax is defined by Ogbuefi (2004) as is a compulsory monetary charge imposed by government on persons, entities, transactions, or properties to yield public revenue. This includes all governmental impositions on individual, corporate organizations and real property. Oni and Ajayi (2011) explained further that taxation is an essential part of contemporary economic systems worldwide, with array of diverse tax models. According to Newell, (1977), Emeni, (2000), Thacker, (2009) and Olusegun, (2003) a tax must be fair, equitable, politically acceptable to the payers, simple and clearly understandable, its administration must not be expensive and must be a good stabilizer. The basis of assessment as avowed by Harvey (2000) should therefore be open market value of a property while the method of tax assessment is on the net annual value of the assessed property. The economic consequence of tax is that there will be long term effect on open market price as it increases if there is higher demand. Equally, if the outgoings in form of tax liability are higher the rent demand by the landlord will be higher on the long run (Lean and Goodall 1977). Also in the short run the tax liability will be borne by landlords as the stock of rented houses is fixed and in the long run supply of houses is more elastic (Harvey 2000).

General overview of the Land Use Charge Law

Land use charge is a form of property tax (Harvey, 2000). Newell, (1977) and Oni (2009), described land use charge as a form of taxation with the objective of financing public spending within the framework of economic objectives of government. The land use charge law was first introduced into Nigeria system of property taxation by the Lagos state Government in order to strengthen its revenue base. The tax charged under the law is called the Land use charge and recognized as Land Use Charge Law Cap. L 61, Laws of Lagos State of Nigeria 2003. It is clearly an improved version of tenement rate, the main objective of the law as stated in the preamble is to consolidate taxes and rates hitherto payable under the land rates law, the neighborhood improvement charge law and tenement rate (Oni 2009). Oni (2009) stressed the importance of Land Use Charge as the means through which State Government raise revenue for maintaining existing infrastructure and providing new ones. This should also be fair to the citizens to avoid hostility and enable government discharge its duties to the public. Infrastructure is crucial for the functioning of communities (Oni 2009). Thus, for national development to be achieved, good infrastructure that affects all sectors is required. Apart from aiding government in generating additional revenue for the provision of infrastructures, Land Use Charge will according to Oserogho (2002) drastically help reduce problem of multiple taxes.

Certain Provisions of the Land Use Charge Law in Ondo State

The situation in Ondo State is a replica of that of Lagos with little disparities in their respective Land Use Charge Laws. The Chairman of the Board of Internal Revenue (BIR) is by Section 5(1)-(3) of the Ondo State Land Use Charge Law empowered to undertake or cause to be undertaken an assessment of chargeable properties subject to the advice of the commissioner for Lands and Housing in such areas of the state as the Governor may designate. In Lagos the Commissioner of Finance is by Law empowered to undertake or cause to be undertaken an assessment of chargeable properties in such areas as may be

designated (Oni and Ajayi 2011). In Section 5 (1) of the of the Lagos state Land Use Charge law, the formula for determining the annual amount payable is stated while in Ondo state the formula for calculating the rate was not stated but was to be determined by qualified Estate Surveyor based on the prototype properties across board for identical structures (Section 7(3) of the Ondo state land use charge law). On the contrary, Oni (2010) opined that the statutory supposition that all properties are homogenous was wrong as no two properties are the same in terms of specific location, road network, accessibility, demand and supply, and state of repair. The law as well negates the uniqueness of each property.

Like the Lagos State Land Use Charge, properties that are exempted from the Ondo state land use charge law according to Section 9 (a-h) include those that are owned, occupied and used by religious bodies exclusively for public worship or religious education, public library, non-profit making cemetery or burial grounds, public parks, diplomatic premises and real property used strictly by public institutions for learning or education. Having considered the relative importance of the Land Use Charge law and part of its provisions, there is need to also see the success of its implementation. According to Oni (2009), for instance, the execution of the law in Lagos State was faced with numerous hitches. This includes the long-run effects of the provisions of the law on the open market values of affected properties and the fair and reasonable basis for calculating the charge. In determining the Land Use Charge, the capital value basis is considered inappropriate while the investment method has however been stated to be appropriate basis by considering the open market rental value per annum after deducting the outgoings and appropriate rate per naira applied. The implication of charging LUC on capital value is that the landlord is made to sell his property annually. The Land Use Charge Law that has been in operation for barely more than a decade ago in Lagos State has been found to be subject of criticisms and litigations from diverse stakeholders (Akinsanya and Oladapo, 2015). Hence, there is need for Ondo State Government to take caution and resolve all controversial areas of the Law before implementation.

METHODOLOGY

The study adopted the survey research design. The motivation for this study stems from the observation on comments from the masses on the introduction of Land Use Charge in Ondo State with its attendant challenges. A closed-ended questionnaires were randomly distributed to the 25 private Estate Surveying and Valuation organisations in the study area. Twenty (20) of the questionnaires (80%) were returned on time. The purpose of the questionnaire was to obtain their opinion on the Land Use Charge Law and the determination of the appropriate methods of assessment. The data gathered from the survey was placed on a five point Likert scale (Strongly Agree = 5, Agree = 4, Undecided = 3, Disagree = 2, strongly Disagree = 1) and was analyzed using descriptive statistical techniques.

FINDINGS AND DISCUSSIONS

Table 1 shows that majority of the respondents established their firms between 6-10 years ago. This implies that a reasonable result would be obtained considering their experience on rating exercise coupled with management of ratable properties. The significant level of their academic qualifications portrays a reasonable justification of the study as they are not novice on property tax issues.

When asked about the most appropriate method of assessment, the respondents strongly agree and agree that the investment method approach is the most suitable, which was evident from the mean score of 4.70. Ajayi (1998), Harvey (2000), Oni (2009) and Oni (2010) also emphasized that the net annual rental value basis is appropriate.

Table 1: The Main Characteristics of the Respondent

	Frequency	Percent
Year of Establishment		
1-5 years	7	35
6-10years	10	50
11-15 years	3	15
Total	20	100
Status of Respondents		
Principal partner	2	10
Partner	5	25
Branch manager	7	35
Senior Estate officer	6	30
Total	20	100
Academic Qualification		
HND only	4	20
B.Sc/B.Tech	14	70
B.Sc/B.Tech/ANIVS	2	10
Total	20	100
Years of Experience		
1-5 years	7	40
6-10years	8	35
11-15 years	5	25
Total	20	100

Table 2: Determination of the appropriate methods

Method	Strongly Agree	Agree	Undecided	Disagree	Strongly Disagree	Mean	Rank
Investment Approach	14	6	0	0	0	4.70	1st
Contractor's Methods	1	11	6	2	0	3.75	2nd
Profit Methods	0	11	5	4	0	3.25	3rd
Market Approach	0	6	10	4	0	3.00	4th

Table 3: Perceptions of Property Managers on the Land Use Charge Law

S/N	Property Manager's Perceptions	Mean	Rank
1.	Similar past laws have not been properly utilized	4.00	1st
2.	Property exempted are adequate	3.90	2nd
3.	Law will increase rate of default	3.30	3rd
4.	The new Tax is not Additional Burden	3.25	4th
5.	Land Use Charge Law will Reduce / Prevent Tax Invasion	2.95	5th
6.	Law will Cause upward review of rent	2.55	6th
7.	The Composition of Admin is Adequate	2.20	7th
8.	Assessment method is straight forward	1.75	8th

The aftermath implication of the existence of the Land use charge law in Ondo state was shown in Table 3. Though the tax was designed to consolidate all other property tax, if the objective is meant to be achieved the above stated perceptions of Professional Property Managers may affect the success rate of the law. Starting from the lowest mean of 1.75, which shows that the assessment method is not straight forward, similarly, the administrative composition which is ranked with a mean of 2.20 indicates inadequacy of the administrative composition. The highest mean on the table is 4.00, which shows that similar past laws have not been properly utilized, while the second in rank mean with 3.90 indicates that property exempted are adequate.

CONCLUSION

The Ondo State Land Use Charge law was conceived in utmost good faith, adopted, as it was in Lagos where it had been tested. It has being a very good initiative meant to increase internally generated revenue in order to provide basic infrastructural facilities for the citizens. The biggest challenge however was at the implementation of the law just as similar past laws. As it was faced with numerous difficulties; ranging from non-involvement of professionals on land matters, non-sensitization of property owners, non-clarification on method of assessment, determination of taxable property, among others. The survey of property manager's in Ondo State, Nigeria was carried out with specific attention on their perception of the land use charge law. The study found out that the most appropriate method in arriving at chargeable fee is using the investment method of valuation that considers net annual rental income. It was also observed that the administrative composition in charge of the law is inadequate. Hence, to ensure a problem free property tax administration, appropriate basis of assessment should be used. Ondo state should also be made more investment friendly so as not to give the impression that government is on the ploy of taking over property rights of the citizens.

In view of this, the following recommendations are made based on the researchers' findings:

i. The government should amend the law and not sideline the contribution of the relevant professionals such as Estate surveyors and valuers.
ii. The so called ghost formula for arriving at the charge is not recognized and alien to the real estate profession. Hence, it should be abolished and, and the service of Estate surveyors and valuers is required in determining chargeable tax based on the appropriate method of valuation.
iii. The composition of the administration of the land use charge is incomplete if the service of professional property manager was not sought. Estate surveyors are the property manager; hence, with their cordial relationship with property owners, they would be helpful collection/payment of the levy.
iv. Funds generated should be channeled to socio-economic development of the dwellers. This will rescind the assertion that Similar past laws are not been properly utilized

Impact of the Federal University of Technology, Akure on Residential Property Values in Akure, Nigeria

Bello, Victoria Amietsenwu

Department of Estate Management, Federal University of Technology Akure, Nigeria
vicbellofuta@yahoo.com

ABSTRACT

The paper examines the impact of the Federal University of Technology Akure (FUTA) on rental values of residential properties. For the study, properties between 5 meters to 1000 meters to the University were considered. Structured questionnaire were administered to 251 tenants occupying residential properties in the area out of which 176 were retrieved for analysis representing 70.1% response rate. The data collected were analysed using Descriptive Statistics and Simple Linear Regression Analysis. The Descriptive Statistics was used to analyse the socio – economic characteristics of the respondents while the Simple Linear Regression Analysis was used to determine the impact produced by the presence of the University on rental values of residential properties. The result reveals that greater number of the student population resides off campus and rents are higher for properties in close proximity to the University. This study therefore, recommends that government should build more hostel accommodation inside the University. Also, the University authority should encourage Public Private Partnership in hostel provision. If this is done, many of the student population will move into campus and this will reduce the pressure in the housing market thereby reducing rental value of residential properties.

Keywords: Residential Property Values, Population, University

INTRODUCTION

In recent time the Nigeria government has shown strong commitment to growth in higher education sector by the establishment of more institutions especially Universities and the liberalization of its ownership. It has the biggest University system in Sub-Sahara Africa with 114 accredited tertiary institutions (Alithei, 2012). Despite this, there is a surge in student's population which has not been matched by a corresponding growth in student accommodation. Hence Alithei (2012) noted that the student's enrolment in tertiary institutions is growing at an average of 12% per annum and the provision of new purpose – built student housing is limited.

Students housing being one of the basic student needs is an aspect of the development economics and therefore, of topical interest to all sectors of all societies. Although, it is regarded as an aspect of pupil personnel management in education and thus not directly in the primary assignments of educational administrators with respect to instruction, it is basically true that academic performance must necessarily be influenced by the quality and quantity of the residential accommodation (an aspect of the learning environment) of the students (Oyetunji, 2014). Unfortunately, in Nigeria not much attention is placed in providing students accommodation on campus especially in Nigeria.

The Federal University of Technology Akure was established in 1982. It operates the dual – residential accommodation system where some of the students (especially the first year and the final year students) are accommodated while others are made to seek accommodation

Bello, V. A. (2016). Impact of the Federal University of Technology, Akure on residential Property Values in Akure, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 699-705

elsewhere around the institution. As a result of this, majority of the university population take solace in the rental market for alternative accommodation. The demand for housing has resulted in the establishment of niche marker because student's market especially appears to be robust. Hence, Peacocke (1999) opined that the major characteristics of students demand is that it monopolizes the market thereby reducing supply to other tenant groups. The result of this is a sharp increase in rent since the available housing accommodation even in the rental market is not enough to meet the demand.

In the past, houses were completed by landlords or property investors, but today, students struggle to make payment even when such accommodation are yet to be completed. The landlords and investors exploit this situation and rents are arbitrary fixed and outrageous. Therefore, this study aims to investigate the impact of the Federal University of Technology, Akure on the rental values of neighbouring residential properties. The paper is organized as follows. The next section (section 2) deals with the university location and neighbouring residential property rental values. This is followed by discussion of the research method employed in section 3 with the results presented and analysed in section 4. The paper concludes with summary of findings, recommendation and conclusion in section 5.

University Location and Neighbouring Residential Property Rental Values

Historically in Nigeria, majority of universities were located at the community outskirts so as to create conducive environment for learning; less difficulty in getting required land size and the minimum financial implication attached. However, these Universities including the Federal University of Technology, Akure have enjoyed circumferential expansion in their neighborhoods primarily because of the functions they perform. The presence of a university in an area may initiate the transformation of the entire neighbourhood through the action of development, regenerating houses in order to attract students, staff, and those providing support services to live (Perry and Wiewel, 2005). Also, universities can function completely apart from the surrounding neighborhoods, ignoring social problems (Anamaria and Melchior, 2007).

Universities and colleges primarily acquire land and structures that support their core mission or immediate growth demands, it is however not uncommon for surrounding communities to criticize universities for their unresponsive development policies or lack of a plan to mitigate negative spillover effects. For neighbourhood residents, some of the major concerns relate to quality of life issues, such as conversion of houses and other buildings to student occupancy; upward pressure on rents; adaptation of shops and facilities to student markets; and increase in traffic, noise, and parking problems (Harasta, 2008). In spite of these Vandergrift, Lockshiss and Lahr (2009) noted that university can provide culture, high technology, recreational facilities, open space, sporting facilities, and fun. A university campus is often the focal point of a municipality. Green areas, water bodies, and open space are all common on campuses. Thus, through higher demand for this unique confluence of amenities, a campus itself may cause house prices to be 10% higher (Vandegrift et al 2009).

Haurin and Brasington (1996) employed the hedonic price model that includes an accessibility index, arts index, population growth index, and recreation index among several other house characteristic variables. Distance to a central business district was positive, but

not statistically significant. The four indices used were all statistically significant except the population growth rate index. This suggests that housing prices within towns that provide arts and recreation increase due to the amenity value present. Since college towns are well known for providing such value to those who are not enrolled, it is hypothesized that housing prices in University towns should be higher due to the availability of recreation and arts.

Hayes and Taylor (1996) examined the extent to which school quality as a location characteristic influences property values in Dallas using hedonic model of property values. They noted that some homebuyers are not only cognizant of differences in school quality but also have revealed their preferences for higher quality schools by paying a premium for their home. Their analysis suggests that this premium for school quality can be among the most important determinants of housing prices. Not all school characteristics appear to be indicators of school quality, however. There was no evidence found that homebuyers are willing to pay for changes in school expenditures or student body characteristics. Evidence was found that the school characteristic for which homebuyers pay a premium is the same characteristic that economists associate with school quality, namely, the marginal effect of the school on student performance. Also, the study of Bradbury, Mayer and Case (1997) used repeat sales analysis to look at the relationship between changes in school quality and changes in house prices in 208 cities and towns in Massachusetts. Percentage changes in house prices between 1990 and 1994 for these 208 cities and towns were regressed on the change in per-pupil operative spending relative to the optimum level of spending, the combined test scores in 1990. The result of Bradbury et al shows that both school quality measures were significant like in the study of Hayes and Taylor (1996), but the study differs in that Elimentary School was the focus.

Shigeru, Hiroshi and Qiang (1999) carried out a study on the effects of University of Kansas on residential house values by using non-parametric assessment. Geographical information system ‘overlay’ and ‘near’ was used to determine the distance of each household to the institution. 6,415 residential sales were analysed. The study found out that house adjacent to the university values more than 40% higher than the comparable house located 2000 meters or more away from it. It was also found out that as the distance to the University gets large, such effects initially declines rapidly and then in a more moderate pace. The study further found out that the reason for the university effect to disappear around 1800 meters is that the walking distance of 20 minutes is the maximum an average person will choose to commute on foot. This view was supported by Owusu – Edusei, Espey and Lin (2007) study that there is a positive value associated with proximity location to schools and a negative value associated with greater than average distance from schools.

Janmaat (2007) carried out a study on the factors affecting residential property rental values in a small historic Canadian University town and found out that view and average sound level were not statistically related to home price. Peak sound level is priced with one decibel increase reducing the average house price by 2%. The study also revealed that given the high population of student tenants in Wolfville, tenants are unlikely to live in areas zoned single family residential; these results suggest that rental externalities - either due to student tenants or landlord practices – are having a strong negative impact on rental values.

Ankeli (2007) carried out a study on the impact of tertiary institutions on residential property values in the Federal Polytechnic, Ede and found out that the establishment of the polytechnic led to the influx of people into the town, thereby, making the residential property market subsector experience a moderate increase in rental values between 1994 and 1997. Another slight increase was also experienced between 1998 and 1999 and the highest rental increment was observed between 2001 and 2005. However, tenement properties close to the Polytechnic experienced the highest rental growth rate.

Anamaria and Melchior (2007) in the study carried out on the impact produced by the presence of university campuses on land and property values using the Hedonic Model and found out that in the immediate area of influence (a radius of 1km from the campus) of the two campuses studied, land and property values were expected to be impacted by proximity of the Universities.

Ajayi and Nwosu (2011) examined the relationship between the Federal University of Technology, Akure and property values. Using the Pearson's product moment correlation, the study revealed a strong positive relationship between population of students and residential property values.

RESEARCH METHODOLOGY

The data for the study was collected from tenants occupying residential properties within 5 meters to 1000 meters to the Federal University of Technology Akure (FUTA). The distance of 5 meters to 1000 meters was taken as appropriate since most students prefer to live close to school. More so, studies carried out in the past were on residential properties within 2000 miles (Singeru et al 1999) and 800 to 2000 miles (Owusu – Edusei et al 2007). The number of residential property that fall within the distance of 5 meters to 1000 meters is 726 and this was obtained through house counting. To obtain the sample size for the study, Cochran (1963) formula modified by Israel (2002) was used and the formula is given as:

$$n = \frac{Z^2 pq/e^2}{1 + \frac{[(Z^2 pq/e^2) - 1}{N}} \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (1)$$

Where n = sample size

N = sample frame of residential properties around the Federal University of Technology, Akure

z = is the abscissa of the normal curve that cuts off an area at the tails for 95% confidence, which is 1.96 assuming the population is normally distributed

p = estimated proportion of attribute that is present in the population which is 50% (0.5)

q=1-p = 1-50% = 1-0.5 = 0.5

e = is the desired level of precision which is 5% (0.05)

Using this formular the sample size obtained is 251. Questionnaires were administered to the tenants of the residential properties in the study area to elicit information on the type of accommodation occupied and rents paid among others,. Out of the two hundred and fifty one (251) questionnaires distributed to the tenants of the residential properties in the study area, one hundred and seventy six (176) were dully filled and returned for analysis representing 70.1% response rate. Descriptive Statistics such as Frequency Distribution was used to analyse the socio – economic characteristics of the respondents while Linear Regression Analysis was used to determine the impact produced by the presence of the University on rental values of residential properties. The form of Regression Function used is

$RV = a_{0 + b\ DIST + e}$ ……. …(2)
RV = Rental Value (₦)
a = Y intercept
DIST = Distance from FUTA in (M)
b = Coefficient of DIST
e = random error term

Table 1: Operationalization of Variables

Variable	Definition of Variables	Measurement
RV	Rental Value	Naira (₦)
DIST	Distance	Meters(M)

DATA ANALYSIS AND DISCUSSION

Background Information on the Tenants around the Federal University of Technology, Akure

The background information of the tenants residing around the Federal University of Technology, Akure is detailed in Table 2 and 3.

Table 2: Tenants Educational Qualification and Monthly Income

EDUCATIONAL QUALIFICATION	MONTHLY INCOME			
	10,000-40,000	40,001-70,000	70,001-100,000	100,001 and above
No formal education	0(0.0)	0(00)	0(0.0)	0(0.0)
Primary School Leaving Certificate	0(0.0)	0(0.0)	0(0.0)	0(0.0)
Secondary School Leaving Certificate/Students	87(49.4)	9(5.1)	0(0.0)	0(0.0)
O.N.D	8(4.5)	8(4.5)	0(0.0	0(0.0)
H.N.D	0(0.0)	12(6.8)	0(0.0)	0(0.0)
B.Sc	13(7.4)	4(2.3)	8(4.5)	12(6.8)
M.Sc	0(0.0)	0(0.0)	0(0.0)	16(9.1)
Total	108(61.3)	33(18.7)	8(4.5)	28(15.9)

The result from Table 2 indicates that 61.3% of the respondents are low income earners who earn between ₦10,000 and ₦40,000 and are students in the University. The low income may be because majority of the students depend on their parents for upkeep.

Table 3: Type of Residential Property occupied by the Tenants

Residential Property Type	% of Tenants in each Residential property Type
Tenement apartment (a room)	81 (46.0)
A room self contain	31 (17.6)
1 bedroom flat	4 (2.3)
2 bedroom flat	16 (19.1)
3 bedroom flat	44 (25)
Total	176(100.0)

Table 3 shows that 63.6% of the respondents residing around FUTA, lives in tenement and a room self contain accommodation. The result is not unexpected as majority of the student population that lives off campus are interested in these type of accommodation. Also, 2.3%, 19.1% and 25% of the respondents lives in 1 bedroom, 2 bedrooms and 3 bedrooms flat respectively. The accommodation type is mostly sought by staff of the University. Duplex were not included in this analysis because the accommodation type was found to be owner occupied.

Impact of distance from the Federal University of Technology Akure on Residential Property Values

As earlier stated, Simple Linear Regression Analysis was employed to estimate the impact produced by the presence of the University on rental values of residential Properties. In this case, residential property value is the dependent variable (RV) while distance is the independent variable (DIST).

Table 4: Model Summary of Distance and Rental Value of Residential Property

Model	R	R^2	Adjusted R^2	Std. Error of the Estimate
1	0.881[a]	0.777	0.775	41675.24427

Table 5: Analysis of Variance of Distance and Property Values

Model	Sum of Squares	DF	Mean Square	F	Sig.
Regression	1.050E+12	1	1.050E+12	604.814	0.000[b]
Residual	3.022E+11	174	1736825985		
Total	1.353E+12	175			

Table 6: Regression Coefficients of Distance and Property Values

Model	Unstandardized Coefficients		Standardized Coefficients	T	Sig
	B	Std. Error	Beta		
(Constant)	241047.244	6470.451		37.254	0.000
Distance	-270.814	11.012	-0.881	-24.593	0.000

The Regression equation is:

Predicted Rental Value = - 270.814 + 241047.244 X (distance to FUTA).

The Linear Regression produced in the Tables above established that distance to FUTA could statistically predict rental values of residential properties. The computed F statistics is 604.814 (Table 5), P value is significant at 0.000 and distance to FUTA accounted for 77.7% (R^2) of the explained variability in rental value of the properties. This confirms the expected relationship between the variables. That is any decrease in the distance of properties to the University will lead to an increase in rental values of properties. Correspondingly, any increase in the distance of properties to the University will lead to decrease in rental values. The result however, is in conformity with the result of Shigeru et al (1999) and Owusu – Edusei et al (2007) who found out that house adjacent to the university values more than comparable house located 2000 meters or more away from it.

CONCLUSION AND RECOMMENDATION

The paper revealed that larger proportion of the people living around the Federal University of Technology Akure have Secondary School Certificate and are students of FUTA earning between 10,000 naira to 40,000 naira. The result also, showed that tenement accommodation and a room self contain accommodation are mainly sought for by the tenants. The regression analysis carried out showed that residential properties in close proximity to the University values more than residential properties located farther away from the University.

The study therefore, recommended that the University authority should build more hostel accommodation inside the University and encourage public private partnership in the provision of student housing on campus. This gesture will reduce the pressure on the private rental market; mitigate high rents and exploitation of students.

Application of Construction Management, Procurement and Project Delivery Systems by Private Housing Developers in Nigeria for Sustainable Development

Raimi, Taofiq Idowu

TAZAS Development and Consulting Limited, Abuja, Nigeria
ritqs@yahoo.com.

ABSTRACT

The purpose of this study is to find out the applicability of the different Project Delivery Systems (PDSs) within the private sector housing developers in Nigeria; conditions influencing the choices they made of PDS and procurement phases, and their pursuit of project objectives of affected stakeholders. The paper presents an overview of different forms of Project Delivery Systems (PDS). It also covered some of the various project procurement phases. It highlighted the implications of the developers' choices in their practice and other stakeholders' interests for sustainable development. There are many existing studies in this research area, but could not find any within the context of the Nigeria private sector housing delivery. Hence, a motivation for this study, to fill a gap in research and contribute to the on-going debate on housing and environmental scholars/practitioners in this identified research area. A questionnaire survey was administered on the housing practitioners through email on member organisations under the Real Estate Developers Association of Nigeria (REDAN). Data collected were analysed using percentage statistical method for subsequent interpretation. Results revealed low response rate and factors likely responsible discussed. Results showed that procurement approach and modern project delivery systems are not alien to the Nigeria private sector housing developers but found DB and PPP most popular among them. The paper made its conclusion for an increase application of modern PDS for improved project performance by the private sector with emphasis on stakeholders' objectives and sustainability for a better world.

Keywords: Housing, Procurement, Project Delivery Systems, Stakeholders, Sustainability

INTRODUCTION

Many previous authors have argued that selecting an appropriate PDS can improve the project performance effectively (Hong, Kim & Leem, 2008; Ojiako, Johansen & Greenwood, 2008; Oyetunji & Anderson, 2006). There are also different procurement phases, a process through which a project is carried out. Admittedly, construction technologies may be similar globally; market environment varies significantly across countries (Qiang, et al., 2015). There are many existing studies in this area of research, but could not find any within the context of the Nigeria private sector housing development. This study, therefore, is a contribution to the on-going debate on housing and environmental scholars and practitioners in this area. Thus, it would be interesting to know the developers responses to questions about what PDS they apply in the delivery of their housing projects and main factors influencing the choices they made; what procurement phases they adopt; how their choices affects the own objectives, environment and other stakeholders benefits. Is the private home developers' application of PDS merely geared towards profit-making or reflecting other objectives? The first part of the paper presented a review of relevant literature on procurement and project delivery systems. A general overview of the Nigerian housing sector was carried out. Following was a discussion of the research method applied; sample, data collection and analysis. The study provided its conclusions, recommendations and limitations for future research.

REVIEW OF LITERATURE

Procurement

Housing delivery entails a process of planning, programming, designing, and constructing facilities. Dell'Isola (2002) categorised procurement process into three phases encompassing

Raimi, T. I. (2016). Application of Construction Management, Procurement and Project Delivery Systems by Private Housing Developers in Nigeria for Sustainable Development. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 706-717

of Planning/Programming (identification of scope, objectives, expectations, budget, schedule and approach); Design (involves three sub-phases- schematic design, design development, and construction documents and Construction. The Nigeria Institute of Quantity Surveyors (NIQS, 2002, p. 67) classified construction projects into six phases comprising namely, Engineering phase, Procurement phase, the Construction and Construction Management, Commissioning and Operation, Project De- commissioning stage and Project Abandonment. However, in Nigeria, the private sector housing developers may undertake procurement of housing in five phases:

i. *Project idea, planning, design and programming*: housing projects ideas initiated may be from market intelligence survey. The ideas get transformed into outline/sketch design upon which an initial cost estimate and timelines are based leading to working drawings submission for government approval before actual construction works can take place.
ii. *Marketing, advertising and promotion*: Private sector housing developers canvass for homebuyers' off-the-plan purchase through different advertisement media such as project fliers, handbills, pricelist, advertising billboard, radio and television jingles, etc. Prospective home buyers are requested to make down payments for Unit (s) allocation before the actual delivery of the homes.
iii. *Construction and completion phase:* whereby approved building plans are implemented into tangible physical (house) leading to physical home delivery.
iv. *Handing over and occupation:* Upon completion of the housing project, subscribers receive their houses either for a living or letting or sale if bought for investment purposes.
v. *Facility management:* developer provides after-sale services to the inhabitants of the homes and may include security, building maintenance, estate cleaning, gardening and water and electricity management services.

A proper understanding of these various procurement phases is important in making a quality decision about selection of a project delivery system to apply for any given housing project.

Project Delivery Systems (PDS)

Project delivery system (PDS) describes how the project participants are organised to interact, transforming the owner's goals and objectives into finished facilities (ASCE, 2000; Chen et al., 2011). Selecting an appropriate PDS for a project can improve its performance effectively (Hong et al., 2008, Ojiako et al., 2008 and Oyetunji and Anderson, 2006). Many authors argued that a reasonable PDS is a critical success factor for any project (Naoum 1994; Sharif and Morledge 1994; Dorsey 1997; Al Khalil, 2002, Chan et al., 2001 and Kumaraswamy and Dissanayaka, 2001) as it affects project schedule, cost, quality and contract management. And that improper selections of PDS portend adverse implications on the overall project performance include cost overrun, delay to completion, poor quality delivery among others (Laedre et al., 2006). Meanwhile, Konchar and Sanvido (1998) presented a comparison of project performance among the various PDS on cost, schedule and quality performance of CM at risk, DB and DBB and were similar to Dell'Isola (2002) examined the impacts of DBB, DB & CM on cost management. Qiang et al., (2015) remarked that PDSs are selected to integrate resources from participating entities, including consultants, designers, contractors and suppliers to make up for the clients' incapability in delivering construction projects. It thus follows that the importance of a proper choice of PDS on a project performance cannot be overemphasised.

Types of Project Delivery Systems (PDS)

The choices for Systems for project delivery have expanded and refined over the last 30 years, and identified were several types of PDS; their peculiarities and applications have gained increasing interest by previous researchers. Discussed below are the various PDSs. They include Traditional Design-Bid-Build (DBB), Construction Management (CM), Design-Build (DB), Engineering Procurement and Construction (EPC), Turnkey, Project Management (PM) (Dell'Isola, 2002; Chen et al., 2005; Liu, et al., 2015).

Traditional Design-Bid-Build (DBB)

According to Pietroforte & Miller, (2002, p.429), a client provides funding for all the various phases of a project including the completion of full design before tendering in DBB. The common practice is for a project owner to hire a design team in an agency relationship (service) and a separate general contractor for the construction in a vendor relationship. Adequate contract documents are usually available which defines a basis of quality and performance and are verified through shop drawings and submittals making pricing also relatively straightforward. Liu et al., (2015) noted there are three players in this approach namely: owners, designers (architects) and general contractors. While the owner pays both the designers and the general contractor, designers act on her behalf and the contractor delivers the required product. More so, owners undertake robust risks, such as political risks (e.g., wars and military coups), social risks (e.g., strikes and civil strife), economic risks (e.g., price increases), legal risks, and natural risks. In the Nigeria housing environment experience, DBB is usually adopted by government and have applied same in the past decades to deliver notable housing projects such as (by the Federal government) 'Jakande Estates' and 'Shagari Estates' built in the 1980s and other many public buildings.

Design and Build (DB)

DB project delivery system requires one general contractor to undertake the two roles of design and construction. A client should, therefore, ensure comprehensive pretender site investigation (Leung, 1999), develop a clear understanding of the project scope (Ashley et al., 1987), prequalify potential tenderers, and assess contractors' proposals thoroughly. Time, cost and quality of design and workmanship represents the key elements of overall success of DB projects (Chan, et al., 2001). Pietroforte & Miller (2002) observed that the market for DB has grown steadily in the private sector for project delivery in the last ten years. Private home developers explore DB for a speculative housing market based on perceived homebuyers' requirements that guide home design and construction. Significantly, a DB system allows design and construction to take place simultaneously and provides improved quality of the final product since new ideas can be injected into the design as work progresses.

Partnering: Public – Private Partnerships (PPPs)

Yuan et al., (2012) argued that PPP is suitable where a government makes a commitment to building a large amount of public housing (building) but is limited by capital gaps and management problems in project operation, resources utilization, and service delivery. Invariably, PPP is adopted by the public sector to attract private investments, to use their advanced management and operation skills, to provide better services to the general public, and to achieve value for money (VFM) (Stewart 2005; Sengupta 2006; Abdul-Aziz and Kassim 2011). Many developed countries such as the UK and most of the Commonwealth countries including developing countries like Eastern Europe and east/south Asia have increasingly adopted PPP (Winch 2000). The primary role of the private sectors is to finance, construct, and operate public housing at the right time as her cardinal involvement in facilities development (Tang et al. 2010). Some of the PPP variants are Build, Operate and Transfer (BOT), Design, Build and Operate (DBOT). Fundamentally, in a BOT, cash flow to support the design, construction, maintenance and operations are generated by the private

investor finances or the financial viability of the project itself (Pietroforte & Miller, 2002). And the BOT private investor recoups its financial investment from financial returns over the duration of the concessionary period at the end of which the property revert to the client (reversionary period). In Nigeria, government at both federal and State level have adopted the PPPs for housing development in the recent years.

For instance, the Federal Capital Territory (FCT) applied PPP in her 'Accelerated Mass Housing Programme' whereby the government provides land to selected private developers to develop mass housing in the under-developed districts of the City. The mass housing private developers provide finances and technical know-how for actual home construction. The resultant housing units are either sold to the government (workers) or third party by the developer to recoup her finances.

Engineering Procurement and Construction (EPC)

In EPC system, a general contractor is handed over general investment requirements by an owner while the former proceeds into detailed engineering designs and its eventual construction. EPC applies mostly to core infrastructure and engineering projects such as rail, manufacturing and processing projects. Higher technical engineering skills are required such as may not be available to the owner or her in-house technical personnel. Owner's involvement in EPC projects is greatly limited considering the technical skills required for design and construction. Giving that the contractor in EPC is in full charge of design and construction, it bears all major if not all the risks associated with the project such as natural and economic risks which also creates ample opportunity to the EPC general contractor to maximise profit due to a lower involvement of the owner in risk sharing. Pre-conditions for EPC application include: few parties participating, an owner does not wish for higher participation, owner's in-house technical personnel is weak, owner's wish contractor take up full risks and owner does not want control over engineering design.

Turnkey

In turnkey, one contractor is charged with the responsibility of full design, construction and finance of the project. Often, a client may desire to have a house and only wish to pay for it at the end of the project when a contractor/developer may have fully delivered it. Some of the influencing factors for selecting a turnkey may include the contractor is fully known to the client and vice versa, client willingness to pay only at completion and handing over, contractor fully pays for the entire procurement process before getting paid and there is joint agreement on terms and conditions between both parties. This approach may be suitable where and individual or homebuyers desire few numbers of houses. It may be impracticable to adopt a turnkey to develop projects such as 'mass housing' that comprise a lot of housing units without a client making any financial commitment.

Project Management

Project management goal is that a project can be effectively managed from its different aspects of cost, quality and time. The primary role of a project manager is to ensure that a housing project meets the cardinal objectives of effective cost management, quality management and time management. He or she is appointed by a project owner to coordinate other participants so that design and construction achieve the defined objectives. A project manager may function within any of the other types of project delivery system and may not necessarily be an independent type of PDS.

Indicators of PDS selection

Admittedly, there might not be an exclusive set of influencing factors for PDS selection (Luu, et al., 2006; Skitmore and Marsden, 1988) as numerous studies constructed various systems of indicators, hence, no universality (Chan, 2007). But often, choice of PDS is based merely

on the in-house experience and or advice by external consultants (Masterman & Duff, 1994). Chan et al., (2001), Love et al., (1998) proposed a multi-attribute utility for PDS selection. Chen, et al., (2011) identified common indicators for PDS selection as speed, certainty, flexibility, quality, complexity, risk allocation, responsibility, arbitration and dispute, and price competition as common indicators. Hughes (1989) revealed how external factors influences PDS selection. Gordon (1994) proposed three groups of factors summarized as project characteristics, client characteristics and market environment. Chen et al., (2011, p.5457) presented four main grouping of indicators. They include project objectives (delivery speed, cost, project quality) and project characteristics (project type, project scale, ability to define the project, flexibility). Others are characteristics of owner and contractor (owner willingness to be involved, owner's available personnel and contractor capability, and the external environment (market competitiveness, regulatory flexibility and technology availability. Therefore, it is agreeable that stakeholders must consider several factors to determine which PDS is most suitable for a project.

The Nigeria Housing Sector- Changing dynamics

For several decades, the formal housing sector in Nigeria has been largely dominated by the government at various levels. Many public buildings and facilities were undertaken through the traditional design, bid and build (DBB) delivery system. But with the dwindling financial resources and competing demand from other critical sectors (education, health, defence) for limited resources, the government in recent years had encouraged private sector participation in housing and other infrastructure development. Also, government past reforms made the dismal performance (Ikejiofor, 1999) necessitating government desire for meaningful and robust solutions to address the over 17 million housing supply deficits (Adeboye et al., 2012; Ifemelunma, 2015). Furthermore, housing demand has been continuously on the increase. All these factors were the impetus for the private sector greater participation in housing delivery as the developers equally saw a business opportunity.

The increased private sector participations have contributed to increasing in housing stock in recent years and created more construction employment/jobs. But increased housing construction activities have brought with some concerns as well. These include inferior and of low-quality houses delivery by some developers and quacks activities exacerbated. Also noticed is a disregard of city Master Plan, depletion of local raw materials and an alarming rate of mining and quarry activities. There is also the importation of construction skills and many other sustainable development issues that have grief implications for human needs of the present and that of the future generations. Private sector housing developers' decision on procurement and PDS for housing delivery must, therefore, take cognizance of these issues to safeguard not only the developer's (owners) objectives but other stakeholders' interests and the planet. Schumacher (1973) noted 'nothing makes economic sense unless its continuance for a long time can be projected without running into absurdities.' Grinde & Khare (2008) argued that many of nature's resources are being harvested at rates where growth is uneconomic and damaging to future production. Consequently, sustainability is seen as 'the ability of a company to make profits while sustaining the environment' (A Dictionary of Business, 2002).

METHOD

The sample for this study is drawn from the private sector housing developers in Nigeria who are members of the Real Estate Developers Association of Nigeria (REDAN). REDAN is the principal agency and umbrella body of the organized private sector responsible for housing development in Nigeria. A list of its (REDAN) members containing 1948 housing developers' organisations was received. A questionnaire survey (email) was the means

chosen to collect data for the study. The email communication method was adopted giving its benefits. Email survey is easy to send, easy to respond, not constrained by geographical location, cost efficiency and applied on a large population (Tuten, Urban and Bosnjak, 1999; Bachmann, et al., 1996; Sproull, 1986; Mehta & Sivada, 1995; Schmidt, 1997; Parker, 1992).

However, only 975 developer organisations have their email addresses indicated on the REDAN register. Hence, questionnaire survey was limited to them using one email address per a developer organisation to prevent multiple entries by one organisation. Meanwhile, 359 bounced invitations occurred and additional six invitees opted out leaving 614 expected respondents. Comely (1996) argued that 'even when a population of e-mail users is chosen, e-mail addresses may be incorrect or inactive, thereby preventing the survey from reaching the intended individual. Importantly, 35 responses were received out of which only 24 fully completed. The response rate was significantly low and of about 6% and many factors may be attributable. Past researches by different authors have reported exceptionally low response rate. Using email for their survey, Swoboda et al., (1997) achieved 20%, Tse et al., (1995) obtained 6% response rate. In this instance, perhaps some developer organisations that received the email survey may have incompatible systems to the one used to send mail for email form to be displayed and filled out correctly (Smith, 1997; Parker, 1992). Second, there may be some developers that are not too familiar with using email but merely provided their email addresses to REDAN while filling membership application form before their registration. Also, some developers may not have imbibed the culture of checking out their email boxes as they would have done for telephone calls, SMS or face-to-face interview schedules. Nonetheless, a multi-mode strategy as suggested by Schaefer and Dillman (1998) was applied to encourage developers' participation in the survey. Reminders emails were sent after the initial notification just as the short survey was designed (Smith, 1997; Bosnjak & Batinic, 2000) with 13 questions so that respondents do not lose interest quickly in participation (Krasilovsky, 1996). However, the response speed was respectable commendable between 2 – 8days. Telephone conversation with all the respondents who returned survey ensures the validity of the data using their telephone numbers provided on the REDAN register. The respondents subsequently provided affirmation.

The questionnaire survey had two sections with the first providing personal background information about the participating organisations. The second section entails key issues on the various types of PDS and each organisation choice and implications of choices developers make.

DATA ANALYSIS

Age of Housing Practice (AHOP)

Table 1 presents the age of the respondent organisations in private housing practice. It shows 41.18% developers have practiced for about10years while another 35.29% were in business within 5 years. Combined, a three-quarter of the entire participating developers have housing experiences spanning within 1 – 10 years. Suffice therefore to say that private sector housing have only evolved within the last one decade ago in Nigeria with very few in practice beyond 10 years. In the recent years, the government liberated the sector by divesting itself from direct housing provision and construction that resultantly made the private sector on the driver's seat of housing delivery. The growing housing supply deficit may also have created ample business opportunities in the sector to fascinate the private developers.

Commendably, the survey was filled by 77.42% CEO and 22.58% senior management indicating the importance the respondents' organisations may have attached to their participation.

Table 1: Age of Housing Practice (AHOP)

SN	Age of Organisation	Responses	% Responses
1	1 – 5	12	35.29%
2	6 – 10	14	41.18%
3	11 – 15	5	14.71%
4	16 – 20	1	2.94%
5	21 and above	2	6.88%
Total		34	100

Housing Project Profile- HOPP (Low-income, Middle-income and High-income)

As shown in Table 2, half of the respondents (developers) reported a mix housing development as their house products, 18.75% developers deliver low-income housing, 25% are Middle-Income, and only 6.65% are high-income developers. A mix-housing development combines more than one class of housing classifications in one housing project (estate). And in this data, the mix-housing developers may have prioritised combination of low-income and middle-income housing in one housing scheme. The developers ensure an inclusive housing demand so that the housing needs of the poor and vulnerable may be considered side by side with the affluent. The developers may also have chosen the lower housing classes since it was where the housing demand is strongest.

Table 2: *Housing Project Profile (HOPP)*

Home class delivery	Responses	% Responses
Low-income	6	18.75%
Middle- income	8	25.00%
High- income	2	6.25%
Mix development (contains more than one type)	16	50.00%
Total	32	100

In addition, about 80% respondents have delivered between 1- 10 housing projects in the past 5 years and the remaining 20% respondents have executed above 10 projects within the same period. This output is comparatively low when compared to the 17 million housing deficit confronting the country.

Procurement Phases for housing projects delivery (PPHOP)

The different procurement phases for housing projects delivery are provided in below Table 3 as adopted by sampled housing developers. 64.52% respondents applied a procurement model comprising six-phases comprising of *Project idea/Planning, Design and Programming, Marketing/Advertisement/Promotion, Construction and Completion, Hand-over and Occupation, and Facility Management* while 31.82% respondents organisations adopted a three-phase procurement model consisting of *Planning/Programming, Design and Construction*. With a clearly defined procurement phases, private housing developers can engage the requisite project participants and procure services towards a successful housing development.

Table 3: *Procurement Phases for housing projects delivery (PPHOP)*

Procurement Phases	Responses	% Responses
A Procurement Phase comprising THREE PHASES: Planning/Programming; Design and Construction.	10	32.26%
A Procurement Phase comprising SIX PHASES: Engineering, Procurement, Construction and Construction Management, Commissioning and Operation, Project De-Commissioning, Project Abandonment.	1	3.23%
A Procurement Phase comprising SIX PHASES: Project idea/Planning; Design and Programming; Marketing/Advertisement/Promotion; Construction and Completion; Handing-Over and Occupation; and Facility Management.	20	64.52%
Others (Please Specify)	0	0.00%

Project Delivery Systems (PDS)

As shown in Table 4, Design – Build (DB) is the highest form of housing project delivery system adopted by the private developers to deliver their housing projects with a percentage score of 37.5%. Public – Private Partnership (PPP) occupies the second position with the system generating 31.25% respondents. Authors as Ke et al., (2009) and Tang et al., (2010) noted that PPPs have been adopted more extensively by governments and have gained importance as vehicles to finance public infrastructure around the globe. Less than 10% developer adopted Project Management as well as Turnkey and no developer currently applied Traditional Design, Bid and Build (DBB) and Construction Management (CM).

The inherent benefits of a DB system to the developer and the organisation may account for higher application. DB enables a developer to take full charge of both the design and construction of the housing projects without many external influences. For instance, the private developer initiates the ideas of the houses, determines what type of houses to be developed and when such projects are delivered. Also, the developer determines the construction method (direct, sub-contracting, general contracting) to apply, the cost of the project, the housing market segment, and the selling price. DB also gives the developer the flexibility to determine how many loans to take for the development, and who the building materials suppliers shall be and so on. All the 35 respondents agreed that a selection of a PDS could make a difference between success and failure of their housing projects.

Table 4: Project Delivery Systems- Housing developers Choice (PDS- HDEC)

PDS choices	Responses	% Responses
Traditional Design, Bid and Build (DBB)	0	0.00%
Design and Build (DB)	12	37.50%
Construction Management (CM)	0	0.00%
Project Management (PM)	3	9.38%
Engineering Procurement and Construction (EPC)	5	15.63%
Turnkey	2	6.25%
Partnering (e.g Public- Private Partnership – PPP)	10	31.25%
Total	32	

Selection of Project Delivery Systems (PDS) - Performance

The respondents (developers) provided an overview of how their chosen PDS has aided attainment of defined projects goals as:

i. *Meeting organisation owner's objectives:* defined as profit maximisation, cost minimization and timely completion. Significantly, 42.11% respondents' developers reported a 'fair' performance; 36.84% remarked 'Good'. In the overall, choice of PDS helps towards achieving the salient business owners' goals.
ii. *Homebuyers' objectives:* defined as price, quality, timely hand-over amenities, and allowance for involvement to make input and house choices. 57.89% agreed to 'Good' and 15.79% stated 'Very Good' indicating that the developers applied PDS to fulfil the homebuyers' objectives.
iii. *Commitment to Environmental issues:* defined as a local community benefit, conformity to city planning, a creation of meaningful employment and local inclusion and efficient use of local materials. Three-quarter of the respondents is a combination of 'Good' and 'Very Good'. The percentage is more so as the majority of the developers reported an adoption of Design and Build, which may allow them to incorporate environmental solutions the project designs such as the preparation of Environmental Impact Analysis (EIA). The goal of EIA is to explore the impact a new (housing) project would have on others, thereby ensuring that it does not cause negative or adverse effects on people, society and earth.

iv. *Other stakeholders' benefits:* defined as the interest of other participants in the project such as timely loan repayment to banks/financiers, use of local building materials, contractors/sub-contractors prompt valuation certificate payment and input of external consultants to enrich project performance. 45.45% respondents posted 'Good' performance and 'Very Good' was 25.00%, thus, illustrating majority of the respondents' satisfaction with their PDS performance on attaining stakeholders' requirements.

Additionally, over three-quarter of respondents agreed that choice PDS can improve the profitability and about 80% developers also believed that modern PDS promote inclusiveness of local community needs in the project. 66% participants contend that modern PDS protect the housing industry and society from environmental degradation and harm. An example is cited of the PPP system whereby government ensures that EIA is incorporated as part of the project documents before the relevant government agencies grant construction approval. The increasing application of modern PDS such as DB is also argued to improve activities by the private sector developers' thereby increasing housing supply. For instance, about 95% respondents agree that PDS (DB, PPP) help the developers to adapt continuously to project changes and variations. The very high percentage is possible as the developers' in-house personnel possess technical and professional skills to identify changes and address it appropriately especially during the construction period to improve project performance. However, 50% respondents agreed to adopt different PDS to future projects to seek new ways of getting better outcomes. The remaining half respondents were 'not sure' of changing their current PDS. Meanwhile, profit making is not reported as the strongest motivating factor influencing the developers' selection of a PDS for housing delivery. Rather 50% respondents insisted are motivated to provide affordable housing so as to generate fair market share, hence, priority development in low-income and middle-income or a mix-development housing comprising the two. Also, 38.89% respondents believed in the factor of 'quality of houses (QHO)' as another consideration for chosen PDS method. The weakest factor determining influencing factors for PDS selection reported by respondents is profit making since the mere emphasis on it pushes them out of competition among other private housing developers.

CONCLUSION

Suffice to conclude that application of some of the modern PDS is not alien to the Nigeria private sector housing developers. However, much of the developers' favoured design and build (DB) as it provides them near absolute control of the entire procurement phases of the project. The Public – Private Partnership (PPP) also has been applied by a good number of the developers considering that such partnering foster beneficial housing delivery and lessons construction cost and marketing by the developers. It is however yet unknown how many housing projects that the partnership has successfully delivered. The study also argued that the bulk of the private housing developer in Nigeria adopts a six-phase procurement approach starting with project idea till hand-over and facility management. Also, the study noted that private sector housing developers no longer embrace mere profit-making objective rather ensures by applying chosen PDS, other stakeholder benefits considered in order to remain relevant in the competitive housing market. In line with the above inclusive project objectives, priority development is given to low-income, middle income and mix development housing and preparation of EIA forms part of the project documents currently in use. The earlier admonition of McDonough et al., (2002, p.117) is apt, 'Insanity has been defined as doing the same thing over and over expecting a different outcome. Negligence is described as doing the same thing over and over even though you know it is dangerous, stupid or wrong. Now that we know, it is time for a change. Negligence starts tomorrow'.

RECOMMENDATIONS/LIMITATIONS

The following recommendations arose from the study:

i. **Housing developers should adopt modern PDS**

It is important for developers to apply modern PDS so as to bring improved participation among different project participants as well as achieve all-inclusive project objectives. Private home developers in their efforts to boost housing quantity, quality should not be jeopardized on the altar of profit-making. The three main classes of housing demand (low-income, middle-income, and high-income) must be represented to ensure sustainable development. Even where the developer maintains full control of the procurement phases such as with DB, building plans and construction must be guided, monitored and controlled using an Environmental Impact Analysis (EIA) to prevent harm to society. Houses should not be built on the waterways to prevent flooding that can lead to wanton of loss of lives and properties. The choice and application of PDS must guarantee sustainable development. The increasing influx of quacks in the housing market must be controlled as their activities are causing untold problems to quality house delivery, project abandonment, death and loss of properties where collapse occurs. A regulatory body should be established to evaluate projects from inception to completion and ensure compliance.

ii. **Apply intensive risk-sharing partnering and monitor EIA performance**

Increase emphasis should be on improved partnership between government and the private sector since each party can bring different values into the housing sector for a drastic reduction in the current housing deficit. Such PPP should also reduce total burden of project delivery on one party since technical, managerial, financial, social, economic, and political and other risks need to be shared for mutually beneficial relationship. Government roles in PPP must encompass not just the provision of non-cash incentives such as land but ensures that EIA prepared for projects development must be strictly adhered and monitored for implementation during the actual construction phase.

iii. **REDAN must update Membership database (email addresses update)**

REDAN needs to update its membership database to include valid email addresses for member organisations without any on her register. There are over 1,000 current member organisations on her register without any email address! Second, at least, a third of email addresses on the REDAN register is invalid and need an update. Developers should be made aware to adapt to modern communication technologies such as effective use of their email addresses to enhance better communication with them.

iv. **Need for study on precise housing stock delivered using different PDS**

Future studies are needed to review in greater details specific number of housing stock delivered by the private sector developers using the various identified PDS. Outcomes of such a research shall provide evidence to help practitioners and scholars to understand the efficiency of each PDS within a given country or clime.

v. **Further study on housing sustainability- deepening the concept of 3Ps (Profit/People/Planet)**

As the private sector housing developers are becoming increasingly committed to other objectives beyond profit-making based on data from this study, additional research is needed to demonstrate how expanded project objectives become achievable. It is imperative that housing delivery would lead to quality homes, quality life and city of beauty and not ‘slums’ due to increasing urbanization and uncontrolled human migration from rural to urban centers.

vi. **Applying email survey for data collection in developing countries**

There is the need for researchers to review the efficiency of applying email for survey especially in developing and under-developed countries where infrastructure is a challenge and users' awareness is minimal. Could the research study outcomes have been different with a higher percentage of respondents?

ABSTRACT

Studies have shown that construction projects are susceptible to problems such as low productivity, poor safety, inferior working conditions, insufficient quality, lack of timely communication and coordination amongst project stakeholders, and rising litigation. The adoption of lean construction (LC) Principles within the manufacturing and other industries had led to notable improvement and resulted in improved time-to-market, reduced production cost, improved quality of the product and active customer involvement. This study appraised the readiness of Nigerian building consulting firms to adopt LC principles. The method of study involved a critical exposition of related literature, VERDICT readiness assessment model for analysis and ANOVA for readiness comparison. A structured questionnaire was issued to a sample size comprising 130 firms drawn from a finite population of 306 Nigerian building consulting firms (Project managers, Architects, Quantity surveyors, Structural engineers and M&E engineers) operating within Northern Nigeria. The result of the study revealed that Nigeria building consulting firms has process/project readiness to adopt LC principles, but do not have management, people and technology readiness to adopt LC principles. The study concludes that Nigeria building consulting firms are not yet ready to adopt LC Principles. The study recommends continuous awareness campaign of LC principles and its potential benefits via education and training to professional bodies, tertiary institutions offering building construction related programmes and stakeholders in the construction industry.

Keywords: Adoption, Consulting firms, Lean Construction, Nigeria Construction Industry, Readiness

INTRODUCTION

Construction is a key sector of the national economy for countries all around the world, as traditionally it took up a big portion in nation's total employment and revenue generation as a whole. However, until today, several countries are still facing numbers of contingent problems that were bounded to be resolved since the past time. The chronic problems of construction *are well* known such as low productivity, poor safety, inferior working conditions, insufficient quality, lack of timely communication and coordination amongst project stakeholders, and rising litigation (Koskela, 2000 & LePatner, 2007). The phenomenon of the poor performance and conditions in construction had long been witnessed and recorded by academics and practitioners throughout the world regardless in developed countries e.g. England (Eaton, 1994) or in developing countries e.g. Chile (Serpell *et al*., 1995). Thus, the UK Government initiated reports such as the Latham Report (1994) and the Egan Report (1998), both of which recommended the improvement of the construction industry's business performance.

The Nigerian construction industry is not also free from such problems. It has severally been characterized as inefficient with low productivity and lack of capacity to deliver and satisfy its clients. Oyewobi *et al.* (2011) attributed the drop in the Nigerian construction industry's contribution to GDP between 1980 and 2007 to poor performance and low productivity.

Olamilokun, O.; Ibrahim, A. D. & Ahmadu, H. A. (2016). Readiness of the Nigerian Building Consulting Firms to Adopt Lean Construction Principles. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 718-726

Similarly, Idrus and Sodangi (2007) asserted that the Nigerian construction industry produces nearly 70% of the nation's fixed capital formation, yet its performance within the economy has been, and continues to be, very poor. Among other criticisms facing the industry are time and cost overruns (Kuroshi & Okoli, 2010; Ameh & Osegbo, 2011; Ogwueleka, 2011), inadequate planning and budgetary provisions, contract sums inflation, inefficient and poor service delivery (Kolo & Ibrahim, 2010).

The need for greater co-ordination and integration within the industry has led to the adoption of various concepts from other industries, for example; partnering (Ibrahim & Price, 2006), concurrent engineering (Khalfan *et al.*, 2000), technological innovations in design and construction processes such as 3D, CAD and modelling (Isikdag & Underwood, 2010; Olatunji, *et al*., 2010); BIM (Abubakar, 2012). Lean Construction principles are one of such innovative processes that bring about the much needed continuous improvement and desired change in the construction industry.

According to Dulaimi and Tanamas (2001), the adoption of lean techniques to construction eliminates non-value steps i.e. waste and better meet client's demands and dramatically improves the Architectural/ Engineering/ Construction (AEC) process and products. Interestingly, unlike Nigeria this has been used with significant benefits in countries like Singapore (Dulaimi & Tanamas, 2001); UK (Common *et al*. 2000); Brazil (Silva & Cardoso, 1999); Chile (Alarcon & Ashley, 1999) and so on. Consequently, it becomes imperative for the Nigerian construction industry, which has been described as a 'sleeping giant' and having no capacity to deliver due to inefficiency and poor service delivery among other problems (Kolo & Ibrahim, 2010), to exploit the widely acclaimed benefits of lean construction in order to practice in line with the global best practices and achieve the continuous improvement needed by its players in the industry.

However, because adoption of innovations such as lean construction principles usually brings about changes in the business processes and operational procedures of an industry or an organization, there is the need to carry out the level of readiness of the construction industry for lean construction implementation by the stakeholders' organizations or the entire construction industry in order to continuously deliver value for money and effectively satisfy the needs of the clients.

LITERATURE REVIEW

Lean Construction Principles

Lean construction has been defined in several ways by different authors. The most popular definition by Koskela *et al*. (2002) states that lean construction is a way to design production systems to minimize waste of materials, time, and effort in order to generate the maximum possible amount of value. This approach is intended to cause the developers, from the outset, to consider all elements of the product life cycle from conception through disposal, including quality, cost, schedule, and user requirements. In the context of the construction industry, another definition states that lean construction is a holistic facility design and delivery philosophy with an overarching aim of maximizing value to all stakeholders through systematic, synergistic, and continuous improvements in the contractual arrangements, the product design, the construction process design and methods selection, the supply chain, and the workflow reliability of site operations (Abdelhamid, 2004).

Benifits of Lean Construction Principles

Broadly speaking, lean construction has led to significant improvement in the performance of construction industry professionals especially in design, construction and facility management. Michigan State University (MSU) reap double benefits of lean construction as a

client and on its own self-performed works, by saving on time and money and improved quality of projects, building relationships with the service providers, and providing value to the end users who otherwise are often not involved in the entire process. The following are some of the benefits of lean construction as reported by Mossman, (2009):

a. More satisfied clients
b. Productivity gains
c. Greater predictability
d. Shorter construction periods
e. Operatives able to make better money
f. Sub-contractors able to make better money
g. Improved design
h. Reduced costs, less waste
i. Improved safety and health
j. Improved quality, fewer defects

Also, a case study taken in USA in 1998 shows remarkable benefits of implementing LC (Garnett *et al*., 1999): Office construction times reduces by 25% within 18 months; Schematic design reduces from 11 weeks to 2 weeks; Turnover increases of 15-20% (Pacific Contracting); Satisfied clients looking to place repeat orders; Reduction of project costs.

Readiness Assessment Models

Readiness refers to a measure of the capability to adopt a new paradigm prior to its implementation. Prior to adoption of a new paradigm**, s**o many readiness assessment models have been developed in recent times.

Some of these tools include the one developed by Harvard University Center for International Development (CID, 2001) called Networked Readiness Index which gauges a country‘s ability to make use of its Information and Communication Technology (ICT) resources. It defined readiness as the degree to which a community is prepared to participate in the networked world and its potential to be part of the networked world in the future (Kirkman *et al.,* 2002). Similarly, the Asia Pacific Economic Cooperation‘s (APEC) e-readiness assessment focused on government policies for e-commerce, while Mosaic global diffusion of the internet project‘s readiness assessment tool aimed at gauging and analysing the worldwide growth of the internet (Ruikar *et al*., 2006; Vaezi & Bimar, 2009).

On the other hand, as these tools were based on measuring the readiness of countries, governments and policies for adopting internet technologies, there are others that focused on assessing the readiness to adopt different engineering concepts and approaches. For example, SCALES (Supply Chain Assessment and Lean Evaluation System) was developed specifically for the manufacturing industry in order to assess companies‘(especially SMEs) readiness for adopting lean manufacturing techniques. Furthermore, there are several other tools that were developed for Concurrent Engineering (CE) such as RACE (Readiness Assessment for Concurrent Engineering) which was developed in the West Virginia University (United States) in the early 90s. It was conceptualised in terms of two major components: Process and technology. It is widely used in the software engineering, automotive and electronic industries (Ruikar *et al.,* 2006). According to Khalfan and Anumba (2000), RACE can be modified to be used in construction and other industries. Similar to this one is the SPICE (Standard Process Improvement for Concurrent Engineering), which was developed in the University of Salford, United Kingdom in a form of a questionnaire. It was designed to evaluate the key construction processes within construction organisations (SPICE Questionnaire, 1998). In addition, the BEACON (Benchmarking and Readiness Assessment Model for Concurrent Engineering) was created to evaluate the construction company’s

readiness level in implementing concurrent engineering with the aim of improving the project delivery process. Others include the Capability Maturity Model (CMM) developed for software development and evaluation, and the IQ Net readiness scorecard (Khalfan & Anumba, 2000; Ruikar *et al.*, 2006; Aminali, 2007).

Another readiness assessment tool that is of particular relevance to this research is the VERDICT (Verify End-User e-Readiness using Diagnostic Tool) developed to assess the overall readiness of end users involved in the construction industry for using e-commerce technologies (Aziz & Salleh, 2011). The VERDICT model is a combination of two e-readiness assessment models-the BEACON model and the IQ Net readiness scorecard. BEACON, as mentioned earlier, assesses the readiness of construction companies to improve its practices for implementing concurrent engineering. It consists of four elements- process, people, project and technology. IQ Net readiness scorecard is web based application developed by CISCO based on a book called Net ready. Aminali (2007) assesses the readiness of IT service providers in such a way that the companies are presented with statements which fall into four categories as leadership, governance, technology and organisational competencies, for which upon completion, they will be shown their e-readiness assessment result.

Similar methodology was adopted in developing the VERDICT model. In it, companies' e-readiness results are presented to them after responding to some statements that fall under four categories- management, process, people and technology. Ruikar *et al.* (2006) the developers of VERDICT argued that to successfully implement any technology, there is need to have the people with adequate skills, understanding of, and belief in the technology, then processes that enable and support the successful adoption of the technology, then the technology tools and infrastructure necessary to support the business functions and another key element to consider is the management buy-in and belief. Therefore, the next is the management that believes in the technology and takes strategic measures to drive its adoption, implementation and usage in order to derive business benefits from the technology (Ruikar *et al.*, 2006; Vaezi & Bimar, 2009). All the four elements have to work complementarily for any organisation to achieve readiness.

The developers claim that VERDICT can be used to assess the e-readiness of construction companies, departments within a company, or even working groups within a department. The assessment is performed by finding an average score for each of the four categories from the judgment of the respondents on the statements of the questionnaire. According to Ruikar *et al.* (2006):

i. An average score greater than or equal to zero and less than 2.5 shows a red colour which indicates that urgent attention is needed to achieve e-readiness.

ii. An average score greater than or equal to 2.5 and less than 3.5 is amber colour which means that certain aspects need attention to achieve e-readiness.

iii. An average score greater than 3.5 shows a green colour which indicates that the organisation is adequately ready and matured enough for e-commerce tools.

The choice of these boundaries was based on simple average scores computed for each of the four elements in the questionnaire.

METHODOLOGY

The study made use of data and information collected with the aid of structured questionnaires which were administered in northern Nigeria (specifically, Abuja (FCT), Kaduna and Kano states of Nigeria). In a study conducted by Kado (2013), the total number

of registered consulting firms with the Corporate Affairs Commission was shown to be 6,990; 34% of which are located in northern part of the country. Making use of Yamane (1986)'s sample size formula i.e.:

$$n = \frac{N}{1+N(e)^2} \quad \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (1)$$

Where n = required sample size;
N = the population size
e = level of precision (0.050), the sample size of the study was computed as 306.

The population for the study comprise the stakeholders majorly responsible for design of building projects delivery in Nigeria. They include Project Management Firms, Architectural Design Firms, Structural Design Firms, Mechanical and Electrical Services Design Firms, and Quantity Surveying Firms. The questionnaire was designed/structured based on the VERDICT readiness assessment model of Ruikar et al. (2006). Respondents were asked to choose based on a 5-point Likert rating scale, (in which 5 represented strongly agree, while 1 represented strongly disagree), the extent to which their firms conformed to the requirements of the VERDICT readiness assessment model. This was carried out to gain a practical view point, testing to see if the ideas identified and outlined in the literature review were a reality in practice.

A reliability analysis using the Cronbach's alpha, was performed to determine the internal consistency and thus, the reliability of the scale used in the survey questionnaire. The study utilized a number of descriptive statistical techniques to facilitate the organization, analysis and interpretation of the data. Mean, standard deviation and relative ranking were also used.

FINDINGS AND DISCUSSIONS

Out of 306 questionnaires administered, 130 representing 43% of the total were returned and found appropriate for analysis. Moser and Kalton (1971) asserted that, result of a survey could be considered significant if the response rate is not lower than 30-40%. In view of this, the 43% response was considered adequate for analysis.

Among the respondents, 27% was engaged in Architectural consultancy, 29% was engaged in Quantity Surveying consultancy, while 21% and 13% were engaged in structural engineering consultancy and project management consultancy respectively. The remaining 10% of the respondents was engaged in Mechanical & Electrical consultancy. The result expresses a fair representation of the major stakeholders of the Industry. Furthermore, 27% of the respondents belonged to the strategic/senior management level, 60% belonged to the middle management level, while only 8% and 5% belonged to the knowledge/lower management level and operational levels respectively**.** In addition, 34% of the respondents had 16-20 years of experience, 24% had 11-15years of experience, 22% had more than 20 years of experience, while 15% and 5% had 6-10years of experience and less than 5 years of experience respectively.

Readiness Assessment of Nigerian consulting firms

Table 4.1 presents average scores indicating the level of readiness of each professional practice firm in each category i.e. management, process/project, people and technology. As outlined by Ruikar *et al.* (2006) an average score greater than or equal to zero and less than 2.5 is red, and indicates that several aspects (within a category) need urgent attention to achieve readiness; an average score greater than or equal to 2.5 and less than 3.5 is amber, and indicates that certain aspects (within a category) need attention to achieve readiness; and

an average score greater than or equal to 3.5 is green, and indicates that the end-user organisation has adequate capability and maturity in these aspects and therefore is ready (in those respects).

Table 4.1: Summarised average scores indicating the level of readiness of each professional practice firm

Consulting firm	Category Name	Average Score	Situation Based on Ruikar's boundaries
Project Management	Management	2.77	Amber
	Process/Project	3.80	Green
	People	3.28	Amber
	Technology	3.18	Amber
Architectural	Management	2.76	Amber
	Process/Project	3.80	Green
	People	3.28	Amber
	Technology	3.23	Amber
Quantity Surveying	Management	2.78	Amber
	Process/Project	3.80	Green
	People	3.3	Amber
	Technology	3.26	Amber
Structural Engineering	Management	2.77	Amber
	Process/Project	3.84	Green
	People	3.28	Amber
	Technology	3.25	Amber
M&E Engineering	Management	2.76	Amber
	Process/Project	3.83	Green
	People	3.31	Amber
	Technology	3.27	Amber

For this study however, it is evident from Table 4.1 that; the average scores for the categories; management, people as well as technology, were all greater than 2.5, but less than 3.5 (amber), for all the consulting firms considered in the study (Project management, Architectural, Quantity Surveying, Structural Engineering and M&E engineering firms in Nigeria). This clearly shows that Project management firms, Architectural firms, Quantity Surveying firms, Structural Engineering firms and M&E engineering firms in Nigeria all require attention on certain aspects to achieve management, people as well as technology readiness for adopting Lean Construction.

Also, as shown in Table 4.1, for all the building consulting firms considered, process/project was the only category in which an average score greater than 3.5 (green) was obtained. This also clearly indicates that Project management firms, Architectural firms, Quantity Surveying firms, Structural Engineering firms and M&E engineering consulting firms in Nigeria have adequate capability and maturity in this aspects and it's therefore ready to adopt new innovations.

The Cronbach's alpha computed to measure the internal consistency among ratings of respondents as well as the reliability of the scales used for determining the readiness of Nigerian building consulting firms to adopting lean construction in the Nigerian construction industry, was very close to one (0.990), indicating that the scales used were reliable and the respondents understood the questions being put forward to them in the questionnaire. The aforementioned findings corroborates the findings of Olatunji (2008) as they suggest Nigerian building consulting firms have low level of awareness with regards to LC principles.

Comparing Readiness of Nigerian Building Consulting Firms to adopt LC Principles

One-way ANOVA was conducted to compare and thus, determine if there is a significant difference between the levels of readiness of the various Nigerian building consulting firms to adopt lean construction, based on these hypotheses:

Null Hypothesis (H0): there is no significant difference in the level of readiness of the various Nigerian building consulting firms to adopt lean construction.

Alternative Hypothesis (H1): there is a significant difference in the level of readiness of the various Nigerian building consulting firms to adopt lean construction.

As shown in Table 4.2, the significance value is above 0.05 (1.00), indicating clearly that the null hypothesis which states that there is no significant difference in the level of readiness of the various Nigerian building consulting firms to adopt lean construction, is accepted.

Table 4.2: Comparing Readiness of Nigerian Building Consulting Firms to adopt LC principles

	Descriptives							
	N	Mean	Std. Deviation	Std. Error	95% Confidence Interval for Mean		Minimum	Maximum
					Lower Bound	Upper Bound		
Project Management	4	3.258	0.424	0.212	2.583	3.932	2.77	3.8
Architectural	4	3.268	0.425	0.213	2.591	3.944	2.76	3.8
Quantity Surveying	4	3.285	0.417	0.208	2.622	3.948	2.78	3.8
Structural Engineering	4	3.285	0.438	0.219	2.589	3.981	2.77	3.84
M&E Engineering	4	3.293	0.437	0.219	2.597	3.988	2.76	3.83
Total	20	3.278	0.381	0.085	3.099	3.456	2.76	3.84
ANOVA								
	Sum of Squares			df	Mean Square		F	Sig
Between Groups	0.003			4	0.001		0.005	1.000
Within Groups	2.750			15	0.183			
Total	2.753			19				

CONCLUSION

The paper appraised the readiness of Nigerian building consulting firms to adopt Lean Construction principles. The VERDICT readiness assessment model developed by Ruikar et al. (2006) was adopted and used for the assessment. The results of the study shows that the Nigerian building consulting firms have process/project readiness to adopt lean construction principles, but needs to give attention to management, people and technology to achieve full readiness to adopting lean construction principles. This study therefore clearly provides the Nigerian Construction Industry with useful information on the nature of improvement needed to set the scene for effective implementation of LC principles and thus improve performance and productivity in the industry. The study also provides a basis for further research on factors inhibiting Nigerian building consulting firms from attaining management, people and technology readiness to adopt LC principles. Finally, the study recommends more awareness of lean construction principles and its potential benefits via education and training to professional bodies, tertiary institutions offering any building construction related programmes and stakeholders in the construction Industry.

Perceptions of Construction Practitioners on the Benefits of Construction Change Management Practices

Adedokun, Olufisayo Adewumi

Department of Quantity Surveying, Federal University of Technology, Akure, Nigeria
fisayoadedokun@gmail.com

ABSTRACT

The panacea to imminent changes, which are inevitable from construction projects, is an effective construction change management (CCM) practices. This study was undertaken with the sole aim of assessing the perceptions of construction practitioners on the benefits accruable from the practice. Survey method was adopted with 131 questionnaires administered to the respondents that are working on building projects in tertiary educational institutions in Ondo State, Nigeria. Percentile and Mean Item Score (MIS) were employed to analyze the data collected via questionnaire survey drawn on a 5-point likert scale. While MIS was used to rank the benefits, Kruskal Wallis H test was adopted in testing the opinions of the respondents. Cronbach alpha test with value of 0.909 attests to high degree of reliability of the instrument used in collecting the data. Out of the 13 benefits accruable from CCM practices, the most highly significant ones include; improvement in the construction process, improved flow of knowledge, enhanced collaboration and coordination among the consultants and managing change places one in a position of being ready for change among others. Kruskal Wallis H test shows divergent views of the respondents in relation to the benefits arising from implementing the practice of CCM and this is without prejudice to the uniqueness of construction projects. The conclusion is that there are significant benefits accruable from adoption of CCM practices; hence construction stakeholders are enjoined to adopt the practice CCM in its entirety as this will enhance the performance of tertiary educational building projects.

Keywords: Changes, Construction changes, Change management practices, Educational institutions

INTRODUCTION

The performance of the construction industry in terms of meeting its objectives or goals has been invariably affected by construction changes. Construction changes could occur in form of variation or change orders, rework, industrial action, inclement weather and Construction Change Directives (CCDs) (Hao et al., 2008) among others. These eventually lead to what has been broadly categorized as time and cost overruns (Aibinu & Jagboro, 2002; Ogunsemi, 2002; Garry, 2005; Ubani, Nwachukwu & Nwokonkwo, 2010; Ademeso & Windapo, 2014). Also building projects tend to lack good quality of its end product which hardly meets client's requirements (Oyewobi & Ogunsemi, 2010; Oyegoke, 2006).

Construction change is defined as the act or an instance of making or becoming different, an alteration or modification culminated with a situation whereby the scope of work performed differs from the scope of work outlined in the contract documents (Egan, Seder & Anderson, 2012; Erdogan, Anumba, Bouchlaghem & Nielsen, 2005). Construction changes during most project execution are inevitable and can lead to cost and schedule overruns (Egan et al., 2012; Hao et al., 2008) and effective management of these construction changes can significantly reduce the risk of claims that often result in costly disputes and litigation. Therefore, construction change management is a practice that requires an integrated solution to discipline and coordinate the process e.g. documentation, drawing, information, cost, schedule and personnel of a project from inception to completion by ensuring that disputes, cost and schedule overruns are managed (Hao et al., 2008).

Adedokun, O. A. (2016) Perceptions of Construction Practitioners on the Benefits of Construction Change Management Practices. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 727-736

It has been established that construction changes will never disappear; the best option is to manage them to prevent negative consequences (Harrison, 2012; Lazarus & Clifton, 2001). The impacts and consequences of changes on an organization and people vary according to the type and nature of changes, but most importantly according to how they are managed (Erdogan et al., 2005). The essence of this construction change management is to maximize the benefits, minimize the penalties, and ensure that both benefits and penalties are distributed equitably (Lazarus & Clifton, 2001; Erdogan et al., 2005). It is upon this pedestal that this study assessed the practitioners' perceptions of the benefits accruable from implementing the practice of construction change management.

LITERATURE REVIEW

Construction Changes

The more the construction changes on a project, the greater the likelihood that they not only become time consuming and costly in the construction projects (Ojo, 2010) but also critically cause extra demands of equipment, materials, labour and overtime (Hao et al., 2008). It is almost becoming a rare thing for a project not to have changes, thus becoming a normal occurrence and inevitable as they are fact-of-life at all stages of a project's life cycle (Hao et al., 2008; Ojo, 2010). Some salient facts are true about construction changes: changes cannot be totally avoided and the riskier the change is, the costlier the consequences if the wrong decision is made in terms of management (Egan et al., 2012). However, in spite of the changes involved, the history of the construction industry is full of projects that were completed with significant cost and time overruns, poor project performance, and quality failures (Adedokun, Ogunsemi, Aje, Awodele & Dairo, 2013; Ademeso & Windapo, 2014; Baloi & Price, 2003; Elinwa & Buba, 1993; Garry, 2005; Ogunsemi & Aje, 2005; Okpala & Aniekwu, 1988).

Therefore, there is the need for the project owners or managers to make an informed decision, one with minimal error and this error free decision is only possible if there is effective construction change management process (Harrison, 2012; Hao et al., 2008) that will adequately manage (identify, evaluate, assess) construction changes. The need to consciously manage construction changes is now recognized as important practice to improving innovation, construction project performance and client's satisfaction. It is then that the resultant effects/impacts of construction changes on project(s) can be minimized and the objectives or goals of the industry achieved at the end of the day because most of the times when construction changes are not dealt with satisfactorily, the industry tend to suffer poor performance.

Challenges facing construction change management practices

Hao et al (2008) opined that developing an effective construction change management process is a challenging task because it requires an integrated solution for coordinating everything involved for the purpose of the change management in question according to figure 4. Change management is a topic that one can hardly get through any resources unlike project management or construction enterprise management software that are readily available on the market.

Hence, the following are some of the challenges facing construction change management practices (Hao et al., 2008): unacceptability of new ideas by professionals, inadequate encouragement as regards learning within the firm, unavailability of change management unit, unavailability of time to exchange ideas, insufficient time for after action review, difficulty in transferring change management knowledge, unwillingness of staff to share knowledge, excessive time associated with construction change management, uniqueness associated with projects which makes knowledge gotten from a project a waste to other

projects, variation on nature of projects, lack of organizing training/ seminars due to insufficient resources, too much work preventing evaluation of previous work, overbearing workload which prevents cross project learning, unwillingness to learn by professionals and resistance to change current practice and adopt new approach.

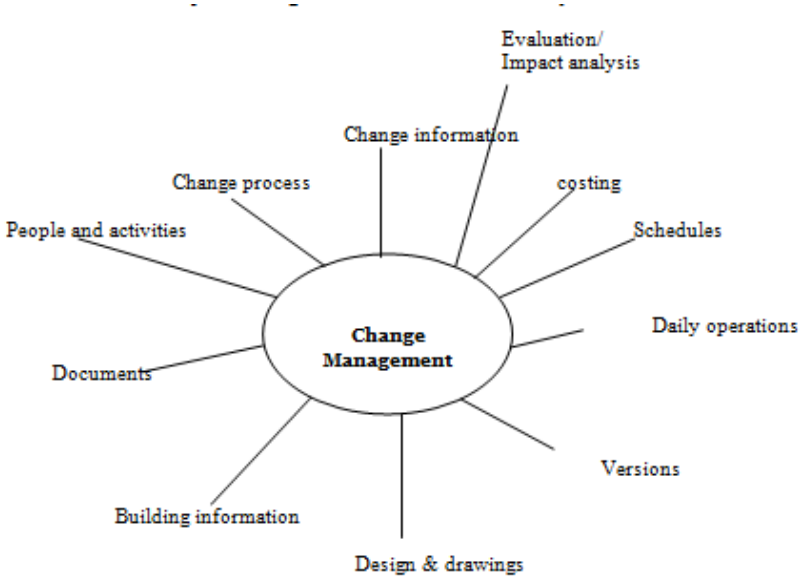

Fig 4: Requirements of an integrated change management system (Hao et al., 2008)

Construction change management

Construction projects are becoming complex in nature; clients are also becoming knowledgeable, more demanding and selective in what they want from consultants (Preece, Moodley & Smith, 2003). This complexity gives rise mostly to unwanted situations leading to construction changes like variations (change orders), reworks (Erdogan et al., 2005), or unexpected events such as industrial action, inclement weather (Love, Holt, Shen, Li & Irani, 2002) and construction change directives (Hao et al., 2008) with their attached effects as aforementioned.

Change management is one of the priority areas of construction practitioners and concerted efforts are being made to cushion the effects of cost and time overruns that characterized construction projects be it vertical or horizontal (Harrison, 2012; Hao et al., 2008). Also, significant poor project performance and quality failures (Adedokun et al., 2013; Ademeso & Windapo, 2014; Baloi & Price, 2003; Elinwa & Buba, 1993; Garry, 2005; Ogunsemi & Aje, 2005; Okpala & Aniekwu, 1988) cannot be over emphasized.

Benefits of Construction Change Management Practices

Each construction project is unique in its entirety; therefore the challenges of one project may require management measure that is quite different from others (Aje, Adedokun & Adedokun, 2015) and thereby yielding benefits that are project specific. Therefore managing changes effectively is crucial to the success of a construction project (The Happy Manager, 2014) as it helps in controlling time, cost and quality right from inception stage of the construction project to completion. According to Happy manager (2014), some of the benefits are:

i. Managing change puts you in a position of being ready for change.
ii. Developing an understanding of the kind of change required – understanding that different characteristics of change need different approaches.
iii. Implementing a process to navigate the change required.
iv. Gaining clarity about what is being achieved – why we are changing.

v. Building commitment to work together, to bring people with you.
vi. Appreciating the best of the way things are done now, so that the future is built on current strengths within the organisation.
vii. Shaping change through principles which establish how you manage change – the principles upon which change is shaped.
viii. Delivering change that makes improvements.

RESEARCH METHODOLOGY

This research employed a qualitative research design in the conduct of the study which involved the use of questionnaire survey administered to key construction stakeholders. The population for this work includes 131 key construction stakeholders comprising 44 Contractors/ representatives, 32 Quantity Surveyors, 28 Architects and 27 Structural Engineers, in the tertiary educational institutions in Ondo state, Nigeria (see Tables 1 and 2). The construction professionals used are both in-house professionals within the client organisation and the consultants outside the client's organisation but working on client's projects and the contractors executing the projects for clients. The targeted respondents were involved in the completed tertiary educational building projects from 2010 – 2014. The choice of the duration is to enable the respondents to quickly remember the activities that transpired during the course of the projects, knowing too well that records are seldom kept in a retrievable manner (Tarr and Car, 2000), hence taking too long a duration will allow guess work to set in.

Table 1: Population breakdown of the respondents

S/N	Institutions	CLIENTS REPRESENTATIVES						Nr. of Kto rs/Rep	**Total**
		In-House Professionals			External Consultants				
		QS	Arch	S/Eng	QS	Arch	S/Eng

2	Tert. Ins. 2	3	1	2	4	3	3	5	21
3	Tert. Ins. 3	0	0	0	1	2	2	5	10
4	Tert. Ins. 4	2	2	2	9	7	6	10	38
5	Tert. Ins. 5	0	0	0	0	0	0	0	0
6	Tert. Ins. 6	0	0	0	4	4	3	8	19
7	Tert. Ins. 7	2	3	1	0	0	0	6	12
	Total	9	8	9	23	20	18	44	**131**

Key:
Tert. Ins. – Tertiary Institution; Nr. of Ktors/ Rep – Number of Contractors/ Representatives; QS – Quantity Surveyors; Arch – Architects; S/Eng – Structural Engineers

The lists of relevant construction professionals were collected from Physical Planning Unit (PPU)/ Works and Services Department of their respective Tertiary Educational Institutions. The adequacy of a sample is assessed by how well such sample represent the whole population of participants from which the sample is drawn (Kothari, 2009). Having found the target population to be 131, it was found to be manageable size and thus census method was employed which involved the use of the entire population rather than picking a sample which might introduce some level of bias in the study.

Table 2: Population of the respondents

S/N	Respondents	Population
1	Quantity Surveyors	32
2	Architects	28
3	Structural/Civil Engineers	27
4	Contractors/ Representatives	44
	Total	**131**

Data Collection Instruments

The research instrument that was used for collecting data from the respondents included a structured questionnaire that was administered using a set of predetermined questions. The questions designed for this research were such that first section dwelt on the background information of the respondents while the other section focused on matters relating to the research study. Questions inherent in the structured questionnaire were multiple-choice type with different checkboxes and tables posed on a 5-point likert scale for ease and uniformity of response. Its application implies that most part of the data analysis was based on a scoring system.

Reliability of the research instrument

Reliability according to Kothari (2009) is an important aspect of research instrument and must be considered to ensure that accurate results are obtained. One of the most commonly used reliability coefficients according to Kothari is Cronbach's alpha test (α). Cronbach alpha test was employed in this study to test the reliability of the questionnaire administered to the respondents during the survey carried out.

Table 3: Test of reliability for measuring scale

Scale of measure	Cronbach ∝-value
benefits of construction change management practices	0.909

Table 3 shows that the Cronbach's α value for scale of measures of the research instruments ranges from 0.800 to 0.946. Since the degree of reliability of the instrument is more perfect as the value tends towards 1.0 (Kothari, 2009), it can then be concluded that the instrument used for this research is significantly reliable.

DATA PRESENTATION, ANALYSIS AND DISCUSSION

Tables were employed in this paper for data presentations while the analyses of the collected data were carried out using percentile, mean item score, and Kruskal Wallis test. The results of the analyses were presented as follows under various headings.

Background Information of Respondents

Out of the 131 questionnaires administered, 87 were filled, returned and found suitable for the analysis. The analyzed questionnaire represent 66.41% of the total questionnaire sent out which is considered sufficient for the study. From Table 4, it can be seen that majority of the respondents in this case are Quantity Surveyors with 43.7% and was closely followed by 29.9% quota, represented by the Structural/Civil Engineers and least was Architects with 26.4%. The professional membership status of the respondents shows that 41 are graduate member, 44 are corporate/ associate members while 2 of them are fellow of their respective professional bodies with 47.1%, 50.6% and 2.3% respectively.

As for the years of working experience possessed by the respondents, it can be seen that 26.4% falls within 1 - 5, 54% of the respondents are within 6 – 15 years of experience, while 8% falls within 16 - 20. On the average, the respondents have 10 years of working experience and the information supplied by this category of professionals is considered adequate and relied upon. These set of respondents have their establishment in existence for an average of 13 years. Analysis in Table 4 reveals that majority of the respondents are Postgraduate Diploma holder with 40.2% and this is followed by respondents with BSc/ BTech qualification representing 20.7% followed by 19.5% and 18.4% representing HND and MSc/ MTech. Only one of the respondents has a PhD as the highest qualification and this translated to 1.2%.

Practitioners' based perceptions of benefits of construction change management practices

Table 5 reveals the benefits of construction change management practices based on the practitioners' assessment (Quantity Surveyors, Architects and Structural/Civil Engineers). Based on the perception of the Quantity Surveyors, the practice offers improvement in the construction process; enhances team collaboration and improves flow of knowledge. Architects are of the opinion that construction change management practice enhances team collaboration; improves flow of knowledge and improves the construction process.

On the part of the Structural Engineers, managing change put one in a position of being ready for the change; delivering change that makes improvement on project performance while

thirdly, it offers improvement in the construction process. Taking cognizance of the most highly ranked three benefits, it is evident that only one benefit cut across the ratings of the respondents being improvement in the construction process, though with different levels of ranking. With reference to the most highly rated three benefits, Quantity Surveyors and Architects had the same benefits but in different order of mean scores.

Table 5: Practitioners' based perceptions of benefits of construction change management practices

Benefits	Quantity Surveyors		Architects		Structural/Civil Engineers	
	Mean	Rank	Mean	Rank	Mean	Rank
Improvement in construction process	4.32	1	4.39	3	4.20	3
Enhanced team collaboration and coordination	4.30	2	4.43	1	4.00	8
Improved flow of knowledge	4.30	3	4.43	1	4.20	3
Managing change puts you in a position of being ready for change	4.27	4	4.13	8	4.32	1
Appreciating the best way things are done now, so that the future is built on current strengths within the organisation	4.19	5	4.30	5	4.16	5
Improved decision making	4.16	6	4.39	3	4.16	5
Gaining clarity about what is being achieved- why we are changing	4.06	7	3.83	11	4.16	5
Delivering change that makes improvement on project performance	4.03	8	4.26	6	4.28	2
Mitigating risk	3.97	9	3.74	12	3.96	10
Developing an understanding of the kind of change required-understanding that different characteristics of change need different approaches	3.97	10	4.00	9	3.96	10
Shaping change through principles which establish how you manage change- the principles upon which change is shaped	3.95	11	3.91	10	4.00	8
Building commitment to work together, to bring people with you	3.81	12	4.18	7	3.92	12
Implementing a process to navigate the required change	3.81	13	3.74	12	3.76	13

Table 5: Benefits of construction change management practices

Benefits	**Group Mean**	**Group Rank**
Improvement in construction process	4.31	1
Improved flow of knowledge	4.31	1
Enhanced collaboration and coordination	4.25	3
Managing change puts you in a position of being ready for change	4.25	3
Improved decision making	4.22	5
Appreciating the best way things are done now, so that the future is built on current strengths within the organization	4.21	6
Delivering change that makes improvement on project performance	4.16	7
Gaining clarity about what is being achieved-why we are changing	4.02	8
Developing an understanding of the kind of change required-understanding that different characteristics of change need different approaches	3.98	9
Shaping change through principles which establish how you manage change-the principles upon which change is shaped	3.95	10
Building commitment to work together, to bring people with you	3.94	11
Mitigating risks	3.91	12
Implementing a process to navigate the required change	3.77	13

Benefits of construction change management practices

Table 6 reveals that despite the fact that the most highly ranked benefits are improvement in the construction process (Mean Score = 4.31) which tied with improved flow of knowledge, the 3rd benefit is having enhanced collaboration and coordination among the consultants (Mean Score = 4.25) which also tied with managing change puts you in a position of being ready for change, all other benefits are also significant with a considerable impact on

construction projects. The least ranked benefits includes implementing a process to navigate the required change (Mean Score = 3.77), mitigates risk (Mean Score = 3.91) and lastly building commitment to work together (Mean Score = 3.94).

Table 7: Significance test on the benefits of CCM practices

	Profession	Group	Mean
Chi-square	.532	Quantity Surveyors	19.38
Df	2	Architects	21.85
Asymp. Sig	0.767	Structural/ Civil Engineers	18.77

Significance test on the benefits of CCM practices

Table 7 reveals that the respondents have divergent opinions on the benefits of construction change management practices on projects. The result of Kruskal-Wallis test carried out shows a low chi-square value of 0.532, P value is > 0.05 i.e. 0.767, hence there is no significant agreement in the opinions of respondents on the benefits of construction change management practices. These divergent views may be due to the fact that each construction project is unique its entirety; hence the challenges of one project may require management measure that is quite different from others and thereby yielding benefits that are project specific.

DISCUSSION OF FINDINGS

Benefits of construction change management practices

Despite the challenges militating against full adoption of construction change management practices in its entirety (Dairo, 2015), all the benefits, according to the ratings of the respondents, were found to be significant after analysis and these closely support the happy manager (2014) and MDC System (2002) that the benefits accruable from adopting construction change management practices are the improvement to the construction process, improved flow of knowledge, enhanced collaboration and coordination among project participants and the fact that managing change puts one in a position of being ready for change among others factors.

CONCLUSION AND RECOMMENDATION

Conclusion

This study assessed benefits accruable from construction change management practices based on tertiary educational building projects in Ondo state, Nigeria. Consequent to the analysis carried out, it can be concluded that construction change management practices offer improvement to the construction process, flow of knowledge, enhanced collaboration and coordination among project participants while the practice also puts one in a position of being ready for the change.

Recommendation

Based on the forgoing, it is hereby recommended that construction practitioners should fully adopt construction change management practices in building projects because it offers improvement to the construction process among others.

ABSTRACT

The construction industry is an important player in the development of any Nation. Hence, it is fundamentally essential to make construction projects completed successfully within time, budget and expected quality. Despite proven importance of cost as a driving force of project success, it is common to see construction projects failing to achieve its objectives within specified cost. This research aims at assessing construction cost escalations in the public sector's projects in Lagos State, Nigeria. The objectives are to identify the rate of occurrence of cost escalation in public sector's construction projects, find the relationship between project size and cost overrun, and identify and rank the most important causes of cost escalations in the public sectors' construction projects as perceived by various construction industry participants (the clients, consultants and contractors). Data were collected and analysed using both descriptive and inferential statistics. The study showed that cost overrun in public sector projects was 19.14% on the average. There was a significant relationship between project size and cost overrun. The most important cause of cost overrun in public sector is additional work to project. As measures against cost overrun, this study recommended, among other things, the necessity of having well defined project scope from inception to completion.

Keywords: Construction, Cost overrun, Nigeria, Projects, Public sector

INTRODUCTION

The construction industry is a dynamic sector and an important player in the development of any nation (Memon, Rahaman and Azis, 2012). It is an important industry that plays a vital role in the socio-economic growth of a country. Yet, it has been regarded as one facing chronic problem of poor performance leading to failure in achieving effective time and cost performance (Olawale and Sun, 2010; Memon et al 2012). Cost escalation has become a very frequent problem that is almost associated with nearly all projects in the construction industry. This trend is more severe in developing countries, where these escalations sometimes exceed 100 percent of the anticipated cost of the project (Memon, Rahman and Azis, 2011). It is a problem because of its inherent effects, some of which are budget short fall of project owners, project delay, poor quality, project extension, project abandonment, litigation (Nega, 2008; Azhar, Fasooqui and Ahmed, 2008; Kaliba et al, 2009).

Morris (1990) observed that if cost overruns in public sector are pervasive, they will increase the cost of investment in real terms and raise the capital-output ratio in the construction industry, an effect which can spread to other sectors. The primary concern of the construction projects' clients, therefore, is to see their projects completed successfully within specified cost, time and quality. Given the large capital amounts associated with construction projects, the performance in terms of cost is supposed to be closely monitored, especially where tax payers' money is involved (Baloyi and Bekker, 2011). This study therefore focuses on

Fatoye, E. O.; Enenmoh R. C.; Opara V. I. & Oyekanmi O. O. (2016). Assessment of Construction Cost Escalations in the Public Sector's Projects in Lagos State, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 737-745

assessing the cost escalations in the public sector of the Nigerian construction industry. This will further assist this sector, and by extension all stakeholders in the construction industry, to identify their peculiarities in the area of cost escalation of projects.

This research is aimed at comparing construction projects cost overrun in the public and private sectors in Lagos State, Nigeria. The objectives are to: (1) identify the rate of occurrence of cost escalation in public sector's construction projects, (2) find the relationship between project size and cost overrun, and (3) identify and rank the most important causes of cost escalations in the public sectors' construction projects as perceived by various construction industry participants (the clients, consultants and contractors).

LITERATURE REVIEW

The construction industry is observed to be one of the most complex fragmental schedule and resource driven industry (Memon et al, 2011). It is also a highly dynamic sector and plays very important role in the development of any nation. The industry is considered as a driver of economic development in a country. The Nigerian construction industry's contribution to the Gross Domestic Product (GDP) is about 2.95% between 2009 and 2010 (Isa, Jimoh & Achuenu, 2013), 2.08% in 2011 (National Bureau of Statistics, 2012; FSDH Merchant Limited, 2013), between 2.19% and 3.01% in 2012 (National Bureau of Statistics, 2012; Centre for Affordable Housing Finance in Africa, 2013; FSDH Merchant Limited, 2013; Isa et al, 2013) and 3.10% in 2013 (African Economic Outlook, 2014). Besides, the all-inclusive effects of this construction sector, and especially its employment generating potentials, makes it a veritable platform for sustainable development especially if proper mechanisms are put in place for the growth of the sector to be stimulated (Isa et al, 2013).

Dantata (2007) however, observed that despite the impressive performance of the construction industry, it faces a significant number of challenges including lack of local skilled labour, power shortage, the unavailability of materials, and the unethical practices that are very common in the industry, and of course, delay schedule and cost overruns. Cost escalation or overrun is the amount by which actual costs exceed the baseline or approved costs (Danso and Antwi, 2012). According to Nyamoki (2012) and Subramani et al, 2014), cost overrun is also defined as the difference between the actual construction cost on completion of work and original estimated costs, with all costs calculated in constant prices.

Causes of Cost Escalations

The history of the construction industry worldwide is full of projects that were completed with significant cost escalations (Azhar et al, 2008; Ameh et al, 2010). A large number of studies and surveys evidenced the fact that cost overrun affects all kinds of projects in all industries, and in all countries either in the public or in the private sector (Boukendour, 2005). According to Azhar et al. (2008); Ameh, Soyingbe and Odusami (2010), the history of the construction industry worldwide is full of projects that were completed with significant time and cost overruns. Memon et al (2011) observed that time and cost overruns vary considerably in their magnitude from project to project. However, the trend is more severe in developing countries where these overruns sometimes exceed 100% of the anticipated cost of the projects.

Azis, Memon, Rahman and Abd. Karim (2013) pointed out that contractors' site management is the most significant contributor to cost overruns in Malaysia. This is followed by information and communication, project management and contract administration, labour related factors, materials and machinery and external factors. Others are design and documentation and financial management.

The construction of new stadia and upgrading of existing ones in South Africa, as reported by Baloyi and Bekker (2011), experienced time delays and cost overrun in nearly all the projects with an average of about 45 percent overrun, ranging between 5.4% and 93.8%. In the study, top ten factors contributing to more than 85% of the cost overrun were ranked as increase in material cost (external factor), inaccurate material estimates (client-related), shortage of skilled labour (contractor-related), clients' late contract award (client), project complexity (external), increase in labour cost (external), inaccurate quantity take-off (client), difference between selected bid and the consultants' estimate (client), change orders by client during construction (client) and shortage of manpower (external).

The study of road construction projects in Palestine by Mahamid and Amund (2012) indicated that 100% of the projects suffer cost deviation from 39% to 98% with an average of 14.6% between estimated and actual cost. The suggested reason for cost deviation could be because of under-estimation of project cost which affected 76% of sampled projects to an average of 22.34% ranging from 0.39% to 98.04%. The results, however, show that the relationship between the project size (length and width of the road) and the cost deviation is very weak. This is at variance with Singh (2009) which reported that cost overruns soar as project size increases for infrastructure projects in India. Results of the perceptions of contractors on factors affecting cost overruns on building projects in Palestine indicated the top five factors as fluctuation in the currency exchange rate, project financing, contract management, level of competition, and cost of materials (Mahamid, 2014).

Investigation into the causes of cost overruns in Uganda's public sector construction projects by Alinaitwe, Apolot and Tindiwensi (2013) revealed that changes in the work scope, delayed payments to contractors, poor monitoring and control, high inflation and high interest rates were five most important causes.

The results of the study of Ameh et al (2010) on telecommunication projects in Nigeria identified and ranked the prevailing causes of cost overruns in order of importance as lack of contractors' experience in telecommunication projects, high cost of imported materials, fluctuations in material prices, frequent design changes due to inadequate site and environmental information, mode of financing, bonds and payments, fraudulent practices and kickbacks. Kasimu (2012) in his study of significant factors that cause cost overruns in building construction projects also in Nigeria identified market condition, lack of experience in contracts works, insufficient time (for pre-tender stage), material price fluctuation and political situation as the major significant factors that cause cost overruns in those projects.

Brunes and Lind (2014) observed that overruns in infrastructure projects in Sweden, occurred in the planning stages up to the final design and are related to design changes because of technical and administrative problems. Other factors are lack of competence among consultants, project managers and higher level staff, as well as psychological (optimism) bias.

The analysis of 58 Australian transportation infrastructural projects revealed that rework during construction as a result of design changes, errors and omission are the major contributors of overruns in projects (Love, Sing, Wang, Irani & Thwala, 2014). In the survey of 74 road projects awarded in the West Bank-Palestine over the years 2007-2010 by Mahamid (2013), 100% of the projects suffered from cost deviation with an average of 16.73% ranging from – 20.33 to 56.01%. A correlation between project size and cost deviation was also observed. According to the findings, as project size increases, its resources increase requiring a more control measure to maintain the project performance in terms of cost, time and quality.

METHODOLOGY

The study made use of cross-sectional and adopts a quantitative research method. Different data were collected from both secondary and primary sources. Data collected from secondary sources include archival information on cost details such as initial contract sum and final account sum of most recently completed construction projects by the public sector (Ministry of Works & Structures and Ministry of Housing in Lagos State). Clients, consultants and contractors were the sources of this information through questionnaires. Other sources of secondary data are publications, textbooks, journals, research works, conference/seminar papers, Internets, etc. Data from primary sources were those collected through questionnaires administered on construction industry professionals, i.e. architects, civil/structural engineers, mechanical/electrical engineers, builders and quantity surveyors working within clients' (project owners) organisations, consultancy firms and constructing organisations. The questionnaire contained demographic information and organisational data of respondents, and their opinions concerning causes of cost escalations.

The study employed a multi-stage sampling technique. Stratified sampling technique was used for picking professionals from each of the five groups. The study area was divided into three strata on the basis of senatorial districts. Thus out of 130 professionals, 50 were sampled from Lagos Central while 40 were sampled from Lagos West and Lagos East respectively. This is based on the consideration of commercial/economic status of the districts and constitutes good representation of the population. The questionnaires were distributed in the senatorial districts by simple random technique. Out of the 130 questionnaires administered, a total of 92 were duly completed and returned, representing approximately 70.77% response rate, for the analysis.

The questionnaire was designed to seek respondents' opinion on level of importance of the listed factors causing cost overruns on a 1-5 Likert-type scale using 1 for not important, 2 for slightly important, 3 for moderately important, 4 for very important, and 5 for extremely important.

On the basis of the data obtained from the respondents, the causes were assessed for their relative importance index using the mean item score (MIS) method. A five point scale was used to calculate the MIS for each factor, which was then used to determine the relative ranking of different factors by assigning ranks to the mean scores, with high mean scores assigned high ranks and vice versa. These ranking made it possible to cross-compare the relative importance of the causes as perceived by the three groups of construction industry participants (the clients, consultants and contractors organisations).

To test for the degree of agreement in ranking of the individual factors between various groups of construction participants, a Kendall tau Rank Correlation Coefficient (analysis) was used for any two groups (clients and consultants, clients and contractors, consultants and contractors respectively). The null hypothesis (H_0) that the two groups of construction participants (the clients and consultants organisations, etc) do not agree on the ranking of significant causes of cost overruns was tested and the coefficient of concordance determined.

FINDINGS AND DISCUSSIONS

Rates of occurrence and percentages of cost escalation in public sector were computed and it was observed that about 68.48% of the total number of executed projects in the public sector experienced cost overrun with an average of 19.14% cost escalation ranging from 1.19% to 81.82%. It is equally noted that projects that were completed at the exact initial contract sum

were 22.83%. Those that were completed with savings (at prices less than the initial contract sum) ranging from -4.30% to -0.14% of initial contract sum were 8.69% (Table 1)

Table 1: Rates of Occurrences of Cost Escalation in Public Sector' Projects

	Range of % of overrun	No. of Occurrence	% of Occurrence
Savings	-4.30-0.14	8	8.69
Zero Escalation	0.00	21	22.83
Positive Escalation	1.19-81.82	**63**	68.48
Total		**92**	**100.00**
Average % of Overrun/Occurrence	**19.14**		**69.39**

Relationship between Project Size & Cost Overrun

A hypothesis was set up to examine whether a statistically significant relationship exists between project size and cost overrun. The result of Pearson correlation analysis revealed a significant and positive relationship (r = .315, N = 92, p = .002) as indicated in the correlation Table 2. From the Table, it can be concluded that the relationship between project size and cost overrun is statistically significant at $p<0.05$. The correlation coefficient (r) equals 0.315, indicating that the strength of the relationship between project size and cost overrun was below average in the positive direction.

Table 2: Relationship between Project Size & Cost Overrun

		Initial Contract Sum	Actual Cost overrun
Initial Contract Sum	Pearson Correlation	1	.315**
	Sig. (2-tailed)		.002
	N	92	92
Actual Cost overrun	Pearson Correlation	.315**	1
	Sig. (2-tailed)	.002	
	N	92	92

**. Correlation is significant at the 0.01 level (2-tailed), correlation coefficient, r = .315, p-value at 0.01 = .002

Relative Importance Indices of Cost Overrun

Table 3 shows the relative importance indices (RII) and ranking of the first twenty factors causing cost escalation in the public sector. In the overall weighted average of the groups of construction industry participants, additional work to the project came first as the most important factor causing cost overrun with a mean item score of 4.184. This factor was also ranked first by contractors but ranked fifth by clients and consultants respectively. The second most important cause is lack of detailed and well defined design brief (4.061). This was ranked first by the clients but ranked 10^{th} and 11^{th} by consultants and contractors respectively. The third factor causing cost overruns is delayed payment and cash flow difficulties faced by contractors (4.020). This was ranked first by consultants, seventh by the clients and 17^{th} by the contractors. The analysis of variance (ANOVA) was carried out to determine the significant difference in the group (clients, consultants and contractors) mean for each cause of cost overrun. From Table 4, p-value is greater than .05 for 18 out of the first 20 ranked causes of cost overrun in the public sector projects. This shows that the results of these 18 causes are not significant at the 5% level, implying that the null hypothesis ($H_{o)}$ will be accepted and the alternative hypothesis rejected. Thus, there is sufficient evidence to conclude that there is no significant differences (or there is significant degree of agreement) between the mean values of these groups (or between the group means) of these 18 causes of cost overrun. With a view of ascertaining the level of agreement / disagreement between any two groups, Kendall tau rank correlation coefficient was carried out and Table 4 shows the result of this for the public sector.

Table 3: Relative Importance Indices (RII) and Ranking of Factors Causing Cost Overrun in the Public Sector Projects

Causes of cost overrun	Category of causes	Clients (N=30)		Consultants (N=34)		Contractors (N=28)		Overall average (N=92)		F-Stat	p-value	Level of Sig.
		Mean	R	Mean	R	Mean	R	Mean	R			
Additional work to the project	Clients	4.111	5	4.133	5	4.571	1	4.184	1	0.566	0.572	NS
Lack of detailed and well defined design brief	Consultants	4.259	1	3.933	10	3.571	11	4.061	2	1.435	0.249	NS

Use of inefficient contractors	Clients	3.926	10	3.867	15	3.571	14	3.857	13	0.214	0.808	NS
Fraudulent practices and kickbacks	External	3.815	15	3.933	11	3.857	7	3.857	14	0.065	0.937	NS
Rework during construction as a result of design changes, errors and omission	Consultants	3.704	17	3.933	13	4.143	4	3.837	15	0.593	0.557	NS
Government bureaucracy	External	3.704	18	3.933	14	3.857	8	3.796	16	0.315	0.732	NS
Project complexity	Consultants	3.778	16	3.933	12	3.429	16	3.776	17	0.617	0.544	NS
Financial difficulties of owners	Clients	3.630	20	4.333	3	3.143	20	3.776	18	3.525	0.038	S
Poor management of uncertainty in project management and administration	Contractors	3.667	19	3.733	19	4.143	5	3.755	19	0.638	0.533	NS
Poor monitoring and inefficient cost control systems	Contractors	3.852	13	3.800	18	3.286	19	3.755	20	0.928	0.403	NS

Note: * Equal mean scores of the individual factors ranked according to the number of respondents scoring 5 and 4 respectively; F-stat = test statistic; p-value = probability that the null hypothesis is true; significant at $p<0.05$.

Table 4: Test of Agreement on Ranking of Important Causes of Cost Overruns in the Public Sector

Construction Industry Participants	Test Statistic	p-value	Accept H_0?	Remark
Clients and Consultants	0.084	0.604 > 0.05	Yes	Not significant
Clients and Contractors	-0.042	0.795 > 0.05	Yes	Not significant
Consultants and Contractors	-0.074	0.650 > 0.05	Yes	Not significant

Note: Kendall tau-b Test Statistic = Correlation coefficient; p-value = Probability that the null hypothesis is true; Significant at p<0.05 (2-tailed).

The result in Table 4 shows the computation of a Kendall tau rank correlation coefficient (r) (analysis) and the decision rule of rejection of null hypothesis for the ranking of causes of cost overrun as perceived by different groups. The p-values (0.604; 0.795; 0.650) > 0.05 indicate that the agreements between groups are not significant. This implies acceptance of null hypothesis (H_0) and rejection of alternative hypothesis (H_1). Thus, there is sufficient evidence to conclude that there are no relationships, meaning there are no agreements between two groups of construction industry participants i.e. clients and consultants, clients and contractors, as well as consultants and contractors in their ranking of important causes of cost overrun in public sector projects.

Discussion of Findings

Frequency of occurrence of cost overrun was 69.39% with a percentage of 19.14% in the public sector. This frequency is lower than that of Malaysia with 92% and Palestine with 100% (Mahamid and Amund, 2012). The average percentage of overrun is higher than the Malaysian situation of 5-10% (Memon et al., 2012) and Palestinian situation of 14.6% (Mahamid and Amund, 2012). This range of percentage of cost overrun is an upward experience from 14% reported in Nigeria by Omoregie and Radford (2006). The finding of this study validates Mahamid and Amund (2012) that the relationship between the project size and cost deviation is very weak. It also supports the studies of Singh (2009) and Mahamid (2013) that there is a positive correlation between project size and cost deviation in Indian and Palestinian public sector projects respectively.

The finding of this research also shows that additional work to the project is the most important cause of cost overrun in the public sector. This was also rated as the most important cause in the work of Choudhry et al. (2012) in Pakistan. Decision by clients to increase the scope of any ongoing contract will change the contract cost and invariably leads to cost overrun unless there is a trade off of any part of the project without compromising the quality.

The result of analysis revealed that there are no agreements in the ranking of causes of cost overrun in the private sector. This is a confirmation of the rankings in Table 3 where it was observed that the first ranked cause of cost overrun, additional work to the project, was ranked first by the contractors and fifth by both the clients and the consultants. These results can be due to different perception in the ranking of possible causes of cost overrun.

CONCLUSION AND RECOMMENDATIONS

Cost overrun is still a severe problem faced by public sector in the Nigerian construction industry. A rise in the average percentage of cost overrun from 14% in previous studies to 19.14% in the public sector as observed in this study should be of great concern to Nigerian construction industry stakeholders. This will pose a serious threat to the success of project delivery if left unchecked. The earlier researchers' call for a percentage increase in contingency allowance to about 15-20% is almost becoming inappropriate in Nigeria's situation with an average of 19.40% cost overrun established from this study. This makes the improvement of the management of financial resources, in both public and private sectors,

inevitable. Cost overrun, for whatever reason, could lead to additional financial burden on the clients in form of claims by the contractor and a total frustration of the projects' objectives.

In the light of the aforementioned research findings and conclusion, this study hereby recommend as follows:

For any project, there must be well defined scope from inception to completion. More time should be invested in the early briefing stages of design (including site investigation) to clearly define project's scope and complexity including completion of detailed design by the consultants before going to tender. Government should put in place strong monetary policies, through proactive strategic planning and approaches, to fight inflation and high interest rates so as to stabilise or/and reduce cost of construction materials. Fluctuation of prices of raw materials and cost of manufactured construction materials are severe when these elements are in short supply. In order to stabilise their costs, government should provide enabling environment towards increasing supply of materials. This will be useful to break the monopoly of few suppliers controlling the supply chain of the market.

ABSTRACT

Engagement of indigenous contractors in the construction sector is one of the several ways the sector boosts the economy. This study was at the instance of the high level of discrimination meted on indigenous contractors from clients on the account of gross incompetence. With this study, the Performance Ability Ratio of indigenous firms on significant construction work items, their competence and readiness for construction activities were evaluated; factors influencing their construction productivity were also identified and analysed. Data obtained from 25 indigenous contractors' site operating on a large scale were used in computing the Performance Ability Ratio (PAR) while data from structured questionnaire administered on 96 clients from public and private sector were analysed using Factor analysis, Mean Item Score and Relative Importance Index. Results showed that the Performance of large scale indigenous construction firms is well above average (PAR=0.83). High competences were found to be demonstrated by these firms in technical and managerial aspects of construction. Results further showed that labour working overtime and stacking of trade had very high impact on the firms' construction productivity. Appropriate project planning among others were strategies for improving their productivity. However, lack of alignment to set goals and contractual conflict were identified barriers to improving productivity. Finally, it is recommended that indigenous construction firms should be given equal opportunity to execute capital intensive construction projects like their expatriate counterpart as results showed that their performances were above average.

Keywords: Competence, Construction Productivity, Construction Sector, Indigenous Construction Firms, Performance Ability Ratio

INTRODUCTION

The construction industry is one of the very important sectors in the economy of every nation. Kazaz and Ulubeyli (2004) opined that the importance stems from a wide range of reasons associated with peculiar features of the industry such as the uniqueness of its products. It covers half of the whole field of fixed capital accumulation; thus, constitutes the most single sector of capital formulation in any national economy (Fagbenle, 2009). Dlakwa and Culpin (2010) hinted that construction investment accounts for over 60% of the Gross Fixed Capital Formation (GFCF) i.e. the total national investment in Nigeria. The industry is also seen as the barometer for the performance of the economy in most developing countries (Kazaz and Ulubeyli, 2004).

Ugochukwu and Onyekwena (2014) opined that the construction process is capital intensive. From inception to completion, cost is incurred at every stage. However, the major cost is incurred during the actual construction stage where irreversible commitment of fund is undertaken in the procurement and deployment of resources such as labour, plant, materials and managerial expertise to achieve the finished product. The contractor is the party who uses these resources to bring the works to fruition. Idoro (2007) explained that these contractors are either foreigners or indigenes; in which case, they originate locally and operate within the immediate project vicinity, state or country.

Akinmoladun, O. T. & Ibironke, E. A. (2016). Assessment of Construction Productivity of Indigenous Construction Firms in Southwestern, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 746-755

Oladapo (2007) concluded that Nigerian indigenous contractors have not had a fair share of major construction activities in the country, as they are often awarded to their foreign counterparts whom are considered more technically and managerially superior and efficient in funds acquisition and project execution. Productivity is considered as one of the most important factors affecting the success and overall performance of every organization, whether large or small, in today's competitive market (Enshassi, Mohammed, and Abushaban, 2009) The construction industry with its several organizations not exempted. Walker and Vine (2000) hinted that construction productivity was traditionally identified as one of the three main critical success factors together with cost and quality for a construction project.

Statement of Research Problem/Question

The need for this study stems from the unproven accusations on indigenous contractors that has forced a lot of them out of business. These accusations added to the problems of high rate of cost and time overrun encountered through inefficient working capital management of majority of indigenous firms (Akinmoladun, 2015). According to Iyagba and Ayodele (1998), the Government is the majority of clients patronising contractors. Idoro (2007) affirmed that the expatriate firms formed majority of the government construction vendors in Nigeria. Unproven accusations on indigenous contractors were, among others, high level of incompetence, lack of technical know-how, shabby quality of work delivered and low managerial capacity (Balogun, 2006). Thus, they do not perform to the satisfaction of the clients.

This discrimination on indigenous contractors by the Government in Nigeria created an atmosphere of fear and uncertainty among indigenous firms in Nigeria. It is in the light of the foregoing, that this research assesses the construction productivity of indigenous construction firms in Nigeria via determination of their various productivity levels, competence levels on construction matters, strategies to improve their productivity and possible barriers to improvement.

Aim and Objectives

The aim of this research is to evaluate the productivity level of indigenous construction firms in other to ascertain their readiness for competition with their expatriate counterparts.
The specific objectives include:

i. To measure on site, the labour productivity level of selected indigenous contractors in the study area through work sampling.
ii. Assess the competence of indigenous firms in construction industry
iii. Identify and assess the factors influencing the productivity of indigenous construction firms;
iv. Identify strategies to improving the productivity of indigenous firms on construction sites;
v. Identify the possible barriers to improving construction productivity of indigenous construction firms.

LITERATURE REVIEW

Emmanuel (2009) opined that productivity has been an essential contributor to corporate success. It corroborated Mojahed (2005), who noted that it is as a result of its direct translation into cost savings and profitability. Productivity has been a key to long-term growth and sustainable improvement and when associated with economic growth and development generates non-inflationary increases in wages and salaries (Mojahed, 2005). An enhanced productivity in the construction industry has a positive effect on the gross domestic product (GDP) of every nation because the industry generally plays a vital role in a national

economy due to the usage of its products such as roads, buildings and dams for the production of goods and services. However, the productivity of the construction industry, according to Haskell (2004), is one of the controversial and least understood factors despite the immense significance of the industry to the economy. Thomas, Skitmore and Lam (2004), opined that site workers in the industry accounts for about 40% of direct capital cost of large construction projects and there is the need to maximise the productivity of human resources. Furthermore, he iterated that about 30% - 50% of workers time is spent directly on the work and, hence, there is the need for proper utilisation. In Nigeria's construction industry for instance, companies are currently applying various non-financial incentive schemes aimed at improving operatives' productivity. This has significantly improved bricklayers' productive time and accounted for 6% to 26% of variations in output between block laying and concreting activities measured (Olabosipo, Aderemi and David, 2004).

Construction industries are faced with the problems of low productivity, poor safety and insufficient quality. Productivity is the one of the most important factor that affects overall performance of any small or medium or large construction industry. There are number of factors that directly affect construction productivity, thus it is important for any organization to study and identify those factors and take an appropriate action for improving their productivity. At the micro level, if productivity were improved, ultimately it reduces or decreases the unit cost of project and gives overall best performance of project. There are number of activities involved in the construction industry, thus the effective use and proper management regarding labour is very important in construction operations without which those activities may not be possible (Honer and Duff 2001).

Productivity is defined as "the ratio of output of required quality to the inputs for a specific production situation. In the construction industry, it is generally accepted as "work output per man-hours worked" (Nabil and Gidado, 2010). Libre (2013) posited that as in many developing economies, productivity is an issue of particular importance all over the world. Nabil and Gidado (2010) opined that productivity is the one of the most important factor that affects overall performance of any small or medium or large construction industry. There are number of factors that directly affect the productivity, thus it is important for any organization to study and identify those factors and take appropriate actions for improving the productivity.

Libre (2013) defined labour productivity as the ratio of the output quantities to the input work hours, or as ratio of the work hours to the quantities (also called the unit rate). For the purpose of this study, the former definition is adopted and labour productivity is expressed as follows:

$$Labour\ Productivity\ = \frac{Output\ Quantity}{Work\ hour}$$

In construction, productivity is usually taken to mean labour productivity, that is, units of work placed or produced per man hour (Nabil and Gidado, 2010). Productivity is the ratio of output to all or some of the resources used to produce that output. According to Libre (2013), output can be homogenous or heterogeneous. Labour productivity has been identified as an index for measuring efficiency because labour is acknowledged as the most important factor of production since it is one of the major factors that creates value and sets the general level of productivity (Ameh and Odusami, 2002). Enshassi, Mohammed, Mustafa and Mayer (2007) identified labour productivity as the key factor contributing to the inability of many indigenous construction contractors to achieve their project goals which include most importantly, the profit margin amongst others.

METHODOLOGY

The study adopted the use of simple random sampling method since data are to be collected from indigenous construction firms across the southwestern States of Nigeria. The data for this research was collected from two major sources, the secondary and primary sources. The secondary data were collected through journals articles, conference proceeding and previous studies to achieve objectives 3-5. The primary data involved data from field survey which consisted direct measurement of output of the operatives on site and data from structured questionnaire which were used to achieve objective 1-2. Twenty Five (25) indigenous construction firms were sampled randomly from the population of the indigenous construction firms (five firms from each State in the Geo-political zones). These five indigenous firms from each State were gathered using the Snowball Sampling method, where one operation active indigenous firm (large scale firm) gave a lead to another large scale operation active indigenous firm. These formed a reflection of the indigenous firms in Southwestern Nigeria. Southwestern Nigeria comprises six (6) States namely: Lagos, Ogun, Oyo, Ondo, Osun and Ekiti State. The researcher ensured that each of the five indigenous firms were located and are in operation in that State.

Data for direct measurement of output on site were collected through work sampling with craftsmen at active operative level as the target group. A well-structured questionnaire was designed on likert scale of 1-5, having the client as the target group. On the scale, Extremely High = 5, High=4, Moderate = 3, Low = 2 and Very Low = 1. The clients were sampled at random from private, individuals and government organizations across the six States which form the population for the clients (Majorly MDAs in Government for Public and Private Institutions such as Banks, Schools and NGOs). A total of 120 questionnaires were administered across the selected sampled population out of which 96 questionnaires were dully completed and returned for analysis. Data collected through work sampling on site was analysed using formula for calculating performance, performance Ability Ratio as adopted from Ugochukwu and Onyekwena (2014). The performance scale ranges from 0-1.

$$\text{Performance} = \frac{\text{Accomplishment}}{Work\ hour} \quad \ldots\ldots\ldots \text{Eq. 1.}$$

$$\text{Performance Ability Ratio} = \frac{\text{Current performance (Pcur.)}}{\text{Exemplar Performance (Pexm)}} \quad \ldots\ldots\ldots \text{Eq. 2}$$

$$= \frac{\text{Pcur.}}{\text{Pexm}}$$

Data collected through questionnaire was analysed using Mean Item Scores (MIS) and Relative Importance Index (RII)

$$\text{MIS} = \frac{5F_5 + 4F_4 + 3F_3 + 2F_2 + F_1}{F_5 + F_4 + F_3 + F_2 + F_1} \quad \ldots\ldots\ldots \text{Eq. 3}$$

$$\text{RII} = \frac{5F_5 + 4F_4 + 3F_3 + 2F_2 + F_1}{5(F_5 + F_4 + F_3 + F_2 + F_1)} \quad \ldots\ldots\ldots \text{Eq. 4}$$

RESULTS AND DISCUSSION OF FINDINGS

Labour Productivity Level of Indigenous Construction Firms

Table 1 showed the average efficient performance of labour output working with the 25 firms on various and significant construction work items while Table 2 showed the best achievable performance of labour output for same activities on the standard radar. For instance, the average Labour output for trench excavation in Firm No.1 is 0.32m^3/hr (From Table 1), while the best achievable output for same work item is 0.33m^3/hr (as shown in Table 2). The

Performance Ability Ratio for firm No.1 on Trench excavation is 0.97 (as shown in Table 3) indicating Firm No.1 is just 3% away from achieving best output on the work item. The overall labour output performance on Trench Excavation for the 25 firms is 0.31m^3/hr. amounting to an average PAR of 0.94, Pit excavation (Output=0.26m3/hr; PAR=0.92) Concrete work (Output=0.10m3/hr. PAR= 0.76), Block laying (Output=0.41m2/hr. PAR=0.40), painting (output=2.16m2/hr. PAR=0.87), making and fixing formwork (output=0.20m2/hr. PAR=0.87), Roofing and Carcassing members (output=0.61m2/hr. PAR=0.88) and so on.

Table 2: Exemplar Performance ($P_{exm.}$)

Work Section	Trench Exc'n	Pit Exc'n	Concrete Work	Block Laying	Painting	Formwork (Mak'g & Fix'g)	Roof & Carcassing	Laying Floor Tiles	Laying Wall tiles	Reinforcement Mak'g & Fix'g
	(m^3/hr)	**(m^3/hr)**	**(m^3/hr)**	**(m^2/hr)**	**(m^2/hr)**	**(m^2/hr)**	**(m^2/hr)**	**(m^2/hr)**	**(m^2/hr)**	**(Ton/hr)**
	0.33	0.28	0.13	1.05	2.50	0.23	0.70	1.85	0.23	0.025

This indicates that the indigenous construction firms from measurement of labour output on site performed a well above average. This is an improvement on the Ugochukwu and Onyekwena (2014) where they recorded a little above average. Thus, debunking the negative perception on the performance of indigenous firms and confirming the fact that indigenous firms can perform well on capital intensive projects. However, the indigenous firm still need to improve on the work output on block laying as it is one of the critical work item, most especially on load bearing structures.

						0.83				

The performance Ability Ratio (PAR) was computed. The PAR can be used to compare current performance of the company/firm to the exemplar performance. It is used as a measure of relative worth of jobsite performance. Balogun (2006) submitted that the higher the PAR values the more chances of improvement for the firm. Performance Ability Ratio value of 0.8-1.0 shows that there are chances of improvement for such firms. The overall average PAR for the sampled population for this study was 0.83; indicating that in all the construction firms sampled, there are greater potentials of improvement in their performance. From the data collected through questionnaire. The numerical scores were transformed to Mean Item Scores (MIS) so as to determine the ranking of the measures of performance. The mean item scale ranges from 0 -5. Table 3 showed the result:

Table 4: Assessment of Competence of Indigenous Firms

S/N	Measures of Competence	MIS	Rank	Remarks
1	Technical Competence	4.15	1	High
2	Managerial Competence	3.90	2	High
3	Quality of Work	3.80	3	High
4	Material Management	3.65	4	High
5	Schedule Variance Management	3.55	5	High
6	Security Consciousness	3.55	5	High
7	Relationship Management	3.55	5	High
8	Workers' Welfare and Safety	3.40	8	High
9	Claims Management	3.15	9	High

From table 4, the study revealed that indigenous firms possessed high competence in technicality (MIS=4.15), management (MIS=3.90), Quality of Work (MIS=3.80), Material

Management (MIS=3.65), Schedule Variance Management (MIS=3.55), Security Consciousness (MIS=3.55), Relationship Management (MIS=3.55), Workers' Welfare and Safety (MIS=3.40) and Claims Management (MIS=3.15).

About 32 factors influencing the productivity of indigenous firms were identified in literature in accordance with previous studies (Alfred (2008), Iyagba and Ayodele (2008), Elgin and Egger (2000), and Libre (2013)). The Bartlett of Sphericity test (Table 5) was conducted to indicate the overall significance of the correlations within the correlation matrix of the identified 32 factors. With the significant p-value (0.000) less than 0.05, it shows that there is significant correlation among the variables and thus they can be reduced. The KMO test (Table 5) carried out on the variables indicated that the use of factor analysis is suitable.

Working in Operating Area		0.581				0.513				
Over-Manning										
Tool & Equipment Shortage										
Area Practices										
Proximity of Work										

The rotated component matrix contained the rotated factor loadings, which are the correlation between the variable and the factor. Weak correlations to each of the factors had been deleted to make the table more interpretable. The reduced factors are shown in Table 7

Table 7: Assessment of the Impact of Factors influencing Construction Productivity for Indigenous Firms'

S/n	Factors	RII	Rank	Remark
1	Overtime	0.905	1	Very High
2	Stacking of trade	0.807	2	Very High
3	Weather and Area practices	0.779	3	High
4	Beneficial occupancy	0.779	3	High
5	Attitude of labourers to work	0.778	5	High
6	Holidays	0.768	6	High
7	Nature of site	0.764	7	High
8	Managerial decisions	0.754	8	High
9	Degree of Site safety	0.746	9	High
10	Over-manning	0.726	10	High

From Table 7, it was observed that working overtime for labour and stacking of trade had very high impact on labour productivity of indigenous firms with Relative Importance Index (RII= 0.905 and 0.807) respectively. From the above, it could be gathered that the issue of overtime and stacking trade during construction should be looked into to enhance construction productivity. Other factors should also be put into consideration as they have high impact on construction productivity.

Table 8: Strategies to Improving Construction Productivity of Indigenous Firms

S/N	Strategies	RII	Rank	Remark
1	Appropriate Project Planning	0.782	1	Agree
2	Labour Management Plans	0.775	2	Agree
3	Regular Meetings with crew	0.768	3	Agree
4	Advanced Equipment and Material planning	0.758	4	Agree
5	Effective Supervision	0.754	5	Agree
6	Training Labour Force	0.744	6	Agree
7	Use of New Technology	0.740	7	Agree
8	Effective Motivation Plan	0.723	8	Agree

The design and use of appropriate project planning and labour management had RII=0.782, Labour Management plan (RII=0.775), having regular site meetings with labourers (RII=0.768), advanced equipment and material planning (RII=0.758), effective supervision (RII=0.754), training labour force (RII=0.744), use of new technology (RII=0.740) and motivation plans (RII=0.723) respectively.

Table 9: Assessment of Barriers to Improving Labour Productivity

S/N	Barriers	RII	Rank	Remark.
1	Lack of alignment to goal	0.853	1	Strongly Agree
2	Contractual conflict	0.849	2	Strongly Agree
3	Difficulties in measuring productivity	0.800	3	Strongly Agree
4	Weak Commitment to continuous improvement	0.793	4	Agree
5	Lack of Labour force focus	0.779	5	Agree
6	Government policies	0.768	6	Agree

A total of six possible barriers to improving indigenous construction productivity were identified in literature. The levels of agreement of the respondent were collected as evaluated in Table 9. According to the table, the respondent strongly agreed that lack of alignment to set goals (RII=0.853), contractual conflict (RII=0.849) and difficulties in measuring productivity (RII=0.800) as great set of barriers to labour productivity. However, respondents agreed to the fact that weak commitment to continuous improvement (RII=0.793), lack of labour force focus (RII=0.779) and Government policies (RII=0.768) could be another set of barriers to labour productivity.

CONCLUSION

Base on the findings of the research, it could be concluded that the performance of Indigenous contractors had improved beyond and should be given equal work opportunity with their expatriate counterpart since they were rated high in core competence of construction works. Result showed that working overtime of labourers and stacking of trade had very high impact on indigenous firms' construction productivity. Also, other factors such as attitude of labourers to work, managerial decisions, nature of site, safety of site, weather and area practices, beneficial occupancy, stacking of trade and holidays were discovered to record high impact on construction productivity.

Among the strategies to improve construction productivity of indigenous firms, appropriate project planning and use of labour management plan were the most supported strategies to improving construction productivity. Regular site meetings of the construction crew, Effective supervision, Good contractual strategy implementation, Adequate communication, Training Supervisors, Training labour Force, Adequate Safety plan and analysing the construction process were also supported strategies for improving productivity in construction works. However, the use of new technology and Effective Motivation Plans were quite supported. Lack of alignment to goals, contractual conflict, difficulties in measuring productivity, weak commitment to continuous improvement, lack of labour force focus and government policies were discovered to be the barriers to improving construction productivity of indigenous contractor in Southwestern Nigeria.

RECOMMENDATION

Based on the study, the following are recommended:

i. Indigenous contractors should carry out periodic studies on client's need evaluation to ascertain the current needs of clients so as to meet their expectation.
ii. Indigenous contractors should enhance the welfare of their workers especially the technical staff to improve their output on site and their general performance.
iii. Indigenous firms should be given equal opportunity to execute capital intensive construction projects like their expatriate counterpart as results showed that the performance of the indigenous contractors are above average.

ABSTRACT

Lean Construction offers valuable techniques to manage construction at improved workflows and minimal waste generation. This research therefore seeks to assess Lean Construction practices in the Nigerian Construction industry by exploring construction practitioners' extent of knowledge of Lean Construction and its approaches as well as evaluate how often these approaches are being utilized, to assess its benefits and the barriers hindering its implementation in the Nigerian construction industry. The target populations were construction professionals in the construction industry, consisting of Architects, Quantity Surveyor, Builders and Engineers. Data collection was done through the use of a structured questionnaire administered to these professionals. The data were analyzed using Mean score ranking statistical tool and results were presented in tables. The results showed that most of the construction professionals are aware of Lean Construction and its approaches. Also, Project needing immediate attention given more importance, Identification of client needs and Look – ahead schedule (program of work) were the most utilized approaches in the construction industry, while improvement of project delivery methods, more satisfied clients and the delivery of products or services that enable clients to better accomplish their goals were the major benefits identified. The study therefore recommends that more should be done on lean awareness and understanding as well as training for exposure to the need to adopt the lean concept.

Keywords: Construction, Lean Construction, Professionals

INTRODUCTION

The construction Industry not only provides infrastructure for all other industries, but also constitutes one of the largest single sectors in the economy on its own (International Investment and Services Directorate, 1999).In many large cities in the world, Waste has been considered to be a major problem in the construction industry (Al-Moghany, 2006). Non-value adding activities (NVA) in the construction process such as waiting time, material handling, over production, inventories, re-work and movement of workers have been discovered to constitute waste which forms about 30% of construction cost (Koskela, 2000). Lean Construction has therefore been introduced into the construction industry as it is a concept in construction specifically set out to increase the sector's productivity level through the elimination of activities and actions deemed to generate waste in the construction process (Abdullah,Abdul-Razak, Abubakar and Mohammad2009).

The emergence of the lean construction concept is seen as a current approach that can be used to produce best practices because it was viewed as an effort to bring construction industry towards a more optimum productivity level with the efficient usage of resources as well as to produce the utmost value. Lean construction is understood as a new paradigm for project management, thereby challenging the traditional thinking about construction and project management (Ballard and Howell, 2004).The direct application of the lean construction concept in a construction project will bring an effect of change towards the way work is conducted by an organization responsible in realizing the related construction activities. This will then forcibly alter the traditional work practices normally undertaken by the construction firms according to the needs and suitability in line with the objectives and principles established in the lean construction concept itself (Abdullah *et al.* 2009).According to Howell (1999), managing construction under Lean is different from typical contemporary practice

Adegbembo, T. F.; Bamisaye, O. P. & Aghimien, D. O. (2016). Assessment of Lean Construction Practice in the Nigerian Construction Industry. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 756-764

because it; has a clear set of objectives for the delivery process; it is aimed at maximizing performance for the customer at the project level; t designs concurrently product and process, and it applies production control throughout the life of the project.

According to Johansen and Walter (2007), the application of the lean concept in the construction industry is still very restricted and sluggish, although various countries gained large benefits by adopting Lean Construction concepts, there seems to be little implementation of lean in the United Kingdom construction industry over the last two decades, because there appears to be some barriers preventing its successful implementation (Mossman, 2009).One of the major barriers to implementation of lean concepts in construction is the low level of awareness among construction professionals in the construction industry. In relation to this, a research work carried out by Olatunji (2008) in Nigeria to determine the awareness level of construction professionals about lean indicates that the level of awareness is very low stating that only two out of the ten respondents signify that they have heard about lean.

Thus, the aim of this study is to assess lean construction practices with a view to know the present state in the Nigerian construction industry. To achieve this, the level of awareness of lean concept among construction professionals in the Nigerian construction industry and the lean principles used in the Nigerian construction industry were assessed.

LITERATURE REVIEW

The Construction Industry in Nigeria

The construction industry according to Leibing (2001) is the tool through which society goals of urban and rural development can be achieved. It embraces a wide range of loosely integrated organizations that collectively construct, alter, refurbish and repair a wide range of different building and civil engineering structures. The industry all over the world has not been static and the reasons for this include: clients' growing demand, complexity of construction projects, advancement in technology and introduction of new innovations amongst others (Oke, 2009).

Construction work covers site acquisition, design, contract, site operation (construction), operations and management. It has a great impact on the economy of all countries (Leibing, 2001). In Nigeria, the construction industry continues to occupy an important position in the nation's economy even though it contributes less than the manufacturing or other service industries, (Aibinu and Jagboro, 2002). Olowo-Okere (1985) gave the genesis of construction in Nigeria as far back as the 1940s when few foreign companies came together under an organized construction contracting in Nigeria and began operation. Since then the Nigeria's economic growth over the last decade according to Isa, Jimoh and Achuenu (2003) has been high and the contribution of construction sector has risen steadily leading to sustainability.

The Nigerian construction is no different from its counterpart around the world where waste abounds. Thus, it is the duty of the professionals to gear up and put into action, new ways of avoiding this common problem.

Professionals in the Construction Industry

In most cases, construction professional who are regularly engaged by the government and other clients include but not limited to: Architects, Quantity Surveyors, Engineers, Builders and Project Managers. All these construction professionals according to Gyadu-Asiedu (2009) are regulated by their professional institutions. On a general note, the *Architect* is a person involved in the planning, designing and over-seeing of a building's construction. He translates the user's need into the builder's requirements and he thoroughly understands the building and operational codes under which his or her design must conform. The Architect is

charged with being generally familiar with the work and reporting the general progress and quality of the work, as completed, to the client. Hence, the standard of care is that the Architect should be responsible for discovering and reporting nonconforming work that is available to be seen (Simson and Atkins, 2006; Anyanwu, 2013). Anyanwu (2013) observed that the *Engineers* (civil, structural and building services) are very important members of the design team whose responsibilities are to assist in the overall design of the project within the scope of their specialist fields. They also produce drawings, specifications, schedules and other relevant data that may be required for the overall construction of the project. The *Quantity surveyor* according to Hussin (2009) is concerned with managing and controlling costs within construction projects and may involve the use of a range of management procedures and technical tools to achieve this goal. A *Builder* is a professional at the centre of the physical construction of buildings (Anyanwu, 2013). He is a man-power capable of interpreting the specifications of other survey and design professionals. A *Project Manager* represents the client on the site and his role is to inspect quality of materials and the workmanship to ensure that they all comply with the drawings and specifications. According to Russell (2006), the services offered by Project Managers vary considerably, as do the qualifications and experience of the people that act in this capacity. The qualifications and experience of people practicing as Project Managers may come from the professional side of the construction industry, as in Architects, Quantity Surveyors or Engineers, or may stem from the contracting side, such as in the management teams of major main contractors.

All these professionals are saddled with achieving one goal, which is delivering the construction project within the budget, at the shortest possible time and with the best quality achievable. Therefore, avoiding waste in terms of time, cost, labour, materials and the likes which according to Al-Moghany (2006) have been a major problem in the construction industry, should be paramount to these professionals.

Lean Construction

Lean concept is a Western interpretation of the Japanese Production Philosophy in the car manufacturing industry (Bertelsen and Koskela 2005).The core concept behind Lean Production is to enable the flow of value creating work steps while eliminating non-value steps (Dulaimi and Tanamas 2001). Howell (1999) highlighted Lean production concepts as: identifying and delivering value to customer by eliminating anything that does not add value, organizing production as a continuous flow, perfecting the product and creating reliable flow through stopping the line, pulling inventory, distributing information and decision-making and pursuing perfection by delivering on order a product meeting customer requirements with nothing in inventory. Abdul-Razek*et al.* (2007) believe that the core idea of Lean Construction is to reduce or eliminate waste, represented in non-value adding activities, and increase the efficiency of value adding activities.

Lean is essentially all about getting the right things to the right place at the right time, in the right quantity and at the same time, minimizing waste and being open and responsive to change. Lean production has an underlying philosophy that, by eliminating waste, quality can be improved, and production times and costs reduced (Kempton, 2006). According to Koskela (1999), lean construction shares the goals of lean production which is; elimination of waste, cycle time reduction, and variability reduction. Lean thinking is lean because it provides a way to do more with less human effort, less equipment, less time and less space, while coming closer to providing customers satisfaction (Mossman, 2009).

Lean Principles and approaches to achieving Lean in Construction

Lean concept is all about getting the right things to the right place at the right time, in the right quantity whilst minimizing waste and being open and responsive to change (Kempton,

2006). Lean primary principles were observed to include: reduction of waste within the value stream; synchronising, aligning and providing transparency as part of the planning process; and integrating Transformation Flow Value production theory as part of the lean implementation process (Chestworth et. al, 2011). Kempton (2006) further argued that the principles of Lean include: perfect first- time quality - achieving zero defects, revealing and solving problems at the source; waste minimization - eliminating all non-value-adding activities and maximizing the use of resources; continuous improvement - reduction of costs, increase quality and productivity; pull processing - products pulled from the consumer end; flexibility - production of different mixes and/ or greater diversity of products, without compromising efficiency; and Relationships - building and maintaining long-term relationships with suppliers. Other researchers have proposed wider principles (Liker, 2004; Ballard, 2006; Robert & Granja, 2006; London, 2004) but the application might differ from one organization to the other (Liker, 2004).

In achieving these principles within a construction project, several approaches are available to the construction professionals. This include from; identification of client needs, project needing immediate attention given more importance, look – ahead schedule, timely delivery of construction materials to site, continuous improvement, conducting of weekly meetings, regular performance measurement of site workers, strict criteria for the selection of subcontractor, involvement of project participants in making of schedules, uninterrupted workflow etc (Chestworth et. al, 2011; Liker, 2004)

Benefits of Lean Construction

The introduction of the Lean Construction concept and its application within the construction industry is reported to have birth a lot of benefits (Abdullah *et al.*, 2009). Evidence of the use of lean thinking has shown that there are many benefits to be made from applying lean principles to construction. These benefits claimed include: improved productivity, increased reliability, improved quality, more client satisfaction, increased predictability, shortened schedules, less waste, reduced cost, enhanced build-ability improvements to design, and improved safety (Mossman, 2009). Also the implementation of Lean Construction in the construction industries will lead to improvement of project delivery methods, delivery of products or services that enable clients to better accomplish their goals, more satisfied clients, productivity gains, minimization of risks and maximization of opportunities, greater predictability, shorter construction periods/ reduced project time, injection of reliability, accountability, certainty and honesty into the project environment, improved design just to mention a few.

Barriers to the Implementation of Lean Construction

There seems to be a number of barriers militating against successful lean implementation. Several studies have been carried out in different countries worldwide to identify the barriers in implementing the Lean construction (Mossman, 2009). Bashir *et al*. (2010) classified these barriers different categories based on a thorough and critical review of international literature relating to the take up of lean practice. These include; lack of training, lack of interest from the client, waste accepted as inevitable, delay in material delivery, etc. According to Abdullah *et al.*(2009) lack of attentiveness and commitment from top management, difficulties in understanding the concept of lean construction, lack of exposure on the need to adopt the lean construction concept, lack of proper training, weak communication among clients, consultants and contractors, the tendency of construction firms to apply traditional management concepts as opposed to productivity and quality management concepts, attitude and ability to work in group, and long implementation period of lean concept in construction processes, are some of the major barriers to the implementation of Lean construction in the construction industry. Bashir *et al*. (2010)

therefore suggested that the measures to these barriers are timely delivery of materials to site, organizing of trainings employees on lean concept and companies being client focused.

METHODOLOGY

The aim of this paper is to assess the Lean construction practice in the Nigerian construction industry with a view to know the present state in the Nigerian construction industry. In achieving this, a survey design was used. This involved the use of questionnaires administered to Quantity surveyors, Architects, Civil Engineers and Builders in the Ondo state, Nigeria. A total of 93 questionnaires were distributed with 77 returned out of which 74 were deemed fit for analysis. This represents a response rate of 79.57% which is far above the usual response rate of 20-30% for questionnaire surveys in construction management studies, as suggested by Akintoye (2000). Mean Item Score (MIS) was used to analyze data gathered using the formula:

$$M = \frac{5(FX^5) + 4(FX^4) + 3(FX^3) + 2(FX^2) + (FX^1)}{X^5 + 4 + X^3 + X^2 + X^1}$$

Where M = Mean Item Score
X = range 1 – 5 with 5 being the highest and 1 being the lowest
F = Frequency of respondent in each factor

The MIS is ranked in descending order with the highest MIS ranked 1st and others in such subsequent descending order.

FINDINGS AND DISCUSSIONS

Respondents Background Information

The respondents sampled include 37.8% Quantity surveyors, 29.7% Engineers, 17.7% Architects and 14.9% Builders. 36.5% of the respondents have between 1 to 5years of working experience while 32.5% have between 6 to 10 years experience. 12.2% of the professionals have 11-15years, 5.4% have between 16 to 20years while 13.5% have above 20years of experience in building construction. Thus, it can be said that the data gathered from the respondents can be relied upon since 63.5% of the respondents have above 5years working experience, hence information would have been given based on their wealth of experience. Research also shows that 50% of the respondents are aware of Lean Construction either through professional practice, school, seminar/conference, printed material/literature, or from colleagues, while 28.4% are strongly aware, 12.2% are somewhat aware while a meager percentage (9.5%) of the respondents are not aware of Lean Construction in Ondo State. This huge percentage of awareness can be attributed to the vast years of experience and exposure of the respondents in the construction sector.

Level of awareness and adoption of the different ways of delivering Lean construction

From table 1 below, it shows that there is an appreciable level of awareness of the different approaches through which lean construction can be delivered in any construction project. These approaches were slightly rewritten as a means to simplify potential awareness and understanding by the respondents. Result reveal that identification of clients need has the highest level of awareness among construction professional with a mean score of 4.22 while Project needing immediate attention given more importance and Look –ahead schedule and Continuous improvement ranked 2nd and 3rd with a mean score of 4.17, and 4.07 respectively. Continuous improvement and involvement of construction professionals right from the inception ranked 4th with a mean score of 4.06 each while direct involvement of foremen in decision making is the least on the table with a mean score of 3.36.

Result showed that in practice, project needing immediate attention is given more priority as this ranked 1st with a mean score of 3.84, while identification of clients' needs and Look – ahead schedule follows with a mean score of 3.78 each. Just-in-Time (JIT) delivery, Continuous improvement and involvement of construction professionals right from the inception ranked 3rd, 4th and 5th with a mean score of 3.73, 3.72, and 3.68 respectively, while and while direct involvement of foremen in decision making is the least on the table with a mean score of 2.89.

Table 1: Level of awareness and adoption of the different ways of delivering Lean construction

Approaches	Level of awareness		Level of Adoption	
	MIS	Ranking	MIS	Ranking
Identification of client needs	4.22	1	3.78	2
Project needing immediate attention given more importance	4.17	2	3.84	1
Look –ahead schedule (program of work)	4.07	3	3.78	2
Continuous improvement	4.06	4	3.72	4
All parties involved in the design (involvement of construction professionals right from the inception)	4.06	4	3.68	5
Weekly meetings	3.94	5	3.59	7
Percent Plan Complete	3.91	6	3.37	12
Regular performance measurement of site workers	3.89	7	3.47	9
Just-in-Time (JIT) delivery (timely delivery of construction materials to site)	3.86	8	3.73	3
Using computer software for estimating	3.85	9	3.61	6
Training of employee	3.83	10	2.98	15
Personnel responsible for procurement	3.83	10	3.52	8
Strict criteria for the selection of subcontractor	3.79	11	3.43	10
Involvement of project participants in making of schedules	3.70	12	3.39	11
Uninterrupted workflow	3.69	13	3.25	13
Site daily meetings	3.56	14	3.14	14
Direct involvement of foremen in decision making	3.36	15	2.89	16

Benefits of Lean construction

Result in table 2 reveals the respondents view of the benefits of Lean Construction in the construction industry. Improvement of project delivery methods was ranked the highest, having the mean score of 4.40 while more satisfied clients and Delivery of products or services that enable clients to better accomplish their goals followed respectively having mean scores 4.07 and 4.00. However, lower degree of disruption of activities (i.e. reduction in variation), less idle time and Increment in workers motivation were the least ranked of the benefits having mean scores of 3.68, 3.56 and 3.49 respectively.

Table 2: Benefits of Lean construction

Benefits	MIS	Ranking
Improvement of project delivery methods	4.40	1
More satisfied clients	4.07	2
Delivery of products or services that enable clients to better accomplish their goals	4.00	3
Promotion of continuous improvement in project delivery methods through lessons learned	3.99	4
Minimization of risk and maximization of opportunities	3.97	5
Delivery of products or services on time and within budget	3.93	6
Delivery of customers product instantly without waste	3.92	7
Increased Percent Plan complete	3.90	8
Less rework	3.86	9
Minimization of direct costs through effective project delivery management	3.85	10
Injection of reliability, accountability, certainty and honesty into the project environment	3.85	10
Reduced project time	3.75	11
Lower degree of disruption of activities (i.e. reduction in variation)	3.68	12
Less idle time	3.56	13
Increment in workers motivation	3.49	14

Barriers to the Implementation of Lean Construction

Result in Table 3 below shows the various barriers to the implementation of Lean Construction. Lack of lean awareness and understanding and Lack of exposure to the need to adopt the lean concept were ranked the highest having mean scores of 4.27 each, while lack of proper training and difficulty in understanding lean concepts were ranked second and third with mean scores 4.11 and 3.94 respectively. Meanwhile, Lack of buildable designs, Fragmented nature of the industry and lack of long term relationship with suppliers were ranked least with mean scores of 3.58, 3.51 and 3.32 respectively.

Table 3: Barriers to the Implementation of Lean Construction

Barriers	Mean	Ranking
Lack of lean awareness and understanding	4.27	1
Lack of exposure to the need to adopt the lean concept	4.27	1
Lack of proper training	4.11	2
Difficulty in understanding lean concepts	3.94	3
Weak communication among clients, consultants and contractors	3.90	4
Waste accepted as inevitable	3.86	5
Inefficient use of quality standards	3.85	6
Poor communication	3.83	7
Delays in material delivery	3.79	8
Delays in decision making	3.79	8
Lack of agreed implementation methodology	3.77	9
Lack of attentiveness and commitment from top management	3.75	10
Incomplete designs	3.74	11
Lack of interest from clients	3.73	12
Lack of long term commitment to change and innovation	3.73	12
Inefficient use of quality materials	3.71	13
Lack of information or help from other organizations	3.65	14
Long implementation period	3.65	14
Ability to work in group (teamwork)	3.59	15
Lack of buildable designs	3.58	16
Fragmented nature of the industry	3.51	17
Lack of long term relationship with suppliers	3.32	18

Discussion of Findings

Findings revealed that a greater number of the respondents of this study are seemingly aware of the term Lean Construction and its techniques. However, this is contrary to Olatunji research in 2008 in Nigeria which indicates that the level of awareness and knowledge of lean is low stating that only two out of the ten respondents signified that they have heard about lean. The level of awareness might have increased drastically considering the year interval between 2008 and 2015.

Also findings revealed that that project needing immediate attention given more importance, identification of client needs and Look –ahead schedule (program of work) are the most utilized approach to Lean construction in the construction industry in Ondo State, Nigeria. This was proven in a study carried out by Satish *et. al.* (2005) were identification of client needs and the Look- ahead schedule (program of works) were mostly used. They were part of the most utilized method of delivery Lean construction used by 16 companies in New York City and various benefits were recorded like cost savings, reduced project time, reduced rework and increased Percent Plan Complete (PPC). Findings from the research shows that the use of lean approach in construction will lead to improvement of project delivery methods, provide more client satisfaction and delivery of products or services that enable clients to better accomplish their goals followed respectively.

Lack of lean awareness and understanding, lack of exposure to the need to adopt the lean concept and lack of proper training were the major identified barriers to the implementation

of Lean construction in Nigeria. This was in concordance with the research study carried out by Sarhan *et.al.* (2013) in United Kingdom (UK) were lack of Lean awareness and understanding was a major barrier identified. This can be mitigated through adequate public awareness and organizing of training of employees on lean concept as suggested by Bashir *et al*. (2010).

CONCLUSION AND RECOMMENDATION

Conclusion

This study assessed Lean Construction in the Nigerian Construction Industry which afterwards reveal the following conclusions;

i. A good number of construction professionals in Ondo State are well aware of Lean Construction through professional practice.
ii. Identification of client needs, project needing immediate attention given more importance and look – ahead schedule are the popular approaches of delivering lean construction among professionals, while the most used is project needing immediate attention given more importance.
iii. Improvement of project delivery methods, provision of client satisfaction and delivery of products or services that enable clients to better accomplish their goals are some of the main benefits of applying lean in construction. Also lack of lean awareness and understanding, lack of exposure to the need to adopt the lean concept and lack of proper training are the major barriers to the implementation of lean construction in the Nigerian construction industry.

RECOMMENDATION

Based on the conclusions the study therefore recommends that Lean Construction should be incorporated in the school's curriculum so that students can have better knowledge of it and can easily build on the foundational knowledge during practice. Also Lean Construction trainings should also be organized in construction companies, government parastatals, and consultancy firms which will be very helpful in moving lean thinking faster into the mainstream of construction education. The findings of the study provide possible directions for further studies in that the researcher was able to assess Lean Construction practice in the construction industry in Ondo State, Nigeria. Further studies can be extended to other locations so as to have a wider study area and also to know the level of awareness in other locations in Nigeria.

ABSTRACT

The research space in sustainable project management tends to focus on skills and knowledge; the specific indicators of sustainability that these competencies generate in projects are less developed. This study validated set of empirically weighted sustainability indicators for evaluating sustainable project management. The sustainability practices were evaluated based on comprehensive environmental management outputs, community engagement and education and training. Explorative research involving questionnaire survey was conducted. The survey engaged 112 stakeholders including (quantity surveyors, civil engineers, builders, architects, and project/construction managers) in Akwa Ibom and Ondo State, Nigeria. Respondents' value judgement of 66 indicators generated from literature and practice were weighted for consistency using pairwise analytical hierarchical process (AHP); test of hypothesis involved analysis of variance (ANOVA). The validated indicators generated varying degrees of important. The social perspective was the most important sustainability objective, environmental, important and economic least important. The test of comparison in respondents' opinion about the indicators in three sectors specified variation. The result was valid in supporting (i) test hypothesis, (ii) context variance in sustainability practices and (iii) validation of the indicators. The outcome buttressed stakeholders' penchant towards sustainability must be improved. The study has evaluated measurable results of sustainable project management towards understanding and embedding sustainability in project management.

Keywords: Indicators, Construction projects, Sustainability, Sustainable construction and Validation

INTRODUCTION

The discourse of sustainability is widespread under varying perspectives and topics generally. The assessment perspective has attracted considerate attention in global view as seen in the succeeding literature section. Increase awareness about sustainability discourse originates mainly from the prominence of assessment (Ghumra, Glass, Frost and Mundy, 2011). However, construction project management sustainability activities are less developed and its context is not apparent. This is seen to be a baseline towards creating a comprehensive standard assessment tool. Advances in current global ecstasy about sustainability are infrequently translated into tangible implementation at the project level (Boyd and Schweber, 2012, Ugwu and Haupt, 2007). Accordingly, a need for a significant departure from sustainability agenda setting currently pursued to reeling out real-time sustainability goals is establish notably for the developing countries. The research problem addressed in this study is to validate sustainability indicators for construction project management activities and to determine prioritised sustainability objective(s). The inclusive need for developing countries to be able to assess their sustainability practices is acknowledged (Ugwu and Haupt, 2007). Such necessities include sustainability being case-custom; and the development of sustainable construction practices depending on local value assessment of social, economic and environmental objectives (Asmar and Underwood, 2013). To achieve local value assessment, indicators are increasingly developed; but are limited at project delivery level. When compared to other phases in project delivery, sustainability assessments have seen focal interest in research. This study seeks to operationalize sustainable project management by

Ekung, S.; Omokhale, E. & Ejekwu, T. (2016). Validated Indicators of Sustainability in Construction Project Management Activities - Stakeholders' Perception. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 765-774

validating indicators of sustainability in project management activities. The expanding discusses of project management skills and competencies in sustainable construction practice are acknowledged. The prominent question is how to evaluate the outcome of sustainable project management input.

The use of indicators for assessing sustainability is popular among decision/policy makers and the academics (Gilmour, Blackwood, Falconer, Isaac and Simpson, 2015). Critically selected indicator has been christened appropriate tools for sustainability assessment (Reed, 2007). Porta & Renne (2005) assert indicator clearly demystify the sustainable development concept and provide a clearer understanding and meaning. Indicators can translate engineering and technological knowledge into useful information for decision-making (Gilmour et al. 2015). Dahl (2012) argues it problematize visibly, creating awareness that will smoothens decision-making when the information is well managed. Gilmour et al. (2015) therefore believe developing indicators is perhaps the first step towards operationalizing sustainability.

The global community have come to the agreement that despite multiple understanding of sustainability, the principles have not differ from Bruntland's (1987) view cited in diverse literatures (Brandon and Lombardi, 2011, and Ihuah, Kakulu and Eaton, 2014). Bruntland perspective advocates a development practice that takes care of current needs without jeopardising the chances of future generations to meet their own needs. This understanding has been interpreted variously across sectors including construction. De varies and Peterson (2008) reported there are over 300 world views about the concept of sustainability. The common understanding is that sustainability provides a spring board for environmental, social and economic development of the society (Ding, 2008). But the theme has been significantly interpreted along environmental perspectives. Ruggieri et al (2009) provided one of the simplest framing of the meaning of sustainability. According to Ruggieri et al (2009), sustainability implies methods and techniques in the process of implementing construction projects that involve less harm to the environment. Schipper (2013) assert sustainability seeks harmony amongst the economic, social and environmental dimensions. Perspectives of cultural, societal, bio-diversity are also very popular. Brandon and Lombardi (2011) attribute the divergent framing to interest, assessment and evaluation strategy (Ihuah, Kakulu and Eaton, 2014). The key emerging problem however, is the determination of whether across sector practice have been utilised in accordance with universal objectives. Accordingly, a common understanding exists in differentiating what constitute appropriate and inappropriate development practices. This is particularly a big concern for project management.

Sustainability Indicators in Project Management

Comprehensive studies of critical sustainability indicators have been undertaken (Matinuzzi, Kudlax, Faber, Wiman, 2012). These include cultural, social and environmental perspectives suggested by Building Research Establishment (Warnock, 2007). Raw material extraction and consumption, land use change (Sev, 2009). Energy consumption and materials, generation of waste and dust, and pollution of air, water. Human wellbeing (Du Plessis, 2007) and enhancing the natural environment (Pitt, Tucker, Riley, and Longden, 2009) are widely used. Construction of durable infrastructure, making future environment safe, using materials from sustainable resources and indoor environment (Arjen, Mark, and Lucas, 2005). Within this thinking, feasibility studies and environmental impact assessment and social performance are deployed to evaluate firms' sustainability practice (Shen, Tam, Tan, and Ji, 2010). Health and safety (disruption of life-quality, security and community engagement are pronounced (Glass and Simmond, 2007). A study by Lingard (2008) adopted fair working hours and adequacy of compensation. Training and education, gender equality, sustainable supply chains and use of natural resources are also projected (Jones, Comfort and Hillier (2006).

Others include Bribery and corruption, illegal price agreement, evasion of taxes and development of cartels (Kolk and Pinkse, 2006).

Generally therefore, attempt to embed sustainability in construction have generated a flagship of indicators including energy and carbon reduction, material usage, minimization of life cycle cost, reduction of land use, increase use of local raw materials and the use of recycled materials. These indicators have targeted inception, design and post construction stages. Design related discusses are also very popular in literature including Iwaro and Mwasha, 2013). Few studies however consider indicators of sustainability at the project delivery (construction stage). Project management success factors for sustainable social housing examined by Ihuah, Kakulu and Eaton (2014) is acknowledged. However, this study focused on social housing thereby failing to explore the critical indicators of sustainability in the wider infrastructure construction project delivery. During project execution, it is sustainable, when project management activities (work breakdown, scheduling and control) are patterned to reduce environmental impact, improve social and economic benefits (Ihuah, Kakulu and Eaton, 2014). But traditional project management is dedicated to cost, time and quality objectives thereby ignoring the long-term impacts that are harmful sustainability of projects (Mishra Dangayach, and Mittal, 2011). Ineffective long-term project management activities and processes orientation impedes quality of life, health and safety and productivity. It remains to be determined what the indicators of sustainable project management are in project delivery.

The need for sustainability-focused project management practiced has been widely advocated. Accordingly, across sector studies have been conducted including mining (Gibson, 2006), general stakeholder approach (Brucker, Macharis, and Verbeke, 2014), approaches for delivering sustainability in infrastructure projects (Jos and Faith-Ell, 2012) and assessment of sustainability in infrastructure (Ugwu and Haupt, 2007). The impact of project management on sustainable development was studied by Chen (2011). Chen's study appraised internal environment of projects and it remains to be determined the external project environment. Aspect of sustainable relationship management was examined by Kumaraswamy and Anvuur (2008). This study proposed a framework to elect sustainable teams for joint venture projects. Learning professional competence in project management model in sustainable development was developed by Guerrero De los Rios (2012). The model provided a blend of expert and experiential knowledge. Related study Hwang and Ng (2013) explored relevant expertise of project managers in delivering 'green construction. A set of skills were validated as essential to internal and external project management coordination.

In Nigeria, the researchers' mind tools are yet focus on sustainable construction embedding issues. These includes perception and awareness (Abolere, 2015 and Nduka and Sotunbo, 2014), sustainable facilities management (Magagi, 2015), and sustainability embedding with construction organisations (Dania, Larsen and Yao, 2013). Others are renewable energy and energy efficiency (Ahmed and Gidado, 2008; Bugaje, 2006 and Odunfa, Ojo, Odunfa and Ohunakin, 2015) and green buildings (Olanipekun, 2015). The needs for assessment rating tool (Adegbile, 2012; Prucnal-Ogunbote, 2013 and Dodo, Kandar and Ossen, 2010) are other areas the research interests in Nigeria have considered.

From these related literatures, it seen that previous studies merely appended sustainable development to differing context that are not related to project management activities. Studies on project management indicators have not wafted from evaluating traditional project management purview. The imminent question yet largely unanswered is what criteria can be used to evaluate the project management success in sustainable construction projects? Wang, Yao, Wu and Jiang (2015) explored critical success factors for sustainable project

management. The study's validated criteria lean towards the traditional success criteria for project management evaluation. There are few studies that detail sustainable indicators for project management (Fernandez-Sanchez and Rodriguez-Lopez, 2010). This study adopted various aspects of project and project management activities, but what project activities are indicative of the project management practice is not apparent. Others came close in its environmental performance criteria but failed to identify the respective indicators. Fernandez-Sanchez and Rodriguez-Lopez (2010) social, economic and environmental indicators are too generic to be linked to respective site activities. The problem identification difficulty in extant studies is linked to human and natural system interface of sustainability. The problem is extended to the definition of sustainable project management. Accordingly, a broad range of traditional project management success criteria still infiltrates understandings of sustainable project management criteria. These include relationship and team management, human resources, communication and internal stakeholder management. To answer imminent research question, a departure is advocated to envision project management as activities that interact internally and externally to realise a project with a duty of care to the environment. The implication is the need to focus on the external perspectives that addresses the social, economic and environmental objectives. The availability of related studies in the overseas context is acknowledged but in-country validation is necessary in the growing quest for standard rating tool in Nigeria.

Research Methodology

The study was an empirical research with explorative strategy character. Therefore extensive literature on the general theme of sustainability assessment was conducted. The literature survey generated 406 indicators but 66 were strictly project management related. These indicators were presented for value rating by selected stakeholders. The survey involved a purposive sample of 112 respondents selected from construction organisations; engineering consultancy services and the general built environment practice specialising in buildings. The population consists of engineers, quantity surveyors, project managers, construction managers, builders, architects and allied professionals such as town planners and land surveyors based in Akwa Ibom State and Ondo, Nigeria. Research design validity, construct validity and scale coherency were conducted using Lee Cronbach's test. Alpha value greater 0.70 was obtained; this is indication of high quality, well captured concept hemisphere and high scale inter-correlation. Analytical Hierarchical Process (AHP) pairwise comparison was conducted to obtain the rating consistency indices. AHP was used for the study because respondents of sustainability perception are capricious, in this case, the relationship between constructs can be examined in a probability sense. The AHP had been used to examine trust as volatile issue in alliancing (She, 2013). The merit of the tool is independence on a statistically significant sample size (Dias and Ioannou, 1996). The pairwise comparison involved a 9-point value rating scale. The Consistency Index is given as Mean Item Score/Number of Items on the value rating scale. The pairwise was used at two levels first, to estimate the relative importance of the sustainability objectives; and second, the estimation of the preference of the indicators. The interpretation is according to She (2013): 1 = indicator equally preferred; 0.33 = moderately preferred; 0.20 = strongly preferred; 0.14 = very strongly preferred; and 0.11 = absolutely preferred.

Hypothesis of the Study

In view to generalising the weighted indicators, a comparison of means and test of homogeneity were conducted. The population was stratified into three means groups that is, construction organisation (CO); engineering consultancy (EC) and building practice (BP). The hypothesis states that there is no significant statistical variation in the opinion of respondents in the three populations. The test involved analysis of variance and Levene

homogeneity tests; and was conducted using SPSS. Validation was based on the critical p-value (accept H_o if $p < 0.05$; and H_1 if $p =< 0.05$).

RESULTS

Forty (40) valid responses was obtained (35% response rate); the proportion is valid for a typical construction related survey. The population consists of built environment professionals; quantity surveyors are more (Table 1). Thirty two (32, 80%) first degrees and higher degrees; 20% possessed Higher National Diploma. Similar proportion are registered and probationers. The average working experience is 15years and 15% of the population below to this category. There are averagely 13 respondents in each category of knowledge of sustainability. The 'very good' category is 50%; 'excellent' (10%) and 'good' (16%). The overall population depicts relevance and suitability to understanding the context, the practice and the principles of sustainable construction.

Table 1: Respondents Characteristics

Profession		**Registration**		**Years of Experience**	
Architecture	5(12%)	Registered	32(80%)	0-10 years	34(85%)
Building	2(5%)	Probationers	8(205)	Above 10 years	6(15%)
Engineering	10(24%)	**Education**		**Context Understanding**	
Project Managers	5(12%)	HND	8(20%)	Excellent	4(10%)
Quantity surveying	15(37%)	BSc	22(55%)	Very good	20(50%0
Town Planners	2(5%)	MSc	10(25%)	Good	16(40%)

Validated Indicators

The total of sixty (66) indicators representing the relevant social, economic and environmental perspectives of sustainability were generated and rated for consistency. Twenty five (25, 37%) each are social and environmental objectives indicators; and (16, 24%) economic indicators. The dominance of the environmental and social objectives aligns to the increasing emphasis placed on these objectives in the mainstream sustainability pursuits. The respondents' value rating of 11 (16%) indicators scored a consistency index score of 0.30 and above. The meaning is that these indicators are 'moderately' preferred indicators of sustainability in construction project management activities. Seventeen (17, 25%) obtained the scores (>0.2 but < 0.3). These set of indicators received 'strong' preference value rating. Nine (9, 13%) others received 'very strong' preference value judgement. Twenty six (26, 39%) others are 'equally' preferred; and 4(6%) are 'absolutely' preferred by all the respondents. Indicators with value rating (< 0.11) are most significant.

In the respective objectives, 11(16%) environmental indicators are equally preferred indicators; 9(13%) are strongly, moderately and equally preferred, and 5(7%), absolutely preferred or very strongly preferred. In economic objective, 12(18%) are equally, moderately or strongly preferred; 2(3%) are strongly and very strongly preferred and 1(1%) received absolute preference rating. Also, in the social objective, 13(19%) are moderately or equally preferred; 6(9%) are strongly preferred, and 6(9%) achieved very strong and absolute rating scores. On the whole, it is seen that, the environmental indicators has the highest 5(21%) indicators with significant value judgement of 'strong', 'very strong' and 'absolute preference'. The social 12(18%) objective retains the second highest number of indicators with three high value rating benchmark (strong, very strong and absolute preference). The economic objective has 3(4%) with strong, very strong and absolutely preference rating. However, the highest 'very strong' and 'absolute' preference rating is the social objective. Based on the objective rating, social perspective is the most important sustainability objective with group consistency index (CI_W 0.29-strong preference); environmental 2nd most important (CI_W 0.32-moderate preference); and economic least important (CI_W 0.34-moderate preference); see Table 2.

Analysis of Variance and Test of Homogeneity

The consistency index score depended invariably on the mean item score, it is therefore requisite to compare the means of the three categories of respondents that is, construction organisations, engineering consultancy and others in general building practice. Similarly, a test of error variance in value judgement is necessary to compare ANOVA outcome. The objective of the hypothesis testing was to evaluate statistical comparison of value judgement across three strata of respondents. The tests involved analysis of variance and Levene Homogeneity test. Validation was based on the critical p-value (accept H_o if $p < 0.05$; and H_1 if $p =< 0.05$); the result is presented in Table 3a and 3b. The result yielded a significant *F* values at varying degrees of freedom. The results are accepted for the three population means. The hypothesis accepted, explaining an insignificant variation in the three population means. The univariate ANOVAs outputs CO (F (2) = 4.59, p = 0.654); EC (F (2) = 0.672, p = 0.849); and BP (F (2) = 18.592, p = 0.620) (Table 5). The homogeneity test of error variance in judgement across the population means are also significant CO (F (2, 2) = 9.678, p = 0.489); EC (F (2, 2) = 3.456, p = 0.838); P_3 (F (2, 2) = 3.450, p = 0.510); and P_4 (F (2, 2) = 3.200, p = 0.238).

DISCUSSIONS

Table 2: Weighted Indicators based on Value Judgement

SN	Objectives	CI_W	Sub-Indicators	CI	Level of Preference
1	Environmental	0.32	Open space maximization	0.29	Strong preference
2			Mitigating pollution	0.27	Strong preference
3			Preserving cultural heritage	0.28	Strong preference
4			Protect wildlife	0.17	Very strong preference
5			Provide post construction management plan	0.26	Strong preference
6			Protect development against future weather	0.24	Strong preference
7			Avoid damaging habitat (green areas)	0.31	Strong preference
8			Promote natural day lighting in designs	0.31	Strong preference
9			Promote recycling waste management appliances	0.32	Strong preference
10			Appointing environmental coordinator for site	0.22	Very strong preference
11			On-site renewable energy use	0.23	Very strong preference
12			Use of environmental management systems	0.20	Very strong preference
13			Identify sustainable waste management guidance	0.17	Very strong preference
14			Covering of hauled waste	0.13	Very strong preference
15			Waste separation on site	0.29	Strong preference
16			Inclusion of waste management in contracts	0.11	Absolute preference
17	Social	0.29	Gender equality (employing women)	0.13	Very strong preference
18			Display work programme in public square to show when heavy shipments are expected	0.11	Absolute preference
19			Provide access for disabled and elderly	0.31	Strong agreement
20			Encourage walking and cycling	0.31	Strong agreement
21			Conducting EIA in project before site works	0.17	Very strong preference
22			Security at construction site in tensed environment	0.25	Strong preference
23			Reward for safety observance	0.20	Strong preference
24			Attending community council meetings	0.11	Very strong preference
25			Exchanging pleasantries with workers	0.29	Strong preference
26			Undertake social responsibilities	0.22	Strong preference
27			Ensure design conform with locals needs	0.16	Very strong preference
28			Provide for academic/industry interface (excursions/exchange)	0.25	Strong preference
29			Encourage staff development through seminars/CPD	0.11	Absolute preference
30			Permit schooling while working opportunity	0.25	Strong preference
31	Economic	0.34	Use of innovative materials (recycled)	0.31	Strong preference
31			Assist low income/disadvantaged groups	0.25	Strong preference
32			Provide employment opportunities	0.31	Strong preference
33			Life cycle cost analysis	0.25	Strong preference
34			Taxes evasion and levies	0.19	Very strong preference
35			Bribery and corruption	0.28	Strong preference

CI = Consistency Index; CI_G = Consistency Index Group

The value preference of the respondents merits a second reflection. The outcome of the social objective represents a significant departure from the global trend that sees emphasis placed on environmental concern. Successive literatures account for this development (Emmanuel, 2011); the result is therefore a surprise. Assessment tools and systems are also environment focus (BREEAM, 2009; LEED, 2007). Various regulations and governmental interventions support environmental sustainability. Nevertheless, two possibilities are devised, first, placing critical importance is placed on social sustainability, second, an improvement on social sustainability objective in contrary to the widely held documented evidences in the literature. Stakeholders in the study environment assign deserving emphasis on the need to address social perspective that affect the employees and community in which the project situates. Responsible factors for the respondents value although not obvious from the survey is attributed to nature of the research environment. The region is rich in oil deposit and production exposes the social dimensions to multi-nationals that come with intensive financial packages. The failings of the successive government to address basic needs saw the community result to arm taking aggression that was transferred to many sector initiatives including construction. Hence, successful construction project management organisations understood the importance of social dimensions in project delivery.

The literature retains deviant view to the study's finding including Teo and Loosemore's (2012) 'NIMBY' controversy in Australia, Ekung, Ogboji and Okonkwo's (2013) community protest in controversial scenarios, Niger Delta, Nigeria, Glass and Simmonds (2007) dearth of training and knowledge are responsible for poor community stakeholders' engagement under CCS. The environmental objective came second, most important objective, and economic least important. Overly, due to the general low value judgement, the implication leans towards the need to improve general practice and economic objectives in particular. The system is infamous in the use of traditional project management practice (Ogunsami; 2012). The failings of this system are popular in the related literature; but the laggard implication to the sagacious objectives of sustainable development calls for immediate improvement.

Table 3a: Analysis of Variance Test

Dependents	df	Mean Square	F	Sig.
CO	2	8.043	4.590	0.654
EC	2	0.849	0.672	0.849
BP	2	4.115	18.592	0.620

CO = construction organisation; EC = engineering consultancy and BP = building practice

Table 3b: Levene Test of Equality of Error Variances

Dependents	F	df1	df2	Sig.
CO	9.678	2	2	0.489
EC	3.456	2	2	0.838
BP	3.450	2	2	0.510

Respondents' value rating perceptions show variation although, insignificant in the population means. Responsible factors are understood in the context of multiple framing, differing understanding, and practices of sustainability (Boyd and Schweber, 2012; Magaji, 2015 and Dania, Larsen and Ewart, 2014). The varying perception is appropriate and useful to validate the weighted indicators for use in assessment. The test of the hypothesis strongly supports desired variation in the three population means. This is true to the extent of explaining the likeness of the weighted indicators to literature. However, the indicators presented in Table 2 are not exhaustive but high value judgement factors and never implies others are irrelevant. In fact all 66 indicators with varying valid degrees of consistency rating are suitable for use in assessment.

CONCLUSION

Based on the persistent lack of standard assessment tools for sustainability evaluation, many developing countries have responded through bespoke indicators validation that resulted in standard rating tool. The growing importance of in-context assessment tool is predicated on sustainability being scene-custom; and developing sustainable construction practices depending on local value assessment of social, economic and environmental objectives. The research problem addressed in this study was to validate sustainability assessment indicators and to determine prioritised sustainability objective(s). Set objectives were achieved through extensive literature review, field survey and analysis using AHP value judgement consistency index. Sixty six (66) indicators received varying degrees of consistency judgement and thirty (35) were validated at value judgements: strongly; very strongly; and absolute preference. Thirty (31) others were moderately or equally preferred. The social indicators were most important sustainability objective, environmental important and economic least important. A test of variation in perception in three sectors using Analysis of Variance (ANOVA) indicated variation. The test result was valid in supporting (i) test hypothesis; and (ii) context variance in sustainability practices. It further validated the 66 validated indicators for assessment of construction organisation project management activities for sustainability.

Despite extant results, the study circumspect that the validated indicators are based on stakeholders' perception thereby not reflecting real-life project scenery. It is therefore needful to apply validated criteria on real-life project assessment to extend it boundaries and validity. It is equally necessary to validate the criteria using samples in other regions to compare and improve existing result for widespread in-country application.

An Appraisal of Key Performance Indicators (KPIs) for Public Private Partnership (PPP) Projects in Nigeria

Okrong, A. S.[1*]; Adogbo, K. J.[2] & Abdulrazag, M.[3]

[1, 2&3]Department of Quantity Surveying, Ahmadu Bello University Zaria, Nigeria
[*] qsokrong@gmail.com

ABSTRACT

Despite concerted efforts by government in Nigeria to improve infrastructure project delivery through Public Private Partnership (PPP), many of such projects continue to fail. Previous researches on PPP projects mainly concentrated on the procurement, success factors and risk management of PPP projects, but paid little attention to the process factors that can strongly influence the performance of PPP projects. This study appraises the key performance indicators (KPIs) for Public Private Partnership (PPP) projects in Nigeria. Questionnaire survey was adopted to elicit data from 76 PPP project participants within the Nigerian construction industry. Data collected was coded and analysed using Statistical Packages for Social Sciences (SPSS) 20.0. The test statistic involved descriptive statistics and Chi-Square test was conducted to investigate the level of agreement amongst the respondents. The internal coherency of respondents ranking was further checked by conducting Cronbach's alpha test. The results of the study revealed the most influential performance indicator as appropriate risk allocation, risk sharing, and risk transfer while the least performance indicator is establishment of learning organisation. The implication is that although all of the 48 performance indicators are important and can be used to monitor project performance, the significance of the indicators from the five packages vary and contribute differently to the overall project performance. With this result, underlying factors influencing PPP project performance are projected and an insightful perspective provided to guide the developing of decision framework for PPP projects in Nigeria.

Keywords: Performance Indicators, Public Private Partnership, Project, Measurement, Nigeria

INTRODUCTION

Over the last two decades, governments in an increasing number of countries across the continents initiated Public Private Partnership (PPP) to involve the private sector in the provision and building of an infrastructure and subsequently operating it to provide public goods or services. This is because PPP employs private sector expertise and skill to provide public goods and services (Nisar, 2013). As pointed out by Kwak et al (2009), if PPP is properly formulated and managed, it can provide a number of benefits to the public sector such as: alleviating the financial burden on the public sector due to rising infrastructure development costs; allowing risks to be transferred from the public to the private sector; and increasing the value for money (VfM) spent for infrastructure services by providing more efficient, lower cost, and reliable services. The policy to involve the private sector in the provision of public services is, however, fraught with a number of difficulties and shortcomings (Nisar, 2013). One major concern is the problem associated with performance measurement for PPP projects. As submitted by Liu et al., (2014) unsatisfactory performance of a PPP project is not costless. Yuan et al., (2012) clarifies that the absence of effective performance measurement in PPP projects acts as a trigger for producing below optimum service quality of infrastructure. However, Yu et al., (2007) in their research established that the core function of performance measurement is to identify, measure, and manage appropriate Key Performance Indicators (KPIs). These findings suggest that a study on key

Okrong, A. S.; Adogbo, K. J. & Abdulrazag, M. (2016). An Appraisal of Key Performance Indicators (KPIs) for Public Private Partnership (PPP) Projects in Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 775-782

performance indicators (KPIs) for PPP projects would be of increasing interest to both the public and the private sectors.

In the past, many of the researches conducted in PPP mainly concentrated on the procurement, success factors and risk management of PPP, but paid little attention to the process factors that can strongly influence the performance of PPP. However, Yuan et al., (2009) in their extensive research, developed a set of key performance indicators for PPP projects that comprises five (5) performance packages. The packages include: physical characteristics of PPP projects (KPI 1); requirements of stakeholders from the perspective of financing and marketing (KPI 2); requirements of stakeholders from the perspective of innovation and learning (KPI 3); requirements of stakeholders from the perspective of stakeholders (KPI 4); and project process (KPI 5). They suggested that the key performance indicators should be tested by an empirical study/research to investigate their significances. They further suggested that the number of KPIs should be kept low, and a consensus should be obtained from future work surveys, with professionals in the industry for effective application in project practice. Therefore, this study is particular related to the research conducted by Yuan et al., (2009) on Key Performance Indicators (KPIs) and aim to appraise key performance indicators (KPIs) for Public Private Partnership (PPP) projects in Nigeria. This aim shall be achieved through the following objectives: to identify key performance indicators for Public Private Partnership (PPP) projects; to determine the level of importance of each indicator on a PPP project in Nigeria and to establish the extent to which each indicator affects the performance of PPP projects in Nigeria.

LITERATURE REVIEW

The Concept of Public Private Partnership (PPP) Projects

Traditionally, most public facilities are developed by the public sector using public money (Li et al., 2001). Thus, the ownership belongs to the public sector (Kurniawan et al., 2010). However, recent transactional evidence points to the benefits of privately financed and managed infrastructure and particularly Public Private Partnership (PPP) through improved procurement outcomes at lower cost than conventional procurement methods (Nisar, 2013). Hence, the whole concept of Public Private Partnership (PPP) is a government policy to tackle financial problems in facility provision, and an integrated private management skill to increase efficiency, effectiveness and quality (Her Majesty's Treasury, 2000). These concepts have been used for decades worldwide to procure economic and social infrastructure (Kwak et al., 2009). Many academics, public agencies and international organisations have given various definitions of PPP in a bid to explain this important method of project procurement that is being increasingly adopted worldwide. However, this study adopts the definition of PPP as given by Kwak et al (2009) that PPP is cooperative arrangements between the public and private sectors that involve the sharing of resources, risks, responsibilities, and rewards with others for the achievement of joint objectives.

Key Performance Indicators (KPIs) for PPP Projects

Considering the large amount of projects that have come to be implemented with PPP model of procurement, it is important to do some serious reflections about the key factors that

characterize them and that have more influence on their success. These factors should serve as support to the definition of key performance indicators (KPIs). There is, to a certain extent, consensus amongst construction management academics and practitioners about which performance objectives are the main critical success factors (CSF) for a construction project. These objectives according to Latorre and Riley (2010) have been coined as 'the iron triangle' and consider three CSF; namely cost, quality and time. They have been the criteria traditionally used to assess the success of a construction project (Chua et al., 1999). However, recent empirical research highlights how traditional project performance objectives (cost, time and quality) are insufficient for the whole life management of long-term projects. Similarly, the performance objectives of a stakeholder group in a PPP project differ due to different expectations (Yuan et al., 2010). Achieving best value for public service and product is the ultimate objective of PPP (Zhang, 2006). Akintoye et al., (2003) submitted that in PPP, best value emphasizes quality, efficiency/ effectiveness, value for money (VfM) and performance standards. In a related research, Robinson and Scott (2009) found that value for money in a PPP/PFI project depends crucially on performance monitoring to provide incentives for improvement and to ensure that service delivery is in accordance with the output specification.

Similarly, Liu et al., (2014) emphasized that based on the characteristics of PPP, a performance measurement framework that deals with multiple-stakeholder complexity is an ideal tool to underpin the performance measurement of PPP projects. Accurate analysis of performance can be achieved only after the Key Performance Indicators (KPIs) are determined and monitored. In fact, according to Chan and Chan (2004) and Ikediashi et tal., (2012) these indicators depend on the objectives of each project and are the basis of incentives and penalties, especially during the exploration phase, since they allow to compare actual performance with the estimated in terms of effectiveness, efficiency and quality. Solomon and Young (2007) submitted that KPIs define 'how good' a system is, in objectively measurable terms. Deriving from the aforementioned definitions, compilations of data measures used to assess and evaluate the performance of PPP operations are hereby refers to as Key Performance Indicators (KPIs) in this study.

METHODOLOGY

The paper adopted quantitative research design with questionnaire chosen as the data collection instrument. The focus of interest in this study is PPP stakeholders in Federal capital territory (FCT) Abuja. This city was selected for the survey because of it strategic importance in terms of volume of construction activities and population performance (Dada, 2005). Also, Abuja, being the Federal Capital Territory of Nigeria houses most of the headquarters and head offices of Government establishments and quite a number of consultant firms (Alao, 2009) with branch offices in other States of the federation. Most of these Government establishments and consultant firms have their PPP projects in Abuja and other States of the Federation but coordinating/managing these projects from their head offices at Abuja.

To ensure adequate representation of respondents, the number of stakeholders used in this survey was drawn from the directories of professional organisations in the federal capital territory-Abuja, Nigeria. They include the Nigerian Institute of Architects, Nigerian Institute of Builders, Nigerian Society of Engineers, Nigerian Institute of Quantity Surveyors and Nigeria Institute of Town planners. A total of 6238 stakeholders/practicing professionals

registered with their respective professional bodies were identified. Because it was impractical to collect data from all the stakeholders in the population, sampling was necessary to make the survey possible. In order to determine a suitable size for the sample, the following formula from Krejcie and Morgan (1970) and Creative Research System (2003) was applied:

$$N = \frac{Z^2 x\, P(1-P)}{C^2}$$

Where: N = sample size; Z = standardised variable; P = percentage picking a choice, expressed as a decimal; C = confidence interval, expressed as a decimal.

As with most other research, a confidence level of 95% was assumed (Creative Research System, 2003). For 95% confidence level (i.e. significance level of α = 0.05), z = 1.96. Based on the need to find a balance between the level of precision, resources available and usefulness of the findings (Krejcie and Morgan, 1970), a confidence interval (c) of ±10% was also assumed for this research. Krejcie and Morgan, (1970) also explained that when determining the sample size for a given level of accuracy, the worst case percentage picking a choice (p) should be assumed. This is given as 50% or 0.5. Based on these assumptions, the sample size was computed as follows:

$$N = \frac{1.96^2 x\ 0.5(1-0.5)}{0.1^2} = 96.04$$

This means that the required sample size for the questionnaire survey is 96 PPP stakeholders. Creative Research Systems (2003) further explained that the figure requires a further correction for finite populations. The formula for finite population is given as:

$$New\ N = \frac{Sample\ size}{1 + \frac{96.04 - 1}{Pop}}$$

$Where: Pop = Population$
Inputting these data, we now have;

$$New\ N = \frac{96.04}{1 + \frac{96.04 - 1}{6238}} = 95.49$$

Therefore the sample size for a finite population is approximately 95 PPP stakeholders. However, to make a round figure and ensure optimal result from the stakeholders identified, 100 questionnaires were administered. Overall, seventy-six (76) completed questionnaires were properly answered and usable. This represents a 76% effective response rate. Questionnaire survey conducted in Nigeria by Ikediashi et al., (2012) for a similar research received a response rate of 64%.

FINDINGS AND DISCUSSIONS

In this research, the ranking of the KPIs was based on arithmetic mean value scores. A lower value indicates a lower level of importance. As shown in table 1, the mean response rating values for the 48 indicators offered to respondents range from a maximum of mean score of 4.80 (Appropriate risk allocation, risk sharing and risk transfer) to a minimum mean score of 2.08 (Establishment of learning organisation). It thus has been shown by the response that there appears to be close correlation between the ranking of the indicators in terms of the

level of importance and the extent of effects of each indicator on a PPP project. In each of the five (5) performance packages, it is obvious that the higher the level of importance of the indicator the higher the extent of effects and vice versa in a PPP project. No indicator mean value scores fell into the 'not important' (< 1.5) category, which indicates that all of the 48 indicators are considered important and can be used to monitor the PPP project performance. From the results of the analysis above, it is obvious that although the survey results show that all indicators are important, performance packages contribute differently to the overall project performance.

Table 1.0: Summary of Key Performance indicators (KPIs), level of importance and extent of effect of each indicator on a PPP project performance

Key Performance Indicators	Mean	S.D	Rank	Level of Importance	Extent of Effect
Physical Characteristics of Ppp Projects					
Type of construction	2.12	1.275	47	Fairly important	Low
Level of design complexity	2.24	1.253	45	Fairly important	Low
Level of construction complexity	2.39	1.287	43	Fairly important	Low
Level of technological advancement	2.37	1.459	44	Fairly important	Low
Concessionaire's knowledge of PPPs	4.20	.693	9	Very important	High
Government's knowledge of PPPs	4.00	.712	11	Very important	High
Competitive tender procedure	3.33	.737	26	Important	Moderate
Standard PPP contract with enough flexibility	3.70	1.007	17	Important	Moderate
General public/social support	2.71	1.043	34	Important	Moderate
Stable and favourable macroeconomic conditions	3.59	.926	23	Very important	High
Stable and favourable legal environment	3.97	.748	12	Very important	High
Stable and favourable political environment	3.64	.934	20	Very important	High
Commitment and responsibility between public and private sector	4.74	.472	2	Extremely important	Very high
Project technical feasibility, constructability, and maintainability	4.05	.671	10	Very important	High
Appropriate risk allocation, risk sharing, and risk transfer	4.80	.433	1	Extremely important	Very high
FINANCING AND MARKETING					
Sound financial analysis	4.24	.690	8	Very important	High
Sustainable profitability	3.20	.783	27	Important	Moderate
Increased marketability	2.96	1.171	29	Important	Moderate
Financial ability of whole shareholders	3.57	.899	24	Very important	High
Perfect tariff/tolls or price adjustment mechanism for the project	3.54	.958	25	Very important	High
Financing cost	2.61	1.721	36	Important	Moderate
Realistic schedule of investment and revenue	2.78	.988	32	Important	Moderate
Insurance coverage	2.12	1.306	46	Important	Moderate
Construction and concession period	3.67	1.012	19	Very important	High
INNOVATION AND LEARNING					
Investment in research and development of new technology	2.42	1.594	42	Fairly important	Low
Establishment of learning organization	2.08	1.294	48	Fairly important	Low
Employee training	2.43	.884	40	Fairly important	Low
Technology innovation (e.g., designing, construction, planning etc)	2.62	.894	35	Important	Moderate
Technology transfer	2.59	.836	37	Important	Moderate
Financial innovation (i.e creative financial package)	3.83	.870	16	Very important	High
STAKEHOLDERS					
Public client's satisfaction	3.86	.989	15	Very important	High
General public/Social satisfaction	4.28	.704	7	Very important	High
Good relationship among the concessionaire, subcontractors, and suppliers	3.63	.907	21	Very important	High
Good relationships within project team	3.68	.927	18	Very important	High
PPP PROJECT PROCESS					
High quality control	4.37	1.005	3	Very important	High
Safety management	3.92	.707	14	Very important	High
Health control	2.45	.944	39	Fairly important	Low
Environmental protection	3.08	.726	28	Important	Moderate
Effective risk management system	3.93	.822	13	Very important	High
Facility management	2.75	1.145	33	Important	Moderate
Stress/Conflict management	2.42	1.691	41	Fairly important	Low
Resource utilization (material and equipment)	2.95	.893	30	Important	Moderate
Contract management	2.79	1.644	31	Important	Moderate
Prominent technical management and skill	2.54	1.012	38	Important	Moderate
Interface management between organization and stages	3.61	.981	22	Very important	High
Cost management (during construction and operation periods)	4.36	1.116	4	Very important	High
Time management (during construction and operation periods)	4.34	.601	5	Very important	High
Good governance	4.29	.935	6	Very important	High

Among the top 10 ranked key performance indicators for PPP projects, appropriate risk allocation, risk sharing, and risk transfer had the highest mean of 4.80, demonstrating that the

improvement of project performance in PPP strongly depends on effective risk management and allocation. Similarly, Akintoye et al., (2003) identified risk transfer as a major performance factor in PPP. As a general approach to risk management and allocation, the risk should be transferred to the party that is best able to control it. The second is Commitment and responsibility between public and private sector with a mean of 4.74, suggesting that the improvement of project performance in PPP strongly depends on cooperation and support among different stakeholders. The result of this survey is generic and consistent with the findings of the previous author. Tutesigensi and Hj-Mohammad (2008) identified commitment of the public and private sectors as a key indicator for the successful implementation of PPP projects. Stonehouse et al., (1996) agreed that successful PPP require commitment, mutual understanding and a high degree of enthusiasm.

Table 2.0: 10 Top Key Performance Indicators for PPP projects in Nigeria

KEY PEATORSRFORMANCE INDIC	MEAN	S.D	RANK
Appropriate risk allocation, risk sharing, and risk transfer	4.80	.433	1
Commitment and responsibility between public and private sector	4.74	.472	2
High quality control	4.37	1.005	3
Cost management (during construction and operation periods)	4.36	1.116	4
Time management (during construction and operation periods)	4.34	.601	5
Good governance	4.29	.935	6
General public/Social satisfaction	4.28	.704	7
Sound financial analysis	4.24	.690	8
Concessionaire's knowledge of PPP	4.20	.693	9
Project technical feasibility, constructability, and maintainability	4.05	.671	10

The third is High quality control with a mean score of 4.37 follow by Cost management (during construction and operation periods) and Time management (during construction and operation periods) with a mean value of 4.36 and 4.34 respectively. These findings also affirm the earlier assertion of (Ibrahim et al, 2006; Yuan et al., 2009; Yuan et al., 2010; Ibrahim et al., 2012; Yuan et al., 2012) that the factors for successful implementation of PPP include acceleration of infrastructure provision, better risk allocation, whole of life cost savings, improved quality of services, access additional revenue sources, benefits for local economic and social development, and improved project scrutiny. Other indicators consistently perceived as highly rated (in order of significance) from the results are: Good governance; General public/Social satisfaction; and Sound financial analysis with a mean score of 4.29, 4.28 and 4.24 respectively. The finding was in tune with Tutesigensi and Hj-Mohammad, (2008). They asserted that good governance, well organised public agency, effective cost/benefit analysis and social/political support are the important factors for successful implementation of PPP. Moreover, Concessionaire's knowledge of PPP had a mean score of 4.20 and is ranked as the ninth top indicator while Project technical feasibility, constructability, and maintainability had the mean score of 4.05 and is ranked as tenth. Similarly, El-Gohary et al., (2006) supported the argument that, knowledge of PPP in both the public and private sectors is very important to the success of PPP projects because many difficulties result from inexperienced participants.

CONCLUSION

Based on the results of this study, it has been established that the identified key performance indicators for public private partnership projects are considered important and can be used to monitor PPP project performance. Forty eight (48) KPIs were identified and was prioritised along the level of their importance. Some of the indicators ranking differ across continent most especially Asia and Europe and may be accounted for by the infancy nature of PPP adoption in Nigeria as a country in procuring public infrastructure. The research also

concluded that the most influential performance indicator revealed by the research is appropriate risk allocation, risk sharing, and risk transfer while the least performance indicator is establishment of learning organisation.

Finally, it is acknowledged that although all of the 48 indicators are important and can be used to monitor project performance, the significances of the indicators from the five packages vary and contribute differently to the overall project performance. Thus, the stakeholders assign greater value to decision-making in the early stages of development and in conjunction with process control during project implementation. Significantly, it has been shown by the response that there is a close correlation between the ranking of the indicators in terms of the level of importance and the extent of effects of each indicator on a PPP project. In each of the five (5) performance packages, it is obvious that the higher the level of importance of the indicator the higher the extent of effects and vice versa in a PPP project. One can then deduce that there is high level of confidence by the PPP stakeholders in using the indicators to monitor their PPP projects. With this result, underlying factors influencing PPP project performance are projected and an insightful perspective provided to guide the developing of decision framework for PPP projects in Nigeria.

ABSTRACT

In the construction industry today, construction professionals are concerned with providing construction that encourages the preservation of the natural environment, promotes social well being of the occupants and provides reasonable economic stands for the investors. This is the concept of sustainability in construction. To achieve this, diverse methods of construction and materials are being developed and one of such materials is the Compressed Stabilized Interlocking Earth Block (CSIEB) which is gaining popularity among construction professionals in Nigeria and other developing countries around the world. This research therefore assessed the sustainability of CSIEB for building construction in Nigeria. A questionnaire survey was used and 48 professionals in the construction industry were sampled. Seven sustainability features of CSIEB were identified and assessed for each of the three dimensions of sustainability (economic, environmental and social). Data collected were analyzed using Relative Importance Index and an average percentage performance of CSIEB in each dimension was derived. Findings revealed that the use of CSIEB will amongst other benefits, save cost of raw materials use for masonry construction, provide faster revenue generation due to its fast construction time, provide a structure that can adapt to the tropical climate, minimize CO_2 emission, and provide an aesthetically pleasing and thermally conducive building. Also, findings showed that the use of CSIEB for building construction will create a balance between the social, economic and environmental pillars of sustainability with percentage of 34%, 33% and 33% respectively. This study therefore recommends that the use of CSIEB should be encouraged among stakeholders as a material for sustainable building construction.

Keywords: Building construction, CSIEB, Sustainability, Nigeria

INTRODUCTION

The world today is moving towards a sustainable environment; one that encourages the preservation of the natural habitat, promotes social well being of the occupants and provides reasonable economic stand for the investors. Chartered Institute of Building (CIOB) (2009) observed that this is as a result of concern that the ever rising population poses tremendous threat to the limited earth resources. The solution according to Brundtland Report (1987) is to provide construction projects that meet the needs of the present without compromising the ability of future generations to meet their own needs. Bearing this in mind, the need to diversify and try other methods of building construction and materials that will yield the expected result and provide sustainable environment is necessary.

Arayela (2002) stated that the building industry place much emphasis on the use of sophisticated building materials and construction methods that are expensive and energy consuming, while Waziri, Kadai and Biu (2014) observed that as a result of limited means within developing countries, the need to reduce construction costs is necessary. This, according to Adam and Agib (2001) can be achieved through the production and use of cheap yet durable locally available building materials. Adedeji (2005) stated that the enormous waste associated with conventional masonry works facilitated the search and subsequent development of more rapid and less workmanship dependent building methods and materials. One of such development is the use of CSIEB for building construction.

Aghimien, D. O. and Awodele, O. A. (2016). Sustainability of Compressed Stabilized Interlocking Earth Blocks (CSIEB) for Building Construction in Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 783-792

CSIEB is made from laterite, stabilized with cement (in most cases) and compressed in an interlocking block making machine. It has proven to be a sustainable material for building construction due to its adaptability to tropical climate, use of locally available raw material, cost effectiveness and huge aesthetic quality (Adedeji and Fasakin, 2008). According to Abeysundara, Babel and Gheewala (2009) the combination of all environmental, economic and social factors can give a clear description of a material, and helps in a decision making process regarding the selection of the materials suitable for buildings. This paper therefore assessed the sustainability nature of CSIEB for building construction in Ondo state, Nigeria, taking into consideration its environmental, economic and social features and its perceived benefits, with a view of providing sustainable homes for individuals through its usage.

LITERATURE REVIEW

Overview of CSIEB for Building Construction

The use of CSIEB for building construction follows the principle of dry stacking. In dry stacking construction, the interlocking blocks are laid without mortar thereby leading to considerable savings in cost associated with mortar. The major material needed for the production of CSIEB is earth, which according to Adewole (2009) is readily available. The soil is gotten from at least 1m below the top soil and must be free of dirt in other to achieve a fine finish product. The soil is mixed with cement in predetermined ratios by hand or in a pan mixer and water added at an average proportion, making sure that the mixture is not watery. The mixture is loaded into the block making machine in which it is hydraulically compressed. It takes an approximate 15-20 seconds per block, after which the compressed block is then stacked and left to cure (Hydraform, 2004).

CSIEB is moulded by pressing along its length from the ends. It is also a solid block, slightly short, wide and thick in size (225x225x112mm). It has a Bed underneath and a Ridge at the top. The recessed under surface of the block is referred to as the bed while the raised top surface of the block is called the Ridge. The ridge of one interlocking block is designed to key in to the bed of another, thereby providing a perfect lock in masonry (Hydraform, 2004; Bansal, 2010).

Williams *et al.* (2010) posited that the structural and thermal aspects of earth block walling meets the current UK Building Regulation requirements for wall strength and thermal performance hence making it suitable for masonry construction. Also, several researches have been carried out on the strength of CSIEB and it has been proven that it is structurally suitable for any type of construction (Bansal, 2010; Chaibeddra and Kharchi, 2013).

In Nigeria, earth blocks are used majorly for walls while their usages in other part of the building like beams and columns are yet to be explored. Adewole (2008) stated that the construction of interlocking earth block structures is limited, since builders pick this particular material mostly for ecological reasons and this special demand normally comes from only a small group of environmentalists, ecologists or people with a keen sense of environmental protection. This notwithstanding, the interlocking building system is gaining recognition among construction professionals and its usage is increasing in most developing countries like Nigeria (Waziri et. al, 2014). Olusanya (2001) observed that the first documented usage of the interlocking masonry in Nigeria was that of a 60-unit housing estate experimented in 1991 at the University of Lagos, Lagos state. Since then interlocking masonry has gradually gained recognition within the country, especially with the introduction of the Hydraform system of building. Evidence of this is its usage in the construction of a clinic, hostels and staff quarters at Elizarde University, Ilara-mokin, Ondo State, the

Electronic Testing Centre at the Federal University of Technology, Akure, and the caring heart Mega School at Famese Isokan, Akure, Ondo State.

Figure 1: CSIEB used for the construction of a caring heart mega school, Famese, Isokan, Akure, Ondo state

Sustainable Development in Building Construction

Sustainable development could be born out of the emerging environmental movement of the 1960s which was concerned that human activity was having severe and negative impacts on the planet (Romiguer, 2011). Meadows, Randers and Behrens (1972) was one of the key works that highlighted this thinking while the Brundtland Report (1987) provided sustainable development as the solution to this problem. Since then there has been various definitions aimed at describing sustainable development. One of such definitions is that of the Forum for the future (2011) which defines sustainable development as a dynamic process which enables everyone to realise their potential and improve their quality of life in ways which simultaneously protect and enhance the earth's life support systems. Awodele (2015) stated that sustainable development focuses on improving the quality of life for all of the earth's citizens without increasing the use of natural resources beyond the capacity of the environment to supply them indefinitely.

According to Langston and Ding (2001) and Raynsford (2000), a sustainable construction ensures that environmental responsibility, social awareness, and economic gains are the major objectives of the key players in the built environment. Akbiyikli, Dikmen and Eaton (2009) observed that a sustainable construction can be seen as a path way through which the construction industry can move towards a sustainable development, bearing in mind the environmental, socio-economic and cultural pillars as observed by Chaharbaghi and Willis (1999) who opined that sustainable development is a concept based on a structure which stands on three pillars, namely economic, social and environmental. Thus, a sustainable development can be said to be a way of finding balance between economic, environmental and social factors in the design, construction, use and maintenance of buildings.

Economic Sustainability of CSIEB

To the lay man, laterite means earth or any type of soil but in the sense of it, it simply demonstrates the ready availability and abundance of laterite (Adewole, 2008) which can lead to cheap and quick onsite production of earth blocks. Ngowi (2005) observed that the great cost saving is made when CSIEB is used; this is as a result of the use of local laterite and only 5% cement in the block production. During construction, the blocks are dry staked, saving more cement, reducing labour costs and recording savings up to 27% compared to conventional mortared masonry. This was further corroborated by Adedeji and Fasakin (2008) assertion that the use of interlocking earth blocks gives an overall reduction in the cost of masonry of about 65%.

Appreciable savings can also be made in area of plastering as the CSIEB may be left unplastered to showcase the different aesthetic colours of the blocks (Adewole, 2008). Anand and Ramamurthy (2003) stated that the conventional blocks require the use of mortar for the laying of the blocks, coupled with the non contributory activities that affect its cost and the net output. All these are eliminated in the operation of interlocking blocks due to its dry stacking method. Muinde (2013) also observed that since the machine for making the blocks can be towed to the site of construction, appreciable savings can be made on cost of transporting blocks.

Environmental Sustainability of CSIEB

The use of stabilized earth blocks, in place of conventional fired bricks, can to a large extent reduce the energy usage and CO_2 emissions (Joseph, 2010). Muinde (2013) further affirmed this by stating that compressed earth technology provides an alternative to the commonly used fired brick, which is responsible for grave environmental degradation due to deforestation, and destruction of wetlands. Adedeji (2005) observed that the use of interlocking blocks minimizes the enormous waste associated with conventional masonry works while Taiwo and Adeboye (2013) observed that since the materials used for construction of stabilized earth blocks are collected onsite, any error can be repaired quickly with little environmental impact.

Lemougnan *et al.* (2011) observed that due to the permeability of CSIEB to water vapour, earth walls remarkably regulate the humidity of indoor air and their production is generally in-situ with no emission of greenhouse gases and without using high amount of energy. Radhi (2009) also observed that the thermal insulation and thermal mass properties of the interlocking stabilized earth blocks have been proven to significantly affect the amount of energy required for heating or cooling and, consequently the total amount of electricity used in buildings. CSIEB require no burning, thus destructive deforestation is avoided, and they are cured under plastic sheeting so very little water is needed. In addition to the water and tree saving benefits, the blocks can be locally manufactured, reducing transport pollution and carbon footprint (Hydraform, 2004).

Social Sustainability of CSIEB

A sustainable structure should be safe, thermally, acoustically and visually comfortable (Queensland department of public works, 2008). To this effect, Radhi (2009) observed that due to its high density and valuable thermal inertia qualities, walls made with laterite earth allows the storage of solar heat during the day and its slow release during the night, thus contributing to indoor comfort. Also compressed earth blocks are generally non-combustible with high fire resistance (Alagbe, 2011), hence providing some measures of safety for occupants during fire outbreak.

No doubt, CSIEB when used in building is aesthetic in nature and very pleasing to the sight (Adewole, 2008). They are extremely beautiful if well arranged and gives some predetermined shapes and patterns after installation. The blocks could also be given different pigmentation to show various glowing colours, thus providing a pleasing structure to which other would-be developers can emulate. This can lead to a beautiful streetscape.

Benefits of using CSIEB as a material for sustainable construction

The use of sustainable building materials can lead to immense benefits for the owner such as: energy conservation, reduction in maintenance and replacement cost, improved occupant's health and productivity, lower costs associated with changing space configurations, greater flexibility in design, improving public image and overall cost savings (Zainul-Abidin *et. al*, 2003). These to a large extent can be achieved using CSIEB.

Figure 2: CSIEB used for construction of school clinic and hostel in Elizade University, Ilara-Mokin, Ondo state

METHODOLOGY

The data for the study were collected with the use of questionnaires administered to selected professionals (Architect, Quantity Surveyors, Engineers and Builders) within the study area. A total of 60 questionnaires were randomly distributed to practising professionals within Ondo state and 53 were retrieved, out of which 48 were ascertained fit for analysis. This represents a response rate of 80%, which is far above the usual response rate of 20-30% for questionnaire surveys in construction management studies, as suggested by Akintoye (2000). In the questionnaire, 7 major features of CSIEB in each of the 3 sustainability dimensions were identified and respondents were asked to rate them in order of importance. Cronbach's α value for scale of measures of the research instruments ranged from 0.919 to 0.927 showing that the instrument is highly reliable since the degree of reliability of an instrument is more perfect as the value tends towards 1.0 (Moser and Kalton, 1999). Data gathered were analyzed using Relative Importance Index (RII) in order to determine the relative importance of CSIEB in the provision of sustainability in construction. A percentage performance of CSIEB in each dimension of sustainability was derived and results were presented in tables and chart. RII was employed for two purposes which are: ranking and determination of significance of different factors of the collected data. The premise of decision for the ranking is that the factor with the highest RII is ranked 1st and others in such subsequent descending order.

The Relative Importance Index (RII) according to Megha and Rajivis (2013) is written as:

$$\text{RII} = \frac{\sum W}{A * N}$$

Where, W is the weighting given to each factor by the respondents (ranging from 1 to 5), A is the highest weight, and N is the total number of respondents.

Table 1: Reliability Coefficients for the Measuring Scales

Scale of measures	Cronbach's α
Economic sustainability of CSIEB	0.923
Environmental sustainability of CSIEB	0.919
Social sustainability of CSIEB	0.927

FINDINGS AND DISCUSSIONS

General information of Respondents

Respondents profile showed that Quantity surveyors and Engineers formed the bulk of the respondents sampled with 39.6% and 25% respectively, while Architects and Builders were 18.8% and 16.7% respectively. 20.8% of the respondents have between 0 to 5 years working experience while 33.3 % have between 6 to10 years working experience. 16.7% have

between 10 to 15 and 16 to 20 years working experience each while only 12.5% have above 21 years working experience. Since a total of 79.2% of the respondents have between 6 to 30 years working experience, it therefore implies that the result gotten from the respondents can be relied upon as answers were given based on experience. Also 95.8% of the respondents are aware of CSIEB for building construction, while only 4.2% are not. This high awareness rate can be attributed to the vast years of experience of the respondents in the construction field. Seventy seven percent (77%) of the respondents are of the opinion that CSIEB can be adopted in place of the conventional masonry materials due to its immense benefits, while 18.8% believe it cannot be totally adopted. A little above four percent of the respondents (4.2%) did not state their opinion as they have never heard of the material.

Economic Sustainability of CSIEB

Result in the table 2 shows that the low cost of raw material and time saving during construction leading to faster generation of revenue from the proposed structure, are the main economic sustainability criteria of CSIEB with a RII of 0.862 and 0.800 respectively. The use of reduced labour was ranked the least with RII of 0.726.

Table 2: Economic sustainability of CSIEB

	RII	**Ranking**
Low cost of raw material	0.862	1
Time saving during construction leading to faster generation of revenue from the structure	0.800	2
Reduction in cost of finishes/maintenance	0.796	3
Considerable cost savings on elimination of mortar	0.788	4
Availability of materials thereby saving transportation cost	0.762	5
Considerable cost savings on air conditioning or mechanical cooling system	0.742	6
Use of reduced labour	0.726	7
Average RII	**0.782**	

Environmental Sustainability of CSIEB

Result in table 3 shows that the ability of CSIEB to adapt to tropical climate makes it a relatively good material for sustainable construction, as it is ranked highest with a RII of 0.842. Use of materials onsite thereby minimizing energy used for transportation, reduce CO_2 emissions and reduction of waste followed closely with a RII of 0.820, 0.804 and 0.800 respectively. The ability of CSIEB to last the life span of the building was ranked the least with RII of 0.688

Table 3: Environmental sustainability of CSIEB

Environmental Sustainability	**RII**	**Ranking**
Adaptability of blocks to tropical climate	0.842	1
Use of materials onsite thereby minimizing energy used on transportation	0.820	2
Reduce CO2 emissions	0.804	3
Reduction of waste	0.800	4
Minimize energy consumption since there is no need for air conditioning or mechanical cooling system due to its thermal properties	0.742	5
Ability to control construction and correct any error quickly on site with little environmental impact	0.734	6
Ability to last the lifespan of the building	0.688	7
Average RII	**0.776**	

Social Sustainability of CSIEB

Result in table 4 shows that the aesthetic nature of CSIEB makes it a very good material in area of social sustainability as it is ranked highest with an RII of 0.866. Also the thermal and acoustic comfort provided by CSIEB, aesthetic nature providing a pleasing structure to which other would-be developers can emulate and provision of employment for people within the

immediate locality follow closely with a RII of 0.850, 0.838 and 0.824 respectively. Better quality construction is ranked last with a RII of 0.730.

Table 4: Social sustainability of CSIEB

	RII	Ranking
Aesthetic nature of the system	0.866	1
Thermal and acoustic comfort	0.850	2
Aesthetic nature provides a pleasing structure to which other would-be developers can emulate. Hence creating a beautiful/pleasing streetscape	0.838	3
Provision of employment for people within the immediate locality	0.824	4
Fire resistance thereby providing some measure of safety for occupants	0.788	5
Provision of low cost housing due to its cost effective nature.	0.758	6
Better quality construction	0.730	7
Average RII	**0.808**	

Overall Sustainability Nature of CSIEB

Using the average RII of each sustainability dimension, a computation of the overall performance of CSIEB was done as seen in figure 3 below. Social sustainability of CSIEB has the highest of 34% followed by economic and environmental sustainability with 33% each.

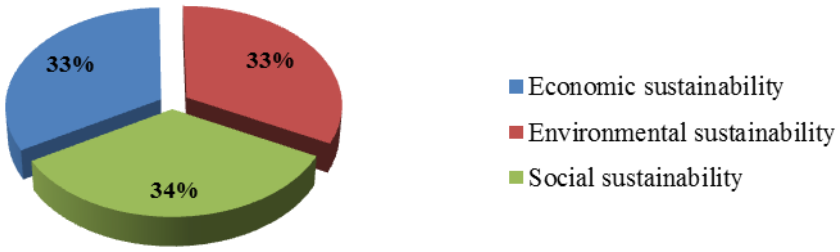

Figure 3: Overall performance of CSIEB in each sustainability dimension

Discussion of Findings

Findings showed that all the sustainability characters of CSIEB within the three pillars of sustainability (economic, environmental and social) performed well above average of 0.5 RII, hence proving that CSIEB is indeed a material worth using in the delivery of sustainability in building construction in Nigeria.

Economic sustainability of CSIEB

Findings showed that low cost of raw material is top of the economic sustainability character of CSIEB with a RII of 0.862. This further corroborates Adedeji and Fasakin (2008) findings that the stabilized interlocking earth block is highly cost effective when used for building construction. Findings also revealed that the use of CSIEB for income generating projects such as shopping complexes/malls, block of flats and estates, can lead to faster generation of revenue from the proposed structure due to considerable time savings during construction as it has a RII of 0.800. Reduction in cost of finishes and considerable cost savings on elimination of mortar were also noted as strong features of CSIEB with a RII of 0.796 and 0.788 respectively, hence affirming Ngowi (2005) statement that more cost saving is recorded in area of cement used for finishes and mortar for joining of blocks as experienced in the conventional masonry system. Findings also revealed that the use of CSIEB can lead to immense saving in transportation cost since materials needed for its production are readily available on site. RII of 0.762 was recorded in this aspect and this corroborates Taiwo and Adeboye (2013) observation that since the materials used for CSIEB are collected locally, no huge mines are required to supply building materials and Muinde (2012) observation that

since the machine for making the blocks can be towed to the site of construction, appreciable savings can be made on cost of transporting blocks.

Although, considerable cost savings on air conditioning or mechanical cooling system and the use of reduced labour ranked between 6th and 7th, they still have a RII of above 0.700. This showed that CSIEB if used for masonry construction can provide immense economic sustainability for an investor.

Environmental sustainability of CSIEB

The ability of CSIEB to adapt to tropical climate makes it a relatively good material for sustainable construction as it has a RII of 0.842. Also since onsite materials are used, energy used for transportation is minimized thereby reducing transport pollution and carbon footprint (Hydraform, 2004). CO_2 emissions experienced in the case of the conventional fired clay bricks (Deboucha and Hashim, 2011) is eliminated with the use of CSIEB as no firing is needed in its production, hence providing a safe and sustainable environment for its occupants.

Findings further corroborate Adedeji (2005) assertion that stabilized interlocking earth blocks minimizes the enormous waste associated with conventional masonry works as reduction of waste had a RII of 0.800. This can be attributed to the fact that faulty blocks can be broken down and reproduced using same material and where material is unused, excess can be recycled on site and reused.

The Ability to last the life span of the building is the least on the table with a RII of 0.688. This can be attributed to the fact that an actual case study on the life span of a building built with CSIEB has not been carried out. Hence little is known as to its life span expectancy.

Social Sustainability of CSIEB

Findings revealed that the main social sustainability nature of CSIEB is its aesthetic nature as it has a RII of 0.866. This corroborates Adewole (2009) observation that an aesthetically pleasing look is achieved if properly constructed. The use of CSIEB for building construction provides some considerable measure of thermal and acoustic comfort for its occupants as this has a RII of 0.85. This according to Radhi (2009) is due to its high density and valuable thermal inertia qualities, which allows the walls to store solar heat during the day and slowly release it at night.

Provision of a beautiful streetscape is an important factor for social sustainability in building construction (Queensland department of public works, 2008). Thus, findings showed that the aesthetic nature of CSIEB provides a pleasing structure to which other would-be developers can emulate, thereby creating a beautiful/pleasing streetscape. This has a RII of 0.838. Also, provision of employment has a RII of 0.824 which shows that most respondents believes that use of CSIEB can serve as a means of employment for people within the immediate locality.

CONCLUSION AND RECOMMENDATION

Due to the increasing popularity and usage of CSIEB for building construction, the need to ascertain its sustainability is necessary in other to achieve a sustainable environment. Using a survey method where construction professionals (Architect, Quantity Surveyors, Engineers and Builders) were sampled, this research was able to ascertain the main sustainability features of CSIEB with the view of increasing its level of usage in building construction in Nigeria, thereby creating a more sustainable environment. The study shows that the use of CSIEB for building construction will give 34% of social sustainability, 33% of economic sustainability and 33% environmental sustainability, thus creating a balance between the three pillars of sustainability.

The research further revealed that the use of CSIEB to a large extent will:

i. save cost of raw materials used for masonry construction, provide faster revenue generation due to its fast construction time, provide adequate savings in areas of finishes and mortar usage and provide adequate savings in cost of transportation of materials needed for masonry construction to site;
ii. provide a structure that can adapt to the tropical climate, minimize energy spent on transportation thereby reducing transport pollution, eliminate the emission of CO_2 and eventually reduce wastage of materials onsite;
iii. provide an aesthetically pleasing and thermally conducive structure, provide a beautiful streetscape and subsequently serve as a means of employment for people within the locality.

The study therefore recommends the use of CSIEB as a means of attaining sustainable building construction. The use of CSIEB should be encouraged among stakeholders as a material for building construction due to its enormous benefits.

The findings of the study provide possible directions for further studies in that the researcher was able to assess the sustainability of CSIEB in building construction in Nigeria. Further work can be done in comparing the sustainability of CSIEB with that of other conventional materials for masonry construction such as sandcrete blocks, fired bricks etc.

Assessment of Organisational Culture and Employee Commitment in Construction Companies in Lagos State Nigeria

Abiola-Falemu, Joseph Ojo

Department of Building, Federal University of Technology, Akure, Nigeria
drabiolafalemu@gmail.com

ABSTRACT

The world of construction companies' business today is dynamic and regularly changing giving ways to challenges and opportunities. This implies that construction companies are expected to compete and survive in the dynamic business world. These changes in the business world impact on other aspects of the companies' corporate existence, such as organisational culture and employees' commitment which impact on organisational outcomes. The culture of an organisation brews the component of commitment exhibited by the employees. This study investigates the correlation and compatibility of existing type of organisational culture and exhibited component of employees' commitment in large, medium and small sized construction companies. The research design is a cross-sectional survey in which validated organisational culture and organisational commitment instruments were used and administered to management staff in 176 construction companies in 2015. Mixed statistical analysis which includes percentile, mean score, and Spearman rank correlation were used to analyse the data collected. The results of the study shows that the strength of relationship between the different types of organisational culture and components of commitment vary from the weakest to the strongest suggesting that certain types of organisational culture is more related and compatible with certain components of commitment. It also reveals that the Nigerian construction companies operate different types organisational culture perceived to be compatible with components of commitment exhibited by their employees. The study recommends that management of construction companies should conduct culture auditing or embark on culture change from top to bottom in order to ensure compatibility and enhance their performance.

Keywords: Compatibility, Construction Companies, Employees' Commitment, Management, Organisational Culture

INTRODUCTION

Organisational culture is a concept that characterises a work environment. Culture is the environment that surrounds the employee at work all of the time. While not simple to capture or define, organisational culture is a discernible, powerful force in any organisation which can be used to cultivate the commitment of its members to the realisation of its goals and objectives. Organisational culture and employees' commitments are necessary ingredients for construction companies to compete and survive in today's dynamic construction business environment which is regularly changing and giving ways to challenges and opportunities. If construction companies are to effectively compete and survive in the dynamic business environment, the management of such companies must focus attention not only on their organisational culture but also on the commitment of the employees.

In the opinion of Pandey (2014), organisational culture is responsible for laying the foundation of an organisation, building and nurturing it, defining its purpose, setting its direction, prioritizing its tasks, guiding its strategies and behaviour of its people in order to ultimately delivers its results. An organization's culture governs the attitude and behaviour of people in the workplace, including their commitment toward the organization and therefore a determinant of commitment (Neelam, Bhattacharya, Sinha and Tanksale (2015). It has also been argued that the culture of an organisation brews the component type of commitment exhibited by the employees. This suggests that there is a relationship between organisational culture and component of employees' commitment exhibited in any organisation. However

Abiola-Falemu, J. O. (2016). Assessment of Organisational Culture and Employee Commitment in Construction Companies in Lagos State Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 793-804

the strength of the relationship has not been fully explored in order to know which type of organisational culture is most compatible with which component of the employees' commitment.

Two questions that arise from literature evidence of the relationship between organisational culture and employees' commitment are: (i) which type of organisational culture highly correlates with which component of employees' commitment? and (ii) Does the same type of organisational culture and component of employees, commitment exist in small, medium and large sized construction companies? It is therefore the aim of this study to investigate the correlation between the type of organisational culture and component of employees' commitment in construction companies with the aim of identifying the most compatible for adoption by the management of the companies.

LITERATURE REVIEW

Organisational Culture

By definition, organisational culture is a basic assumption, as well as the findings, invention, and development of an organisation in dealing with external adaptation and internal integration (Wu and Lin, 2013). Organisational culture is considered by some scholars as the glue that holds every member of an organisation together (Clark, Hartline and Jones, 2009). Some other scholars compare it to a compass providing direction for the ship of the organisation. Its function is to create a common ground for the employees and, provide a sense of order such that all employees know what is expected of them at any given time. The culture of any organisation is manifested in the values and business principles preached by its management, in the attitudes and behavior of its employees, in the legends people repeat about happenings in the organization (Sharma and Sharma, 2010).

Literature is replete with various definitions of culture hence it has no universal definition.However, one of the most commonly cited definition was offered by Schein (1985). It defined organisational culture is understood as a pattern of basic assumptions which is invented, discovered, or developed by a group since it learns to cope with its problems of external adaptation and internal integration that has worked well to be considered valid, and therefore, to be taught to new members as the correct way to perceive, think, and feel in relation to those problems. Building the culture of an organization and shaping its development is essentially the function of leadership. Naturally whether the culture of an organisation is purposely planned or not, it will surely develop in due course. Generally, culture forms the context within which a group of people judge the appropriateness of their behaviour.

Culture at the Construction Industry Level

Industry cultures represent groups of organisations that share common values, assumptions, socialisation and norms; and includes all those organisations to which individual organisations have direct or indirect links (Bosch, Tait and Venter, 2006). The construction industry in Nigeria is not homogeneous like in any other country. It is a fragmented industry with the design and production aspects under different management umbrella and it comprises large number of privately-owned, small and medium sized companies; and a small number of large sized companies (Abiola-Falemu, 2013). Construction has an image of being a difficult, demanding and unbecoming occupation with an adversarial culture (Harvey and Ashworth, 1993).

The industry has historically been known more for its adversarial nature than for its collaborative spirit (Barbara, 2010). According to Ball (1988), the industry also has a culture of intimidation within the working environment where the many small companies tend to act

as subcontractors to the large companies. The physical nature of the industry's products which are manufactured in the client's premises; one-off designs and lack available prototype models; separation of design from construction; organisation of the construction process; and methods used for price determination are some of the characteristics that separate construction industry from other industries (Barthorpe, Duncan and Miller, 2000 reflecting Harvey and Ashworth, 1993). All these characteristics serve as agents that partly shape the construction organisation's culture and commitment of its employees.

Culture at the Organisational Level

Wu and Lin, (2013) suggests from his definition of culture that at the organisational level, culture evolves as members of the organisation carry out their jobs and interact with one another. Two decades earlier Rowe *et al.,* (1994), had observed that organisational culture develops as a result of many factors, some of which are the type of business interest of the organisation, its products, customers, size, location and operational methods. Further research into the construct by Barthorpe, Duncan and Miller (2000) revealed that culture within organisations is reflected in the way that people perform tasks, set goals and objectives and administer the necessary resources to achieve the goals and objectives. Culture knits a collection of individuals into an integrated entity called "organisation." A collection of a number of key elements, factors, observations and experiences that have been recognized as being inherent within an organisation is known as "organisational culture". It affects the way people in organisations make decisions, think, feel and act in response to the opportunities and threats affecting the organisation (Thompson, 1993).

Types of Organisational Culture

There are four types of organisational culture that have long been commonly referred to in the literature and which are still contemporary subject of research focus as indicated in Erdem and Keklik (2013). Construction companies can be identified with any one of the four types which are each described as follows:

People or Clan Culture

This is characterised as a family type of organisation; and a friendly place to work. It is an organisation that concentrates on internal matters. It shows flexibility, concern for people, and sensitivity for customers. The people culture views its leaders as having the role of mentors or facilitators. The glue that binds the organisation together is loyalty and tradition and its members exhibit a high level of commitment. People culture organisations emphasise individual development, morale, teamwork participation, and consensus (Cameron and Quinn, 1999). The goal of people culture is to manage the environment through teamwork, participation and consensus.

Task or Adhocracy culture

This refers to a non permanent organisation which focuses on realizing organizational goals (Aina, Adeyeye and Ige, 2012). It is a temporary organisation structured to solve a particular issue and is disbanded once the issue or task is completed (Hodge and Anthony, 1991). It is an organisation that concentrates on external positioning with a high degree of flexibility, individuality and discretion rather than seeking stability and control. Its key values are creativity and risk taking. Organisational charts are temporary or nonexistent. Roles and physical space are also temporary. This type of organisation typifies a construction organisations engaged in construction contracts.

Power or Market Culture

This is an organisation that focuses on external maintenance with a need for stability and control in order to have a competitive position. The power culture is valued for stability and control. It focuses more on external (market) rather than internal issues. This culture tends to

view the external environment as threatening, and seeks to identify threats and opportunities as it seeks competitive advantage and profits (Cameron and Quinn, 1999).

Role or hierarchy culture

This refers to an organisation that focuses on internal issues with the need for stability and control. It values tradition, consistency, cooperation, and conformity. The culture also values stability and control over flexibility and discretion. In this type of culture there are commands, written rules, job descriptions and standardization (Erdem and Keklik, 2013). It is the traditional "command and control" model of organisations, which works well if the goal is efficiency and the organisational environment is stable and simple with very few changes in customers, customer preferences, competition and technology. This type of organisation typifies large construction organisations that have established rules, regulations and procedures for the conduct of their business activities and have in the process become bureaucratic.

Framework and Instrument for Measuring Culture

Literature is replete with some frameworks for measuring culture. Competing Values Framework, Value Survey Module, Handy's Framework and Stakeholder Framework) are familiar frameworks for measuring culture. The Quinn (1988) Competing Values Framework was found most suitable because of its universal application. The framework is organised along two axes based on the four dominant culture types to complement the dimensions. The model uses quadrants to differentiate the four types of organisational culture in form of a 2 x 2 matrix in which the organisational culture types on the diagonals are competing with each other while those adjacent are complementary to each other (Maloney and Federle, 1993). Organisation that operates in the upper-half is oriented towards decentralization and differentiation with an emphasis on impulsiveness and flexibility. Organisation in the bottom-half of the figure is disposed towards centralisation and integration with emphasis on predictability and control. The organisation on the left side focuses on a long-term horizon while the right side is oriented towards the competitive position of the overall system and it focuses on short-term horizons. The values of organisations in the upper-half side are competing with the values of those of bottom side. Those values on the right side are also competing with those on the left side (Maloney and Federle, 1993).

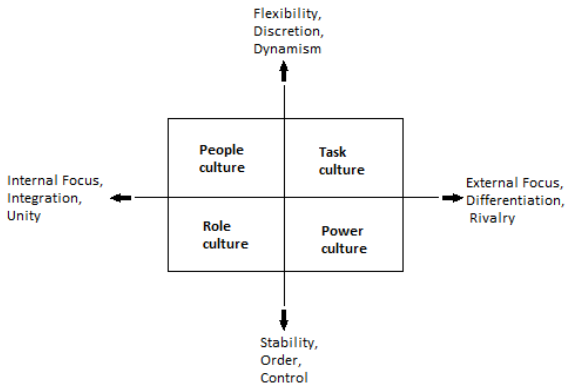

Figure 1: Competing Values Framework (CVF) Source: Adapted from Quinn (1988)

Employees' Commitment

Commitment is the bond employees experience in their working relationship with their organisation. Employees' commitment is about the attitudes of employees towards the entire organisation (Adeyinka, Ayeni and Popoola, 2007). Northcraft and Neale (1996) view commitment as an attitudinal issue reflecting an employee's loyalty to his or her current organisation; and as an ongoing process through which organisation members express their concern for the organisation and its continued success and well being. Employees'

commitment is believed by some scholars (Meyer and Allen, 1997) as multidimensional work attitudes which have different types or simply different components. It is therefore an important organisational issue that makes committed employees less likely to leave for another job and more likely to perform at higher levels.

Employees' Commitment Defined

Employee commitment has been defined in numerous ways (Lee, and Chen, 2013). Though many definitions of employees' commitment exist, there is no significant variability among them and hence one definition can suffice to convey understanding of the construct. Therefore, commitment is a condition in which members of a group give their abilities and loyalties to the organisation in which they work currently and the pursuit of its goals in return for satisfaction (Hodge and Anthony, 1991). Meyer and Allen (1991) and Meyer, Allen and Smith (1993) acknowledging the construct as multidimensional, have identified three aspects of commitment as affective commitment or desire-based (wanting to stay with the organisation), normative commitment or obligation-based (feeling obliged to stay), and continuance commitment or cost-based (staying because of the high cost associated with leaving the current organisation). Hence Meyer and Allen (1991) offer the following definition of the three types of employees' commitment

Affective or Desire-based Commitment

This refers to the employee's positive emotional attachment to, identification with, and involvement with the organisation. This translates to mean that employees with a strong affective commitment continue employment with their current organisation because they want to do so and not out of any influence. An employee who is affectively committed strongly identifies with the goals of his or her current organisation and desires to remain a part of the organisation. Affective commitment is different from normative commitment in that it is motivated by personal enjoyment rather than a sense of duty as in normative commitment.

Normative or Obligation-based Commitment

This reflects a feeling of compulsion to continue employment in the current organisation whatever the situation may be. It Normative commitment is a feeling of moral or legal duty by an employee to remain in his or her current organisation. This feeling of compulsion may be as a result of a combination of factors like investment (e.g. training, loans of any category, etc) made in the employee by the organisation, family ties, religious leaning and extra curricula activities. For example when an organisation trains an individual employee, such an employee feels duty-bound to serve the organisation or pay back the cost of training him. Some employees exhibit this component of commitment out of the belief that it is the norm to be loyal and dutiful to one's organization and reciprocate a good gesture. This is typically an African value

Continuance or Cost-based Commitment

This is the awareness by an employee of the costs associated with his or her leaving his or her current organisation. It is exhibited when an employee perceives high economic or social losses associated with leaving his or her present organization for another one. The reason for leaving is different from the obligation felt by those employees that exhibit normative commitment. This type of commitment emanates from a negative sense of fear regarding the consequences of leaving. Employees whose primary link to their organisation is based on continuance commitment remain with their current organisation because they need to do so out of fear. The cost of their leaving the organisation outweighs the cost of remaining with it otherwise they will leave no matter the amount invested in them by the organisation.

Organisational Culture and Employees' Commitment

Conflicting research outcomes of relationship between organisational culture and commitment have been reported. In 2012, Mahmudah reports that a significant relationship exists between organisational culture and commitment. On the other hand, Lahiry (1994) in his own report finds only a weak correlation between organisational culture and commitment. Nongo and Ikyanyon (2012) argue that when organisational culture is strong it enables employees understand and work towards the organisation's goals thereby increasing their level of commitment. Jermier and Berkes (1979) also show there is a relationship between job satisfaction and employees' commitment which impact on performance. Their findings show that job satisfaction yields higher levels of employees' commitment and by extension improved performance. Employees' commitment is a strong predicator for individual motivation, desire to leave, turnover, and job performance (DeCotiis and Summers, 1987) but it is driven by organisational culture.

Thus, having a committed workforce would be an added advantage to an organisation. However this is gained through integration and good management practices around a small number of key values inherent in the culture of the organisation. Oboh (2004) reflects this when he states that management concern for staff welfare and career development through structured training are means of ensuring staff commitment and loyalty and also means of entrenching the culture of service by workers.

RESEARCH METHODOLOGY

This is a cross-sectional survey research in which data was collected at one point in time in 2015. Modified Organisational Culture Assessment Instrument (OCAI) developed by Cameron and Quinn (1999) and Meyer and Allen's (2004) Organisational Commitment Instrument (OCI) for assessing employee commitment were used. The choice was based on their relative reliability and validity as attested to in the literature and compared to other tools. The research was based on census survey and the population consisted of 176 construction companies that registered with the Federation of Construction Industry (FOCI) and the Nigeria Business Directory (NBD). The questionnaire was administered on one management staff in each of the 176 companies. Since the research population is finite and manageable, it was considered appropriate to use the entire population for the study.

Questions were asked on a five point Likert type scales with 5 representing strongly agree and 1 representing strongly disagree with statements about organisational culture and employees' commitment. This score provides an indication of the cultural orientation and employees' commitment within the organisations with respect to each of the indices. Mixed statistical procedures were employed in the analyses of the data. Percentile, mean score, and Spearman rank correlation were employed.

FINDINGS AND DISCUSSIONS

Types of Organisational Culture in the Nigerian Construction Companies

From Table 1, it can be seen that the small sized (1-50 employees) construction companies predominantly operate task culture with a mean score of 3.85 while role culture appears to be the least common among the small sized companies. The highest mean score for the medium sized (51-300 employees) construction companies is 3.68 for role culture. Task culture has the least mean of 3.58. Therefore role culture is favoured among the medium sized companies in Nigeria. As for the large sized (> 300 employees) construction companies, the highest mean score of 3.90 is for the power culture which is their dominant culture. From broad perspective, the dominant type of organisational culture in the Nigerian construction industry is the power culture with a mean score of 3.73 which is only marginally higher than the mean

score of 3.72 for the task culture. This means that most of the construction companies are either operating power culture or task culture.

Power culture is dominant because no construction organisation can stay in business without competition which most often entails competitive bidding. Task culture is also common because of

the need for construction organisation to meet schedule and deliver to time. People culture appears to be the least common type of culture within the industry though the difference between role culture (3.66) and people culture (3.63) is equally marginal

Types of Employees' Commitment in the Nigerian Construction Companies

Table 1 show that employees in the small- sized construction companies exhibit all the three components of commitment. However, the prevalent component of commitment being exhibited by the employees is normative with a mean score of 3.59. This is followed by affective commitment while continuance commitment is least exhibited. This indicates that the employees are more committed in terms of normative and affective than continuance. In the medium-sized companies, employees' affective and normative commitments are stronger than continuance commitment which appears to be very weak. However, affective commitment seems to be the dominant type of commitment in the medium-sized companies with a mean score of 3.23 followed by normative commitment with a mean score of 3.07.

The commitment pattern of the employees in the large-sized companies is the same as that of the small sized companies. The employees appear to exhibit more of normative (ms = 3.20) and affective (ms = 3.10) than continuance (ms = 2.93). The overall mean score for each of the three types of commitment shows that normative component of commitment with a mean score of 3.29 is most prevalent in the Nigerian construction companies. This is followed by affective commitment with a mean score of 3.20 while continuance commitment with a mean score of 2.85 is least exhibited. The higher positive correlation with continuance commitment may be due to some attributes in the power culture. The role culture is positively correlated with all the types of employees' commitment. Both affective ($r = 0.346$, $p = .000$) and normative commitment ($r = 0.334$, $p = .000$) are more positively related to the role culture than continuance commitment ($r = 0.175$, $p = .023$). However affective commitment shows the highest coefficient of correlation with task culture ($r = 0.522$, $p = .000$) which may mean that affective commitment is the most compatible with this type of culture.

Table 1: Types of Organisational Culture and Commitments Components in Construction Companies

Variables	Small sized companies			Medium sized companies			Large sized companies			*OMS*	*OR*
	N	*Mean Score*	*Rank*	*N*	*Mean Score*	*Rank*	*N*	*Mean Score*	*Rank*		
People Culture	73	3.59	3	32	3.64	2	25	3.65	4	3.63	4
Task Culture	73	3.85	1	32	3.58	4	25	3.74	3	3.72	2
Power Culture	73	3.68	2	31	3.6	3	26	3.9	1	3.73	1
Role Culture	73	3.56	4	32	3.68	1	26	3.75	2	3.66	3
Affective Commitment	70	3.27	2	32	3.23	1	25	3.1	2	3.2	2
Normative Commitment	73	3.59	1	32	3.07	2	25	3.2	1	3.29	1
Continuance Commitment	73	3.08	3	31	2.53	3	26	2.93	3	2.85	3

Note: OMS = Overall Mean Score, OR = Overall Rank. The decision rule is based on <2.5 = strongly disagree; ≥2.5 but <3.0 = disagree; ≥3.0 but <3.5 = somehow agree; ≥3.5 but <4.5 = agree; 3.5; ≥ 4.5 but ≤ 5 = strongly agree

Types of Organisational Culture and Employees' Commitment

Judging from the attributes of power or task culture oriented companies, the result implies that most companies are oriented towards maximization of output as well as expansion and transformation. It further indicates that they are also competitive and goal oriented. People culture appears to be the least common type of culture within the industry. This is probably because most of the construction companies are not disposed to having an organisational setting where their employees would work as a family because this will hinder the

management from hiring and firing at will as is commonly the case. Human capital development which is one of the hallmarks of the people culture seems unimportant to most of the companies. The economic situation in Nigeria lends ready excuse as to why the companies appear not to favour people culture. The large pool of unemployed in the labour market gives the construction companies the opportunity to hire and fire at will especially as ICT has made recruitment much less difficult.

In terms of employees' commitment, normative form of commitment is generally prevalent. This is closely followed by affective commitment. One observable reason why normative commitment is prevalent in the industry is because, many construction employees are engaged through friends and family links and sometimes they receive one favour or the other from their employers; and they therefore have the moral obligation to stay with the company. Apart from this, the African culture teaches that one should reciprocate a kind gesture, and so this drives the commitment behaviour of the employees and they tend to exhibit normative commitment in appreciation of any investment made by their employer on them. However the results show that differences exist based on the size of company in the type of culture and employees' commitment most dominant in any construction company.

Small-sized construction companies

From Table 1, the small-sized construction companies predominantly operate the task culture. This is because they are still growing with the need for expansion and transformation. Hence, they need simple organisational structure for their operations. Based on the CVF (Fig.1) it can be said that small-sized construction companies value the end result of growth and acquisition of resources probably due to the need for expansion. Furthermore they encourage creativity and experimentation and are motivated and driven by the desire to achieve new and challenging vision. External positioning and the need to be recognised is their focus and hence they always strive to meet schedules. Innovativeness is assumed to be the key to their success.

The small-sized companies can equally be described as dynamic, entrepreneurial and creative. As such their employees would tend to embrace innovation and risk-taking. The binding force among their employees would most likely be a commitment to experimentation and freedom of thought. This is consistent with the views expressed by Tharp (2009) that experimentation and thinking differently is a unifying force of employees in small-sized companies. However, the end results will depend on the values placed on flexibility, adaptability and innovativeness.

In terms of employees' commitment, most employees working in the small-sized construction companies agree that they exhibit normative component of commitment with a mean score of 3.59. The prevalence of normative commitment indicates that a sense of obligation to maintain association with and loyalty to their respective companies appears to be common among the employees. Since the small-sized construction companies are more task culture-oriented than other types of culture with the desire for growth, investments are made in their loyal and trustworthy employees through various ways. Hence, the African norm of reciprocity that employees should remain loyal to an organisation that has invested in them seems to be responsible for the high level of employees' normative commitment in this category of construction companies.

Medium-sized Construction Companies

As for the medium-sized (51-300 employees) construction companies, role culture with a mean score of 3.68 is preferred. In the context of the CVF in Figure1, this could be attributed to the need to have formal laid down rules and procedures to govern their business conduct as well as the behaviour of their employees. This implies that they are formalized and structured

and also suggests that they are concerned with stability, predictability and efficiency in the long term. It is also most likely that the medium-sized companies place emphasis on creating a well-defined hierarchical structure where employees are given well-defined roles as well as provided with clear rules and policies which they are expected to follow to bring about stability, predictability and efficiency. Of course, experience has shown that this is the case with most medium-sized companies. Hence in agreement with Tharp (2009), managers in such companies are expected to be seen as good coordinators and organizers having efficiency at the back of their mind.

In terms of employees' commitment in the medium-sized companies, affective commitment with a mean score of 3.27 seems to be commonly exhibited by the employees. Affective commitment refers to the employee's emotional attachment to, identification with and involvement in the organisation on the basis of positive feelings or emotions toward the organisation. The extent to which employees could rely on their companies to cater for their interest; and the extent to which they could influence decisions and matters that concern them could be responsible for their being affectively committed. This means that dependability and participatory management could have played a role. Additionally, age, job satisfaction and organisational tenure which this category of company expressed as important to them could be attributed to the employees' affective commitment. Affectively committed employees stay with the organization out of their own volition rather than any underlie factors. However opportunity for growth in such companies cannot be ruled out as factor for being affectively committed. Hence, such employees tend to exhibit higher levels of commitment to their organisation and they also tend to perform more effectively in their managerial work than those that exhibit normative or continuance commitment. Therefore the level of performance of the medium-sized construction companies is expected to be better than small-sized companies whose employees exhibit normative form of commitment.

Large-sized Construction Companies

Large-sized (> 300 employees) construction companies operate power culture with a mean score of 3.90. This choice of power culture could be explained in the context of attainment of business development maturity level. As companies attain this level, they need not only to prospect and maintain customer relationships but also put in place business development entrepreneurship. This would make all their employees accept responsibility to identify and champion new opportunities for further business growth. Explaining this result in the context of CVF as in figure 1, it can also be said that large-sized construction companies value the end result of productivity and efficiency to a great extent. This is in agreement with the findings of Buckner and Williams (1995) that organisations operating power culture greatly value productivity and efficiency as end result.

Other attributes of such power-culture-oriented companies are emphases on producing as many services as possible, focused attention on bottom-line and profits; and employment of planning and goal setting as the means of achieving the results. Furthermore, goal and task clarification, direction, and decisiveness are the cultural values of such power-culture-oriented companies. Due to the pervasiveness of cultural dimensions in such companies, their employees are assumed to respond normally when given instructions by a superior who administer rewards for work well done. These attributes are evident in the way and manner the few large construction companies in Nigeria operate.

The employees in the large-sized companies are competitive, goal-oriented and motivated to increase productivity. They exhibit normative form of commitment as indicated in Table 1 with a mean score of 3.20 though marginally higher than affective commitment. Anecdotal evidence has shown that there is reasonable level of job security in large-sized construction

companies coupled with better conditions of service and welfare packages. It is therefore not surprising that there is tendency for the employees to be emotionally attached to the organisation which in turn reflect in their performance. Their managers are demanding and hard-driving with focus on external maintenance with a need for stability and control. The emphasis on winning unifies the organization; and reputation and success are common concerns. Such company is equally competitive and success means market share and penetration (Tharp, 2009). The foregoing might be the reason why the few large-sized construction companies in Nigeria are able to perform and attract more patronage from various quarters which give them the opportunity to dominate the Nigeria construction landscape.

Relationship between Types of Organisational Culture and Employees' Commitment

The dimensions of organisational culture play significant role in determining the component type of employees' commitment that should be expected in each of the organisational culture types as expressed in Table 2. This shows that all the types of organisational culture are positively correlated with the three components of employees' commitment in varying degree of strength. The implication of these results is that in the people culture, affective commitment would be more pervasive and most times be expected among the employees especially in medium-sized construction companies.

Both types of culture are common to medium-sized companies. Individual development and personal commitment in the people culture are most likely responsible for the emotional commitment of employees in medium-sized construction companies. Therefore, attachment of the employees with the organisation would be very high. This finding is also in agreement with Rashid, Sambasivan and Johari (2003) that affective commitment is more positively related to consensual (people) culture. This desire-based component of commitment coupled with a family type of organisational culture will no doubt produce job satisfaction which in turn impacts positively on organisational outcomes.

In the case of task culture; values like creativity, commitment to innovation and development; and risk taking associated with the culture would influence the emotional attachment of the employees to the companies that are task-culture oriented. These values could likewise place an obligation on some of the employees to be normatively committed. Therefore in task culture, normative commitment should be expected since it appears more compatible than the continuance commitment. This type of culture and commitment will work perfectly well in small-sized construction companies.

Table 2: Correlation between the types of organisational culture and employees' commitment

Types of Organisational Culture	Types of Employees' Commitment		
	Affective commitment	Normative commitment	Continuance commitment
People culture	.448**	.373**	.216*
Task culture	.522**	.461**	.273**
Power culture	.204*	.216*	.263**
Role culture	.346**	.334**	.175*

**Correlation is significant at the 0.01 level (2-tailed); *Correlation is significant at the 0.05 level (2-tailed)

The strong strength of relationship between power culture and continuance commitment suggests compatibility. This indicates that employees who exhibit continuance commitment remain in the employ of their companies due to the cost associated with leaving the organisation and also to values in the power culture that relate to stability; and competitive advantage and profits in agreement with Cameron and Quinn (1999). The results further show that the employees would stay with the organisation as a matter of necessity and not based on emotional factors. In accordance with thoughts of Rashid, Sambasivan and Johari (2003), this means that managers need to focus attention on boosting the morale of the employees

including their dedication to work so as to make them emotionally attached in order to improve their performance.

In role culture, affective commitment appears to be most compatible since it has the highest correlation coefficient. Values in role culture like cooperation, traditions and; formal rules and policies would influence the employees to be emotionally attached to companies that operate this type of culture. The medium-sized types of construction companies perfectly exhibit this match as both role culture and affective commitment were ranked first. The focus of medium-sized companies on internal than external issues as they strive for further growth, stability and control makes the perfect match possible. Alternative to this affective commitment is the normative type of commitment which can bring about the same results if properly channelled. Therefore either types of commitment can be cultivated in role-culture oriented companies as exemplified by medium-sized companies.

CONCLUSION

Organisational culture and commitment of employees in construction companies play important role as both are related and affect organisational outcomes through their interaction. The results of the study have provided important insight into the implications and strength of relationship between organisational culture and employees' commitment. To this end, certain type of organisational culture is more related to certain component of commitment suggesting compatibility. The Nigerian construction companies have been assessed as operating different types organisational culture perceived compatible with the component of commitment being exhibited by their employees. The small, medium and large-sized construction companies are characterised by different organisational culture and employees' commitment with power culture and normative commitment being generally the most prevalent in the overall assessment.

The management of these companies is encouraged to ensure compatibility of their respective organisational culture with the prevailing component of commitment being exhibited by their employees so as to derive the benefit of their interaction. This can be done by auditing their organisational culture and the commitment of their employees or by embarking on culture change which should be initiated from the top echelon of the management.

ABSTRACT

Risk is an inevitable occurrence in all activities, which cannot be exempted from the different phases of construction and the influence it has on the performance of stakeholders. Therefore, this study assesses the risks associated with project stakeholders at the pre-contract stage of construction projects in Ondo state, Nigeria. The study objectives assesses the effects of risks on the performance of stakeholders and the effectiveness of the strategies adopted by stakeholders in reducing these risks. Primary data were collected through questionnaire survey from a total of seventy-eight (78) out of eighty-one (81) construction stakeholders comprising client, consulting and contracting organizations. Mean score and regression analysis was used to analyze the primary data. The study revealed that poor communication between project stakeholders, unethical conduct among project stakeholder, government building policies and delays in approval of design by the government are the risks with very high occurrence and which are most severe at the pre-contract stage. The most effective strategies adopted by stakeholders includes carrying out in-depth investigation of site conditions directly from site, identifying possible risk at the early stage and assessing them appropriately and clearly defining clients brief. Also, the significant value shows that the performance of stakeholders is affected by risks. The implication is that the stakeholders should ensure to work in collaboration based on recognized conduct and ethics and, operate with proper contract documentation in order to enhance their performance throughout the construction project's life.

Keywords: Construction Project, Ondo State, Pre-contract Stage, Risk, Stakeholder

INTRODUCTION

Risks cannot be exempted in construction from the pre-contract stage to the completion stages of a project's life and less information are available at the inception of a construction project, which makes the level of risks and uncertainties high at this stage (Winch, 2002). According to Diffi (2003), risk is defined as the conditions or events that may occur and negatively affect the attainment of objectives and they are assessed in relation to the likelihood of it occurring, and the expected consequences it will entail for attaining objectives if it occurs. The pre-contract stage of a construction project is regarded as the stage where the client makes his intention known to the consultants to the stage where contract terms are being agreed to and signed by the stakeholders involved and at this stage feasibility studies done leads to production of design of the project, bill of quantity and other documents necessary to make up a contract document. On the other hand, Fewing (2005) defined a stakeholder as anyone who has an interest in the process and outcome of a project. In a typical construction project, the stakeholders are the clients, project managers, architects, civil engineers, builders, service engineers, quantity surveyors and contractors. The performance of these stakeholders often determines the output of the projects (lester, 2007).

According to New South Wales department of finance (2012), risks are involved in every stage of construction right from its planning stage to the contractual agreement stage to the completion stage, so identification, assessment and treatment of problems, threat and risk are integrated to most process of projects and individual procurement.

Moyanga, D. & Ayodele, M. (2016). Risks Associated with Stakeholders at the Pre-Contract Stage of Construction Projects in Ondo State, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 805-813

Risk is an inherent element of construction contract, so at the pre-contract stage construction organization must estimate the risk and make management decisions to reduce the level of risk to the barest minimum (Marcus and David, 2001). An effective risk assessment method can help to understand not only what kinds of risks are faced by the stakeholder at the pre-contract stage, but also how to manage these risks in different phases of a project. Owing to its increasing importance, risk assessment has been recognized as a necessity in the construction industry today. Thus, set of techniques have been developed to control the influences brought by potential risks (Luka and Ilyasu, 2014). Smith and Bohn (1991) opined that decision makers can take steps to minimize the impact of those problems and that effort expended in managing risk at the pre-contract stage should be consistent with estimated cost procurement cost and complexity, significant and nature of the process. Hence, this research work seeks to assess the various risks associated with stakeholders at the pre-contract stage of a contract so as to assist construction stakeholder i.e. clients, consultants and contractors in reducing or avoiding these risks. Flanagan & Norman (1991) purported that the adverse effect of risks will be financial loss either on the path of the client or the contractor. Chapman and Ward (1997) said that risk is viewed within the context of the probability of different outcomes and that the general attitude towards risk is its identification, assessment, control and management. Also Odeyinka (2006) asserted that risk at the pre-contract stage could be due to changes in design, inadequate program scheduling, poor selection of contractors, defects in design, under-estimation inadequate specification, feasibility of construction methods, corrupt/fraudulent practice and increase in interest rates. Baccanni and Arche (2001) discovered that the risks inherent in a construction project are responsible for the observable deviation between the tender sum and final account. Hence this research looks at what is the assessment of risk associated with stakeholders at the pre-contract stage of a construction contract and how they affect the execution of the contract at in the long run.

Several studies have been carried out to analyse and asses risks in various form of construction projects using different principles and theories (Duffey and Dorp, 2001; Odeyinka, 2006; Kikwasi, 2011; Luka and Ilyasu, 2014). Little has been done to assess the occurrence of risks at the different stages of construction and analyse the impact of risks on construction stakeholders. Therefore, the paper explore risks associated with the construction stakeholders based on its occurrence and severity, the strategies that can be adopted in reducing these risks and its effect on the performance of the stakeholders for public projects in Ondo state, Nigeria.

LITERATURE REVIEW

Risks in Construction

Risk has been defined in several studies to mean different thing based on individual's viewpoint, attitudes and experience. Baloi and Price (2001) concluded that risk is generally seen as an abstract concept which is very difficult to measure. Smith (1999) defines risk as a decision which has a range of possible outcomes and that a known probability can be attached to each of these potential outcomes. Diffi (2003) defined it as the conditions or events that may occur and negatively affect the attainment of objectives and they are assessed in relation to the likelihood of it occurring, and the expected consequences it will entail for attaining objectives if it occurs. Winch (2002) argued that in statistical terms risk refers to unexpected events where the outcome is either to the benefit or detriment of the decision maker. He also goes on to say that in common practice risk is only used to refer to the probability of a detrimental effect, with the word reward being used to signify the probability of a beneficial event occurring. Similarly, Wideman (2003) opined project risk as the chance of certain occurrences adversely affecting project objectives. Chapman (1999) asserted that

risk as an exposure to either economic loss or gain due to involvement in the construction process. However, this paper sees risk as an inevitable occurrence in all activities, in which the construction activity is not exempted and occurs at different stages of construction projects.

Risk Factors at Pre-Contract Stage of Construction Projects

According to Agerberg (2012), risk is always at the highest level at the pre-contract stage i.e. the stage where the client makes his intention known to the consultant team to the point where contractual agreements are being signed by the various parties involved in the contract. Worcester (2012) classified risk in various categories as they occur in several form. The risk factors listed in this study has been identified from different literature (Chapman & ward, 1997; Kumaraswamy and Chan, 1998; Frambach and Schilleweart, (2002); Morgan, 2004; Celvin, 2005; Noor, 2005; Harvey, 2006; Zou, 2006; Patrick and Guomin, 2006; Aiyetan, 2008; Yusof, 2011; Chereja, 2013; Al-Khatybih and AL-Qaralleh, 2013; Roxas, 2013; cunnigham, 2013) it include poor communication between project stakeholders, unethical conduct among project stakeholders, poor organization structuring of project team, government building policies, misuse of resources by stakeholders, dispute between consultants, reduction in firm, inadequate time at the pre-contract stage, clients delay in making decision, poor interpretation of client needs, insufficient site investigation, failure to adequately address enquiries from tenderers, insufficient number of responses from tenderers and high tender figure and breach of confidentiality in tendering process.

Activities at the Pre-Contract Stage

Traditionally, construction project activities can be split into two distinct but interdependent phases: pre-contract/design phase and post-contract/construction phase (Flanagan & Norman, 1991). The project stakeholders command and control the activities spanning both phases. The performance of project to time, cost and quality will not be realized unless effective pre-contract management has resulted in a contract that addresses all stakeholders' specifications with the utmost professional skill (Harvey, 2006). A failure in pre-contract phase will result in post-contract management time and effort being wasted on trying to resolve and correct omissions and failures of the earlier phase. Truman, (2014) categorises the pre-contract activities into three categories, which are:

a. The conceptual phase, including the owner's development of the project's first goals, design concepts, initial design calculations, and order of magnitude cost estimates, identification of financing mechanisms, taking the pulse of the public and regulatory agencies on the concept, etc.

b. The preliminary phase, including preliminary design calculations and preliminary plot plans and basic design drawings, development of permit packages and filing major permit applications, development of a contracting strategy, obtaining approval of major financing, ordering of long lead time equipment, and development of the Contract and bid package.

c. The bid phase, including identification of qualified bidders, solicitation and analysis of bids, clarification of the bids, and negotiation and awarding of Contract. According to him, all these stages are affected by the actions and in-actions of construction stakeholders.

Strategies Adopted in Reducing Risks

Strategy is been described in literature based on individual's opinion. Karen (2009) describes it as a reduction process which is the procedure that an organization follows to protect itself, its staff, its clients, and its volunteers. Reducing construction risk is more than just looking

out for potential problems and avoiding them. It is an ongoing process. These process guides and offer stakeholders ideas as to how risk can be reduced to the barest minimum.

Harvey (2006) describes it as a mitigating measure to curtailed risks. Large organizations may have formalized policies and managers whose job is to oversee risk management. However, for small and medium-sized organizations with little resources of larger groups, these policies may simply mean ensuring that a systematic, well-planned series of steps is readily available for program managers to follow in order to minimize risks. However, this study adopted Harvey (2006) list of risk reduction strategies used by stakeholders at the pre-contract stage. This strategy includes;

Constructing a well organized structure for the consultants

An organizational structure is the framework that helps employees achieve their goals and do their jobs (Lamar, 1991). An efficient company structure can benefit the organization in several ways, including making it easier to delegate responsibility and effect change throughout the organization' it also helps develop a good communication strategy and delegate responsibility without dispute (Harvey, 2006). To benefit from a strong framework, it is important to understand the advantages of organizational structure.

Clients should clearly define what they want in the brief

The responsibility of the consultants is to interpret and develop the Clients brief during the various stages of the project (Kikwasi, 2011). They will define the Client's requirements, identifying constraints, advise in terms of feasibility studies and option appraisals, arrange site investigations, establish the preferred solution, advise on sustainability, manage health and safety issues, develop the design, prepare room data sheets, obtain Client sign off of the design at appropriate stages and advise on materials selection etc and with due respect to the client's brief , prepare a design which meets all the clients requirements, including budget and timescale.

Carrying out site investigations directly from site for prompt approval

Inadequate geotechnical investigations can arise from lack of client awareness, inadequate finance, insufficient time and lack of geotechnical expertise. The reliability of the information contained in the geotechnical report has strong influence on design, construction, project cost and safety. Thus, it is quite important to have a clear, concise and accurate geotechnical report by qualified engineers in order to ensure the reliability of the investigation results. Inadequate geotechnical investigations usually force the geotechnical engineer to reduce the risk of failure by over-designing the foundation, thereby increasing the cost of the project (Zumrawi, 2014).

Maintaining close relationship with government officers

There is a great necessity to managed and diagnosed early in the most proper and efficient relationship so as to be acquainted with government bureaucracy. The relationship among the fundamental party of any project has the ability to mar or break the project success from the perspective of finance. It has been indicated that the partnership and ventures among the public and the private are the optimum and best way to alleviate the confliction occurrence among the parties (fewing, 2005).

Constantly reviewing contract documents before selecting a contractor

Good risk control system is more than just creating a simple check list. Extensive risk assessment procedures should be conducted at the first phase of the project and rigorous review of contract documents (Kikwasi, 2011). This review process should get directly and more detailed as project proceeds and new risk emerge.

METHODOLOGY

The paper adopted quantitative research approach. Primary data was collected from the size of eighty-one (81) selected randomly from one hundred and three (103) construction stakeholders including the clients, contractors, architects, quantity surveyors, and engineers who are cooperate members of their institute/professional bodies in Ondo state, Nigeria. The data was collected through the questionnaire on a 5-points likert scale and questions were asked on the background information of the respondents, risks associated with stakeholders at the pre-contract stage of construction project, strategies adopted by the stakeholders in reducing risk and the effect of risks on the performance of stakeholders at the pre-contract stage of construction project. Out of the eighty-one questionnaires administered, seventy-eight (78) which represents 96% healthy response rate was found suitable for the analysis. The background information of the respondents was analyzed using the frequency distribution and percentage while the main objectives of the study was analyzed using the mean score and multiple regression analysis.

FINDINGS AND DISCUSSION

The data was adequately analysed and the results presented on tables.

Risks associated with Stakeholders at Pre-Contract Stage

Risks associated with stakeholders at the pre-contract stage of construction were assessed based on the level of occurrence and level of severity.

Table 1 shows the level of occurrence of risk factors that are associated with stakeholders at the pre-contract stage of construction. The result shows that poor communication between stakeholders, unethical conduct by stakeholders and breach of confidentiality in tendering process are the risks with very high occurrence at the pre-contract stage of construction. Other risk factors have high occurrence except misuse of resources by stakeholders, inadvertently creating a contract without the delegate's prior approval, insufficient number of responses from tenderers and reduction in firm size of organization which occur low. This implies that most of the risks occurred at the pre-contract stage of construction projects.

Table 1: Level of Occurrence of Risks

Risk Factors	Mean	Rank
Poor communication between project stakeholders.	3.71	1
Unethical conduct among project stakeholders.	3.60	2
Breach of confidentiality in tendering process.	3.56	3
Government building policies.	3.43	4
Inadequate time at the pre-contract stage.	3.37	5
Delays in approval of design by the government.	3.36	6
Impractical timeframe.	3.36	6
Clients delay in making decision.	3.35	7
Dispute between consultants.	3.35	7
Misinterpretation of client needs.	3.32	8
Inadequate information dissemination.	3.32	8
High tender figure of tenderer.	3.30	9
Insufficient site investigation.	3.24	10
Poor organization structuring of project team.	3.19	11
Understatement of clients need.	3.06	12
Overstatement of clients need.	3.03	13
Failure to adequately address enquiries from tenderers.	3.03	13
Unfair requirements on the tenderer in the contract conditions.	3.01	14
Misuse of resources by stakeholders.	2.99	15
Inadvertently creating a contract without the delegate's prior approval.	2.81	16
Insufficient number of responses from tenderers.	2.67	17
Reduction in firm size of organization.	2.62	18

Table 2 shows the severity of the risk factors assessed. The result revealed that unethical conduct among project stakeholders, government building policies, delays in approval of design by the government; inadequate information dissemination, poor communication between project stakeholders, insufficient site investigation, etc are the most severe risks. Other risks are severe while inadvertently creating a contract without the delegate's prior approval, insufficient number of responses from tenderers and reduction in firm size of organization are the less severe risks. This implies that most of the risk are severe at the pre-contract stage of construction project.

Table 2: Level of severity of risks

Risk factors	Mean	Rank
Unethical conduct among project stakeholders.	4.07	1
Government building policies.	3.76	2
Delays in approval of design by the government.	3.72	3
Inadequate information dissemination.	3.59	4
Poor communication between project stakeholders.	3.58	5
Insufficient site investigation.	3.56	6
Overstatement of clients need.	3.53	7
Inadequate time at the pre-contract stage.	3.52	8
Impractical timeframe.	3.49	9
Misinterpretation of client needs.	3.47	10
Dispute between consultants.	3.45	11
Poor organization structuring of project team.	3.43	12
Misuse of resources by stakeholders.	3.41	13
Clients delay in making decision.	3.36	14
Breach of confidentiality in tendering process.	3.27	15
Understatement of clients need.	3.22	15
Unfair requirements on the tenderer in the contract conditions.	3.12	17
High tender figure of tenderer.	3.09	18
Failure to adequately address enquiries from tenderers.	3.08	19
Inadvertently creating a contract without the delegate's prior approval.	2.97	20
Insufficient number of responses from tenderers.	2.93	21
Reduction in firm size of organization.	2.76	22

Strategies adopted by Stakeholders in reducing Risks

Table 3: Strategies Used in Reducing Risks

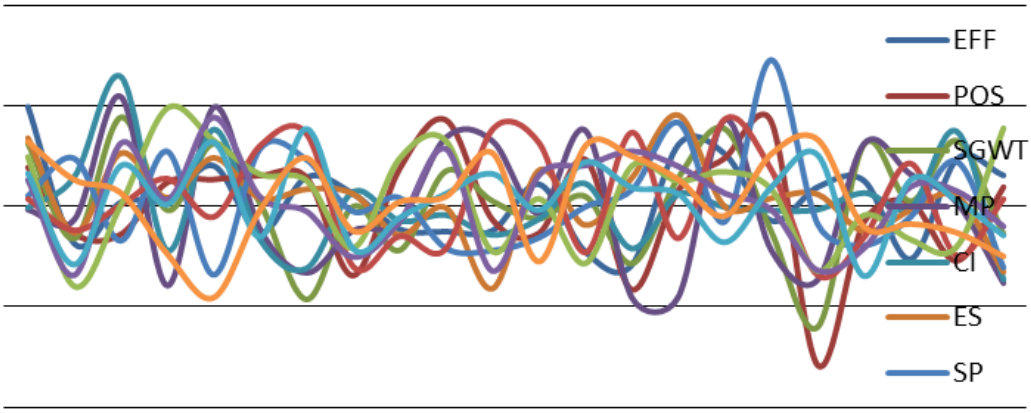
Strategies	Mean	Rank
Consultants should carry out in-depth investigation of site conditions directly from site for prompt approval.	4.36	1
Identify possible risk at the early stage and accessing them appropriately.	4.31	2
Clients should clearly define what they want in the brief.	4.21	3
Constantly reviewing all specification before selecting a contractor.	4.13	4
Client contingency is to be reviewed prior to the appointment of contractor.	3.97	5
Project team should always maintain close relationship with the government officers to shorten the time for approvals.	3.95	6
Constructing a well structured organization for the consultants.	3.86	7
Government bodies should avoid bureaucracy and create a swift environment to support the project development.	3.60	8

Table 3 shows the strategies that can be used by the stakeholders in reducing risks at the pre-contract stage. The result revealed that all the identified strategies are effective in reducing risks at the pre-contract stage of construction. Though the strategies which are consultants should carry out in-depth investigation of site conditions directly from site for prompt approval, identifying possible risk at the early stage and accessing them appropriately, clients should clearly define what they want in the brief and constantly reviewing all specification before selecting a contractor are the most effective strategies in reducing risks at the pre-contract stage.

The Effect of Risks on Performance of the Stakeholders at Pre-Contract Stage

The effect of risks on the performance of stakeholder was determined using the multiple regression analysis. The result in figure 1 shows the regression coefficient and this indicates that the identified severe risks has significant effect on the performance of the stakeholders though poor organization structuring of project team has no significant effect on the capital intensity of the stakeholders, so also unfair requirements on the tenderer in the contract conditions has no significant effect on stakeholders' profit.

Figure 1: The Effect of Risks on the Performance of Stakeholders



Discussions

This section of the report discusses the findings of the study with respect to past studies.

Risk Associated with Stakeholders at the Pre-contract Stage

From the data analyzed, it was discovered that risk occur at the pre-contract stage of construction projects in various forms such as poor communication between project stakeholders, unethical conduct among project stakeholders, breach of confidentiality in tendering process, government building policies, inadequate time at the pre-contract stage delays in approval of design by the government. This finding corroborates the assertion of Winch (2002), that the level of uncertainty is at the highest at the pre-contract stage and also that of Odeyinka (2006) which state that inadequate information at the pre construction stage often leads to design risk at the construction phase of construction project.

The severity of the risk factors was also assessed, the result shows that all the risk were severe at the pre-contract stage of construction project. Unethical conduct among project stakeholders, government building policies, delays in approval of design by the government, inadequate information dissemination, were rated as the most severe risk. This is in support of Winch (2002) assertion that the risk has severe impact at the design phase of construction and most of the impact are felt at construction phase of construction project.

Strategies Adopted by Stakeholders in Reducing Risk at Pre-contract Stage

Result from the study shows that stakeholders uses several strategies in other to reduce risk at the pre-contract stage among this strategies are consultants always carrying out in-depth investigation of site conditions directly from site for prompt approval, identifying possible risk at the early stage and accessing them appropriately, clients clearly defining what they want in the brief and constantly reviewing all specification before selecting a contractor. The strategies listed were all found relevant in reducing risk and this corroborate the findings of Harvey (2006) who purported that strategy adoption level is relatively high for risk adoption and mitigation and that 62 percent of firms believe that formal risk assessment and mitigation procedure are used for reducing risk by firms. The findings in this study is also in support of Kikwasi (2011) finding that good risk management involves more than creating a simple

check list of risk and that firms conduct extensive risk mitigating procedures as soon as they become involved in a project. While the findings in the this research work is in contrast with Zumrawi (2014) which stated that 55 percent risk is reduced by choosing the right procurement method and suggested that public private partnership reduces risk when used to build new project as it has helped in addressing shortfalls currently faced in U.S infrastructure.

The Effect of Risks on performance of stakeholders at the pre-contract stage

The effect of risks on the performance of stakeholders at the pre-contract stage of construction project was assessed and the finding showed that the listed performance variables are significantly affected by risk at the pre-contract stage of construction project. This corroborates the findings of Tesma (2002), that the performance of stakeholders efficiency of services rendered by stakeholders reduces due to the impact of risk.

CONCLUSION

The paper assesses the risks associated with stakeholders at the pre-contract stage of construction project. The findings shows that risk with very high occurrence at the pre-contract stage of construction includes poor communication between project stakeholders, unethical conducts among project stakeholders, breach of confidentiality in tendering process and government building policies. Unethical conduct among project stakeholders, government building policies, delays in approval of design by the government and inadequate information dissemination among others are the most severe risks associated with stakeholders at the pre-contract stage. The most effective strategies used by stakeholders in reducing risk includes carrying out in-depth investigation of site conditions directly from site for prompt approval, identification of possible risk at the early stage and accessing them appropriately and clients should clearly define what they want in the brief.

The performance of stakeholders at the pre-contract stage is significantly affected by risks at the pre-contract stage of construction. The implications of the study are that project managers should construct the project organisation structure and coordinate other stakeholders in other to avoid the very high occurring risks at the pre-contract stage and delays in approval of design by the government. The project stakeholders should maintain swift relationship with government agencies and building policies so as to guide against the most severe risks. Also, the most effective strategies should be continuously adopted by stakeholders at the pre-contract stage of construction project since risks can be transferred to the post contract stage of construction. Lastly, stakeholders should carefully assess and manage the risks which can affect the efficiency of their service, growth, quality and quantity of resources and so on

ABSTRACT

This study examined the impact of macroeconomic factors on production costs of selected storey building elements in the South-South region of Nigeria. Cost data of two hundred and forty (240) projects were collected from building contractors using stratified sampling technique. The survey covered the period between 2003 and 2012. Multiple regression technique was used in examining the relationships between dependent and independent variables of the study. Pearson product moment correlation coefficient (r) was used for assessing the contribution and direction of the relationships among the variables of the study. The major finding is that macroeconomic variables impact production cost of building project in the study area. The paper recommends that Government should adopt appropriate measures in curbing inflation and also minimize high and fluctuated exchange rate of the Naira to US dollar in order to achieve reliable cost estimate and enhance overall project cost performance.

Keywords: Building project, Macroeconomic indicators, Production cost

INTRODUCTION

The building industry plays a major role in the economic growth and socio-economic development of a nation. This industry is a subset of the construction industry and is rated as one of the most important sectors of the Nigeria economy (Adedeji, 2008). Some achievements of Nigerian building industry are the construction of housing estates, industrial complexes, public and institutional buildings (Jambol & Yusufu, 2004). Lam, Chan and Chan (2010) view building as valuable assets of a nation that provides people with shelter and facilities for work and leisure. The nature of the industry allows the participation of both private and government institutions as its key players. However, government influences most of the actions of the industry through its institutions, policies and economic/regulating tools. The unique features of the industry, number of stakeholders, myriad of tasks and environment it operates makes the building process complex. Prediction and realization of project objectives in terms of cost, time and quality form a global phenomenon which calls for the concern of every stakeholder in the industry. Researchers have therefore continued to intensify studies to proffer solutions to the various challenges of the industry because of its roles and contribution to the nation at large.

Building projects consume a lot of resources which oftentimes increase production cost. Prominent among the resources are material, labour, plant and equipment, finance, and other overhead costs. These resources are critical to the achievement of the final product of building project because of the contributory effect on production costs. Researchers have different view of what constitutes production cost. Chitkara (2008) defines production cost as the direct and indirect costs of resources associated with construction activity which are classified as cost of material, plant, and other costs (overhead costs). Haron and Mutalib (2012) view production cost as contractor's expenditure which includes all the resources involved during production excluding profit. These resources according to Rahman, Memon, Azis and Abdullah (2013), include material, manpower, machines and finance. The study

Adu, E. T. & Lamptey-Puddicombe, A. D. (2016). Impact of Macroeconomic Factors on Production Costs of Building Project in South-South Region of Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 814-824

observes that since the first three resources have element of finance, it will amount to repetition to classify finance as part of the resources. Production cost in this study is therefore identified as the direct and indirect costs of material, labour and plant for completing a construction activity.

A typical building cost component for social housing schemes in Denmark, according to Bertelsen and Nielsen (1997), is divided into materials 50 percent, labour 30 percent, heavy equipment 5 percent, while construction management and supervision absorb the other 15 percent. The result of the study by Skoyles (2000) confirmed that the cost proportion of material in building construction projects vary from 55% to 65% while materials, according to the findings of Ibrahim, Roy, Ahmed, and Imtiaz (2010), account for 50-60% of the total project cost in Nigeria. Labour on the other hand is an indispensable input in construction and one of the largest parts of construction cost (Nwachukwu & Emoh, 2011). The study by Hanna, Taylor, and Sullivan (2005) indicates that labour cost in construction industry is estimated at 33%- 50% of the entire project cost. Plant and equipment are also crucial in achieving time and cost objectives of project work. Plant and equipment being a vital input play the role of transformation in construction projects though most Nigeria construction industry compared to other developed countries still depends on manual methods.

Establishing accurate production cost of building project at tendering stage is one of the challenges facing the industry. The industry is reputed for project construction beyond the initial budget. This concurs with observation by Achuenu (1994) that one of the major problems facing the Nigerian Construction Industry is the fact that almost all projects are completed at sums higher than their initial contract sum. Factors that are affecting cost prediction in the industry are diverse and can be traced to a large extent to the economic situation of the nation in which it operates. This is due to the ripple effect of a change in the economic indicators over other sectors including the building industry. For instance, high rate of inflation increase the cost of living and a shift of resources from investments to consumption. Conversely, low inflation implies lower cost of borrowing. Prices of construction resources including material and labour increase during inflation and this will invariably increase production cost.

Abimbola (2000) attributed the rising trends of construction cost to government policies, inflation in the economy and project design variables. Dwindling of the macroeconomic indicators has presents a big challenge to the cost estimator in ensuring that the gap between initial and final budgets is kept close. The problem of inaccurate cost prediction is as old as the building industry. Several studies have been carried out to ensure that the "big monster", inaccurate cost prediction is surmounted (Enshassi, Mohamed, & Abdel-Hadi, 2013; Dysert, 2006; Odusami & Onukwube, 2008) but the realization of accurate production cost estimate is still far from reach which is the main concern of this study. There is need to understand the trend and impact of macroeconomic factors on building project in order to increase accuracy of cost prediction. The study observes that little research has been done to establish the relationships between construction cost especially production cost which is a major component of the overall project cost and macroeconomic indicators.

Macroeconomic indicators unleash much impact on construction industry as such, this study intends to investigate the effect of selected macroeconomic variables on production cost with the view of enhancing the contractor`s bidding decisions and to be informed in advance of the factors to focus on during construction. The research objective is to establish if there is a relationship between macroeconomic factors and production cost of building project in Nigeria. The key macroeconomic indicators selected for this study are inflation rate, interest rate, exchange rates, money supply, and Gross National Product (GNP). The hypothesis for

the study is stated as: macroeconomic indicators have no impact on the production cost of building projects. The result of the study will better inform the contractors for their bidding decisions based on macroeconomic performance and to develop strategies to achieve cost performance of their building projects.

LITERATURE REVIEW

Effect of Macroeconomic Indicators on Building Production Cost

One of the key factors affecting building production cost is the overall health of the nation`s economy. This is generally measured by economic indicators such as the GDP, employment data, manufac turing activity, the prices of goods, etc. Khalid, Iqtidar, Muhammad, Mehboob (2012) identify macro-economic factors which are real GDP, the unemployment rate, the inflation rate, the interest rate, the level of the stock market, and the exchange rate. Macroeconomic indicators influencing housing prices in Malaysia according to Tse (2013) include interest rate, cost of construction, population and inflation rate. Oladipo and Oni (2012) opine that economic indicators that are significant the overall construction cost in Nigeria include exchange rate of local currency to other currencies, inflation rate and interest rate charge on loans. Gambo and Ashen (2012) observe that the declining Nigeria economy with its effect on construction pricing have posed a major problem to both public and private sectors, clients and contractors.

Macroeconomic indicators are directly or indirectly responsible for increase in production cost of construction project. This is as a result of their direct and indirect effects on production components such as material, labour, and equipment/plant which collectively affect overall project cost. Since construction industry is import dependent, Udeh (1991) stated that about 50% of the building materials and components used in the industry are sourced from overseas. Plant and machinery used in the construction industry are manufactured in developed nations and imported to the developing countries which are equally subjected to inflation rate of the local currency and foreign exchange. Raw materials used for the manufacturing of the building materials are imported (e.g., clinker for making cement) (Humphrey and Dorothy, 2013). Gyntelberg (2007) also realizes that most machine and equipment used in the developing nations are foreign sourced and their costs may be influenced by government fiscal policy; these factors and many more are affected by variables such as inflation rate, exchange rate, money supply and GDP. Oyediran (2006) opine that projects that are financed solely by the contractor during an inflationary period may put the contractor in a difficult position financially except a serious calculation of cost increases for both anticipated and unanticipated increase had been included in the estimate process.

Research questionnaire carried out by Oladipo and Oni (2012) revealed five most significant factors impacting building material prices in developing countries. The factors are inflation, exchange rate, import, interest rate and money supply. Aliyu, Kasim and Martin (2011) identified scarcity and high cost of imported building materials or those with foreign components as factors affecting housing development. Ogun, Ogunsina, and Ugochukwu (2014) undertook a study on assessment of the impact of inflation on construction material prices in Nigeria, with a focus on Lagos for the period 1998 to 2007. The study employed descriptive analysis and regression model in inferential analysis. The result of the study showed that increase in construction material prices is not only caused by inflation, but also other macro-economy factors such as importation, interest rate and GDP. High cost of building materials has been identified as one of the major problems militating against the construction industry in most developing countries (Humphrey & Dorothy, 2013). Oladipo and Oni (2012) strongly believe that increase in prices of building materials (which constitute

a major component of building production) would have multiplier effect on construction industry. David, Umeh and Ameh (2010) also examined the effect of exchange rate fluctuations on Nigerian manufacturing industry. They employed multiple regression econometric tools which revealed a negative relationship between exchange rate volatility and manufacturing sector performance. In a study of the Nigerian Construction Industry, Omoregie and Radfort (2005) sampled the opinions of contractors, consultants and clients and they discovered 15 factors responsible for project delays and construction cost escalation in Nigeria. Their survey revealed price fluctuation as the most severe cause of project cost escalation which is attributed to the limitation in exchange rate which in turn affects construction material prices and general price level. Obansa, Okoroafor, Aluko and Millicent (2013) also examined the relationship between exchange rate and economic growth in Nigeria between 1970-2010. The result indicated that exchange rate has a strong impact on economic growth. The key macroeconomic indicators adopted in this study are discussed below.

Inflation rate

Demberg and McDouglall referred to inflation as continuing rise in prices as measured by an index such as the Consumer Price Index (CPI) or by the implicit price deflator for Gross National Product (Jhingans, 2002). According to Fatukasi (2004) inflation is characterized by a fall in the value of the country's currency and a rise in her exchange rate with other nation's currencies. Leaders all over the world see inflation as an economic phenomenon to worry about (Oyediran, 2006) and are one of the most important macroeconomic indicators that truly influence economy of any nation**.** Exchange rate is a major determinant of inflationary rate in Nigeria (Fatukasi, 2014). When inflation begins to move upward, it likely leads to tight monetary policies which result in increase in the discount rate. The effects of inflation on the economy are diverse and can be both positive and negative. Fatukasi (2014) states that inflation has had adverse effects on savings, investment, productivity and balance of payment in the Nigerian economy, hence the fall in the growth rate of the GDP from 26.8% (1981) to 5.4% (2000) and 3.5% (2002). Oyediran (2006) explains that the effects of inflation on the construction industry may be as a result of the nature of the process and the rate of return for work undertaken on construction projects. The negative effects are however more pronounced and comprise a decrease in the real value of money as well as other monetary variables over time (Blanchard, 2000). This has caused serious effects on building production cost in Nigeria.

Interest Rate

The primary role of interest rate is to help in the mobilization of financial resources and to ensure efficient utilization of resources for the promotion of economic growth and development (CBN 1970). If the financial banks increase the availability of credit, it means that the bank will provide lower lending rates and encourage current and future activity (Tse, 2013). When interest rates increase, investment, net exports and consumption tend to go down. The case is the opposite when it comes to decreasing interest rates. An increase in interest rate means that the consumer i.e., households have to pay more to finance their consumption. High interest rate regimes lead to high cost of borrowing and hence a reduction in economic activity (Victor and Kuwornu, 2011) especially in construction which also impacts on production cost and corporate profit. High interest rates for financing of equipment and machinery discourage firms to invest in construction.

Exchange Rate

Exchange rate is the price of one country's currency expressed in terms of some other currency (Adeniran, Yusuf & Adeyemi, 2014). Exchange rate defines the price of Nigeria's naira expressed in terms of one unit of the United States dollar. It can affect the relative

prices especially foreign products required in a given construction project. Arize, Osang, and Slottje (2000) found a significant negative relationship between increases in exchange rate volatility and exports in developing countries. Exchange rate changes can affect the relative prices, thereby the competitiveness of domestic and foreign producers (Fatukasi, 2014). When the domestic currency depreciates against foreign currencies, export product prices will decrease, and consequently, the volume of the country's export will increase, assuming that the demand for this product is elastic. According to Ewa (2011) the exchange rate of the naira was relatively stable between 1973 and 1979 during the oil boom era and when agricultural products accounted for more than 70% of the nation's GDP. The reverse is the case as the naira has depreciated since 80`s despite various efforts by the government to maintain a stable exchange rate. Exchange rate as an indicator of a currency is a monetary variable that affects the building industry in a way similar to inflation variables.

Money supply

Money is a collection of liquid assets that is generally accepted as a medium of exchange and for repayment of Debt (Singh, Mehta, & Varsha (2011). There is a strong link between money supply and inflation rate. When the money supply increases, the inflation rate decreases. If the inflation rate increases the money paper demand drops to get in balance (Blanchard, 2003). Increasing in money supply in an economy also leads to decrease in interest rate and construction industry in activities during this period as a response to a higher demand by the clients.

Gross Domestic Product

The gross domestic product (GDP) is the total market value overall for all final goods and services produced in a country in a particular year (Tze, 2013). The formula for the GDP is equal to the total consumer, investment and government spending, plus the value of exports minus the value of imports.

METHODOLOGY

The study area is the South-South region of Nigeria comprising Akwa Ibom, Bayelsa, Cross River, Delta, Edo, and Rivers State. Data for the study consists of average production cost of six selected building elements of storey building projects and key Nigerian macroeconomic indicators such as inflation rate, interest rate, exchange rate, money supply and GDP. The six selected one to two storey building elements are substructure, frame, upper floor, internal and external walls, roof and finishing. The choice of the select building elements was on the basis of characteristic and availability of data from educational and office building projects completed during the study period. The production cost of each of these elements was sourced from contractors` cost files of completed federal and state storey building projects in each state. The data on macroeconomic indicators were sourced from various annual reports and statements of account of Central Bank of Nigeria and issues of Statistical Bulletin. The sample covers 2003 to 2012. The time frame was considered adequate to reflect the economic climates and political influence in Nigeria during the period. The study uses stratified random sampling technique. The study was carried out from the state capital of each state being the hub of each state where most construction activities are concentrated.

The mean of building production cost per square meter of 240 projects of the selected building elements over the study period were computed on yearly average using excel package and presented together with macroeconomic indicators as presented in Table 1. Multiple regressions were used in determining the existence of relationships if any between the dependent and independent variables of the study. Pearson moment correlation was used in assessing the magnitude and the direction of the relationships between and among the variables of the study. The Y variable of the multiple regressions is given as the building

production cost per square meter while the X variable is the macroeconomic indicators specified in its functional form as follows:

$$BPC = Bo + \beta 1INF + \beta 2INR + \beta 3EXR + \beta 4MNS + \beta 5GNP + \varepsilon$$

Where:
BPC= the building production cost
B_o= the intercept,
β_1 to β_5 = the partial slope coefficient,
ε= the stochastic disturbance term,
INF= inflation rate (percent),
β_2INR= interest rate (percent),
β_3EXR= exchange rate (₦: US$),
β_4MNS= money supply,
GNP= gross national product.

Presentation and Analysis of Data

This section presents data for the study and empirical analysis of the impact of macroeconomic indicators on production cost of storey building projects. The obtained data spanned the period between years 2002 to 2013. The secondary data was organized in excel spread sheets and analyzed using SPSS version 17.0.

Table 1: Inflation rate, interest rate, exchange rate, money supply and GDP (2002-2013) and Average Production Cost/m²

Correlation Analysis

Data sampled were employed for the analysis of the Pearson moment correlation between and among the variables of the study. The Pearson correlation coefficient is a measure of strength of association between two variables. Pearson correlation coefficients assume the data are normally distributed. The values of the correlation coefficient range from -1 to 1. The sign of the correlation coefficient indicates the direction of the relationship (positive or negative). The Pearson Moment Correlation was used in analyzing the data obtained in Table 1. The results of the Pearson Moment Correlation coefficients for each pair of the variables selected for the study are presented in Table 2.

Table 2: Results of Correlation Coefficients computed between Building Production Cost and Macroeconomic Indicators

VARIABLE CODE	VARIABLES	BPC	INF	INR	EXR	MNS	GDP
BPC	Building Production Cost						
INF	Inflation Rate	-.309					
INR	Interest Rate	-.248	.143				
EXR	Exchange Rate	.806**	-.017	-.295			
MNS	Money Supply	.980**	-.214	-.255	.825**		
GDP	Gross Domestic Product	-.475	.111	-.009	-.159	-.403	

* * Correlation is significant at 0.01 level (2-tailed)

The Table shows the existence of an inverse and weak relationship between inflation, interest rate, Gross Domestic Product and building production cost at $p < 0.01$ level of significance (2-tailed). The relationships between each of the variable and building production cost indicated in the Table by their Pearson Moment Correlation coefficient in Table 2 are -.309, -.248 and -.475 respectively. However, the results from Table 2 revealed the existence of a positive and strong relationship between exchange rate, money supply and building production cost with their Pearson Moment Correlation coefficient of 0.806 and 0.980 respectively.

Regression Analysis

The dependent variable was regressed against independent variables: inflation rate, interest rate, exchange rate, money supply and GDP. The regression analysis was undertaken at 5% confidence level. The criteria for comparing whether the predictor variables were significant in the model was done by relating the corresponding probability value obtained and $\alpha = 0.05$. F-table statistic was compared with the one obtained from the regression analysis. If the one from the table was smaller than the computed value from regression analysis, the value was significant in predicting a change on the dependent variable. Otherwise, the variable was insignificant in the model. The result of regression analysis is presented below.

Model Summary Statistics

The study obtained the model summary statistics as shown in Table 3 below.

Table 3: Model Summary ([b])

Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Change Statistics	
					F Change	Sig. F Change
1	.990[a]	.981	.957	612.06636	40.795	.002

a. Predictors: (Constant), Gross Domestic Product, Interest rate, Inflation rate, Exchange rate, Money supply

b. Dependent Variable: Production cost / m^2

The coefficient of determination or adjusted R^2 shows the extent to which changes in the building production cost in Nigeria varies with the independent variables, inflation rate, interest rate, exchange rate, money supply and GDP. Research findings indicate that there is a very strong positive relationship between the variables with an adjusted R square of 0.957. The study therefore establishes that any variability in building production cost is explained in inflation rate, interest rate, exchange rate, money supply and GDP. The results from Table 3 also indicate the value of R^2 as 0.981 which implies that the macroeconomic indicators used as predictor variables used in this study contribute to an equivalent of 98.1% of variability in building production cost as indicated by the R-Square value of 0.981.

Analysis of Variance

The study conducted an Analysis of Variance, in order to test the significance of the model. The results of the analysis are presented in Table 4 below.

Model		Sum of Squares	Mean Square	F	Sig.
1	Regression	7.641E7	1.528E7	40.795	.002[a]
	Residual	1498500.895	374625.224		
	Total	7.791E7			

Results from Table 4 indicate that probability value of 0.002 was obtained implying that the regression model was significant in predicting the relationship between building production cost and the predictor variables as it was less than α=0.05.

Model Coefficients (a)

The results of the analysis obtained the model coefficients and corresponding statistics as shown in Table 5 below.

Model		Unstandardized Coefficients			
		B	Std. Error	t	Sig.
1	(Constant)	16190.57	6198.173	2.612	0.059
	Inflation rate	-92.246	56.663	-1.628	0.179
	Interest rate	13.954	94.158	0.148	0.889
	Exchange rate	43.427	49.247	0.882	0.428
	Money supply	0.001	0	5.398	0.006
	Gross Domestic Product	-196.385	136.795	-1.436	0.224

a. Dependent Variable: Production cost / m^2

The regression analysis results indicated that the relationship between real estate investment growth and the predictor variables can be expressed using the following regression equation:

$$Y = 16190.57 - 92.246X1 + 13.954X2 + 43.427X3 + .0.001X4 - 196.385X5 + \mu e$$

The results showed that inflation rate and GDP have negative relationship with building production cost; while interest rate, exchange rate and money supply displayed positive relationship. The level of significance of results is acceptable for inflation with p-values not greater than 0.05. However, p-values of inflation rate, interest rate, exchange rate and GDP with corresponding values of 0.179, 0.889, 0. 0.428 and 0.224 respectively > 0.05 while money supply value is 0.001< 0.01.

Interpretation of the Findings

The results in Table 2 indicate the existence of an inverse and weak relationship between inflation, interest rate, GDP and building production cost. Conversely the results from Table 2 also reveal the existence of a positive and strong relationship between exchange rate, money supply and building production cost. The results of regression analysis establish a strong statistical relationship between the selected macroeconomic variables - inflation rate, interest rate, exchange rate, money supply and GDP and the building production cost since R and R-Square was 0.953 and 0.908 respectively. This suggests that macroeconomic indicators contribute 98.1% to changes in building production cost among other factors that affect building production cost. The R value of 0.953 shows that the relationship between building production cost, on one hand, and macroeconomic indicators, on the other hand, is also highly significant. The R-Square value in this study was greater than R-Square (0.5133) in predicting project cost performance level by assessing risk factors of building construction in South Korea by Cha & Shin (2011). Based on the results of regression analysis the relationship between building production cost and the predictor variables can be expressed using the following regression equation: $Y = 16190.57 - 92.246X_1 + 13.954X_2 + 43.427X_3 + .0.001X_4 - 196.385X_5 + \mu e$. The coefficients corresponding to inflation rate and GDP are negative; the study therefore establishes a negative relationship between building production cost and inflation rate and GDP. The results of the analysis also indicate coefficients corresponding to interest rate, exchange rate and money supply are positive which proves a

positive relationship between building production cost and each of the macroeconomic variables. As a result, the study establishes a positive relationship between building production cost and interest rate, exchange rate and money supply. The level of significance of results is acceptable for money supply with corresponding p-value less than 0.05. Inflation rate, interest rate, exchange rate and GDP have their p values greater than 0.05, an indication of an insignificant relationship. The results of ANOVA further establishes a p-value of 0.002 which implies that the regression model is statistically significant in predicting the relationship between building production cost and the predictor variables as it was less than α=0.05.

The study agrees with the study of Zhu (2004) who establishes a strong and long-lasting link between inflation and housing price which is a product of production cost. The finding is also consistent with the work of Chileshe and Berko (2010) that identified inflation as the third most important factor contributing to project overrun in Ghana. Harrison (1981) attributes increasing costs to inflation of project. The results of the study are however at variance with Gambo and Ashen (2012) who establish negative coefficient of interest rate and positive coefficient of inflation rate in predicting construction cost escalation for residential buildings in Nigeria using economic indicators. Inflation causes price fluctuation of building production components which eventually could cause general project cost increase especially in the developing countries. The construction industry in Nigeria is foreign driven where majority of cost elements in building production are sourced abroad. Chan and Park (2005) attributed high cost of machineries to market related problems which has severely affected building production

CONCLUSION AND RECOMMENDATIONS

This study is on the evaluation of the impact of macroeconomic factors on production costs of building project. Macroeconomic variables used in this study are inflation rate, interest rate, exchange rate, money supply and GDP. From correlation analysis, exchange rate and money supply have a linear relationship with building production cost but evidence from regression analysis indicated that only the P-value of money supply is < 0.05 while P-value of exchange rate is > 0.05. Others variables including inflation rate, interest rate and GDP did not have a linear relationship with P-values > 0.05. From the findings in this study, the study concludes that there is a strong relationship between macroeconomic variables and production cost of building project. The study also concludes that there is negative relationship between building production cost and inflation rate and GDP. Conversely, there is a positive relationship between building production cost and interest rate, exchange rate and money supply. The model is expected to form a basis for decision making by providing reliable estimates for production cost of building projects. Based on the findings of the study, it is recommended that Government should adopt appropriate measures to curbing inflation and also minimize high and fluctuated exchange rate of the Naira to US dollar. Contractors should adopt suitable contractual strategies to cushion the effects of inflation and other macroeconomic variables in their projects. The model developed in this study if adopted will provide reliable estimates at early project stage and further enhance overall project cost performance.

ABSTRACT

Transportation is an essential need for humanity, be it land, air or sea based. It should devoid of operational handicaps. However, in Lagos State, In-land water based transportation encounters various kinds of impairments ranging from human induced to natural cause. To this end, this study explores the challenges encountering In-land water based transportation system in Lagos state. Adopting survey research design, both secondary and primary data were employed for the study. Secondary data were sourced from libraries, journals and relevant institutions such as Lagos State Waterways Authority (LASWA) wherein patronage data was gotten, while primary data were gotten through field observations, interview and structured questionnaires. Total of 228 (0.05%) users in three most patronized jetties, one each in a local government were purposively sampled, and administered a set of questionnaires, using accidental sampling technique. The study hypothesized that In-land water based transportation varies significantly between the Local governments areas (P=0.000). However, they encountered similar challenges according to findings. The study revealed that 34.6% of the respondents complained of the presence of water hyacinth. 44.3% of the respondents complained of poor safety measures. 26.8% of the respondents suggested clearing of the water hyacinth. 25.0% of the respondents suggested that the obstacles can be resolved through adequate funding and investment on Inland Waterways Transportation. This study recommends an integrated control method which is biological and mechanical removal of the water hyacinth for easy navigation on the waterways.

INTRODUCTION

Movement is a basic activity of man and it is impossible for man to do without it. Based on this need, and pursuit of development through science and technology, movement of man is aided through transportation. Transportation represents one of the most important human activities worldwide. Transportation is defined according to Oni (2009), as the conveyance of goods and people over land, across water, and through the air from one location to another.

Ighodalo (2009) observed that several modes of transportation exist for both man and goods; and that these modes, can be grouped into four basic categories, namely: rail, road, water and air. Water transport is associated with inland waterways, coastal waters and the deep sea (Ismaila, 2008). Inland waterways are navigable water bodies which include: rivers, lakes, coastal creeks, lagoons and canals, found within the geographical dimensions of a state (Aderemo and Mogaji, 2010). The movement of goods and services along inland waterways is one of the oldest means of transporting goods and services from point to point (Fellinda, 2006). This is largely due to the fact that inland water transport (IWT) offers the most economical, energy efficient and environmental friendly means of transporting all types of cargo from place to place (Ojile, 2006).

The development and efficient functioning of IWT is very essential highly congested cities to cushion the high demand and over stressed other means of transportation such as land. Example is a megacity like Lagos state, which has a high demand on urban transport, especially road mode whereby six million passengers hustle daily between Lagos mainland

Akinbamijo, O.; Ipingbemi, O. & Bayode, T. (2016). In-Land Water Based Transport in Lagos State: Challenges and Remedies. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 825-831

and island. In Lagos State over 98% of movement is done by road, and cities of this size cannot survive on one mode of transportation (Frontier Market Intelligence, 2014).

It is unfortunate that Lagos, a coastal city with abundant navigable waterways has its waterways minimally exploited. If optimized, it could help in eliminating congestion, pollution, and provide a low cost alternative to long haul passages. Despite these many rewards, In-water based transportation system encounters a number of challenges which if managed; it will effectively complement and reduce the pressure on road transport in Lagos State. Obed (2013) lamented that there has been a considerable decline in the use of IWT in Nigeria. This was attributed to several physical constraints impending growth and performance in the IWT sector in Nigeria. This creates an urgent need for innovative actions and strategies to radically improve the sector for it to continue as the bedrock in facilitating trade, industrial and economic growth. Therefore, this study examines the challenges militating the effective usage of In-water based transportation system with the view of finding solutions to managing the challenges encountered by this mode of transportation.

Few researches have been done on challenges of waterways in Nigeria. Among the few researches, Ezenwaji (2012) in his study on the constraints on effective water transportation in some riverine communities of old Anambra local government area identified some challenges confronting IWT with the hope that the elimination of such constraints would serve as a catalyst to economic development of such areas. The result of the analysis showed that there are four prominent constraints namely environmental, economic, craft and market.

Environmental constraint is the most important underlying factor militating against effective water transportation. The length of the river covered by water hyacinth seems to pose a great problem as it is difficult for boats to ply where there are large numbers of the water weeds. Rangaraj and Raghuram (2007) emphasized that unless the waterways are cleared of water weeds no meaningful transportation can take place. In Anambra River and its tributaries, water weeds at times cover over 75% of the width of the river for a continuous stretch of upwards of 3kms accounting for the high risk of boat capsizing. The absence of budgetary provision for water transportation over the years is a big constraint to effective water transportation. For a long-time now, Anambra State Government has made no budgetary provision for this sector and as a result no funds have been released to the sector by the government. Absence of markets or attraction between origin and destination of places linked with waterways often times affect the level of patronage of the transport mode. This results in low business profit for the operators. Based on the findings, Ezenwaji (2012) recommended prompt and adequate intervention of State Governments to the mode, through inclusion of the sector in the budget; very low water transportation fares and high cost of boat maintenance should be addressed both by the State government and boat operators through their transport union.

Some other inherent challenges facing the sector noted by UN-ESCAP reviewer (2003) include: Safety - Safety is often compromised because IWT tends to be ignored by existing government transport regulations and environmental safety standards. Certain environmental problems and risks associated with IWT include canalization and dredging (reactivation of polluted sediments into surface waters); shipping operations (pollution through oil spills; noise pollution; risks of accidents with dangerous cargoes); and import of invasive species: (bacteria and other microbes, small invertebrates and the eggs, cysts and larvae of various species) (Gascho *et al*., 2006).

Study Area

The study area is Lagos state with a particular focus of waterways where water based transportation operates. Lagos State is the smallest state in geographical terms in the Nigerian

Federation, it occupies an area of 357,700 hectares (3,475.1km^2), which is just 0.4% of the total land area of Nigeria (Adejare *et al*., 2011), of which 22% of the total land mass consists of lagoons and creeks. Lagos State lies between longitudes $2^0$42' East and 3^0 42' East and Latitude 6^0 22' North and 6^0 52' North, in the southwestern area of Nigeria and shares boundaries with Ogun State both in the north and east, by the Republic of Benin in the west and the Atlantic Ocean, stretching for almost 180 kilometres of coastline, in the south (Olayiwola *et al*., 2006).

Lagos state is a mega city with an estimated population of about 9 million inhabitants which is about 6.5% of the total population of Nigeria (Census, 2006). However, according to Michael (2012), the city of Lagos is expected to hit the 24.5 million population mark and thus be among the ten most populous cities by the year 2015. Twelve (12) out of the twenty (20) Local Governments of Lagos state are drained by rivers, which are: Badagry, Ojo, Amowo - Odofin, Apapa, Lagos Island, Eti - Osa, Kosofe, Somolu, Lagos Mainland, Ikorodu, Epe and Ibeju Lekki. However, Lagos state is running water transport on 12 routes under the supervision of Lagos State Water Authority (LASWA). The routes are Ikorodu-Marina/CMS; Marina-Mile 2; Ikorodu-Addax/Falomo; Ikorodu-Ebute Ero; Marina-Ijegun Egba-Ebute-Ojo; Mile 2-Marina/CMS-Mekwen-Falomo; Badore-Ijede; Badore-Five Cowries; Marina-Oworonshonki; Ebute Ojo-Ijegun Egba; Oworonshonki-Five Cowries; and Baiyeku-Langbasa. The metropolitan area accounted for the seventeen out of the twenty local government areas in Lagos State as shown in Figure 1.

METHODOLOGY

This is a non-experimental study, cross-sectional and descriptive in approach. The study employs the use of both secondary and primary data. The secondary data were sourced from libraries, journal publications, internet, institutions and archives. Secondary data consisting of statistics on water transport services, number of users and operators etc. were obtained from Lagos State Waterways Authority (LASWA). Techniques used for primary data collection include structured questionnaires, open ended individual conversation and field observations. Having gotten the patronage data between January to September, 2014 of the various jetty according to their local government of operations from LASWA as shown in Table 1, the

jetty with the highest patronage were purposively sampled, and they are Majidun in Ikorodu Local Government; Liverpool in Island and Ijegun Egba in Badagry/Ojo Local Government as shown in Table 2. A total of 228 questionnaires (0.05%) were administered to Inland water based transportation users using accidental sampling technique. The study hypothesized that Inland Waterways users does not vary significantly between the Local Government Areas; Analysis of variance (ANOVA) was used to test the variation in the number of users in the local government areas. Statistical Package for Social Sciences (SPSS) was used to obtain frequencies for the descriptive statistics.

FINDINGS AND DISCUSSION

Obstacles hindering water transportation

According to Table 3, 5.3% of the respondents responded that the river course is shallow thereby hindering navigation in some part of the waterways. 34.6% of the respondents complained of the presence of water hyacinth. The water hyacinth appears August and remains till February of the following year if not cleared. Water hyacinth has been a threat to operators on waterways because it damages the boat engine propeller. 44.3% of the respondents complained of poor safety measures. The life jacket giving to passengers were of poor quality and sub-standard. 15.8% of the respondents complained of other reasons which are lack of funding and investment from government and private body respectively, poor quality of vehicle, poor maintenance, facilities and waterways transportation management. Plate 1, 2 and 3 shows the presence of water hyacinth on the waterways, poor facility of Liverpool and CMS jetty respectively.

Table 3: Obstacles hindering water transportation

Obstacles hindering use of waterway transportation	Number of respondents	Percentage
Shallow river	12	5.3
Water hyacinth	79	34.6
Poor safety measures	101	44.3
Others (poor quality of vehicle, poor maintenance and waterways transportation management).	36	15.8
Total	**228**	**100.0**

Ways of overcoming challenges facing water transportation

Table 4 presents ways of overcoming challenges facing water transportation. In a bid to find a remedy to the obstacles encountered, the users also gave their opinion. 26.8% of the respondents suggested clearing of the water hyacinth. 25.0% of the respondents suggested

that the obstacles can be resolved through adequate funding and investment on Inland Waterways Transportation such as access to business loans and attracting investors to water transportation sector. These funding and investment can also be inform of provision of vehicles and facilities etc. 6.6% of the respondents noted that the operators (captain) lacks competent skills, they therefore suggested it is paramount they go for regular training on inland waterways transportation. 35.5% of the respondents of the also suggested that ensuring stringent safety measure is necessary to curb the poor safety measures practices such as non-compliance to laws governing IWT as directed by LASWA, non-use or misuse of life jackets, refusal to purchase fire extinguisher and life ring for their vehicles etc. 6.1% of the respondents did not give any suggestion.

Table 4: Ways of overcoming water transportation obstacles

Ways of overcoming waterways transportation obstacles	**Number of respondents**	**Percentage**
Clearing the water hyacinth	61	26.8
Funding and Investment	57	25.0
Personnel training	15	6.6
Stringent safety regulations	81	35.5
No response	14	6.1
Total	**228**	**100.0**

To test statistically the null hypothesis which stated that Inland waterways users does not vary significantly between the local government areas, Analysis of Variance (ANOVA) was used to compare the variation in the numbers of users between the local government areas in the study area. The result of the analysis presented in Table 5 shows that, there is significant difference between the numbers of users in the study area. The ANOVA is statistically significant at 95% level of confidence at the p value of 0.000. Since the p value is less than 0.05 ($P<0.05$), the null hypothesis is therefore rejected.

Table 5: ANOVA-Variation in Inland Waterways users between the local governments

b. Predictors: (Constant), local government

CONCLUSION AND RECOMMENDATIONS

This study explored the challenges encountered by In-land water based transportation system in the coastal areas of Lagos state with a view to finding a visible remedy to those challenges. Consequently, the study revealed that water hyacinth is a threat on the water channels. This highly invasive aquatic weed surfaces on the waterways in August till February every year, it blocks the routes by forming a mat on the waterways which makes movement difficult on the waterways. The government should ensure that agency responsible, be it government agency, should respond to this challenge appropriately. This study recommends an integrated control method which is biological and mechanical removal. Mechanical removal of the bulk of material followed by a multiple herbicide treatments of remaining plants can be used to control severe water hyacinth infestations, while minimizing water quality impacts.

Provision of security and safety measures like use of standard life jacket should be provided by the government. Also, the operators lack formal waterways transportation education. Consequently, their lack of formal education in this sector has affected their operations. Therefore, the government or agency responsible for IWT should ensure the operators upgrade their knowledge of IWT by going for workshops, training and obtaining relevant certification. Consequently, this will also reduce accident rate and improve customer (users)

management on the waterways. Lastly, government should dredge the shallow river course to aid navigation on the waterways.

Social Tenure Domain Model for Informal Land Title Registration in Akure, Nigeria.

Ojo Babajide

Department of Estate Management, Federal University of Technology Akure, Nigeria.
bojo@futa.edu.ng

ABSTRACT

Social Tenure Domain Model (STDM) is developed to support pro-poor land management; and to address the technical gaps that is associated with unregistered land, the upgrading of slums, urban and rural land management. In developing countries less than 30% of the land has cadastral overage. The implication here is that about 70% of the land is outside the formal land registration. This caused problems for billions of people living in slums without proper water, sanitation, community facilities, and security of tenure. This model was developed to accommodate a continuum of land rights; which include rights that are documented and undocumented; STDM provide a flexible and unconventional land administration system. It accommodates different types of spatial data with varying degree of accuracy in an integrated manner to generate a social tenure relationship and then integrate the data with formal land administration system (LAS). STDM main objective is to make every right on land to count and device a means of recording all spectrums of land rights; in order to open up new markets to the land industry. The methodology here include application of STDM in capturing unregistered land rights in pilot study and such land rights are integrated into formal land administration framework thereby creating new market opportunities. It is an unconventional method of gathering spatial data on property rights. The model is expected to be used for spatial data collection of land rights in informal settlements; the data so generated can then be integrated with formal land administration system. This model is recommended as a relevant documentation that is flexible, user- friendly and capable of being scaled up to address a wide range of land tenure issues with the aim of empowering the poor. STDM has the capacity to broaden the scope of land administration by providing land information management framework which can integrate formal, informal and customary land system.

Keywords: Land rights, Informal settlements, Social Tenure Domain Model, Registration, Administration

INTRODUCTION

The process of land administration includes an institutional arrangement for implementing land policies and land management strategies. It further include a legal framework, process, land information, management of information systems and technologies needed to support land market development, control of land use and sustainable development of interest and rights in land.

The infrastructures needed to carry out most of these functions are not readily available in many developing nations and where it exists, it is not at national coverage (Lemmen, 2010). The conventional Land Administration System (LAS) has its short comings; judging from the fact that LAS could not adequately take care of informal and customary tenures processes.

Several land tenure policy specialist working in Africa, Asia and South America since 1998 had identified technical gap in convectional land administration which was found to be unfit for some tenures due to what they attributed to their ranges of social tenures which conventional Land registration system could not accommodate. (UNECA, 1998, Migot-Adholla, Hazell, Blare and Place, 1991; Bruce and Migot-Adholla, 1993).

A number of people working on land administration field noted that conventional land administration systems were not appropriate for lands held under customary; pastoralist and slum areas. (Barry and Fourie, 2002; Fourie, Vander Molen and Groot, 2002). Augustinus,

Ojo, B. (2016). Social Tenure Domain Model for Informal Land Title Registration in Akure, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 832-840

Lemmen and Van Oosterom (2006) also emphasize the inability of conventional land administration system to handle customary and informal tenures. It was noted that conventional land titling had failed to deliver expected results due to its inappropriateness and inflexible process of providing tenure security. Observation revealed that this process had limited implementation; lacks coordination and partnership among stakeholders. Unfortunately, most developing nations lack the tools, systematic strategies to address the challenges of delivering secure land and property rights for all spectra of her society.

The concept of Social Tenure Domain Model (STDM) was developed to bridge this gap by providing a prototype for representing the relationship that exists between people and land. In tackling the technical gaps associated with unregistered land, upgrading of slums both in rural and urban centres; the social tenure domain model (STDM) was developed. (Augustinus, et al, 2006) (Global Land Tool Network (GLTN)).

STDM accommodates a continuum of land rights that ranges from documented to undocumented, legal and illegal land rights (GLTN). STDM is able to accommodate spatial data with varying degree of accuracy and the spatial data can still be integrated to generate a social Tenure relationship (Augustinus, 2010).

LITERATURE REVIEW

Challenges in Urban Land Management

Land dealings in most developing nations Nigeria inclusive are generally lacking in transparency. About 70 percent of the land areas are outside the land registry of many developing countries. The situation is directly linked with the chaotic and unsustainable cities development, conflicts and proliferation of slums (UM-HABITAT, 2008; Mabogunje, 2005)

Urban growth rate was estimated by the United Nation to be growing faster in developing nations. Several of the cities have slum formation and informal settlement. About 90% of the new urban settlements are in slum formation. A slum household as defined by UN-HABITAT, (2008) “are group of individuals living under same roof lacking one or more of the following: access to improved water; access to improve sanitation facilities; sufficient living area; structural quality and durability of dwellings, and security of tenure.

In Nigeria context and Akure in particular, it is still very difficult to establish the genuiness of land claim. The problems of “Omo-Onile” -the indigenous land owners – still persist; this is not unconnected with the fact that majority of the land owners in most cases cannot boast of formal title to their land holding. There are lacks of adequate databases for recording land holding unlike what operates in developed World.

The Land Use Act of 1978 is the major law that regulates land administration in Nigeria. This law notwithstanding; the confirmation of claims (rights) through the registration of title document or the statutory Certificate of Occupancy (C of O) in the land registries are very difficult to come by due to lack of efficient data capture and safeguarding of the integrity of information recorded. Application of new technological advances in the use of Aerial photography, Satellite imageries, Global Positioning Systems (GPS), Geographical Information System (GIS), Computerization, as well as, provision of land information software to manage information generated on land are still in infancy stage. (Nwilo and Osanwuta, 2004)

Lack of well developed modern land registries equipped with adequate infrastructure and information technology system to deliver information on land has been a critical challenge to effective urban land management. Majority of the thirty six (36) states in Nigeria lack properly developed land registries. Oboli and Nwilo, (2005) pointed out that out of the one

hundred and twenty (120) urban centres and seven hundred and seventy-four (774) local government headquarters in Nigeria, only twenty (20) cities and thirty local government headquarters in Nigeria have up-to-date land maps that can aid Land administration and land registration.

The existence of bureaucratic establishment that are involved in land matters even makes the procedures very difficult. The bureaucratic manage the urban land in a non-transparent manner. Corrupt practices are instituted that gives no room for accountability. The land managers are noted for perpetrating long, tedious and frustrating procedures for land title, perfection (Bisiriyu, 2008). The cost of title perfection is equally beyond the reach of common man.

In overcoming most of these problems there are needs for looking for alternative approach to bridge the gap technically created by conventional land administration system (LAS). This approach or tool must be pro-poor, affordable, gender sensitive, sustainable and capable of systematic scalability.

The Social Tenure Domain Model (STDM): Why STDM?

The Social Tenure Domain Model (STDM) was designed as a complimentary approach in land administration. The concept is to bridge the gap that exist in conventional land administration, by providing a prototype for representing the relationship that exist between people and land with a varying degree of technical accuracy. The STDM concept view rights to land lying on a continuum.

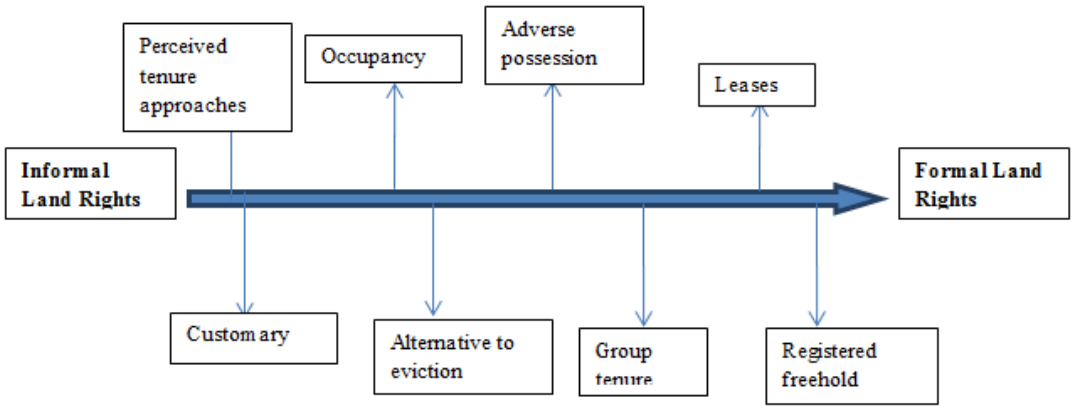

Figure 1: The Continuum of Land Rights (Adapted from GLTNs Continuum of Land Rights, Lemmen, 2010)

At the formal end of the Continuum are informal rights: a group of individuals such as clan, customary rights, traditional rights, pastoralist rights etc. these are sets of right to a piece of land that emerge from traditional rights. The boundaries of the land may not be clearly marked on the ground or presented in a map. There may not be an official paperwork certifying who owns such rights but they exist and are commonly recognized.

At another extreme are formal land rights, where owners of such rights are individual who hold a set of registered rights to a parcel of land that are enshrined in law: the parcel is delineated on a map; held in a record office. The owner has the right to occupy, transfer and prevent other people from using it.

However between these two extremes are a wide range of rights as simply illustrated in Figure 1 above. These rights sometimes overlap with one another. The registered freehold requires a complicated and costly administrative system with a reliable survey of the land parcels and good land governance. Unfortunately, the costs of formalization of land rights are far beyond the reach of the majority. The continuum of tenure types is a range of possible

forms of tenure. It provides different sets of right and degree of security and responsibility. Each of these rights requires different degree of enforcement.

STDM as sponsored by UN-HABITAT/ GLTN came up with land tool to capture the gaps that was identified with conventional land administration approach. Observation showed that conventional land administration is not suited for continuum of land rights and may not deliver security of tenure on large scale. The LAS only benefits the elites at the expense of the poor majority. In bridging this gap Social Tenure Domain Model (STDM) was developed.

STDM Conceptual Model

The STDM conceptual Model is presented in Figure 2 below:

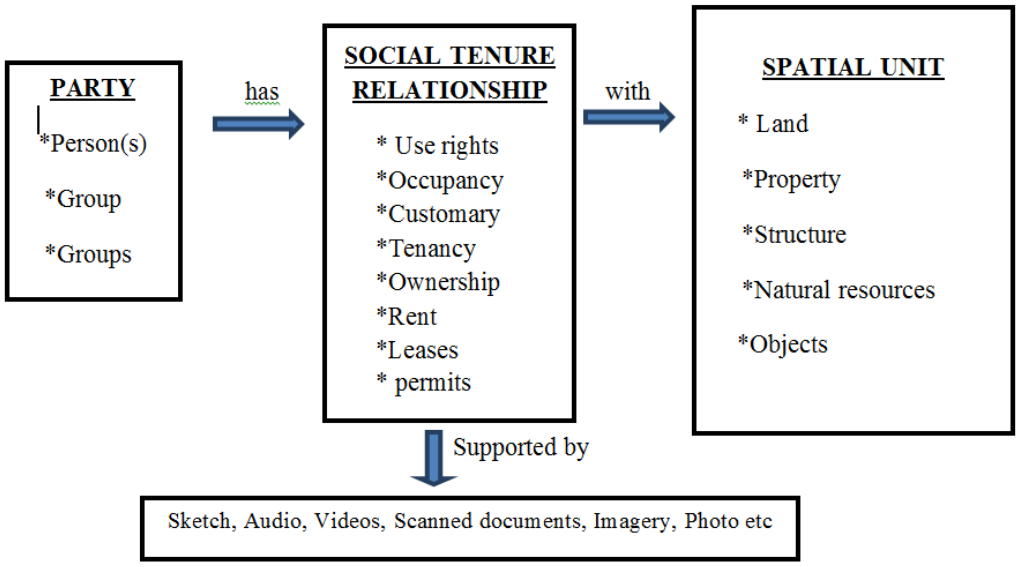

Figure 2: STDM Conceptual Model (Adopted from GLTN, FIG, UN-HABITAT, 2010)

STDM is an information tool for improved and efficient land recording. The STDM catch on the use of ICT tools that are now readily available and are becoming more efficient in recent time. STDM was born out of the urgent need to have a land information system that works differently and in addition to the conventional land information system.

Land tenure types that are not based on formal cadastral parcels and not registered require a new form of land administrative system. In most cases, the official land administration structures deny the poor legal access to land. In such situation, people opt for informal and customary arrangement to access land in areas that would otherwise be unaffordable or not available for them (UN-HABITAT, 2008). As can be seen in figure 2, Social Tenure Domain Model (STDM) is about people. It is about "People-land" relationship. People depend on land for living. Every human relationship with land must be accommodated in a spectrum.

The STDM is specifically designed for developing countries to support pro-poor land administration. Developing countries like Nigeria are characterized by very little cadastral coverage in urban areas with slums or in rural customary areas. The focus of this model is on the relationship between people and land, which is independent from level of formalization or legality of this relationship. Land rights in this model may constitute formal ownership, apartment right, usufruct, freehold, leasehold or state land. It can equally be a Social Tenure relationship like occupation, tenancy, non-formal and informal rights, customary rights of various forms, indigenous right and possession. Sometimes, these rights are with over lapping claims which lead to disagreement and conflicts (Lemmen, 2010)

The spatial units in this model are area of lands where these rights and Social tenure relationship are exercised. It may concern the identification of the spatial units on a photograph, an image or a topographic map. it may be on a locally produce sketch map or the photograph of the sketch map may be taken as evidence. STDM make the process of a land rights identification to be flexible by recognizing the fact that parties spatial units and social tenure relationship may be presented in many format depending on local tradition, culture, religion and general behaviour of the people. Recording spatial unit under STDM may not be based on formal registration but may be based on observation in real situation resulting in recordation of informal land use rights.

Simple Approach and Non-Conventional Land Recording Tools

The land rights are recorded in several ways in land administration system. Such land rights are recorded in cadastral maps, land registers and other records. Having land rights recorded this way confer benefits of greater tenure security, increase willingness to invest on such land or use such land as collateral in financial institutions.

However, the formal land administration has some limitations. It tends to marginalize many people most especially the poor, women and the weak in the society. Their relationships to land are not always included in the formal land administration system. In sub-Saharan African, the beneficiaries of the formal land recording are the rich and highly connected in the society. Most attempts made at expanding formal land registration systems usually benefit elite and very many poor people end up with less access and security to land.

Land administration system sound simple. It described who has what relationship to which resource and where. The system also collect, store and update these information. However, most conventional systems introduce hoops to jump through before the final information can be entered or updated. The ways and manner the detailed information on land are to be recorded are complex with the use of many gate keepers such as notaries or conveyancers to handle legal aspects, land surveyors to handle the maps, planners to deal with changes in land use and valuers to determine the worth of the land.

The costs of these services are beyond the reach of the poor and middle class are excluded from formal land administration system. Unfortunately they have relationship with land too. In relation to government agencies, clients are often made to pay “facilitation fees” or other forms of informal payments to have access to the conventional land administration system. Expanding the formal land-recording is not only slow but equally expensive to the poor and women. Conventional land administration is not suited to cater for continuum of rights. It is too cumbersome for this process.

There is now the need for innovative, cheaper and simpler ways of recording land rights that is affordable to the poor and the majority. There are now new technologies using computers, Satellite Images and Geographical Positioning System to the rescue.

GLTN has come up with various land tools to improve tenure security. These tools are:

i. The Social Tenure Domain Model - a pro-poor system land information management;
ii. Participatory enumerations through community-led data collection;
iii. Building of local record of land transactions; and
iv. Use of non-conventional approaches in collecting land data.

METHODOLOGY

Collections of data on customary rights with different form of tenures require a broad approach to data collection in the field:

Information at household level may be collected by representative of the community using pre-determined and tested questionnaires ; for example, information about name of owners, witnesses, family members, gender, age, social tenure relationship and a link to specific spatial unit.

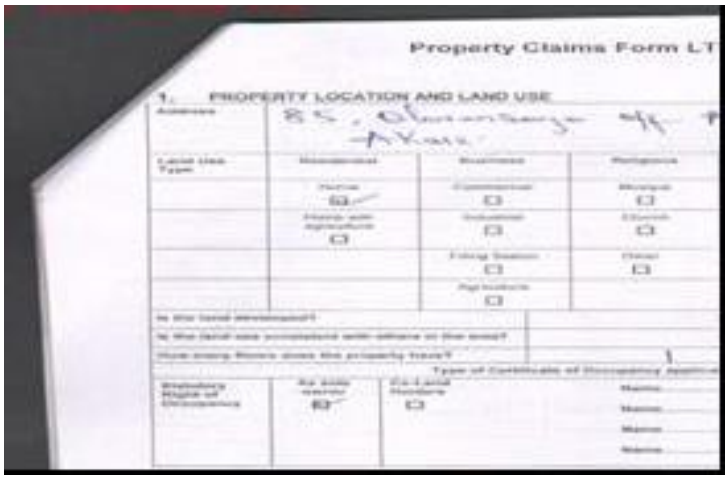

Figure 3: Sample of scanned questionnaire
Source: Ondo State Land Records Bureau Pilot Study, 2014

Information on spatial unit can be hand-draw on paper, marked on an existing map on aerial photo or satellite image. The position may be surveyed with hand-held global positioning system equipment with traditional or modern surveying equipment or digitalized form a pre-existing map.

Figure 4: Showing Satellite Image of central mosque area of Akure, along Adesida road.
Source: Prepared From Orthorectified Satellite Imagery of 50cm Resolution Dated: January 2013 and Using GeoxH 6000 GPS.

An enlarged satellite image or aerial photo is now common and well recognized by local people. People can identify almost immediate the roads and spatial units on the images. High resolution image can be enlarged and printed and used as a basis for data collection. As can be seen from satellite image of central mosque area of Akure along the popular Adesida road in figure 4; the major Adesida road, the pedestrian bridge, the central mosque, the democracy park, Oja-Oba market and the adjoining properties can be easily identified from the satellite image. The boundaries on the images can be identified by the people and traced on the image. Accuracy of this data may not be exact, but it is useful for identification. Later the correctness of these identified drawing can be certified by surveyors through accurate land mapping which is somehow expensive. Recordation in STDM need not be based on formal registration but on observation in reality.

The information is collected form occupants in the presence of their neighbors who act as witness and validates the information.

The information collected is publicly displayed in the local area for correction and validation.

The collected information is loaded into social tenure domain model software. This software allows the data to be updated. Its design is simple to allow it been run by local people. The local people are trained with the help of mobile team on how to manage and periodically update the records

Applicability of the Model in Akure, Nigeria

Akure is the State Capital of Ondo State, Nigeria. Akure is a traditional Nigerian city and like other traditional Yoruba towns in the country, it exists before the advent of the British Colonial rule in the country. Akure, the capital city of Ondo state is located in South Western part of Nigeria and one of the 36 states of Nigeria. It lies approximately on latitude 70171 North of the Equator and longitudes 50141 East of Greenwich Merdian. The population of the city according to the last population census conducted by the National Population Commission in 2006 put the population at 353,211 (NPC, 2006). The population of Akure is made up of civil servants, professionals, artisans, traders', farmers and students. Being a state capital, Akure is the hub of economic, social and political activities. The figures 5 show the geographic location of Akure city.

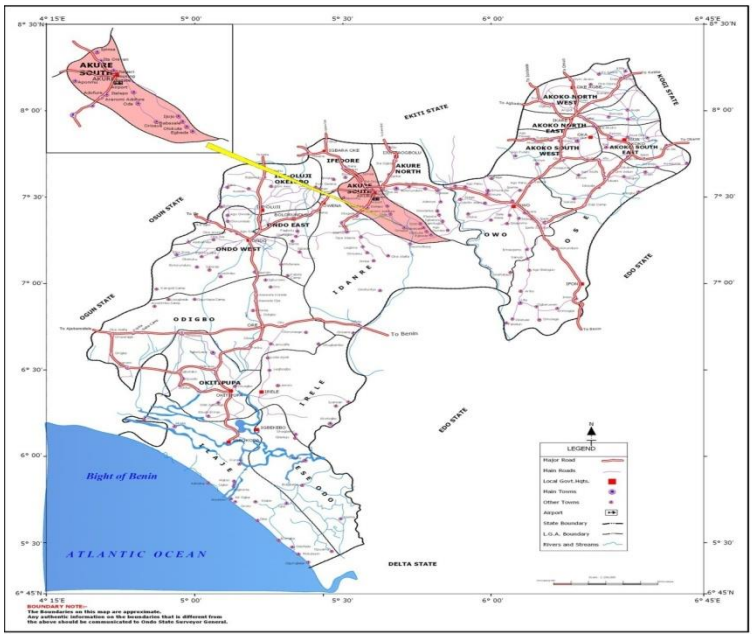

Fig. 5: Map of Ondo State Showing Position of Akure
Source: Abuja Geographic Information System, Maitama, Abuja.(2006)

There are issues with family lands in Akure and the conventional land administration system is not able to cover all land in Akure. In fact, there are numerous informal settlements development in Akure city alongside few formal estates owned by government and organized private sectors. Family land is a form of communal tenure and it is common in the study area. It is equally problematic to administer and in most cases lead to conflicts and litigations primarily because of lack of information on such lands. Land data on these lands are not captured and are not readily available to government in their formal registry.

There must be a way of recording these extra-legal but legitimate rights in an inexpensive way to boast land administration and security of tenure on such land. Social Tenure Domain Model was developed as a logical and structured standard format for describing the land - human relationship. Its design can cope with land administration components that do not fit

into more conventional land administration system. (Griffith-Charkes, 2011). Social tenure domain is a tool developed by Global Land Tool Network (GLTN) and facilitated by UNHABITAT. Its design is to cope with area where there are poor data on land most especially in Sub-Saharan Africa. STDM help in filling the data gap experienced in most developing countries.

In our local context, the process involved in the application of STDM to spatial data collection in Akure includes the followings:

Pilot test of STDM
Careful selections of some information/slum settlement are made within Akure city as a pilot study.

Participatory enumeration
The residents of the selected settlement would choose leaders and residents among them to be trained on participatory enumeration. The data gathering proceed must be jointly designed and conducted by the people who are being surveyed. The training would be on how to record details of the settlements i.e. who lives there, how long, reasons for living there, types of houses built etc.

The software package
it has two components namely a satellite imagery map, which shows the existing structure, roads and settlements and a database where the details of each household, pictures; photocopies of document and finger prints can be stored. The process must not be too restrictive so that the process does not bring us back to the trap of the conventional system - too inflexible, too formal and too expensive. There must be a balance.
Validation of information: the resident would be made to validate all information collected in the presence of their neighbours. The data and plans will be presented to the local or national authority via city citizen's forum for further integration with existing formal land administration. If the exercise is successful, the project can be scaled up for city wide coverage.

CONCLUSION

STDM among other things stand to benefit the professionals in land matters by bridging the gap that exists between conventional land management and customary land tenure system in one hand; and informal settlements and slum by providing systematic recordation that is flexible and does not follow conventional procedures. It will improve security of tenure at scale to many poor that rely on informal / customary land rights which are not often administered conventionally and are not systematically documented. STDM is designed as a pro-poor land information management system. There would be in existence a form of documentation that is affordable to the poor and relevant to their situation and social tenures in support of their land rights. STDM could be used to document land rights claims and over-lapping rights prior to conventional adjudication, surveying and registration, which in most cases is expensive and beyond the reach of the poor in the society.

For slum upgrade, the current trend is community focus project because of lack of city wide land information and management. However, STDM can make a city wide land management possible by linking the STDM information with the conventional cadastral information management system. STDM provide information on land at macro level and information is power. The poor are made to understand simple land information management and this will improve transparency about land allocation, acquisition, inheritance and transfers. The totality of this improves land governance. Women are highly affected by poverty and this has been linked to their lack of access to land. Fewer women have rights over land than men. STDM

contributes to overcoming gender disparity as it can also hold the record of women land rights.

Factors Affecting Construction Project Handover and Feedback Mechanism

Oke, Ayodeji Emmanuel [1*]; Olatunji, Samuel O.[2] & Ajulo, Abel Adetoye[3]

[1, 2&3]Department of Quantity Surveying, Federal University of Technology Akure, Nigeria

ABSTRACT

Handing over and feedback is the last stage of construction. While handover is the transfer of constructed project and necessary information from design team to the project owner, users or facility manager, feedback gives the overview of the project and the lesson (s) for future engagements to the constructed project participants. With the ever increasing demand for quality service from project teams by clients, it therefore follows that poor handover and feedback mechanism can have a huge impact on clients' satisfaction. It is based on this premise that this research was carried out to assess the factors affecting construction project handover and feedback mechanism and their effect on project success with the view of providing overall effective project and client satisfaction. A questionnaire survey was used and 36 professionals in the construction industry in Ondo state were sampled. Data collected were analyzed using descriptive statistics: mean and percentile. Findings revealed that handover and feedback mechanism are not new to construction professionals but most times some vital process and documents are left out. Also factors affecting effective handover and feedback amongst others are: project failure/abandonment (a failed project cannot be handed over); project variation; inability of the client to pay the contractor and; insolvency in the course of the construction. This study therefore recommends that handover and feedback mechanism should be taken as a crucial stage with all necessary information properly communicated and measures taken to guide against the limiting factors in order to achieve a successful project.

Keywords: Feedback, Handover, Construction project, Project success, Nigeria

INTRODUCTION

The Construction Industry has been a large and ever growing industry with a lot of professionals working towards a common goal of a said project. The work of construction companies is project-oriented according to Zwikael (2009) and it is also one of the largest job creators in developing countries (Hari, Jeevarathnam & Thulani, 2012). Project Management Institute (1999) defined project as a series of tasks, arranged in a defined sequence or relationship that produces pre-defined output or effect. Several phases abound in the course of carrying out a project, and this includes: conception phase; planning phase; production; handover; utilisation and; close down. Munns and Bjeirmi (1996) observed that handover is the fourth stage of the six phases in construction that allows the transition from project delivery to occupation and operations. The strategic objectives of the handover stage are to ensure the building is free from identified defects, fully functional and operational, and to prevent disruption to operations during the handover transition.

On the other hand, customer/client feedback system enables organizations to monitor customer perceptions of their service and to improve their service performance (Sami, Juha & Jouko, 2014). The chartered institute of building (CIOB) (2002) stated that project feedback reflects the lessons learnt at various stages of the project and also includes recommendations to the client for future projects. Thus it is important to note how this twin issue (handover and feedback) affect the success of a project in other to give optimum satisfaction to the client.

Several research works conducted on project success has given recommendations on issues that are needed to be resolved in order to have successful project. Every day, clients are

Oke, A. E.; Olatunji, S. O. & Ajulo, A. A. (2016). Factors Affecting Construction Project Handover and Feedback Mechanism. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 841-850

increasingly looking for high quality service from their teams. This high quality service must be experienced from initial contact, throughout the phases of a project, through completion and hand-over and beyond (Preece & Tarawneh, 1997).

It is imperative to note that no matter how good the beginning is when the end is bad then all the process is bad. Poor handover have a strong impact on overall client satisfaction (Sami *et. al*., 2014), also the importance of reflecting the lessons learnt and suggestion for future projects called feedback, cannot be over emphasized. Australian Government (1998) stated that the completion of a project should not signal the end of any further actions. This research therefore assess the factors affecting construction project handover and feedback mechanism and their effect on project success with the view of providing overall effective project and client satisfaction. In achieving this, the problems associated with project handover and feedback, the factors affecting project handover and feedback mechanism in building construction and their effect on project success were assessed.

LITERATURE REVIEW

Handover Stage of Building Project

Queensland Department of Public Works (QDPW) (2010) opined that handover is a major milestone in the construction work management process that occurs as the transition between project completion and commencement of building operations. In its opinion at this stage, all construction issues are resolved and the building is deemed ready for use and also the strategic objectives of the handover stage are to ensure the building is totally free from any identified defects, it is fully functional and operational, and to prevent disruption to operations during the handover transition. Jennifer, Carmel and Nurain (2012), suggested that handover procedures and training should begin before the key delivery professionals leave, that this will enable facilities and asset managers to discuss operations with designers before they are disengaged.

The CIOB (2002) viewed project completion or commissioning and handover as an interlinked final stage of work executed by the contractors and consultants prior to acceptance of the facility by the client. It went further to explain the stages involved or things that must be done to achieve an effective handover. Necessities like, certificate of completion, sectional completion (stage construction), final account, health and safety file, as-built and install drawings and specifications and maintenance manual.

In similar view handing over building to the occupants is one of the key milestones of a building's life. Initial commissioning will have proved that the building's systems work, although they may need continual fine-tuning during the first year as loads change. This fine-tuning is much more effective with the involvement of maintenance staff or training the client on the usage of the facilities in the building (Carbon Trust, 2012). This indicates that this stage of construction is necessary in determining the success of a project.

The Activities Involved in Handover

Summarising the opinions of QDPW (2010), Carbon Trust (2012), Guide to Building Handover (GBH) (2012), The CIOB (2002), handover activities may vary in accordance with the specific project and contractual arrangements. The handover may be progressively staged (during project delivery), with each stage following the completion of an agreed level of partial building works as specified in the contract.

Handover activities can be grouped into the following stages: Pre-handover activities (including commissioning); Practical completion; Post-handover activities; Final completion; Project close activities.

Pre-Handover Activities

Commissioning

Commissioning is the process of verifying that building systems are performing in a way that meets client's requirements. Commissioning prior to handover is necessary to ensure that it is functioning, operational and ready for use. This can lead to a fully optimised building, using less energy and keeping occupants comfortable and productive. Commissioning is often thought of as a single point in a construction project, carried out before handover (QDPW, 2010; Carbon Trust, 2012; GBH, 2012; T CIOB, 2002)

The commissioning team should be formed early in the process and involve the following people: client representative, commissioning specialist, design representatives, cost management representative, construction specialist, facilities or premises manager (where appointed). This team should define, prepare and control commissioning activities. The facilities manager or another member of the client team needs to take responsibility for checking the commissioning plan. They will also need to make sure the commissioning records are complete and comply with the contract.

Receipt of building documentation

Prior to handover, it is expedient that the contractors and consultants transfer all building documentation to the project manager. Copies of this documentation should then be transferred by the project manager to the building owners/users and the maintenance provider (s) (QDPW, 2010; CIOB, 2002).

As built and as installed drawing

This according to GBH (2012) is a reference drawings needed to troubleshoot or resolve building issues. As installed drawings also specially shows concealed or underground cable and piping routes, been concealed by backfilling of excavation or concreting of floor slab or installation of non-removable ceiling. It also provides critical dimensions and access points (Property Services, 2011).

Operating and maintenance manual

Operating and maintenance manual contains user-friendly instructions that effectively guide the Owner/Operator in the proper operation and maintenance of building systems, materials, finishes, components and equipment (GBH, 2012). According to The Ontario Association of Architects and General Contractors (OAAGC) (2007) this documentation provides information with regards to the regular maintenance and cleaning instruction of materials, necessary instructions in order to operate systems and equipment. This instructions shows the upkeep required for finishes and various components of equipment and systems, it specifies the cleaning methods and materials or regularly scheduled maintenance of equipment.

The Health and Safety file

The Health & Safety File is a document which is prepared by the project manager, with assistance from the design team, main contractor and the subcontractor. This file contains all relevant information to allow the Client to effectively occupy, utilise, manage and maintain the building safety. The Client is also responsible on receipt to update the file regularly, in case of changes made to the building (Advance procurement for university and colleges, 2009).The CIOB (2002) opined that health and safety file is produced right from the onset of the project construction that is been updated at completion of the project and handed over to the client, the concise updated health and safety file of the built product highlights any potential risks to the end user.

Other documents according to QDPW (2010), Carbon Trust, (2012) and GBH (2012) includes: plant, equipment, services and system information/schedules, as well as

recommendations related to lifecycle costing; service maintenance requirements, certificates, warranties and guarantees, occupational instructions and any training packages.

Practical Completion

The practical completion marks the end of the construction stage and the time when the building is handed over to the building owners/users. Practical completion is achieved when project requirements have been delivered, in accordance with the project brief, approved design and intent, contractual obligations and statutory requirements.

Confirmation of practical completion usually occurs at the conclusion of Commissioning/Pre-handover activities. It is at this time that the maintenance provider (s) should be advised of all maintenance-related design and construction issues. At practical completion the above named significant documents are handed over by the contractor to the project manager, subsequently the project manager hands over to the client. The project manager needs would have ensured on behalf of the client, that these documents are available and that they are to the necessary quality (QDPW, 2010; GBH, 2012, CIOB, 2002).

Post-Handover Activities

Defects liability period

Sdn Bhd, Burns and Ong Sdn Bhd (2007) defines defects liability period as a period when the contractor is obliged and liable to rectify defects that appear as from the time the Certificate of Practical Completion is issued and its expiry time. Most building contracts defects liability period spans for twelve to six months (base on the contract agreement) from the practical completion milestone. Alejo (2013) argues that defects liability period practice in Nigeria building industry should be extended more than six month, as it is done in other developed countries in the world.

During this period, the contractor (or their nominee) is responsible for: addressing minor omissions and defects outstanding at handover; and rectifying building defects identified during the defects liability period. Thus, maintenance activities should be monitored and maintenance records should be continually updated to reflect any new defects and/or rectification works. These records should be incorporated into a defects report, which includes details of maintenance activities undertaken, defects identified and/or rectified and other building issues requiring attention. These records should also be retained in the maintenance manuals for easy access to information on the condition of assets. By the end of the defects liability period, the building should be fully operational and all identified defects and omissions should have been addressed (Public Works, 2010; GBH, 2012; CIOB, 2002).

Final completion and Project close out activities

The completion stage is achieved after the finalisation of construction and when the facility is handed over to the client (Australian Government, 1998). Hence, final completion marks the conclusion of the building project. The certificate of final completion (issued following satisfactory final completion inspection) confirms that all contractual requirements have been met, including the rectification or acceptance of all outstanding defects and attendance to all omissions (Zarabizan, Syuhaida & Aminah, 2012).

Final account which is the sum agreed to be paid at the end of the contract by the owner to the contractor, comes in at this stage. This according to Zarabizan *et. al,* (2012) is sometimes delayed and disputed. In fact, the bottlenecks in settlement of final account have existed for decades and undue prolonged inaction to curtail it has made settlement of final account more difficult and frequently gives rise to dispute unnecessarily (Kwok, 2009). This stage allows the Project manager closes auditable project files, releases final payment to Contractor and close financial accounts.

Feedback in Building Construction

CIOB (2002) emphasized the necessity project feedback as a way of reflecting the lessons learnt at various stages of the project, including recommendations to the client for future projects. Its opinion shows that feedback should be obtained from all of the participants in the project team at various stages and also that feedback can be obtained at the end of a key decision-making stage. In addition to this, project feedback form should include: brief description of the project, outline of the project team, form of contract and value, feedback on contract (suitability, administration, incentives, etc.), technical design, construction methodology, comments on the technical solution chosen, any technical lessons to be learnt, form of consultant appointments, comments on consultant appointments, project schedule, comments on project schedule, cost plan, comments on cost control, change management system, values of changes, major source (s) of changes/variations, overall risk management performance, overall financial performance, communication issues, organisational issues, comments on client's role/decision-making process, comments on overall project management including any specific issues, other comments and finally close-out report.

Project Audit

Project audit give the brief description of the objective of the project, summary of any amendments to the original project requirements and their reasons, brief comment on project form of contract and other contractual or agreement provisions. It reviews project milestones and key activities highlighting planned versus actual achievements, unusual developments and difficulties encountered and their solutions, and also brief summary of any strengths, weaknesses and lessons learnt (CIOB2002).

Measure of Project Success

The construction industry is dynamic in nature (Behm, 2008). The concept of project success has remained vaguely defined in the construction industry. The measure for project success varies among professionals and stakeholders in the built environment. While some consider time, cost and quality as the predominant targets, others suggest that success is something more complex (Chan, 2001). Cheung, Suen and Cheung (2004) opined that project performance can be measured and evaluated using a large number of performance indicators that could be related to various groups such as time, cost, quality, client satisfaction, client changes, business performance, health and safety. Chan (2001) reviewed eight leading journals on project success and revealed that cost, time and quality are the three basic and most important performance indicators in construction projects. He went further to mention other measures, such as safety, functionality and satisfaction, among others that are attracting increasing attention.

METHODOLOGY

The aim of this paper is to assess the factors affecting construction project handover and feedback mechanism and their effect on project success with the view of providing overall effective project and client satisfaction. In achieving this, a survey design was used. This involved the use of questionnaires administered to Quantity surveyor, Architects, Civil Engineers and Builders in Ondo state ministry of works, Federal ministry and the selected contracting firms within Ondo state, Nigeria. Using convenient sampling, 65 questionnaires were distributed with 36 returned which represents a response rate of 55.4%. Mean Item Score (MIS) was used to analyze data gathered and this was employed for two purposes which are: ranking and determination of significance of different factors of the collected data. The premise of decision for the ranking is that the factor with the highest MIS is ranked 1st and others in such subsequent descending order. Since a Likert of 5-point scale was employed for the collection of data, the formula for MIS is written as:

$$MIS = \frac{5n^5 + 4n^4 + 3n^3 + 2n^2 + 1n^1}{n^5 + n^4 + n^3 + n^2 + n^1}$$

Where n is the frequency of each of the rankings

FINDINGS AND DISCUSSIONS

Findings of Research

Background Information of Respondents

The respondents sampled include 41.7% Quantity surveyors, 25% Architect and Civil engineers each, and 8.3% builders. 38.9% of the respondents have between 1 to 5years of working experience while 33.3% have between 6 to 10 years experience. 8.30% of the professionals have 11-15years, 2.8% have between 16 to 20years while 13.90% have above 20years of experience in building construction. It therefore follows that the data gathered from the respondents can be relied upon since 61.1% of the respondents have above 5years working experience, hence information would have been given based on their vast wealth of experience. Also 36.11% of respondent have been involved in 1 to 5 construction projects, 19.44% were involved in 11 to 15 projects, and 13.89% were involved in 6 to 15 projects, while 25% in above 20 projects and 5.56% did not respond to the question asked.

Problems Associated With Project Handover in Building Construction

Table 1 shows the result of polled professionals' opinion about the problems associated with building project handover, they are asked to assess the occurrence of the problems as they arise in building project handing over process. From the table taking only problems with 3.0 mean score and above, it can be deduced that according to occurrence in descending other is as follows: Disputed final account comes first, next is the certificate of completion not issued, then absence of as built and as installed drawing, then non availability of overall financial performance, next is change management system not well documented, then absence of operating and maintenance manual, avoidance of project audit, the last of the list of eight (8) problems that scaled through the bench mark mean score of 3.0 is, absence of health and safety file.

Similarly for problems associated with feedback process, taking only problems with 3.0 mean score and above, it can be deduced that according to their ranking of occurrence in descending other is as follows: Non availability of overall financial performance , absence of as built and as installed drawing, disputed final account, change management system not well documented, certificate of completion not issued, omission of certificate of practical completion, avoidance of project audit, Close-out report not presented, no concern for comments from parties involved, absence of health and safety file, absence of operating and maintenance manual, and Non availability of brief description of the project.

This same constituent study for handover where only eight (8) were respondents choice, was used for feedback and all the constituents were selected as any omission will cause problem in feedback

Factors Affecting Construction Project Handover and Feedback Mechanism in Building Construction

Result shows that out of the 13 identified factors affecting project handover and feedback mechanism, project failure/abandonment topped the list with a mean score of 3.74 (a failed project cannot be handed over). Next is project variation with a mean score of 3.69, followed by the inability of the client to pay the contractor which ranked 3rd with a mean score of 3.67. Result shows that if 3.0 is set as the minimum mean score for a factor to be considered

relevant, then all the 13 factors have reasonable effect on project handover and feedback except ignorance as indicated in table 2.

Table 1: Problems Associated with Project Handover and Feedback

Problems of Handover and Feedback	Mean for Handing over	Ranking	Mean for Feedback	Ranking
Disputed Final Account	3.49	1	3.48	3
Certificate of Completion not Issued	3.29	2	3.36	4
Absence of As Built and As Installed Drawing	3.29	2	3.50	2
Non Availability of Overall Financial Performance	3.24	4	3.64	1
Change Management System not Well Documented	3.15	5	3.36	4
Absence of Operating and Maintenance Manual	3.15	5	3.09	11
Avoidance of Project Audit	3.03	7	3.28	7
Absence of Health Safety File	3.00	8	3.12	10
Omission of Certificate of Practical Completion	2.97	9	3.30	6
No Concern for Comments from Parties Involved	2.91	10	3.18	9
Close-Out Report not Presented	2.85	11	3.22	8
Non Availability of Brief Description of The Project	2.76	12	3.03	12

Table 2: Factors affecting construction project handover and feedback

Constituent of Handover and feedback	Mean Score	Ranking
Project failure/abandonment	3.74	1
Project variation	3.69	2
Inability of the Client to Pay the Contractor	3.67	3
Insolvency in the Course of the Construction (Contractor)	3.64	4
New government policies	3.61	5
Insolvency in the Course of The Construction (Client)	3.47	6
Client desire	3.44	7
Inability of the client to pay the consultants	3.42	8
Contractor's shoddy job	3.40	9
Conflicts	3.39	10
Architect instruction	3.23	11
Statutory obligation	3.14	12
Ignorance	2.94	13

Effect of Project Handover and Feedback mechanism on Overall Project Success

Table and short explanation was used to present findings from respondents on the effect of six (6) project handover and feedback constituents on three measures used to measure construction project success.

i. Completion of the project to cost

Result in table 3 shows the opinions of respondents on handover to completion of the project to cost. It was revealed that out of the constituents of handover, final account top the table and next to it is; certificate of completion and certificate of practical completion respectively, even though other factors are beyond the average level, the first three was considered. Final account, certificate of completion and certificate of practical completion deals directly with cost at the final stage of a project in view of this affects the cost of construction project, this has been shown in the below result.

Result shows out of the constituents of feedback, considering the first 3, Project audit was ranked 1st, next to it is Overall financial performance, while Brief description of the project

was the third, even though other factors are beyond the average level, the first three was considered.

ii. Completion of Project To Quality

Table 3 indicate the result of the opinions of respondents on handover to completion of project to quality, out of the constituents of handover; as built and as installed drawing was ranked most, then to certificate of practical completion and certificate of completion.

Table 4 also explained the result of the opinions of respondents on effect of feedback on completion of project to quality. Project audit and overall financial performance was ranked most, Brief description of the project was ranked third.

iii. Completion of Project To Time

Table 3 indicate the result of the opinions of respondents on handover to completion of project to time, out of the constituents of handover; certificate of completion was ranked most then as built and as installed drawing and certificate of practical completion came behind respectively.

Table 4 shows the result of the opinions of respondents on effect of feedback on completion of project to time. Overall financial performance report of the project was ranked most, then project audit and taking and recording comments from parties involved respectively.

Table 3: Effects of Handover on Construction Project Success

Effect of Handover	**Completion of Project to Cost**		**Completion of Project to Quality**		**Completion of Project to Time**	
	Mean	Rank	Mean	Rank	Mean	Rank
Certificate of practical completion	3.66	3	3.94	2	3.62	3
Final account	4.00	1	3.76	4	3.47	4
Health safety file	3.13	6	3.16	6	3.41	5
As built and as installed drawing	3.64	4	3.97	1	3.76	2
Operating and maintenance manual	3.26	5	3.52	5	3.26	6
Certificate of completion	3.84	2	3.79	3	3.78	1

Table 4: Effects of Feedback on Construction Project Success

Effect of Feedback	**Completion of Project to Cost**		**Completion of Project to Quality**		**Completion of Project to Time**	
	Mean	Rank	Mean	Rank	Mean	Rank
Brief description of the project	3.77	3	3.61	3	3.35	4
Project audit	3.88	1	3.70	1	3.42	2
Change management system	3.21	6	3.48	4	3.35	4
Overall financial performance	3.81	2	3.70	1	3.69	1
Comments from parties involved	3.48	5	3.42	5	3.41	3
Close-out report	3.55	4	3.39	6	3.19	6

Discussion of Findings

Problems Associated With Project Handover and Feedback

Based on empirical evidence from the research conducted it was discovered that; disputed final account, certificate of completion not issued, absence of as built and as installed drawing, non-availability of overall financial performance, change management system not well documented, absence of operating and maintenance manual, avoidance of project audit and absence of health safety file was rated above average of the twelve problems associated with construction project handover and feedback. This agrees with the opinions of QDPW (2010), Carbon Trust (2012), GBH (2012), CIOB (2002) that the above named eight constituents are important to have a hitch free handover and feedback. In fact Zarabizan et. al., (2012) ascertained that disputed final account causes bottleneck in handover and feedback.

Factors Affecting Construction Project Handover and Feedback Mechanism
Findings revealed that; project failure/abandonment, project variation, inability of the client to pay the contractor, contractors insolvency in the course of the construction, new government policies, clients insolvency in the course of the construction, client desire, inability of the client to pay the consultants, contractor's shoddy job, conflicts, architect instruction and statutory obligation had proven themselves as factors affecting construction project handover and feedback.

Kandeil, Hassan and Nady (2010) agrees with some of the factor listed above as affecting handover, factor like; Project variation and contractor's poor job (quality). Kandeil et. al (2010) also observed that insolvency in the course of the construction (client), inability of the client to pay the consultants, inability of the client to pay the contractor, insolvency in the course of the construction (contractor) in form of lack of cash flow as factor affecting handover.

Effect of Project Handover and Feedback on Overall Project Success
When a construction project is successful at completion and the transfer and information are not managed well, the end stage can sour the whole earlier process. In view of this, the findings in this research have shown that project handover and feedback will affect project success in terms of cost, time and quality. This agrees with the combination of Queensland department of Public Works (2010), Guide to Building Handover (2012), The Chartered Institute of Building (2002) presented guide for effective handover and feedback and that of Hari et. al (2012), measure of construction project success.

CONCLUSION

This research has been able to assess the effect of construction project handover and feedback mechanism on project success. The following are the conclusions of the research:

i. Construction project handover and feedback is the final and transition stage of construction where proper information must be communicated.
ii. It is not a ceremony but a crucial stage of construction to determine the final success of a construction project in the sense that any omitted document of constituents of this stage will affect construction project success.
iii. Problems associated with this stage are: Disputed final account, Certificate of completion not issued, absence of as built and as installed Drawing, non-availability of overall financial Performance, change management system not well Documented, absence of operating and maintenance Manual. Avoidance of project audit and Absence of health safety file.
iv. Ignorance is not a factor affecting effective handover and feedback but; project failure/abandonment, project variation, inability of the client to pay the Contractor, insolvency in the course of the Construction (contractor), new government policies, insolvency in the course of the Construction (client), client desire, inability of the client to pay the Consultants, Contractor's shoddy job, Conflicts, Architect instruction and Statutory obligation.

RECOMMENDATIONS

The following were recommended based on the findings of the research:

i. This stage of construction should not be taken as a ceremony stage but as a crucial stage, as it connects the client, the design team, contractors and the users or facility managers together to bring about the completion and post completion of the project.
ii. All necessary information should be communicated in order to achieve a successful project.

iii. The identified mostly omitted constituents of handover and feedback must be enforced at this stage to enhance its success.
iv. Measures should be taken to guide against identified limiting factors affecting this stage of construction

The application of HSE in building construction – A case study of Moroto Regional Referral Hospital in Northern Uganda

[1]Ishaq Ahmed Sohag & [2]Mumtaz Ahmed Sohag

[1]Student/Internee of Civil Engineering, Kampala International University, Uganda.
[2]Professor & Director – Department of Sustainable Built Environment, Federal University of Birnin Kebbi, Nigeria.

ABSTRACT

The Health, Safety and Environment are the fundamental pre-requisites of the construction industry, to be applied by the builders/ and contractors. The requirements of clients, contractors, donors, local regulations or laws may stipulate higher and/or additional requirements in certain cases. In that situation, higher standards have to be followed. This paper discusses about a large general hospital site "Moroto Regional Referral Hospital", located in Northern Uganda where construction and repairing works were carried out. The project was funded by the World Bank, therefore, stringent HSE procedures were followed in conformity with local laws and regulations. In this regard, construction staff, comprised mainly of skilled and unskilled labour, was given early morning briefing before the start of work. Every worker had to wear the necessary gear including special construction clothes, gloves, shoes/gumboots and helmets. The staff was always given proper rest by ensuring strict compliance of working times. The construction material was also provided proper care as stuff like sand was always kept covered, excavated pits were given fencing to avoid falling and electrical installations were fully protected. The project was of 18 months duration, and it was successfully completed within the contract time period and handed over to the client in September, 2015. Although the site was located in a remote place where availability of necessary facilities, materials and skilled labour was a challenge, however, HSE guidelines were strictly followed resulting in timely completion of the project without incurring any health or safety issue, verified through preliminary medical check-up of the staff.

Keywords: Health Safety and Environment, Construction, Hospital, Project

INTRODUCTION

HSE, which stands for Health Safety and Environment, has the main aim of protecting environment, general public, workers, and to follow the set laws and safeguard the reputation of the organization (Duijm et al. 2008). In some organizations, HSE departments have the responsibility of protecting the occupational health, environment, and the safety of workers and materials, when various operations are carried out at the site/workplace.

In the perspective of health & safety, it includes preparation of well-organized and well-managed methods and applications for determining the hazards of a workplace and diminishing sudden accidents and vulnerability to the harmful materials and circumstances. According to Ligard & Holmes (2001), it also involves the training of workers in the usage of Personal Protective Equipment (PPE), responding to the sudden accidents, its prevention, and emergency alertness.

Whereas, from the environmental perspective, it includes the preparation of an organized and well-thought approach to follow the set rules and regulations of environment, such as handling the air pollutants and waste materials in a way to assist in reducing the carbon footprint of the workplace.

Sohag, I. A. & Sohag, M. A. (2016). The application of HSE in building construction – A case study of Moroto Regional Referral Hospital in Northern Uganda. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 851-854

Importance of HSE in building construction

HSE deals with the health and safety of both the employees/workers and surrounding environment of a particular workplace where construction activity is taking place, and is therefore an essential component of the organization which has to be given due importance (Shamsuddin et al. 2015).

Mohamed (2002) explained that in order to monitor the health & safety of employees and the workplace environment, most of the reputable organizations usually appoint HSE officer on the construction/building site and is provided an office to work in.

The HSE officer guides his/her workers about their safety through a daily/weekly meeting called Toolbox Talk in which he/she informs the workers about their daily construction activities and its related PPE and further explains on how to remain safe on site by wearing PPE equipment whenever they are working on the site. In case of any unfortunate mishap takes place and the worker gets an injury, he/she has to report to HSE officer, who then treats the worker in emergency room present on the site. However, if the injury is serious, the HSE officer takes the worker to a nearby hospital.

Proper signage is also an integral part of HSE which plays a great role in keeping the working environment, workers and visitors safe and sound. It increases the vigilance of both the workers and visitors on the site. It is also the responsibility of HSE officer to do the proper signage on the site every time a construction activity takes place or construction material is stored/placed on the site.

Figure 1 - Signage of high flammable area where fuel was stored

Description of site activities

In lines of the standard HSE rules and regulations, the construction activities of Moroto Regional Referral Hospital used to start in the morning with a Toolbox talk, which used to take place on every Monday, Wednesday and Friday at 07.00 am before the commencement of works and continued till 05.30 pm, while on Sundays it was limited up to afternoon.

During the last days of handing over of the project site, the contractor worked tirelessly day and night in order to hand over the project on time. The need of working day and night aroused due to the extended works and variation orders of the work, provided by the stakeholders. Around 200 people worked every day which included mason, plumber, painter, electrician, helper, etc.

Proper health, safety and environment measures were adopted on the project site. During the night hours, tower lights had been used in order to ensure that the workers do not face any challenge in work and remain safe. During the work, site workers had to wear personal protective equipment (PPE) which included gloves, overall, helmet, gum boots, goggles and face mask.

During the rainy season, polythene cover used to be placed over the sand in order to keep its moisture content stable. Similarly, in case, if concrete has been casted or plastering of the structure has been done and the rain starts, polythene cover used to be placed over the structure.

Figure 2 - Polythene cover was placed after placing mortar between kerbstone and paver block

Figure 3 - Planted grass protected with the help of warning tape

As shown in the photo above, the ground on which grass was planted can be seen protected with help of a warning tape. Similarly, the deep excavation works which were carried out on the site were given proper signage and the warning tape was placed around the excavated area for the safety of workers and visitors on the site.

Observations

During the course of construction work, the HSE regulations were strictly followed on the construction site and no serious incident ever took place during the whole project. Moreover, the construction process carried out smoothly and the hospital was successfully handed over to the client on the due date after execution of repairing/construction works. The workers did not suffer any serious injury or health issue during the course of works, which shows that implementation of HSE regulations keep the workers in good health. This ultimately helps the employers by non-interruption of works or placement of new workers. This also provide a healthy and conducive environment where workers try to deliver efficiently with commitment as being practiced in the developed countries where even in laboratories HSE is strictly

applied (Ishaq & Riaz, 2015). As such, a good working environment helps in better delivery as observed by the timely completion of the project. The regular briefing also helps in the refreshing of the HSE rules for the workers.

CONCLUSION

HSE applications greatly enhance the health and safety of workers and visitors present on the construction site. Sudden accidents and mishaps which can damage the health of people present on construction site, jeopardize the whole construction process and environment, can be avoided with the help of proper application and management of HSE regulations.

It was a World Bank funded project, therefore, HSE rules and regulations were followed religiously, which had a good impact on the execution of the project, conservation of environment, health of the workers and developing conducive working environment. It is urged that HSE implementation on civil projects should not be limited to the donors funded projects. Infact it should be strictly followed in all the civil, whether in private or public sector. In this regard, government agencies need to devise a holistic strategy whereby all the stakeholders are involved in the implementation of HSE in civil works.

ABSTRACT

One of the barriers that have been identified during the implementation of Public Private Partnership (PPP) globally which have led to project failure is stakeholder opposition. This paper focused on the key concepts underlying stakeholder involvement and the criteria to measure their satisfaction level with the PPP infrastructure projects in Niger-Delta region of Nigeria. Both qualitative and quantitative approaches were employed in generating preliminary data for field testing. This involved 41 respondents selected from concession companies and 19 end users in the region using stratified sampling technique. The study revealed that The State PPP directorates considered satisfaction in terms of the project meeting the quality specification; function as intended; completed as schedule; and benefiting the end users. The promoters/ investors considered satisfaction in terms of the project being self-financing; users demand for the services; return on capital Invested; and minimum operation/ maintenance cost. The end users viewed the satisfaction in terms of involvement of the host community from inception till operation; improve standard of living of the host community; serve as means of employment; and a source of relief but not to add to their stress. The study recommended that confident-building measure through establishment of forum between the private and public sectors and end users' to discuss economic impact and social value of the infrastructure projects for growth, determination of the priority of the infrastructure projects and the challenges be put in place to eradicate future conflict.

Keywords: Stakeholders' Involvement, Satisfaction, Public private partnership, Infrastructure, Nigeria

INTRODUCTION

Series of PPP initiatives around the world have encountered various problems that eventually led to the PPP infrastructure project failure. One of the most important factors identified is the Public opposition due to various reasons such as: unaware of the concept of PPP; not sufficiently educated about PPP; and denied access to detailed information contained in the consortium's PPP proposals. For instance, the failure of major PPP transportation initiatives in the United States and unsuccessful initiative to privatise sewer system in Malaysia were due to public opposition.

The Stakeholder involvement (SI) in infrastructure projects plays a significant role in the success of PPP infrastructure projects. Stakeholder involvement in PPP infrastructure projects has replaced the more limited term of Public involvement in the context of infrastructure development. According to El-Gohary, Osman, and El-Diraby (3006) described a stakeholder as any person or organization that has a legitimate interest in a project. PMI (2000) affirmed that each project typically involves a unique combination of stakeholders: persons or organisations that are actively involved in the project, or whose interest may be positively or negatively affected by the project. Olander (2003) argued that stakeholder analysis is used to identify stakeholders, assess their claims on the project and each stakeholder's interest and power to influence project decisions, in order to form and choose appropriate strategies. The stakeholder analytical tool is used to determining the strengths and weaknesses of project stakeholders influence in PPP infrastructure projects.

To capture stakeholder input, a thorough stakeholder involvement programme has become an integral part of infrastructure projects. The programme can be administered by the project

Lashinde, A. T.; Ogunsemi, D. R. & Awodele, O. A. (2016). Stakeholders Management for Public Private Partnerships in Niger-Delta Region of Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 855-863

owner, designer or contractor depending on project specific requirements. (El-Gohary *et al.*, 2006). In terms of the stage in which stakeholder is involve in PPP infrastructure projects. Accordingly, the Involvement of the beneficiary community should be from the implementation to the delivery of infrastructure projects. I.e. Stakeholder involvement is from planning, designing, construction and operation. Interns of stakeholder in planning and design, Stanford (2000) opined that in order to ensure a true stakeholder involvement programme in planning and design phases, the public has to be taken in full confidence that their involvement will influence the decision making process. Levy (1996) affirmed that during this phase of infrastructure project development all stakeholders are involved, but the way of involvement is different. Local and regional stakeholders are concerned with the influence of construction activities on their daily routine activities and life style. Attention has also been drawn to the importance of involving stakeholders in the design process of construction projects for identifying and understanding the values of the stakeholders in a project (Thompson *et al*., 2003). For construction-related projects, it is typically the responsibility of the project management team to identify the stakeholders, determine what their needs and expectations are, and then manage and influence those expectations to ensure a successful project (PMI, 2000). This entails establishing interfaces between the stakeholders, obtaining feedback as appropriate throughout the project, resolving conflicts between the stakeholder needs, and paying adequate attention to changing stakeholder needs, including new stakeholders, throughout the project (Gardiner, 2005). In order to achieve best value for money, there should be alignment between the stakeholders of the PPP project. Best value for money, on the other hand, represents the optimum combination of whole-of-life costs and quality (or fitness for purpose) of the goods or services to meet the user's requirement (HM Treasury 1998). .

LITERATURE REVIEW

Identification and Value of PPP Stakeholders

Olander (2003) developed a model for evaluating stakeholder influence on the project process as illustrated in figure 2.1. The model focuses on the impact of each stakeholder on project decisions and the consequences of the outcome. According to Olander (2007), evaluating the total impact of stakeholders in relation to a project requires more than identifying the impact level and probability of impact, but also requires the project managers assessing the stakeholder attributes and classes. Project participants include the granting authority, usually a government agency; the project sponsor; and usually one or more financial institutions.

The granting authority identifies project requirements, establishes the concession period, solicits tenders, and awards the contract. The project sponsor typically is a consortium or a joint venture of engineering, construction, and venture capital firms. Investment capital may come from commercial banks, insurance companies, or the sale of bonds (John & Isr, 2003). For the purpose of this study, the stakeholder of PPP can be classified in to three: government agency as the granting authority; project Investors involves the consortium and Investment capital and the end users were the beneficiaries of the services. The expectation of the government from the investors are financial capability, Technical capability, Managerial capability, Ability to accommodate adjustment in risk allocation, Health and safety performance and Strong private consortium. While the Investor's Expectation from the host country are political stability, creating a favourable social, legal, economic, and financial environment for PPP, clear division of responsibilities/objective, attractive incentive packages and tourism and welcome attitude of host community. The end users' requirements from both the government and investors are project benefiting the host community, Involvement of the host community, project being means of employment or source of relief and function as

intended. Three of the major challenges facing a prospective sponsor are estimation of project costs, projection of revenues during the concession period, and selection of an appropriate financing strategy.

Values are the deep-rooted beliefs about what is right or wrong, and what is important and unimportant. When thinking about value, it is helpful to consider the interaction between societal, organisational, group/team and individual levels of values as for instance: the values of a society influence organisations; and an organisation's values can influence the values of teams and individuals within it (Martin & Henderson, 2004). National Audit Office NAO (2004) described value as the function of the relationship between the 'satisfaction of needs' (in terms of business benefits and requirements) and the resources needed to deliver them. Dallas (2006) argued that one way of describing the critical factors required for the delivery of value through the useful life of a facility is through the use of value drivers, which he described "*as the various components of value, which together contribute to the overall benefits of the completed project to its stakeholders*". A good understanding of the stakeholders' values has been argued to play a vital role towards successful project outcomes (Kamara *et al.*, 2000; & Thompson *et al.*, 2003).

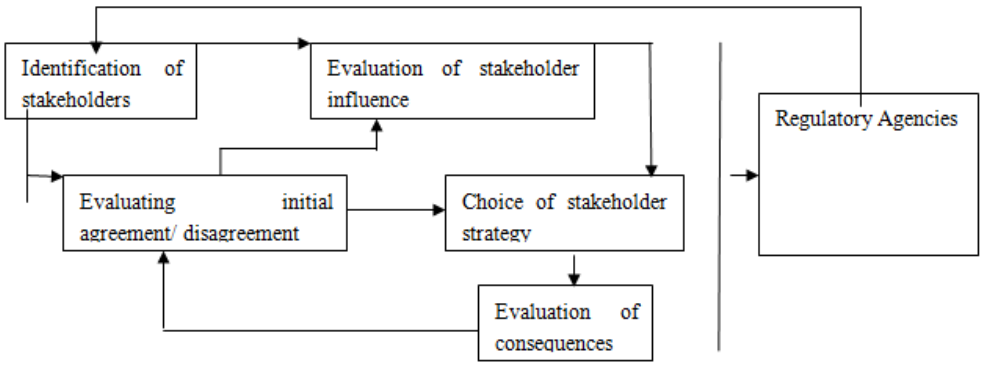

Figure: 2.1 Model for Evaluating Stakeholders Influence on Project Process
Source: OLander (2003)

Previous researchers were investigated on stakeholders' involvement in PPP: Bingham (1994) what does the public really think; Dunn et al. (2000) a systematic approach to community relation for the next millennium; Ernzen and Woods (2001) Contractor-led public relations on a design-build highway project; Hansen & Jackson (2001) redefines community engagement. Transport Res Record; Howard/Stein-Hudson Associates, Inc. (2003) Public involvement program for Northern Sub-Area Study & GA 400 Corridor Analysis; Plank et al. (1997) Public involvement helps supply project succeed; Sherman (2001) Effective use of public involvement to achieve aesthetic quality in bridge design; and Sinclair et al. (2003) Public involvement flood management in the Red River basin.

PPP Stakeholders' Satisfaction

In order to investigate on the PPP Stakeholders' Satisfaction, case studies of 12 PPP infrastructure projects in Niger-Delta region of Nigeria. The 12 notable PPP infrastructure projects identified in Niger Delta region are 2 airports, 3 power plants, 2 hotels, a hospital, a science park, a resort, a farm and a modern motor park and transit. These projects were located within the 3 sectional areas of the region. They were grouped into six categories: Agriculture, Energy and Power plants, Hospital and health care, Hotels and resort, Technology and Transportation.

What stakeholders considered as the criteria to measure the satisfaction level varies from one stakeholder to another. Consequently, their level of satisfaction varies per project. . The

granting authority, usually a government agency considered satisfaction in terms of the project met the quality specification; function as intended; completed as schedule; and benefiting the end users. The promoters / investors considered satisfaction in terms of the project finance itself; high level of users demand for the services; return on capital Invested; and minimum operation/ maintenance cost. The end users view the satisfaction in terms of involvement of the host community from inception till operation; improve standard of living of the host community; serve as means of employment; and a source of relief but not to add to their stress.

METHODOLOGY

Qualitative approach based on interview was adopted in this paper the reason is to have direct contact with the group of stakeholders of the 12 case studies PPP projects in the region. The semi-structured interview was conducted through vis-à-vis with 5 interviewees per identified PPP infrastructure project given a total of 60 interviewees on the completed identified 12 PPP infrastructure projects in the region. Among these 60 interviewees, 41 were directly affiliated with the identified infrastructure projects while 19 had indirect involvement in any of the infrastructure projects but are users of one facility or another. The information obtained during the interview sessions were analysed and evaluated following the principles of Content analysis.

FINDINGS AND DISCUSSIONS

Characteristics of the Interviewees

Table 1 shows the characteristics of the interviewees in terms of their, status, organization and designation. The respondents interviewed cut across all the stakeholders of the identified infrastructure projects. 15 interviewees were from the public sector (9 from State PPP Directorates and 6 from NDPHCN); 26 were from private sectors (investors); and 19 were end users (2 were clan heads, 3 were ex-militants, 6 were market women and 8 were youth). The interviewees from public sectors and private organizations had a range of different professional backgrounds: Project Management; Quantity Surveying; Architecture; Civil / Structural Engineering; Electrical Engineering; Mechanical Engineering; Building Construction; Business Administration; and Facility Management. The users interviewed were Clan Heads; Traders; Students in schools; and Students out of school.

The interviewees revealed that the level of satisfaction of the stakeholders varies and what each stakeholder considered as the criteria to measure the satisfaction level also varies. The government officials (state PPP directorates) considered satisfaction in terms of the project met the quality specification; function as intended; completed as schedule; and benefiting the end users. The promoters / investors considered satisfaction in terms of the project finance itself; level of users demand for the services; return on capital Invested; and minimum operation/ maintenance cost. The end users view the satisfaction in terms of involvement of the host community from inception till operation; improve standard of living of the host community; the project serve as means of employment; and a source of relief but not to add to their stress. The 12 notable PPP infrastructure projects were: 2 Airports; 1 Agriculture; 2 Hotels: 1 Business Resort; 1 Hospital & Healthcare Facility; 3 Power Plants; 1 Science and Technology Park; and 1 Modern Motor Park & Transit. The characteristics of the interviewees in terms of their, status, organization and designation is shown in table 1 above. The respondents interviewed cut across all the stakeholders of the identified infrastructure projects. Fifteen interviewees were from the public sector (9 from State PPP Directorates and 6 from defund NDPHCN); twenty-six were from private sectors (investors); and 19 were end users (2 were clan heads, 3 were ex-militants, six were market women and 8 were youth)

Ogwashi-Uku poultry farm Asaba; the interviewees involve one government official from the state PPP directorate, three private sectors (investors) and one user. The government official comments that he was highly satisfied with the poultry farm project based on its functionality. He comments that the poultry farm is function as intended while in terms of whether or not benefiting the end users, He said that it really benefiting the users. The investors were highly satisfied with the poultry farm in terms of its functionality and users' demands. They comments that the poultry farm is producing 1,000 crates of eggs daily and the farm feed mill is producing 25 tonnes of feed daily. While In terms of the user's demand, they said that the user's demands are highly encouraging, the distributors evacuate daily products of the farm very day. They agreed that the projects would be self sustaining as it could generate about N20 million monthly. The end user was highly satisfied with the farm products. He said that the farm had boosted economic activity in the community, provides a daily means of income to young people in the area and reduce the crime rate in the community to the beeriest minimum. Therefore, it can be concluded that the stakeholders were highly satisfy with Ogwashi-Uku poultry farm.

Ibom power plant Ikot Abasi; the interviewees comprises two government officials from the defund Niger Delta Power Holding Company (NDPHC) a division of Power Holding Company in charge of power distribution and importation of equipments for Niger Delta region of Nigeria, two investors and one user. The government officials comment that they were highly satisfied with Ibom power plant. In terms of the functionality of the plant, they comments that the Ibom power plant is function as intended. In terms of whether or not benefiting the end users, they agreed that it is really benefiting the users. The investors were highly satisfied with the power plant in terms of its location, source of the gas for the generating of the electricity and functionality of the plant. They agreed that the plants met the quality specification and function as intended. It was reveal that the gas turbans installed at

Ibom power plant were all good and working to the capacity. The end user was highly satisfied with the power plant. He said that there is slightly improvement in electricity supply in the state. Although, the power generated is integrated on to the national grid, He said that the power plant has creates employment to the people of the state and some people from other parts of the country. It can be inferred that the stakeholders were highly satisfy with Ibom power plant.

Omothoso power plant Ore; the interviewees consist of two government officials from the defund NDPHC, two investors and one user. The government officials agreed that they were highly satisfied with the power plant. In terms of the functionality of the plant, they comments that the plant is function as intended and benefiting the end users. The investors were highly satisfied with the power plant in terms of its location, source of the gas for the generating of the electricity and functionality of the plant. They agreed that the plants met the quality specification and function as intended. It was reveal that the gas turbans installed at the power plant are not working to the capacity due to the fact that only 2 of the 5 installed turbans are good the remaining 3 are scrap. They blame the NDPHC for the importation of such turbans. The 3 turbans need total overhauling. The end user was satisfied with the power plant. He said that there is slightly improvement in electricity supply in the state due to the fact that the power generated is integrated on to the national grid. He said that the power plant has creates employment to some people. It can be inferred that the stakeholders were satisfy with Omothoso power plant.

Sapele phase II power plant (Ogorode Generating Company); the interviewees involve two government officials from defund NDPHC, two investors and one user. The government officials comment that they were highly satisfied with Sapele power plant. In terms of the functionality of the plant, they comments that the power plant is function as intended while in terms of whether or not benefiting the end users, they agreed that it is really benefiting the users. The investors were highly satisfied with the power plant in terms of its location, source of the gas for the generating of the electricity and functionality of the plant. They agreed that the plants met the quality specification and function as intended. It was reveal that the gas turbans installed at Sapele power plant were all good and working to the capacity. The end user was highly satisfied with the power plant. He said that there is slightly improvement in electricity supply in the state. Although, the power generated is integrated on to the national grid, He said that the power plant has creates employment to the people in the state. It can be inferred that the stakeholders were highly satisfy with Sapele power plant.

The interviewees on Calabar hospital and healthcare facility consist of one government official from state PPP directorate, two investors and two users. The government official comments that she was somehow satisfied with the Calabar hospital and healthcare facility. In terms of the functionality of the hospital and healthcare program, she comments that the hospital and healthcare program is function as intended while in terms of whether or not benefiting the end users, she said that it extremely benefiting to the people of Cross River state and people from other parts of the country comes for medical assistance especially on eyes cataracts since treatment is free, the patient pays for the drugs at a reasonably subsidized price. The investors were somehow satisfied with the healthcare program because the government could not really fulfill her part of the agreement. Although the market demand is high and the patient are willing to pay for the drugs at subsidized price. The patients/users agreed that they were satisfied with the quality of treatment and services provided at the hospital. Although, its takes a whole day to see consultant doctor due to very high numbers of patients patronizing the hospital. It can be inferred that the stakeholders were somehow satisfy with Calabar hospital and health care facility project.

Ibom Le Meridien hotel Uyo; the interviewees involve one government official from the state PPP directorate, two investors and two users. The government official comments that she was highly satisfied with the hotel and the international standard golf course makes the hotel a very unique one in Nigeria. In terms of the functionality of the hotel, she comments that it is function as intended while in terms of whether or not benefiting the end users, she said that the hotel is really benefiting the users. The investors were highly satisfied with the whole concept of the hotel and golf course. They agreed that the hotel is function as intended and the market demand for reservation is highly encouraging. People come from various part of the country for reservation and holds conferences / annual general meetings of various professional bodies. They unanimously agreed that the projects would be self sustaining. The end users were highly satisfied with the Ibom Le Meridien hotel. They agreed that the hotel has creates employment to the people of the state. The market women leader at Uyo main market comments on the Le meridien hotel Uyo as being highly attractive but not for market women or middle class set of people. Although she stated that she had attended some government functions at the pavilion of the hotel. Therefore, it can be concluded that the stakeholders were highly satisfy with the Ibom Le Meridien hotel.

The interviewees on Le Meridien Ogeyi palace hotel Port Harcourt comprise one government official from the state PPP directorate, two investors and two users. The government official comments that he was highly satisfied with the hotel based on its functionality and meeting international standard. In terms benefiting the end users, he said that the hotel is really benefiting the users. The investors were highly satisfied with the level of users' demands for the hotel. They agreed that the hotel is function as intended and the market demand for reservation is highly encouraging. People come from various part of the country for reservation and holding of conferences. The end users were highly satisfied with the hotel. They agreed that the hotel has creates employment to the people of the state. Therefore, it can be inferred that the stakeholders were highly satisfy with the Le Meridien Ogeyi palace hotel Port Harcourt.

Tinapa business resort Calabar; the interviewees involve one government official from the state PPP directorate, two investors and two users. The government official comments that she was highly satisfied concept of the business resort and the beauty the resort is adding to the state. At the same time he was not satisfy with the current situation of the business resort in terms of its functionality and whether benefiting the users. He comments that currently the resort is neither not function as intended nor benefiting the end users. He added that the resort benefiting no one presently because no business activity is going on there. The investors were not satisfied with the current situation of the resort. Although, it was successfully completed and highly attractive but making no returns because there is no business activity there. They agreed that the resort is not function as intended and the market demand is zero. The end users were dissatisfied with the Tinapa business resort. They agreed that no business is taking place in the business resort currently. A market women comment bitterly that the resort is like ghost area. She called on both the federal to assist the state government to resuscitate the resort Therefore, it can be concluded that the stakeholders were dissatisfy with the tinapa business resort.

The interviewees on Uyo science and technology park involve one government official from the state PPP directorate, two investors and two users. A top government official comments that she was not satisfied with the current situation of the science and technology park because it neither functions as intended nor benefiting the end users. She further comments that the concept the science and technology park was good and would have boosted the standard of living of the people in the state if not due to game of politics. The investors were not satisfied with the current situation of the science and technology park. Although, the

phase one was successfully completed and fully equipped and commissioned. But doe to game of politics or political reason the nothing takes place and the whole place is under lock. The end users were dissatisfied with the science and technology park. They agreed that no business is taking place and place is under lock. Therefore, it can be deduced that the stakeholders were dissatisfy with the science and technology park.

The interviewees on Akwa Ibom international airport involve one government official from the state PPP directorate, two investors and two end users. The government official from the state PPP directorate was highly satisfied with Akwa-Ibom airport projects. He based his comment on the whole concept of the airport in terms of meeting the international standard, contain both training and maintenance sections that turns Akwa Ibom into a regional hub for aviation. In terms of the functionality of the airport, his comment was that the airport project functions as intended. In terms of whether or not benefiting the end users, he lamented that it is really benefiting the users. The investors were highly satisfied with the airport in terms of its functionality and user's demands. They agreed that the airport is function as intended and the user's demands are highly encouraging because on daily bases airlines connecting Uyo - Lagos and Uyo - Abuja and vice versa at the airport. The end users were highly satisfied with the airport projects. They agreed that they were relieved from going to Calabar to board airplane. They further agreed that the airport has creates employment to the people of the state and some people from other parts of the country. The airport has being a great source of relief and means of employment. They appeal to the state government to complete the remaining aspect of the second phase in order to connect directly from Akwa-Ibom state to UK and the rest of the world to fulfill being a real international airport. It can be deduced that the level of satisfaction of the stakeholders with Akwa-Ibom International Airport is high as they were indicated in their comments.

The Asaba International airport; the interviewees involve one government official from the state PPP directorate, two investors and two users. The government official comments that he was highly satisfied with airport projects. In terms of the functionality of the airport, he comments that the airport project is function as intended while in terms of whether or not benefiting the end users, he said that the airport is really benefiting the users. The investors were highly satisfied with the airport in terms of its functionality. They comments that the airport is function as intended while In terms of the user's demand, they said that the user's demands are highly encouraging and that on daily bases airlines connecting Asaba - Lagos and Asaba - Abuja and vice versa at the airport. The end users were highly satisfied with the airport projects. They agreed that they were relieved from going to Owerri to board airplane. Furthermore, they also agreed that the airport has creates employment to the people of the state and some people from other parts of the country. Therefore, it can be concluded that the stakeholders were highly satisfy with Asaba airport.

The interviewees on Itam motor park and transit involve one government official from the state PPP directorate, two investors and two users. The government official comments that he was highly satisfied with the Itam park and transit based on its functionality and concept of modern motor park and transit. The Itam park is divided into three segments: AKTC, Lagos and local park In terms of whether or not benefiting the end users, he said that it is really benefiting the users. The investors were highly satisfied with the level of users' demands in terms of patronages. They agreed that the Itam park and transit is function as intended and the users' demands are highly encouraging. About 50 buses of 14 passengers travel from AKTC section of Itam motor park to various parts of the country. The end users were highly satisfied with the facilities at Itam motor park and transit. They agreed that the fare is fairer at AKTC park than the other segment of the park called Lagos park. Therefore, it can be inferred that the stakeholders were highly satisfy with the Itam motor park and transit.

CONCLUSIONS

It is a known fact that Nigeria main source of economy is crude oil, located within the Niger-Delta region. Despite this relative oil wealth, it is evidence that the region is peculiar with fewer infrastructural facilities and those that were available are in bad condition especially in the oil exploration areas within the region. Therefore, mush infrastructure is needed in the region and the government alone cannot provide the entire needed infrastructure. The government needs collaboration with the private investors in order to give the region uplifted phase value. The results of this research will provide a useful tool for rapidly understanding between the three stakeholders of PPP infrastructure project. Hence, for stall cordial relationship and satisfactory security needed for investment. Finally, The Involvement of the beneficiary community in the implementation and delivery of infrastructure projects is recommended. In order to let the end-users know the benefits and challenges of investment in PPP infrastructure projects in the region as well as having sense of belonging in the projects. This increased confidence and capacity of individuals or groups and also build mutually supportive networks that hold communities together. Collaboration involves an attempt to work with the other person to find a win-win solution to the problem in hand - the one that most satisfies the concerns of both parties. The win-win approach sees conflict resolution as an opportunity to come to a mutually beneficial result and forestall satisfactory security needs for investment in the region.

Confident-building measure through establishment of forum between the private and public sectors and end users' to discuss economic impact and social value of the infrastructure projects for growth, determination of the priority of the infrastructure projects and the challenges. The decisions are taken immediately in order to make effective resolution. This kind of partnership between the government, private sector and end users' will improve the investment climate in Niger-Delta region or any other conflict zone.

An Appraisal of Performance Measurement Practice of Construction Firms in Nigeria

Paul, C. A.[1]; Zaki, Y. M.[2]; Kolo, B. A.[3] & Adogbo, K. J.[4]*

[1, 2, 3&4]Department of Quantity Surveying, Ahmadu Bello University, Zaria, Nigeria

ABSTRACT

Performance measurement (PM) is crucial to the construction industry (CI) in order to improve the performance of the industry and most importantly as a tool for continuous improvement. Unfortunately, unlike several CI in the West, especially in the UK, US, Chile and Brazil, most firms in Nigerian CI are still holding on to the traditional approach to PM which has been widely criticised. The study appraised the PM practice of construction firms in Nigeria. A questionnaire survey was conducted on randomly selected small and medium sized construction firms in Abuja, Nigeria. A total of 50 questionnaires were distributed and 23 were returned and used for analysis. Data were analysed using the descriptive statistics method including tabulation, percentages and charts. The results of the study revealed that most construction firms are interested in how they perform and do measure their performance. The study also shows that most of the construction firms still rely on financial measures (which has been highly criticised). Findings from the study also indicate a low awareness/implementation of PM and PM concepts. The most adopted PM framework was found to be the Balanced Scorecard. It is recommended that proper documentation and efficient information system of construction firms' overall function be encouraged within the Nigerian Construction Industry.

Keywords: Performance measurement, Continuous improvement, Performance measurement frameworks

INTRODUCTION

The construction industry (CI) is a fundamental economic sector that permeates most of the other sectors as it transforms various resources into physical, economic and social infrastructure necessary for socio-economic development (Ministry of Works, 2003). In Nigeria, the industry occupies an important position in the economy and has great potentials of becoming one of the biggest construction markets yet; it contributes less than other industries (Aibinu and Jagboro, 2002; Construction Overview, 2011). The Nigerian Construction Industry (NCI) contributes only 3.2% to the Gross Domestic Product (GDP) which is very low (Dantata, 2008; Construction Overview, 2011).

The performance of the CI has considerable impact on the economy (Bon-Gang and Fan, 2010). The industry, globally, has been under tremendous pressure to improve its performance and several calls have been made in this regard (Kulatunga et al., 2005). In Nigeria, the NCI is faced with problems such as construction delays, time and cost overruns, abandonment of projects at various stages of completion, lack of skilled local labour, power shortage, unavailability of materials, corruption, unethical practices and lack of capacity to deliver (Aibinu and Jagboro, 2002; Dantata, 2008; Kolo and Ibrahim, 2010; Ayodele et al., 2011; Oyewobi et al., 2011). The industry suffers the problems of inefficient policies and practices, weak institutions and adverse business environment, alongside complex social and cultural practices (Aniekwu and Audu, 2010). The performance of the industry has been a concern to its stakeholders who have called for improvement in its performance (Okuwoga, 1998; Aibinu and Jagboro, 2002; Kolo and Ibrahim, 2010).

One of the key areas identified for the improvement of the construction industry's performance is the area of performance measurement (PM) (Latham, 1994; Egan, 1998;

Paul, C. A.; Zaki, Y. M.; Kolo, B. A. & Adogbo, K. J. (2016). An Appraisal of Performance Measurement Practice of Construction Firms in Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 864-871

Bassioni et al., 2004). According to Mbugua et al (1999), Baldwin et al (2001), Wegelius-Lehtonen (2001) and Martinez (2005), PM is vital for continuous and progressive improvement in most businesses and organisations. PM is defined as 'the quantification of efficiency and effectiveness of past actions by means of data acquiring, collection, sorting, analysing, interpreting and disseminating (Neely et al., 1998).

The call for improvement in the construction industry and interest in PM led to its adoption by several countries. The UK construction industry adopted PM in its agenda leading to the implementation of PM by several construction firms (Lattifi et al., 2001; Bassioni et al., 2004). In Nigeria, the Public Procurement Act of 2007 was formulated to improve the performance of the NCI. Performance measurement has evolved through the years (Wilcox and Bourne, 2003). PM in its early phase involved the use of financial measures such as profit, return on investment and productivity (also known as traditional measures) and was heavily criticised for been misleading, difficult, confusing and also hindering continuous improvement (Ghalayini and Noble, 1996).

Over the last few decades, there was a paradigm shift since it was apparent that the use of financial measures alone was not enough to manage modern organisations (Wilcox and Bourne 2003; Khan and Shan, 2011). Several frameworks containing non-traditional measures were developed to counter the limitations of the traditional measures. They include European Foundation for Quality Management (EFQM), Balance Scorecard and Performance Prism.

Construction firms within the construction industry benefit a lot from PM practice when they evaluate their current performance and then identify strategies to maintain good performance in the future. PM also helps organisations achieve their goals and objectives, be more competitive and successful (Backinsell, 2001; Bassioni et al., 2004). Although construction firms derive several benefits from measuring their performance, PM has not been widely implemented and information on the performance of the construction industry is scarce (Costa et al., 2004). Another setback for PM practice is that most construction firms still depend on traditional measures that focuses on profitability, efficiency and return on capital which has been criticised severally (Kagioglou, 2001; Bassioni et al., 2004).

RESEARCH METHOD

The study appraised the PM practice of construction firms in Nigeria. The scope of the study was limited to construction firms in the Federal Capital Territory of Nigeria, Abuja. The quantitative approach using questionnaire survey was used for this study to allow for respondent's convenience and high response rate (Statistics Canada, 2010). The sample survey approach for data collection was adopted and used to collect data on PM from a sample of construction firms in Abuja.

The data were collected through a well-structured questionnaire. The questionnaire was first piloted before it was finally administered to the construction firms. The population for the study is construction firms (mainly small-size and medium-size as outlined by Odediran et al., 2010) in Abuja. Abuja was selected due to the on-going development and unprecedented growth that has led to massive construction work and influx of people from all over Nigeria in the last 36 years (Jubril and Garba, 2012).

Questionnaire was administered to 50 construction firms through random sampling technique based on the list of registered construction firms in Abuja. 23 copies were retrieved representing a response rate of 46% as shown in Table 1. The response rate of 46% is acceptable and is a little above what is obtainable based on the opinions of Chinyio et al

(1999); Akintoye (2000); Dulami et al (2003) and Takim et al (2004). They all reported that in the construction industry, the response rate of 20-30% is what is usually obtainable for questionnaire survey (Akadiri, 2011)

The data collected were analysed using the descriptive statistics method. The descriptive statistics method is the simplest method of analysis that provides a general overview of the results and also gives an idea of what is happening and analyses survey percentages, actual numbers (totals), averages and proportions (Naoum, 2007; Statistics Canada, 2010).

Table 1 Questionnaire rate of response

Respondents	Questionnaires issued	Responses	% Response
Construction firms	***50***	**23**	**46%**

RESULTS AND DISCUSSIONS

Construction Firms' interest in Performance

22 construction firms representing 96% responded that they are interested in measuring their performance; while 1 construction firm representing 4% responded that they are not interested in measuring their performance. When further probed, the respondent responded by saying 'the organisation is only interested in profit and nothing else'. Profit (a financial measure) is a performance measure; meaning, that organisation relies on only financial measure.

The construction firms further responded that they are interested in measuring performance due to various reasons as shown in Table 2. Responses show that construction firms measure their performance due to two major factors; to improve future performance (26.6%) and to sustain competitiveness (20.3%) as shown in the table below.

Table 2 Reasons for organisations' interest in performance

Reasons for interest in performance	Frequency	Percentage
In order to survive	*7*	*10.9%*
Improved future performance	*17*	*26.6%*
Attract future investment	*8*	*12.5%*
Increase share value	*8*	*12.5%*
Attract higher calibre of employees	*3*	*4.7%*
Sustain competitiveness	*13*	*20.3%*
Survive in national and international markets	*8*	*12.5%*

Performance measurement (PM) practice

91% of construction firms admitted that they do measure their performance while 9% responded that they do not measure their performance. However, out of the two organisations that do not measure their performance; one of the organisations responded they are only interested in profit. It is possible that those firms who responded 'no' do measure their performance (since profit is a performance measure) but rely mainly on financial measures such as profit, quality and specification. When construction firms were asked if their organisation have PM in their policy or mission statements, 78% of respondents say they do even though this cannot be proven by this researcher based on the research instrument used.

Globally, several factors led the construction industry to begin to measure its performance. In this research, one of the major factor that led construction companies to measuring their performance is 'increasing global competition' (31.25%) as shown in Table 3. Other notable ones are; changing nature of work (18.75%) and power of information technology (18.75%).

Performance Measures and adoption

Several researchers have identified PM and have been adopted by several construction industries. In this research, construction firms responded that they adopted PM such as quality

(13.24%), turnover (11.03%), delivery (11.03%), profit margin (7.35%), cash flow (7.35%) and very few non-financial measures like client satisfaction (10.29%). The result is summarised in Table 4 below.

Table 3 Factors responsible for measuring performance

Factors	Frequency	Percentages	Rank
Changing nature of work	*9*	*18.75%*	*1*
Increasing global competition	*15*	*31.25%*	*2*
Changing organisational roles	*8*	*16.67%*	*3*
Changing external demands	*7*	*14.58%*	*4*
Power of Information Technology	*9*	*18.75%*	*1*

Table 4 Performance measures used by construction companies

Performance measures	Frequency	Percentages	Rank
Quality	*18*	*13.24%*	*1*
Cash flow	*10*	*7.35%*	*4*
Employee satisfaction	*7*	*5.15%*	*6*
Specification	*7*	*5.15%*	*6*
Leadership	*3*	*2.21%*	*8*
Capabilities (Technology, Infrastructure)	*4*	*2.94%*	*7*
Cost	*9*	*6.62%*	*5*
Turnover	*15*	*11.03%*	*2*
Market share	*4*	*2.94%*	*7*

Customer loyalty	*7*	*5.15%*	*6*
Number of customer complaint	*3*	*2.21%*	*8*
Stakeholder satisfaction	*3*	*2.21%*	*8*
Delivery	*15*	*11.03%*	*2*

Construction firms responded that 52.4% get their measures from existing PM frameworks, 23.8%get theirs from strategy and policy and 23.8% also get theirs from both frameworks and strategy/policy as shown in Table 5 below.

Table 5 Sources of Construction Firms' Measures

Sources of Performance Measure	Frequency	Percentages
From the organisation's strategy/policy	*5*	*23.8%*
From existing performance frameworks	*11*	*52.4%*
From both organisation's strategy/policy and existing frameworks	*5*	23.8%

In order to consider a performance measure adoptable by a construction firm, it must possess certain attributes. The two most common attributes a performance measure based on the response from this study are; reliability (22.8%) and credibility (21.5%) as shown in the Table 6 below.

Table 6 Attributes of Performance Measures

Attributes of Performance Measures	Frequency	Percentage	Rank
Validity	*12*	*15.2%*	*4*
Responsiveness	*9*	*11.4%*	*5*
Abuse-proof	*4*	*5.0%*	*7*

Functionality	*13*	16.5%	*3*
Availability	*6*	7.6%	*6*

Construction firms were asked if their performance measures adopted. 81% of organisations responded they do undergo periodic review while 19% do not at all.

The time frame for this periodic review is quarterly (47.1%), yearly (29.4%) and the least is monthly (23.5%).

Benefits of measuring performance

The major benefits of measuring performance according to respondents are in accountability (14%), control (14%) and improvement in productivity (15%).

Table 7 Benefits of measuring Performance

Benefits of measuring Performance	Frequency	Percentage	Rank
Accountability	*13*	*14%*	*2*
Profitability	*12*	*13%*	*3*
Achievement of objectives and strategy	*10*	*11%*	*4*
Control	*13*	*14%*	*2*
Track progress	*12*	*13%*	*3*
Strategy formulation	*9*	10%	*5*
Long term competitive advantage	*9*	10%	*5*
Improvement in productivity	*14*	15%	*1*

PM Frameworks

The awareness of existing PM frameworks is important in order to select the most appropriate ones to use. 71% of construction firms responded that they are aware of existing PM frameworks (even though awareness may not imply usage of same) while 29% lacked awareness.

Respondents were asked to tick the frameworks they know and mention other ones not listed in the questionnaire. The three most popular frameworks used by construction companies are performance measurement matrix, balanced scorecard and the performance pyramid as shown in Table 8.

Table 8 Known existing PM framework

Existing framework	Frequency	Percentage	Rank
Performance measurement matrix	*10*	*35.7%*	*1*
Balanced scorecard	*8*	*28.6%*	*2*
Performance pyramid	*8*	*28.6%*	*2*
Performance prism	*0*	*0%*	*4*
European Foundation for Quality Management Model (EFQM)	*2*	*7.1%*	*3*

In terms of the adoption of these existing PM frameworks, 79% construction firms responded that they've been able to adopt them while 21% are yet to adopt them.

The most adopted PM framework by construction firms is the balanced scorecard representing 40%. Next to the balanced scorecard is the PM matrix with 35% representation.

Table 9 PM frameworks adopted

Adopted PM Framework	Frequency	Percentage	Rank
Performance measurement matrix	*7*	*35%*	*2*
Balanced scorecard	*8*	*40%*	*1*
Performance pyramid	*5*	*25%*	*3*
Performance prism	*0*	*0%*	*4*
European Foundation for Quality Management Model (EFQM)	*0*	*0%*	*4*

Challenges associated with PM implementation

When asked to outline the challenges associated with PM implementation in their organisation, some of the construction firms outlined the below as some of the challenges associated with PM implementation as summarised in the table below. Some of the firms did not outline any challenge.

DISCUSSION

The study appraised the PM practice of construction firms in Nigeria. The result of the research shows that most construction firms are interested in their performance and the most common reason for this interest is to improve future performance. This result agrees with Love and Holt (2000) and Backinsell (2001) who pointed out there is so much interest in performance especially within the construction industry.

On whether the construction firms measure their performance or not, 91% of them do measure their performance and the major reason for measuring performance is due to increasing global competition. This also agrees with some of the reasons for PM outlined by Lee et al (2000). The study also established that most of the construction firms still relied on traditional or financial performance measures as earlier established by Kagioglou (2001) and Bassioni et al (2004).

Table 10 Challenges associated with PM implementation

Challenges associated with PM implementation
Inconsistent profit margin
customer disloyalty
Lack of adequate cash flow
Employee dissatisfaction
Type of organisation's leadership
Difficulty in data collection for evaluation,
Time involved in evaluating performance,
Lack of skilled personal who can measure performance
Lack of reliable structure in place
Inability to deliver
Uniqueness of clients/clients' needs and
Lack of technical know-how among personnel
Lack of proper documentation and malpractices
Client's demands and meeting up with global trend
Data collection
Diversity in customers/clients need
High competition
Inefficient information system
Collection of data needed for excellent evaluation
Difficulty in collection of data
Lack of interest in measuring performance
Lack of proper sourcing of data
Improper recording of information
Communication problem

The most common measures adopted are; quality and delivery. The study also shows that the two most common attributes a performance measure must possess is reliability and credibility and one of the benefit of measuring performance is improved productivity. In the area of awareness of existing PM frameworks, about 71% of construction firms are aware of them and the most known framework is the PM matrix while the most used or adopted framework is the Balanced Scorecard.

This result agrees with what Kulatunga et al (2006) and Khan and Shah (2011) stated in their works that the Balanced Scorecard is the most popular PM framework in terms of adoption. Some of the challenges construction firms face in the implementation of PM are; difficulty in data collection, lack of reliable structure in place, lack of proper documentation, communication problem and uniqueness of clients' need. Some of these challenges agree with Costa et al (2004) assertion in the area of scarcity of information.

The study concluded that a lot still needs to be done in the area of PM practice among construction firms in Nigeria.

SUMMARY

In summary, the study appraised the PM practice of construction firms in Nigeria and the following as major findings:

i. Majority of the construction companies are interested in how they perform and actually measure their performance.
ii. Only a few of the construction firms have understanding on PM concepts.
iii. The most used performance measures are the traditional measures (which has been highly criticised) with few adopting the non-traditional measures.
iv. The most popular and most used framework is the Balanced Scorecard.
v. Most construction firms are faced with certain challenges when implementing PM. Some of these challenges are; lack of proper documentation, lack of reliable structure in place and lack of technical know-how among personnel.

CONCLUSION

In conclusion, the study shows that construction firms have high interest in their performance and do actually measure their performance. However, the awareness of PM and its concepts are still low with no structure on ground to guide. The lack of proper and adequate data documentation and also reliance on financial measures in most construction firms is evident in the course of the research. Finally, the most adopted PM framework is the Balance Scorecard.

RECOMMENDATIONS

i. Construction firms should be trained on ways of properly documenting their data and subsequent access to these data.
ii. There need to be more awareness of PM and its concepts among construction firms.

ABSTRACT

Risk is associated with every human endeavour. Project risk has been viewed from different perspectives which can determine the outcome of a successful project apart from other variables which include cost, time and quality. This study aims at evaluating the effects of project risk factors on civil construction cost accuracy from contractors' and consultants' perspectives with the view to achieving the overall project success in terms of cost performance. In order to achieve this aim, the objectives of the study are to identify and evaluate the effects of project risk factors responsible for inaccurate prediction of civil construction cost in the Niger Delta Region of Nigeria. Extensive literature review was carried out to assess the risk factors affecting civil construction cost. Based on the comprehensive assessment of the risks, twenty-five (25) factors were identified. A purposive survey of 36 valid responses comprising 18 contractors and 18 consultants was carried out with structured questionnaire. Data obtained were analysed using Percentile and Relative Importance Index (RII).The results revealed that ten factors have very high significant effect on the cost of civil construction projects. This study also revealed that there is high agreement between contractors` and consultants' perceptions of the effect of the risk factors on civil construction cost. This study therefore recommends that contractors and consultants should focus on risks related to cost, resource management, elements of construction sustainability, construction environment as an effective management and control tools to bringing risks on civil construction projects to the barest minimum and enhance the possibility of attaining good success on the overall construction cost delivery.

Keywords: Construction Cost, Consultants, Contractors, Cost Delivery, Risk Management

INTRODUCTION

Civil construction projects involve large capital outlay, complex contractual arrangement, unbalanced cash flow and inflation. This is majorly due to changes in economic, financial, political and environmental activities resulting in regulatory policies. All these bring with them some element of risks. The way and manner these risks are managed is very important as the success and failure of any project depend on it.

Risk management forms one of the nine management areas in the project management body of knowledge by the Project Management Institute (PMI, 2008). This is key as every human endeavour is associated with one form of risk or the other and construction activity is not excluded especially civil construction projects. Risks play a significant role in decision making and may affect the project performance in construction projects.

According to Oyegeko and Phen, (2006), construction projects are always unique and element of risk emanate from different sources, dynamic and complex and gives room for multiple processes in terms of feedback (Uher, 2006).

There are major variables that play vital roles in the successful completion of any construction activity. These include cost, time and quality. Most times, these factors are influenced by some elements of risk especially cost. Cost is the bedrock of any development

Anjiba, D. LP. & Adu, E. T. (2016). Project risk factors effects on civil construction cost in the Niger Delta Region Contractors' and Consultants' Perspectives. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 872-883

project as it is inevitable to achieve any project without an element of cost. It becomes imperative to ensure that cost is well understood at the planning stage before implementation.

Cost is risky when there is no total consideration. Cost of risk is a concept that has not been considered by many construction industries despite the fact that it is the factor that is most expensive (Cavignac, 2009). Different project stakeholders have different skills and expertise that are determinants to the outcome (Dey, 2004). It then means that, risk management will help project stakeholders (client, contractor, consultant, supplier and beneficiaries) meet their set goals and bring to the barest minimum the negative impacts on construction success in term of cost, time and quality.

A lot of researchers have highlighted the causes of risks factors in construction projects, life cycle, environmental factors but little research has probed effects of risks from the contractor's and consultant's perspectives to enable evaluate these factors and minimise or eliminate them from the feasibility study stage of the project.

This study seeks to evaluate the effects of risk factors viewed from the contractors' and consultants' on cost of civil construction projects in the Niger Delta Region of Nigeria with the administration of questionnaires. The region was well chosen as it is always characterized with a lot of construction activity per time. The factors so highlighted from the two perspectives will give a holistic view of how to tackle risk at every point in the projects life cycle.

LITERATURE REVIEW

Civil Construction Industry

The construction industry is a complex, heterogeneous and dynamic one with infrastructural development in the build environment fraught with risks and uncertainties. The problem multiply in size due to the nature of construction project (Dey, 2011, Dey and Ogulana, 2002)

These include buildings, civil, mechanical and electrical installations. Civil construction projects include; high-rise buildings, overpasses, bridges, tunnels, dams, reservoirs, rail tracks, swimming pools, hydro power etc. The success parameter for these developments is enshrined in cost, time and quality but these can be truncated along the project life cycle owing to some inclination of risk factors.

Impacts of risks on project strategies with respect to cost was the focus of Chen *et al.,* (2004), while Shen, 1997 looked at time while Tam et al 2004 related risk to safety. Other researchers viewed risk factors management for construction projects at the life cycle of the project. Project conceptual and feasibility phases were viewed by Uher and Toakley (1999), and design phase by Chaoman, 2001 and construction phase by Abdou, 1996

Risk Defined

The word 'risk' has been used differently by different researchers. Risk is defined as a combination of the probability, severity and exposure of all hazards of an activity (Jannadi and Almishari, 2003), hazards or uncertainty (Al-Bahar and Crandall, 1990), likelihood of occurrence and the degree of impact of a negative event adversely affecting an activity (Chapman, 2001), a threat to project success, where the final impact upon the success of the project is uncertain. According to Chitkara, (2011), risk is an abstract term, uncertain event, situation or condition which may occur. It may have a positive or negative effect on project objectives. Therefore, risk can be viewed as the potential for unwanted or negative impacts of an activity.

It can be generally recoginised among those within the construction industry as the phenomenon of continually facing a variety of situations involving many unknowns,

unexpected, frequently undesirable and often unpredictable. A newer definition defined risk as the chance of something happening that will have an impact on objectives positive or negative (Australia Standards, 2004). From all these definitions, authors have viewed risk as negative but some risks are beneficial. With these understandings, risk is bound to emanate from different sources.

Sources of risk in civil construction projects

According to Fidan et al., (2011), source of risk is defined as any factor that has a potential to cause harm to a project either owing to an adverse change from initial project conditions or expected situation. Construction projects risks is crucial in decision making and if not dealt with properly, can cause cost overrun, project time slip, fluctuation and loss/expense claims.. Project risks differ and different strategies should be used to minimise cost and time overruns.

Project's performance and success is being influenced by some variables as indicated earlier which has to do with time, cost and quality in beneficial or detrimental ways. According to Akinlola et al., (1997), these sources could be grouped as environmental, construction, operation, physical, political, legal, financial, design, logistic risks. Risk was also grouped as external and internal. Internal risks involve, design, contractual, financial, construction, personal and operational risks while the external risks has to do with environmental, economic, political, social, public, legal and logistic risks (Nguyen and Ogulana, 2007). Internal risks can be controlled by project managers while the reverse is the case for external risks.

Many methods exist on how to classify risk associated with construction projects. The PMI (2008) grouped as internal and external. The internal risks include; technical risks (government regulations, force majeure, labour stoppage, cash flow, and safety issue), non-technical risks (technology changes, state-of-the art changes, issues of operation, maintenance issues) and legal risks (licenses, patent rights, lawsuits, subcontractors' performance and contractual failures). External risks include; costs, borrowing and interest rates and availability of raw materials. These distinctions became necessary to enable manage or curb risks when they occur. As the saying goes, 'problem known is half solved'.

Cost – Related Risk

A lot of risks occur in the project life cycle and others by some factors in the cause of project execution. However risks occur, it is important to envisage before their occurrence. The table below suggests the different risk factors affecting cost of construction projects according to (Wiguna and Scott, 2005).

Table 1 shows that high inflation and increased price, design change by owner, defective design, weather condition and delayed payment of contractors were the first 5 factors that affected cost of construction projects.

Impact of risk

Australia Standards, (2004) has earlier defined risk as either positive or negative which can be seen as an event. Risk event therefore, can be best described as variations (increase or decrease) in quality and quantity of work, performance, productivity, project schedules in time, progress payment in terms of cost. The outcome of an event definitely has an impact or variance on the projects' objectives and delivery. The effects of risk factors were viewed by Al-Bahar and Crandall, 1990 and Zhang, 2007 with respect to projects' objectives such as cost, time, quality and safety.

Difference Between Risk and Uncertainty

Risk can be classified as beneficial or detrimental. Beneficial risk can enhance the achievements of the objectives of the project. Beneficial risks are called opportunities.

Detrimental risk: This may pose a challenge or adverse exposure to the achievement of the objectives of the project. Detrimental risks are called threats. Risks increase with hazards but can be decrease with safeguards.
Risk is quantitative while uncertainty is qualitative. Flanagan et al., 2006 and Mills, 2001 opined that risk and uncertainty can potentially have damaging effects for construction projects.

Table 1: Risk factors causing cost of construction projects

External and site condition	Mean of risk factor	Ranking	Economic and financial	Mean of risk factor	Ranking	Technical and contractual	Mean risk factor	Ranking	Managerial	Mean of risk factor	Ranking
Unforeseen site ground condition	0.4191	7	High inflation and increased price	1.4552	1	Defective design	1.1932	3	Defective construction work	0.3649	11
Weather condition	0.6979	4	Delayed payment on contract	0.5509	5	Design change by owner	1.2147	2	Low labour and equipment productivity	0.3288	12
Difficulty in obtaining permits and ordinances	0.0918	15	High interest rate	0.2142	14	Inadequatel y compensated variation order	0.3060	13	Inadequate project programme	0.3781	9
Changes in govt policies	0.0627	16	Poor cost control	0.3774	10	Delay in providing detailed drawing	0.4138	8	Problem with availability of labour, material and equipment	0.5266	6

Risk Management

Management of risk in civil construction sense is a systematic way of identifying, analyzing, and dealing with risks associated with project with the singular aim of achieving the project objectives. Risk management is one of the nine knowledge areas by the Project Management Institute (PMI). The PMBOK Guide recognizes nine knowledge areas typical of almost all the project. These include:

i. Project integration management
ii. Project scope management
iii. Project time management
iv. Project cost management
v. Project quality management
vi. Project human resource management
vii. Project communications management
viii. Project risks management
ix. Project procurement management

PMI defined management of risk as the processes concerned with conducting risk management, planning, identification, analysis, responses, monitoring and control on a project.

In all the key areas, there are inherent characteristics, e.g. risk management has the following according to (PMI, 2008)

i. risk management and response planning
ii. risk identification, monitoring and control

iii. Qualitative and quantitative risk analysis

Risk identification

Several risk identification and assessment methods have been proposed to facilitate project risk management. The first step to risks management is risk identification.in which potential risks associated with construction projects are identified, (Akinci and Fischer, 1998, Zou et al., 2007) Several risk identification and assessment methods have been identified to facilitate project risk management. The proposed methods include risks checklists and risk breakdown structures are used to identify potential risks of projects.

Azhar et al., (2008) was able to identify 42 cost overrun factors and arranged them in three categories which include macro economies, management and business and regulatory environment. In this regard, Enhassi et al., (2009) identified 110 delay factors and causes which were classified into 12 groups which include time and cost overruns in Gaza construction projects.

Risks associated with projects also emanated from construction stakeholders which include Client, quantity surveyor, architect, structural engineer, services engineer, contractor and subcontractor, suppliers and external factors that caused project delays,(Aibinu and Odeyinka, 2006) Other risk factors can be project, client, contractor, design team related, material, labour, plant and equipment and external factors as asserted Kumaraswamy, 1996 in Hong kong. The author identified 83 factors and classified them into 8 categories. Others classified risk factors as it relates to finance, owner, contractor, consultant, project attributes, co-ordination and environmental problems, in Vietnam,(Long et al., 2004). Some were also grouped as an act of God, physical, financial, economical, design and job site related risks according to (Mustafa and Al-Baha, 1991). Frimpong et al., (2003) also identified some factors that caused delays and cost overruns.

Risk is associated with every human endeavour but effective risk management method can help understand not the kind of risks the project faces but how to manage these risk at all project phases.

It is a necessity in most industries and a set of techniques have been developed to control its effects (Baker and Reid, 2005 and Schuyler, 2001). Irrespective of the root causes of construction projects risks factors, there is need to assess these risks as it relates to the contractor and consultants as major stakeholders to enable project managers tackle risks factors that may affect the project from its outset.

Construction projects cannot be predicted and risk management is very important in the process in order to achieve the objectives of the project in terms of cost, time and quality.

Project risk management is an iterative process which may be beneficial when it is implemented in a systematic manner from feasibility to hand over in the life cycle of the project

The systematic risk management process has been divided into:

i. Risk classification
ii. Risk identification
iii. Risk analysis
iv. Risk response

According to Berkeley el al., (1991) and Flanagan and Norman, (1993). Risk response includes retention, reduction, transfer and avoidance. If these risks responses can be controlled, then risk can be managed.

Risk management in the construction project management context is an holistic way of identifying, analyzing and responding to risk to achieve the objectives of the project (ICE/RAMP 2005 and PMI 2007) When risks are identified and analysed with construction projects management improvement and use of resources ,effective risk management becomes beneficial. Management of risks is consciously proffering solutions to risks –prone areas. The management tool is geared towards identifying sources of risk and uncertainty, determining their impacts and developing appropriate management responses (Uher, 2003)

Risk Management Technique

Risk analysis and management techniques have been tackled by researchers which include (Ahmed and Kayis, 2007, Cretu et al., 2011, Chapman and Ward, 2003, Klemetti, 2006 and Smith et al, 2006) but risk management techniques were identified to include the following key steps, (Wysocki, 2009)

i. Risk identification
ii. Risk assessment
iii. Risk mitigation
iv. Risk monitoring

Risk Mitigation and Allocation

Risk mitigation measures to aim at minimizing the loss, damage or disruption in a project due to unforeseen event (Chitkara, 2011). The author went further to document the measures of risk mitigation and allocation. These include; risk transfer, risk deferred, risk reduction, risk acceptance, risk avoidance and risk sharing. These factors are to be considered when risk has already occurred.

Role of the Project Manager in Risk Management

Civil construction projects are always exposed to risks that affect the projects' objectives. This could be economical, financial, environmental, stakeholders, statutory, political etc. and also in the project's life cycle. The performance of project managers impact on the project either way (successfully or unsuccessfully).

METHODOLOGY

The research methodology chosen to evaluate the effects of risk factors on cost of civil construction projects comprised a comprehensive literature review, structured questionnaires to the stakeholders in the industry and a statistical analysis tool.

The questionnaire had 2 sections. The first section had to do with the demography of the respondents while the second part dealt with risk factors that affected civil construction cost. .The study identified twenty-five (25) risk factors affecting project cost through a comprehensive literature and administration of questionnaire. Other risk factors include; management, economic and finance, contractual and technical, external and site condition, environment and safety related risks but only the cost related risks shall be dealt with in this study.

Prior to the distribution of the structured questionnaire, a pilot study was conducted with an academia and contractor to test whether the questions were unambiguous. The feedback so obtained was satisfactory and a total of 60 questionnaires were distributed to construction stakeholders (contractors and consultants) in the six (6) core Niger Delta states of Nigeria. The survey data concentrated on projects executed and completed between 2005- 2009.

Feedback was received from 36 participates and 24 invalid responses due to incomplete answers. This represents a valid response of 60%, which is adequate according to Moser and Kalton (1971) assertion. The respondents who are industry's practitioners were asked to

assess the likelihood that the risk factors accessed would occur on their project and impact of occurrence on the cost of the project using a 5-point likert scale of 1-5 using a Relative Importance Index (RII) spanning from strongly agree(5), agree(4), neutral(3), disagree(2) and strongly disagree (1). A total of 12 civil construction projects were chosen from the six (6) core Niger Delta Regions and 18 of each of the contractors and consultants were also accessed for homogeneity from government companies constructed and completed between2005– 2009. Most of the contract sum ranged from 5Million – 5Billion as at the time of the construction. The government projects were chosen because civil construction projects are capital intensive.

DATA PRESENTATION AND ANALYSIS

A total of 60 questionnaires were distributed in the region. A response rate of 60% was achieved and variety of years of experience groups between 5 -30 years old and education level were included in the study.

Table 2: Distribution of respondents' years of experience and level of education

Year of Experience	Frequency	Percentage
‹ 10	14	38.89
› 10	22	61.11
Total	36	100.00

Table 3: Level of Education of Respondents

Level of Education	Frequency	Percentage
Doctor	10.00	27.78
Master	11.37	31.58
Bachelor	14.63	40.64
Total	36.00	100.00

Table 2 highlighted the years of experience of the contractors and consultants. From the table, it is obvious that greater percentage had years of experience over 10years while table 3 listed their education level. They are all read, that means, they understand fully well the research area.

There are several risk factors that affected the cost of civil construction projects but in the Niger Delta Region, the cost-related risk factors will be holistically viewed from literature. In appendix 1, all the projects that cut across the Niger Delta Region had a cost overburden between N300, 000.00 to N1, 800,000,000.00. This is not healthy for a developing economy like Nigeria where there is a dare need of infrastructure development for economic prowess. Table 5 shows the effects of project risk factors on the cost of civil construction projects in the region. This was further represented in a pie chart as shown in figure 1.

Table 5: Effect of project risk factors on the cost of civil construction projects

SN	Effect of risk factor	Frequency of Respondent	Percentage (%)
1	Delay of completion dates of the project	7.20	20
2	Cost variation in form of cost overrun	10.80	30
3	Conflict	3.60	10
4	Claims	1.80	5
5	Disputes	3.60	10
6	Risk	9.00	25
	Total	36.00	100

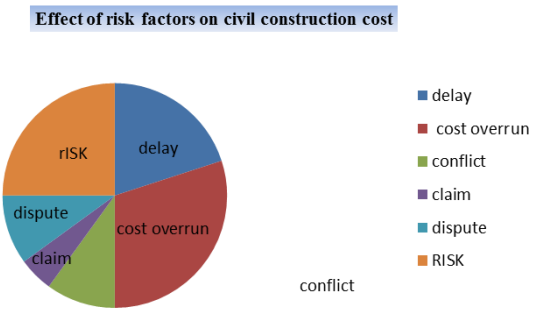

Figure 1: Effect of risk factors on civil construction cost

DISCUSSION OF FINDINGS

As earlier discussed in literature, all researches have dealt with factors that affected construction cost but its effects on are yet to be viewed from the contractors' and consultants' perspectives. This section shall mirror the risk factors and its ranking as viewed by contractors and consultants. The effects of these risk factors on cost highlighted and a control measure to check and curb these factors.

Key risks versus Contractor

The research assessed 25 key factors and the first five (5) most significant factors include; Change order by client with an RII of 0.97, ranking the 1st . This was closely followed by high inflation of exchange and interest rate with an RII of 0.95. Variation by client was ranked 3rd as perceived by contractors it an RII of 0.90. Design variation ranked 4th with an RII of 0.89 and incomplete or inaccurate cost estimate had an RII of 0.86 and was ranked 5th. This is shown on appendix 2.

Key risks versus Consultant

The research equally assessed 25 key factors and the first five (5) most significant factors include; Change order by client with an RII of 0.98, ranking the 1st. This was closely followed by Variation by client was ranked 2nd as perceived by consultants it had an RII of 0.97. High inflation of exchange and interest rate with an RII of 0.95. Design variation ranked 4th with an RII of 0.93 and incomplete or inaccurate cost estimate had an RII of 0.92 and was ranked 5th. Appendix 2 clearly shows the statistics.

Summary of the key factors viewed from the contractors' and consultants' perspectives

From the result, it could be seen that both contractors and consultants ranked change order by client as the most critical factor that affected cost of civil construction projects. They also jointly agreed that design variation and incomplete or inaccurate cost estimate were also significant factors that affect cost of the project though with different RII values. The effects of these risk factors include, cost overrun, risk, delay of completion date, dispute, conflict and claims. These effects so far listed as perceived by respondents have the potentials of ultimate project failure. It is important to view these risks by using the project life cycle and all potential stakeholders.

CONCLUSION

Effective management of risk factors will help the construction industry to identify and quantity the risk factors and consider risk mitigation measures. When risks are efficiently and effectively managed, cost saving is inevitable, great success rate and economic advancement.
The Niger Delta Region of Nigeria is a complex and volatile region because of its natural endowment and therefore calls for a well-articulated plan before execution. It is worthy to note that, change order by client and design variation, variation order, high inflation of exchange/interest rate and inaccurate cost estimate were top on the list of the risk factors.

Most of these factors can be controlled by the projects' team if there is a programmed understanding. The system needs to encourage all project stakeholders' participation as the need arises in the projects' life cycle. The industry needs to include risk as an integral part in the management process of the project. Risk must be planned for in any construction project.

RECOMMENDATION

i. Price escalation and fluctuation: This study has revealed that price escalation and fluctuation are the most prominent causes of cost slip of construction projects caused by risk factors. There is therefore an urgent need to improve the current trend in the Nigerian economy. During the period under the study, the prices of construction resources have always been on the increase.

ii. Delay in progress payment by client has been identified as a very significant cost slip factor, government should as a short-term measure consider the financial assessment before embarking on all construction projects in the country as this is capital intensive. This should be tied to the procurement of significant materials and plant items that will be needed during project execution

iii. Stakeholders' early participation: Both clients initiated and necessary variations have been identified as major factors leading to poor cost performance. The most effective way to reduce this is a thorough, complete and clearly presented project brief from the clients. Contractors and Consultants should be given reasonable time for detailed design and documentation.

iv. Currently in Nigeria, cost planning which is a most viable tool during the design process is almost neglected even in major construction works. All professional bodies in the construction industry should as a matter of urgency sensitise other consultants of the dare need for the design team to put cost planning into effective use in Nigeria.

v. Change order by client: Change order should be eliminated. Clients must be certain of what they want at the feasibility stage before embarking on the project

ABSTRACT

Accurate prediction of final tender sums (contract sums) of building projects depends on reliable projections of baseline cost plans developed at the design development stage. However, no matter how much care and effort is put into the preparation of design stage elemental cost plans, deviations are usually observed between these cost plans and the final tender sum. This makes accurate predictions challenging for construction practitioners in New Zealand. The major attributable factors for the observed variability are inherent risks in the design stage elemental cost plan development. Whilst this is recognized, this study evaluates the reliability of elemental cost plans in traditional building procurement. The study seeks to answer the question: is elemental cost plan a reliable budgetary tool for construction projects? The study was undertaken based on twenty completed building projects from which secondary data were collected within the New Zealand construction industry. Data analysis was carried out using document analysis and percentage deviation of final tender sums from the cost plans. Further analyses were carried out using root mean square and relative mean absolute deviation methods of analyses. The results showed that the budgetary reliability of elemental cost plans varied depending on project types. Whilst a deviation of -3.67% and +3.95% was obtained on the residential projects analysed, the deviation on educational projects was between -3.98% and +12.15%. Commercial projects attracted -14.22% and +16.33% while in the case of refurbishment projects, a deviation of -10.07% and +30.14% was obtained. These findings suggest that the larger or more complex a project is, the less reliable it is to use elemental cost plans to guarantee a reliable final tender sum prediction.

Keywords: Elemental cost plan, final tender sum, New Zealand, reliability, traditional building procurement

INTRODUCTION

The main concerns of construction clients in New Zealand are projects delivered within budget, on time, to the expected quality and with no surprises (Alan et al., 2008). Potts (2008) suggested that most clients work within tight pre-defined budgets or cost plans prepared by the consultant Quantity Surveyor at the design development stage. This is normally not expected to be exceeded; otherwise the whole scheme may fail. According to Odeyinka (2010) risks in traditional procurement are covered through the allocation of contingencies to cover both foreseen and unforeseen circumstances in design stage elemental cost plans. This is expected to ensure the completion of a project within the budget or cost plan. However, there are evidences in construction management literature indicating that it is difficult to find a project in which the final tender sum is the same as the design cost estimate/cost plan estimate (Akintoye, 2000; Aibinu & Pasco, 2008; Odusami & Onukwube, 2008; Enshassi et al., 2013).

Related studies conducted in the UK, Middle East, Asia and Africa concluded that in procurement methods where cost plans are used, deviations between the cost plan sums and final tender sums are common. Such deviations in the region of +1% to +12% are mentioned in: Morrison (1984), Cheong (1991), Oladokun et al. (2011), and Enshassi et al. (2013).

Adafin J.; Wilkinson S.; Rotimi J. O. B. & Odeyinka H. (2016). Budgetary Reliability of Design Stage Elemental Cost Plan in Building Procurement. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 884-893

According to Zou et al. (2007) the major attributable factors for these deviations are risk elements that are inherent in construction project developments.

Whilst these risk factors are recognised, the study determines the reliability of design stage elemental cost plan in building project procurement. This study provides information on cost plan and final tender sums of selected case study projects in New Zealand. This represents a benchmark for measuring cost planning accuracy or reliability. Although the usefulness of design stage elemental cost plan and final tender sum as pre- and post-contract cost control tools in traditional procurement has been documented, to the best of the knowledge of the researchers, there is no recent documentary evidence of an investigation into the budgetary reliability of design stage elemental cost plan in traditional building procurement in New Zealand construction. As such, the study finds its significance.

LITERATURE REVIEW

An Overview of Elemental Cost Planning

An earlier study by Dent (1978) defined cost planning as a system for monitoring cost at building design stage such that: tenders do not exceed preliminary estimates; and costs are developed in a way that gives project owners the best value for money. According to Seeley (1996) cost planning is a systematic application of cost criteria to a building design process to maintain in the first place, a sensible and economic relation between project parameters (cost, time, quality and functionality) and in the second place, provide overall control of proposed expenditure as circumstances might dictate. Several contemporary authors: Ashworth (2004), Ashworth and Hogg (2007), Kirkham (2007), Smith and Jaggar (2007), and Ashworth (2008) have expressed that cost planning is not only a pre-tender estimating method but also seeks to offer a control mechanism during the design stage.

Building cost planning was originally developed within the framework of the traditional procurement arrangement using conventional documentation, tendering and administration processes. With the advent of alternative forms of procurement and with more fluid approaches to design stage processes and documentation, the need for sound cost planning has not diminished (Smith et al., 2004). Thus, as a process established on solid theoretical foundations, Smith et al. suggested that cost planning should be robust enough to adapt and flourish in a variety of procurement environments.

In view of the above expressions and within the context of the current study, cost planning is simply a term that describes any system of bringing cost advice to bear upon a design process. In the same vein, design stage elemental cost plan is a pre-contract or specifically, a design stage cost control strategy based on elemental cost analysis which is prepared during the design development to give construction clients value for money. This bears in mind the need to meet specific requirements and ensure that available funds for a project are rationally distributed among the elements of the building. In this context, measuring the reliability of an elemental cost plan (a budget) means assessing the quality of the cost plan in terms of the expected accuracy range. Consequently, the reliability of a cost plan is determined by whether the expected accuracy range matches the required accuracy range. Meanwhile, the accuracy of a cost plan can be defined as the difference between final tender sum (contract sum) and elemental cost plan sum; this can be measured by the error rate calculated from Equation (1) (An et al., 2011):

$$[1] Error\ rate\ (\%) = (|\ Final\ Tender\ Sum - Elemental\ Cost\ Plan\ Sum|/\ Final\ Tender\ Sum) \times 100.$$

Similar view was illustrated in Ashworth (2004) whereby a range of -4% to +15% was recommended as an acceptable parameter for measuring estimating accuracy.

Previous Studies

Substantive research has been carried out in the field of pre-tender estimating for construction projects, a significant outcome of which is the identification of numerous risks that influence budgetary performance (Zou et al., 2007). Also some studies have investigated the accuracy of design stage elemental cost plans and their respective measure of influences, which is similar to the focus of the current study. Several researches (Akintoye, 2000; Enshassi et al., 2005; Aibinu & Pasco, 2008; Odusami & Onukwube, 2008; Onukwube et al., 2009; Oladokun et al., 2011; Jafarzadeh, 2012) have indicated that pre-tender estimating accuracies are significantly affected by the level of risk information available to estimators. These are recognised by this study as fundamental evidence of risk factors causing variability between elemental cost plans and final tender sums (Choy & Sidwell, 1991; Ling & Boo, 2001; Baloi & Price, 2003; Hlaing et al., 2008; Tsai & Yang, 2010).

The disparity between design stage elemental cost plans and final tender sums received in competition for a project would provide further evidence to the issues relating to the accuracy of pre-tender cost estimates in this study. For example, Morrison (1984) investigated this disparity in the United Kingdom by collecting and analysing data from seven separate quantity surveying firms. Morrison found that a mean deviation of 12% was obtained by the quantity surveyors. Also Ogunlana (1991) reported significant deviations of design cost estimates from accepted tenders using information held by seven design offices in the United Kingdom.

Cheong (1991) found that the disparity between cost plan estimates and contract sums is generally between 5% and 10%. Cheong's study had collected opinions across a wide range of Quantity Surveyors in Singapore. Significantly, Cheong's analysis of 88 projects from one quantity surveying consultancy in Singapore found that variability values between cost plan estimates and contract sums ranged from 33.79% (over-estimates) to 31.30% (under-estimates).

Similarly in Nigeria, Odeyinka and Yusif (2003) using cost data on preliminary cost estimates and lowest tenders that were supplied by 24 quantity surveying firms, found the following: 17 of 40 building projects (42.5%) had their lowest tender sums lower than the Quantity Surveyors' estimates and this ranged between 1% and 47%. 23 of the projects (57.5%) had their lowest tender sums higher than the Quantity Surveyors' estimates and this ranged between 1% and 174%. An analysis of pre-tender cost estimating performance of a Nigerian consulting quantity surveying firm by Oladokun et al. (2011) found that on 81 building projects there was an estimate bias reflecting underestimates of about 34%.

Odeyinka (2010) asserted that no matter how much care and effort is put into the preparation of design stage elemental cost plans, deviations observed between them and the final tender sums are usually significant. According to Zou et al. (2007) the major reason for this is inherent risks in both design and construction. The traditional way of dealing with these risks is merely to allow a percentage as contingency allowance. Thus, the essence of having an elemental cost plan as a budgetary tool for building projects is defeated if these risk elements are not captured or properly evaluated. Overall project objectives regarding cost, time and quality targets become threatened.

Risk and Cost Predictability

Risk could have different meanings to different people (Baloi & Price, 2003). The concept of risk can vary according to individual's perceptions, attitudes and experiences. For instance; architects, engineers and contractors are more likely to view risk from a technological perspective while lenders and developers tend to view it from an economic and / or financial point of view. Baloi and Price therefore concluded that risk is generally seen as an abstract concept that is difficult to measure. Rezakhani (2012) defined risk as a potential for complications around project completion, achievement of project objectives and an uncertain future event or condition whereby the occurrence rate is greater than 0% but lesser than 100%. Risk generates an effect on at least one of the main project objectives in terms of cost, time and quality targets. Earlier study by Akintoye and MacLeod (1997) explained that risk has been significant owing to the occurrence of budget/cost and schedule/time overruns associated with construction project developments. Joshua and Jagboro (2007) submitted that risk is inevitable and exposes project activities to adverse consequences of future events. The effect of risk on a project can be positive or negative. To align with the common usage of the word risk, this research embraces the view that benefits or positive impacts of risks on project objectives could be achieved by minimising risk occurrence and its detrimental impacts.

Potts (2008) explained that the budgeted cost established by the consultant Quantity Surveyor at the pre-contract stage forms the basis for the assessment of the tender sums submitted by bidding contractors. The successful tender therefore becomes the final tender sum (contract sum) for the project. Potts suggested that most clients work within tight pre-defined budgets/ cost plans which are usually part of a larger overall scheme. If a budget or cost plan is exceeded, the whole scheme may fail. Pre-contract estimating produces the original budget or cost plan and this forecasts the likely expenditure for the client. The budget or cost plan should be used positively to make sure that the design stays within the scope of the original scheme. Thus, many budget overruns are due to circumstances observed as risk factors and an important issue is the ability to predict such factors and the impact they have on the project. The smaller the level of information available at the early stages of a construction project, the higher is the level of uncertainties and hence risks. This view was shared by Zou et al. (2007) and Taroun et al. (2011). Therefore, as project information increases, risk is expected to decrease.

There has been lesser attention paid to the disparity between design stage elemental cost plan and final tender sums in New Zealand. Recently, Adafin et al. (2014) undertook a preliminary exploration of the theoretical concepts and methods for assessing risk impacts on the variability between design stage elemental cost plan and tender sums in New Zealand. It is apparent that there is a dearth of literature on this subject matter, which is being addressed by this study.

METHODOLOGY

This study was carried out primarily through the use of secondary data. The research approach collated data on elemental cost plan and final tender sums from completed building projects located in Auckland (AKL), Christchurch (ChC) and Wellington (WLT), New Zealand. Access was obtained to project records held by three quantity surveying firms based in Auckland. Project records and documents produced by professionals and organizations were explored as the main data analysis for the study (Gibson & Brown, 2009). A thorough examination of their project files within the limitations of the Privacy Act was undertaken. Apart from this project information, five senior partners within the three firms who had worked closely with the projects were interviewed. Project data were collected from four different types of building projects.

Tables 1-5 present the project information obtained for residential, educational, commercial and maintenance projects. These project details were analysed to achieve the research objective, which was to evaluate the budgetary reliability of design stage elemental cost plans in each of the four project types. For the purpose of anonymity, the projects are coded P01 - P20. In this study, the use of document analysis helped to justify the theoretical conclusions generated from the review, regarding cost predictability. Simple descriptive analysis was used to express the percentage difference between cost plan and final tender sums (Nworgu, 2006). Two further analyses were carried out using root mean square (RMS) deviation, and relative mean absolute (Rel. MAD) deviation methods of analyses as adopted by (Odeyinka et al., 2009). The *RMS* is expressed mathematically as follows:

$$[2]\ RMS = \sqrt{\left\{\frac{1}{n}\sum_{i=1}^{n}(c_i - o_i)^2\right\}}$$

Where *RMS* is the root mean square deviation measure; n is the number of projects investigated, c_i is the cost plan sum for individual project and o_i is the final tender sum for the individual project.
The *Rel. MAD* is expressed mathematically as follows:

$$[3]\ \text{Rel.}\,MAD = \frac{1}{n}\sum_{i=1}^{n}\frac{|(c_i - o_i)|}{c_i}$$

Where *Rel. MAD* is the relative mean absolute deviation measure; n is the number of projects investigated, c_i is the cost plan sum for the individual project and o_i is the final tender sum for the individual project.

FINDINGS AND DISCUSSIONS

Demographic information obtained from participants included their designation, academic and professional qualifications and work experience. Generally, all of the respondents hold tertiary education at HNC/HND/Bachelor's degree levels in quantity surveying, while one of them holds an MBA. They are senior partners in their individual firms and are professionally qualified (three full members and two fellows) with the New Zealand Institute of Quantity Surveyors (NZIQS). The participants have an average of 28 years of work experience in their consultancies. This demographic information indicates that the participants have been involved with running of projects and therefore have some knowledge of issues relating to project cost planning. This also enhances validity of survey data. Therefore, the secondary data provided by them could be relied upon for this study.

Table 1 presents elemental cost plan sums and final tender sums for five residential building projects studied. An analysis of the percentage difference between the cost plan sum and final tender sum gives an indication of the budgetary reliability of the elemental cost plan. It is evident from the Table that the percentage difference between the cost plan and final tender sums ranges between -3.67% and +3.95%. This falls within the ±5% range adopted by Morrison (1984) as the acceptable accuracy range between the Quantity Surveyor's estimate and the accepted or final tender sum. Similarly, a range of -4% to +15% was recommended by Ashworth (2004) as an acceptable standard for measuring estimating accuracy.

Though, traditional contracting systems in New Zealand require contractors to prepare their own quantities in a lump sum competitive contract. The schedules of quantities prepared by contractors are usually in a trade format while cost plans are produced in an elemental format by the consultant Quantity Surveyors during design development stage. Hence, this does not

allow a compatible platform for comparison. It is noteworthy that the budget or cost plan established by the consultant Quantity Surveyor during the design development stage forms the basis for the assessment of tender sums submitted by bidding contractors. The successful tender therefore becomes the final tender sum (contract sum) for the project. A thorough examination of the cost plan and final tender summary for each of the five projects studied showed a minimal difference between the cost plan sums and final tender sums. This then suggests that in traditional procurement where elemental cost plan based on New Zealand Institute of Quantity Surveyors (NZIQS) Elemental Analysis of Costs of Building Projects is used, the cost plan tends to be a reliable budgetary tool. This is not unsurprising because residential building projects are usually well defined in terms of design and specification at their pre-construction phases. This view was shared by Ling and Boo (2001) explaining that the risk of variation and change in scope is usually very low during the construction phase for this category of projects.

Table 1: Budgetary reliability measures for residential building projects

Project Code	Elemental Cost Plan Sum (NZ$)	Final Tender Sum (NZ$)	Cost Difference (NZ$)	Percentage Difference (%)	Year	Project Location	Procurement System Adopted
P01	7,210,250.80	6,859,266.32	-260,984.48	-3.67	2013	AKL	Traditional
P02	794,456.98	815,257.68	20,800.70	2.62	‘12-13	ChC	Traditional
P03	905,500.00	924,680.00	19,180.00	2.12	’12-13	ChC	Traditional
P04	1,914,848.40	1,878,417.15	-36,431.25	-1.90	2013	AKL	Traditional
P05	1,034,360.00	1,075,210.00	40,850.00	3.95	’12-13	ChC	Traditional

Table 2 presents the cost plan data and final tender sums for five educational building projects. An analysis of the percentage difference between the cost plan and final tender sums gives an indication of the budgetary reliability of the cost plan. Data on the Table show that the percentage difference between the cost plan and final tender sums range between -3.98% and +12.15%. This range is significant. The high disparity observed, may suggest that the cost plan is not a very reliable budgetary tool in educational building projects. As evident from the cost plan and final tender summary, high variability was observed in some cases which suggested the occurrences of risk factors such as client’s change, incomplete design information and site investigation information among others. This finding justifies Potts’ (2008) suggestion that failure to keep within the provisions of pre-defined budgets or cost plan is one risk that impacts on a project’s budgetary performance and consequently the client’s cash flow position.

Table 2: Budgetary Reliability Measures for Educational Building Projects

Project Code	Elemental Cost Plan Sum (NZ$)	Final Tender Sum (NZ$)	Cost Difference (NZ$)	Percentage Difference (%)	Year	Project Location	Procurement System Adopted
P06	994,678.00	1,084,000.00	89,322.00	8.98	2013	AKL	Traditional
P07	2,403,619.00	2,477,000.00	73,381.00	3.05	2013	AKL	Traditional
P08	944,000.00	906,409.00	-37,591.00	-3.98	2013	AKL	Traditional
P09	34,922,850.00	38,628,000.00	3,705,150.00	10.61	2012	ChC	Traditional
P10	48,833,750.00	54,768,250.65	5,934,500.65	12.15	2012	ChC	Traditional

Table 3 presents the cost plan data and final tender figures for five simple and complex commercial building projects. An analysis of the percentage difference between the cost plan and final tender sums shows a range between -14.22% and +16.33%. This is a very significant deviation. Further scrutiny of the percentage difference for each of the five projects indicates that the larger the scope of the commercial building, the higher the level of disparity between the cost plan sum and final tender sum. A thorough examination of the cost plan and final tender summary for each of the five projects showed a high disparity between

the cost plan sums and final tender sums. The observed high variability therefore suggests that the elemental cost plan is not so much a reliable budgetary tool for commercial projects, especially where the project is large in scope and of a complex nature. This further suggests that there is uncertainty in a lot of project information available where large and complex projects are involved. Hence, it is noteworthy that the more uncertain the project information is at the pre-construction stage when elemental cost plan is prepared, the more risky it is for cost certainty to be guaranteed to the client at the end of the tendering process.

Table 3: Budgetary Reliability Measures for Commercial Building Projects

Project Code	Elemental Cost Plan Sum (NZ$)	Final Tender Sum (NZ$)	Cost Difference (NZ$)	Percentage Difference (%)	Year	Project Location	Procurement System Adopted
P11	1,985,000.00	2,085,369.83	100,369.83	5.06	'12-13	AKL	Traditional
P12	31,000,000.00	26,593,185.00	-4,406,815.00	-14.22	2012	ChC	Traditional
P13	33,225,000.00	38,650,125.00	5,425,125.00	16.33	'11-12	ChC	Traditional
P14	2,850,000.00	3,058,252.85	208,252.85	7.31	'12-13	AKL	Traditional
P15	28,245,000.00	31,285,225.00	3,040,225.00	10.76	2010	AKL	Traditional

Table 4 presents the cost plan data and final tender figures for five refurbishment projects. An analysis of the percentage difference between the cost plan and final tender sums shows a range between -10.07% and +30.14%. This presents a highly significant deviation. It is important to note that the highest positive variability emanated from a small maintenance project and the Table does not reflect a clear-cut pattern of percentage variability. A thorough examination of the cost plan and final tender summary for each of the five projects showed a high disparity between the cost plan sums and final tender sums. The observed significant variability suggests that the elemental cost plan is less reliable as a budgetary tool in refurbishment projects. This is not a surprise as refurbishment projects harbour loaded estimates and assumptions that cater for higher risks due to unknown items involved in terms of scope and complexity at project inception, hence unpredictability regarding cost certainty.

Table 4: Budgetary Reliability Measures for Refurbishment Projects

Project Code	Elemental Cost Plan Sum (NZ$)	Final Tender Sum (NZ$)	Cost Difference (NZ$)	Percentage Difference (%)	Year	Project Location	Procurement System Adopted
P16	2,266,000.00	2,522,725.36	256,725.36	11.33	2011	WLT	Traditional
P17	380,341.12	342,045.24	-38,295.88	-10.07	2010	AKL	Traditional
P18	666,000.00	866,725.36	200,725.36	30.14	2011	WLT	Traditional
P19	805,134.60	736,687.56	-68,447.04	-8.50	2010	AKL	Traditional
P20	2,023,490.94	2,233,773.04	210,282.10	10.39	2011	WLT	Traditional

Further analyses were carried out to determine the budgetary reliability of the elemental cost plan for procuring the different types of buildings previously analysed. *RMS* deviation measure was expressed mathematically in Equation 2. This was converted to a percentage measure through normalization adjustment in order to make it comparable to other measures. In Table 5, this is regarded as the adjusted RMS measure. Odeyinka et al. (2009) justified the relevance of the normalization process as the RMS values obtained in their study are more of the function of tender and final account figures. This is applicable to the current study regarding the comparison between elemental cost plan and final tender sum. Moreover, the adjusted values are relative values that are more comparable.

The fourth analysis is the *Rel. MAD* measure that was expressed mathematically in Equation 3. The results of these analyses are presented in Table 5. As shown in the Table, the normalized / adjusted *RMS* measure and *Rel. MAD* measure are moderately close. This indicates that the two measures are reliable for measuring the budgetary performance of the

design stage elemental cost plan under study. From the Table, the reliability ranking based on the normalized *RMS* and *Rel. MAD* measures shows that the elemental cost plan is most reliable as a budgetary tool for procuring residential building projects (Ranked1). This is followed by educational, commercial and refurbishment projects respectively (Ranked 2, 3 and 4). The reliability ranking showed that the elemental cost plan is least reliable as a budgetary tool for procuring maintenance or refurbishment projects. Meanwhile, it is important to note that this result reveals the level of threats involved in relying considerably on elemental cost plan as a budgetary tool. Besides the residential building projects with a budgetary reliability of ± 2.85% that is quite reliable and acceptable, the deviation margins for other project types are quite significant. Hence, Quantity Surveyors need to attach some level of confidence limits to the estimate they give to project owners if interested in cost certainty. This is very important because the deviations observed are as a result of inherent risks in the design stage elemental cost plan development.

Table 5: Elemental Cost Plan (ECP) Budgetary Reliability Measures of Different Building Types

Building Type	RMS Measure (NZ $)	Adjusted RMS Measure (%)	Rel. MAD Measure (%)	Reliability Ranking
Residential	119,924.48	3.00	2.85	1
Educational	3,129,255.85	9.15	7.75	2
Commercial	3,410,231.99	12.96	10.74	3
Refurbishment	176,956.90	17.16	14.09	4

Results and findings could be presented either in tables or figures for illustration purposes. These presentation modes could be adopted in the earlier and latter sections (2, 3, 4 and/or 5) when deemed necessary. The table caption should be numbered and positioned before the table as shown in Table 1.

CONCLUSION AND FURTHER RESEARCH

The aim of the study was to investigate the budgetary reliability of design stage elemental cost plan in procuring building projects using secondary data from completed building projects. This study therefore concludes within the limitations of the data set confined to New Zealand, that in traditional procurement where elemental cost plans are used, there are deviations between elemental cost plan sums and final tender sums. The percentage deviation ranges between -3.67% and +3.95% for residential building projects. It ranges between -3.98% and +12.15% in the case of educational buildings. Commercial buildings attract a range of -14.22% and +16.33%, while it ranges between -10.07% and +30.14% for refurbishment projects. This suggests that besides the residential projects with little and acceptable deviation, the deviations observed in other projects are very significant.

The study concludes further that the elemental cost plan was most reliable (Rel. MAD of 2.85%) as a budgetary tool in procuring residential projects. This was followed by educational projects (Rel. MAD of 7.75%) and commercial projects (Rel. MAD of 10.74%) respectively. The design stage elemental cost plan was found to be least reliable as a budgetary tool in procuring refurbishment projects (Rel. MAD of 14.09%). An awareness of the possibility of deviations in different project types in quantitative terms offered by this study makes the design stage elemental cost plan a relevant tool for risk management to avoid budget overrun. Further, given construction projects procured using the elemental cost plan in traditional procurement, inherent risks could be subjected to quantitative assessment and management. Hence, the observed deviation measures could offer a relevant background towards the application of risk management techniques in budgetary and cost control in order to avoid budget/cost overrun in construction project developments.

ACKNOWLEDGEMENT

The authors gratefully acknowledge the research fund provided by the University of Auckland, New Zealand through its PReSS account to facilitate data collection for this study. The authors would also like to express their thanks to the same university for the award of doctoral scholarship to the corresponding author for his PhD research.

ABSTRACT

Reliable prediction of final tender sums of building projects from the cost plan is of great importance to construction clients and practitioners to prevent unpleasant consequences of cost overrun, disputes and project abandonment. Researchers over the last two decades have employed forecasting methodologies which utilize various elements of price forecast equation. However, in spite of these research efforts, a model that could improve the accuracy of final tender sum predictions is yet to be developed for New Zealand. Different countries may require specific empirical studies to investigate budget / cost overruns, but a similar methodology could be used and findings compared. The research reports part of an on-going research concerned with assessing the impacts of risks during pre-tender cost estimating. It attempts to review the need for project information during cost planning, with a view to providing a case study background to confirm cost planning inaccuracies. A review and conceptual classification of tender price forecasting methodologies is undertaken towards developing a conceptual framework for risk assessments in traditionally procured commercial projects. The framework described, allows improved assessment of the impacts of risks on the variability between design stage elemental cost plan and final tender sum. Overall, it suggests an economical predictive-model for the New Zealand construction industry.

Keywords: Commercial projects, elemental cost plan, final tender sum, New Zealand, traditional building procurement

INTRODUCTION

One aspect of client expenditure management that requires attention is the accuracy in tender price prediction (Skitmore & Picken, 2000). Several researches indicated that pre-tender estimating accuracies are significantly affected by the level of risk information available to estimators (Akintoye, 2000; Aibinu & Pasco, 2008; Odusami & Onukwube, 2008; Enshassi et al., 2013). Proper risk analysis could offer at least a partial solution by reducing the variances between design stage elemental cost plan and final tender sums (contract sums) of construction projects (Adafin et al., 2015). Clients need to be informed in advance of their likely financial commitments specifically the cost implications as designs evolve, hence reasonably accurate predictions of final tender price cannot be overemphasised. This requires the preparation of more accurate cost plans based on the analysis of cost data generated from previous similar design / projects.

Various approaches have been adopted in tender price forecasting, ranging from statistical/mathematical to the use of artificial intelligence techniques. Most of these approaches employed the individual elements of tender price equation to model their forecasts. In the same vein, many researchers have attempted to model risk in construction projects using various methodologies such as multivariate discriminant and regression analyses, fuzzy and artificial neural network based on the United Kingdom, Australian, Asian and African construction industries (Ng et al., 2004; Sonmez, 2004; Lowe et al., 2006; Odeyinka et al., 2006; Odeyinka, 2007; Aibinu & Pasco, 2008; Aibinu et al., 2011; Larkin et al., 2012; Odeyinka et al., 2012). Similar research in New Zealand (NZ) is thin and no attempt has been made to develop a model that could assist NZ construction industry practitioners to have a better and reliable prediction of final tender sums from cost plans.

Adafin, J.; Wilkinson S.; James O.B. R. & Odeyinka, H. (2016). Methodological Approaches to Risk Assessments during Cost Plan Production. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 894-902

Furthermore, there is a gap in research regarding the impact of risks on variabilities observed between design stage elemental cost plans and final tender sums. Knowledge in this area is therefore fragmentary and this is the focus of the current study.

LITERATURE REVIEW

Project Information during Cost Planning

The traditional view of cost planning is that it moves through stages of increasing accuracy starting with fairly low accuracy at the inception stage of a development process. According to Smith and Jaggar (2007) the level of accuracy depends on the level of project information available in the preparation of design stage elemental cost plan. Thus risk is inherent in construction project developments from inception to completion stages of projects' lives. As less information is available at the inception of construction projects, the level of uncertainties and hence risks becomes higher. Winch (2002) and Odeyinka et al. (2010) suggested that accuracy of cost estimates at the design development is impacted by risks linked to level of project information.

Cost planning by the clients' quantity surveyors essentially relies on information from three principal sources (Seeley, 1996; Ferry et al., 1999): information supplied by clients, members of the design team, and those acquired directly by the quantity surveying office e.g. historical cost information. Kirkham (2007) and Ashworth (2008) explained that information required at the final sketch plans/scheme design stage to enable full cost plan preparations include: sketch drawings, outline specification, and contractual information e.g. selected method of tendering, selected type of contract, cost plan date, proposed tender date, contract period, and (4) a comparable cost analysis from a previous similar project. In agreement, Smith and Jaggar (2007) further specified that details of project information are developed in form of more detailed plans at the final sketch plans stage (scheme design stage) of development process. Hence, full cost plan is prepared on the basis of the amount of information that may be available namely: project brief, architectural sketches, structural sketches, site layout, outline cost plan, preliminary schedule of finishes, specification notes, and outline development control approval from the planning authority.

In the current study, project information/risk assessment during cost planning would provide further evidence on issues relating to accuracy of pre-tender cost estimates which have been discussed in construction management literature over the decades (Akintoye, 2000; Ng et al., 2004; Sonmez, 2004; Soutos & Lowe, 2005). For example, Morrison (1984) had investigated this disparity in the United Kingdom by collecting and analysing data from seven separate quantity surveying firms. Morrison found that a mean deviation of 12% was obtained by the quantity surveyors. Ogunlana (1991) reported significant deviations of design cost estimates from accepted tenders using information held by seven design offices in the United Kingdom.

In Singapore, Cheong (1991) found that the disparity between cost plan estimates and contract sums is generally between 5% and 10%. Cheong's study had collected opinions across a wide range of Quantity Surveyors. Significantly, Cheong's analysis of 88 projects from one quantity surveying consultancy in Singapore found that variability values between cost plan estimates and contract sums ranged from 33.79% (over-estimates) to 31.30% (under-estimates). In the US, a coefficient of variation of 7.82% was obtained by Skitmore and Picken (2000) when they carried out an analysis of pre-tender estimating performance of a USA consulting firm on 217 building projects.

Similarly in Nigeria, Odeyinka and Yusif (2003) using cost data on preliminary cost estimates and lowest tenders that were supplied by 24 quantity surveying firms, found the following: 17 of 40 building projects (42.5%) had their lowest tender sums lower than the

Quantity Surveyors' estimates and this ranged between 1% and 47%. 23 of the projects (57.5%) had their lowest tender sums higher than the Quantity Surveyors' estimates and this ranged between 1% and 174%. An analysis of pre-tender cost estimating performance of a Nigerian consulting quantity surveying firm by Oladokun et al. (2011) found that on 81 building projects there was an estimate bias reflecting underestimates of about 34%.

However, Odeyinka (2010) asserted that no matter how much care and effort is put into the preparation of design stage elemental cost plans, deviations observed between them and the final tender sums are usually significant. According to Zou et al. (2007) the major reason for this is risk which is inherent in both design and construction. Several researches (Akintoye, 2000; Aibinu & Pasco, 2008; Odusami & Onukwube, 2008; Oladokun et al., 2011; Jafarzadeh, 2012; Enshassi et al., 2013) have indicated that pre-tender estimating inaccuracies are significantly influenced by the level of project information available to estimators. The current study posits that these submissions could offer a fundamental evidence of risk factors impacting budget variability.

Case Study Background

The case study collated data on elemental cost plans and final tender sums from completed projects in New Zealand. Access was obtained to project records held by three quantity surveying firms based in Auckland. A thorough examination of their project files within the limitations of the Privacy Act was undertaken. Data were sourced from five NZ-based consultant Quantity Surveyors of three randomly selected firms through interview sessions held over a period of two months April-May 2013. Initially ten out of seventeen registered quantity surveying firms were contacted by telephone after a random internet search limited to the website of New Zealand Institute of Quantity Surveyors (NZIQS). Ten firms were preferred owing to the fact that project cost planning / pre-tender estimating falls within their areas of concentration in practice. From these, three firms replied that they were willing to participate in the research. Meanwhile, five senior partners within the three firms were subsequently communicated with via telephone and e-mail requests for thirty minutes' one-on-one interviews.

Table 1 presents the project information for three commercial and four educational building projects located in Auckland and Christchurch, New Zealand. For the purposes of anonymity, the seven projects were coded: P01 – P07. More supporting information on the projects was obtained from key personnel within the host organizations through interviews. Apart from empirical collection, some underlying contextual information was also gained from the interviews.

Hence, general knowledge about cost and risk issues with a focus on the risk factors responsible for the disparity between design stage elemental cost plans and final tender sums in the selected commercial and educational building projects were obtained. There was also an aspect of the interview questions that sought possible solutions to this disparity. The table shows that disparity between design stage elemental cost plan and final tender sum is in the region of -14% and +16%. The risk factors generally responsible for the disparity observed in this study include: market conditions, client's change, design enhancements/variations, site investigation information, co-ordination errors, documentation errors/omissions, incomplete design information, incomplete documentation for cost plan and inadequate tender documentation. Meanwhile, improvement in design cost planning functions and improvement in market conditions are considered as opportunities rather than risk factors. These represent savings made on two different projects (see P02 and P05).

Specifically, P01 recorded a budget overrun of +5% as a result of such risks as market conditions, inadequate tender documentation, incomplete design information and site

investigation information. P03 registered a budget overrun of +6% and the risk factors responsible were market conditions, inadequate tender documentation, documentation errors/omissions, client's change and site investigation information. Budget overrun of +1% was noted on P04 while the risk factors found in the archive data were late client's changes, incomplete documentation for cost plan and co-ordination errors at tender documentation stage. Similarly, P06 overran +10% consequent upon market conditions, client's change, design enhancement and site investigation information. Also, P07 recorded an overrun of +16% as a result of client's change, design variations, market conditions and site investigation information as the evident risk factors. The generality of interviewees opined that the final tender sum is usually higher than the elemental cost plan on building projects.

TENDER PRICE FORECASTING METHODOLOGIES

The need for objective forecasting methods and the benefits of quantitative predictive cost models generally in the construction industry cannot be underestimated. Studies in Tender Price Forecasting to date have focused on developing and adopting mathematical / statistical models. Figure 1 shows a conceptual classification of these forecasting methodologies. As a result, a diversity of cost models of varying complexity were developed (Ng et al., 2004). As evidenced in Ng et al. (2002; 2004), Fuzzy sets (Chang et al., 1997; Mason & Kahn, 1997) and artificial neural network approaches (Williams, 1994; Fang & Tam, 1999), statistical methods were further extensively applied, with Regression Analysis (RA) being the most popular approach (Boussabaine & Elhag, 1999). In addition, multivariate discriminant analysis was adopted by Ng et al. (2000) for predicting tender price index directional changes.

Researches further suggested that the integration of techniques may enhance accuracy and predictive ability (Granger & Newbold, 1986; Granger, 2001). In Tender Price Index (TPI) prediction, the Regression Analysis (RA) and Time Series (TS) modelling received favourable attention and were most highly developed, with RA establishing the relationship between TPI and significant economic indicators (see Fellows, 1991; Fitzgerald & Akintoye, 1995; Akintoye et al., 1998; Chau, 1998).

Most recently, artificial intelligence techniques have been applied in modelling risk impacts on construction cost performance. Based on related previous studies and integration of predictive techniques, Odeyinka et al. (2012) applied artificial neural network (ANN) to model the risk impacts on the variability between contract sum and final account in traditional building procurement. Jafarzadeh (2012) employed both regression and neural network approaches for seismic retrofit cost modelling of existing structures, with critical comparison of results from both techniques. Ameyaw et al. (2015) applied the fuzzy technique for modelling risk impacts on variability between contract sum and final account in government-funded construction projects. Ameyaw et al. concluded that different countries may require specific empirical studies to investigate cost overruns, a similar methodology can be used and, findings compared.

After a review of the various forecasting methodologies, this study found that an integration of methodologies would be useful. The integration of Regression Analysis (RA) and Artificial Neural Network (ANN) employed by Jafarzadeh (2012) and Odeyinka et al. (2012), with a critical comparison of results from both modelling techniques could prove useful in assessing the impacts of the previously identified risk factors on the variability between design stage elemental cost plan and final tender sum. These methods could be useful in this study because of their predictive ability and reliability. Wilmot and Mei (2005) and Jafarzadeh (2012) suggested that each of the modelling techniques (RA and ANN) contains a unique combination of the most statistically significant predictors.

Table 1: Project information on commercial and educational building projects in Auckland and Christchurch, New Zealand without GST or value added tax (VAT) Exchange rate: NZ$1.00 = US$0.85 = AU$0.91 = £0.51 sterling (2014)

Project Code	Project Type	Elemental Cost Plan Sum (NZ$)	Final Tender Sum (NZ$)	Cost Difference (NZ$)	Percentage Difference (%)	Year	Project Location	Procurement System Adopted	Risks Identified
P01	Commercial building	1,985,000.00	2,085,369.83	+100,369.83	+5	2012-13	Auckland	Traditional	Market conditions, inadequate tender documentation, incomplete design information, and site investigation information

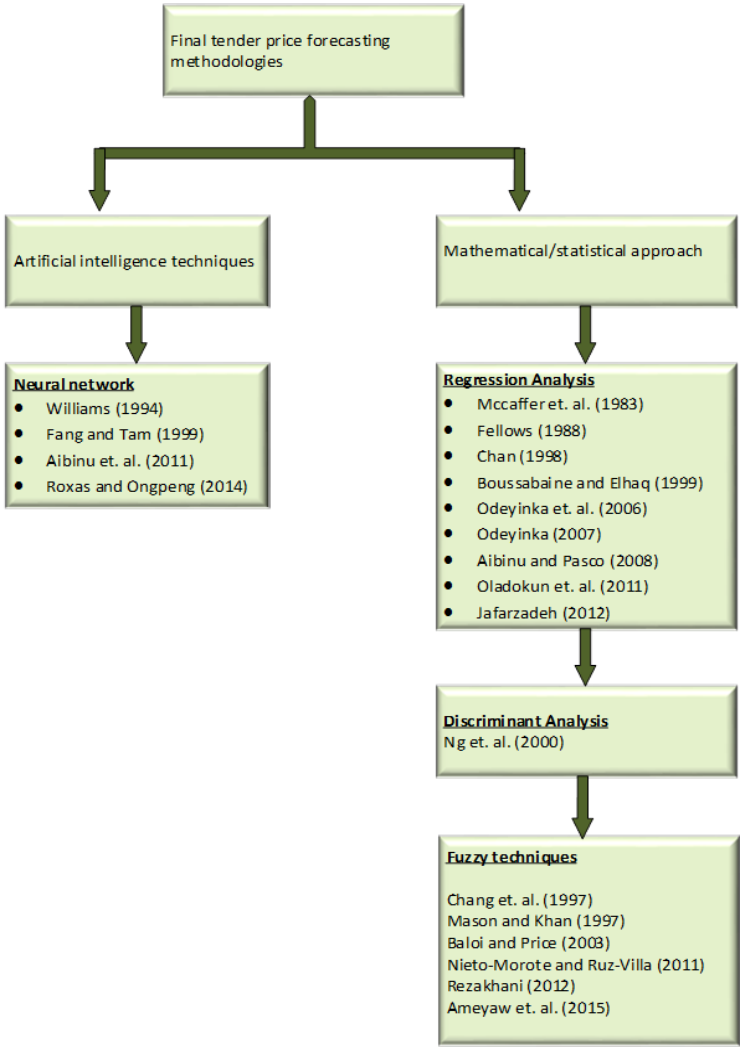

Figure 1: Conceptual Classification of Final Tender Price Forecasting Methodologies
Adapted from Odeyinka et al. (2012)

A Conceptual Framework for Assessing Risk Impacts during Cost Plan Production

Larkin et al. (2015) suggested the need to consider certain groupings in the analysis of risk factors impacting budget variability. These include the building type, procurement method employed and project participants. These groupings are employed in developing a conceptual framework for assessing risk impacts on budgetary performance in Figure 2. Basically, the framework considers the building type, for instance commercial building, it looks into the procurement method adopted for the particular project, say traditional method and the project participants depending on the procurement system adopted, say Architects, Quantity Surveyors, Engineers, and Project Managers.

Elemental cost plan sum and final tender sum data from the selected project in New Zealand are then obtained under the various groupings based on choice of building type, procurement method and project participants. Adopting an integration of predictive techniques (e.g. ANN and Fuzzy models or MLR and ANN) produces a more accurate result (Jafarzadeh, 2012; Odeyinka et al., 2012; Ameyaw et al., 2015). This suggestion has been taken into consideration; hence the framework anticipates the use of elemental cost plan sum and final tender sum data for risk modelling alongside the suggested groupings. Investigation of

inherent risk factors that occurred in executing the selected project is then carried out by project participants.

According to Soutos and Lowe (2005) regression analysis is a statistical process for estimating the relationships among variables. This includes the techniques for modelling and analysing several variables when the focus is on the relationship between a dependent variable and one or more independent variables. The most suitable approach for this study is the MLR. It is a flexible method of data analysis that is appropriate whenever a quantitative variable (dependent variable) is to be examined in relation to other factors expressed as independent variables. The linear additive regression model could be used to include any number of independent variables as expressed usually in the form stated below (Berger, 2003; Soutos & Lowe, 2005):

$$Yi = A + \beta iXi + \beta 2X2 + \cdots \ldots \ldots + \beta nXn + Ei$$

Where

Yi = the dependent variable (e.g. actual or project cost); A = the intercept;
βi = regression coefficient for the ith independent variable;
Xi = independent variable for the ith observation (e.g. risk factor); and
Ei = random error of the ith observation

MLR will be used to develop the predictive model on the complex interaction of significant risk factors impacting observable variability between the design stage elemental cost plan and final tender sum. The dependent variable is the final tender sum while the independent variables are the significant risk factors.

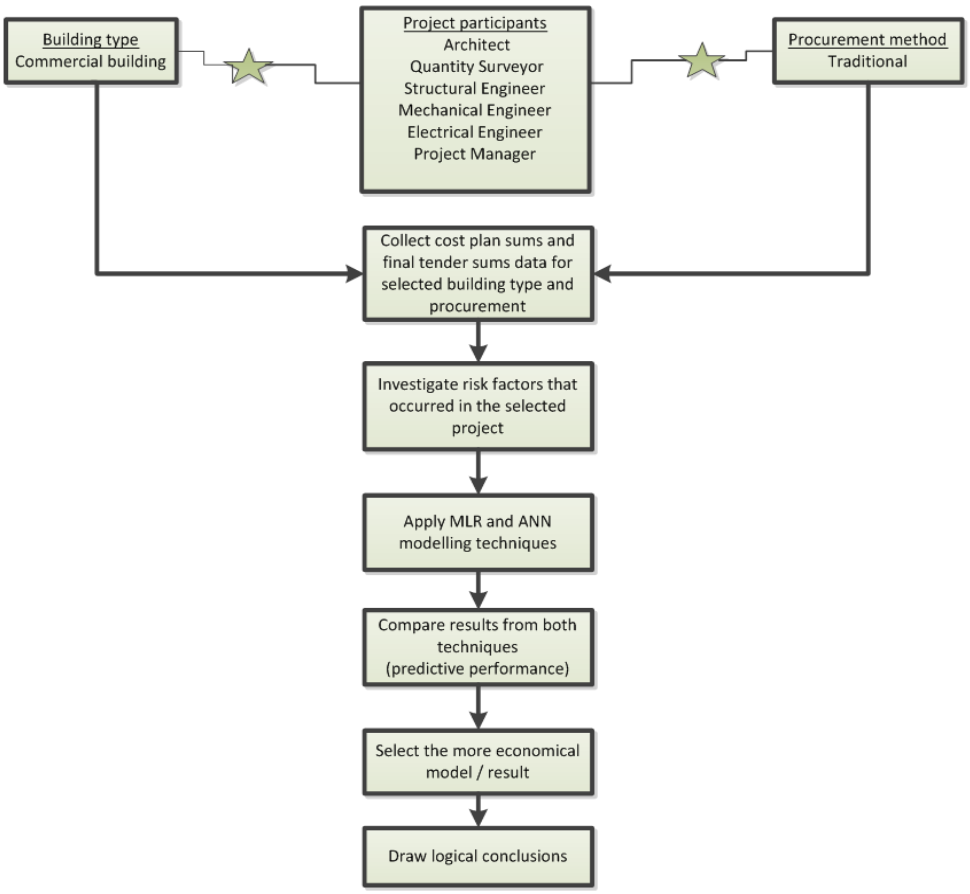

Figure 2: A conceptual framework for assessing risk impacts on budget variability based on New Zealand study
Adapted from Larkin et al. (2012)

Meanwhile, ANN is an information processing system whose architecture is inspired by the structure of human biological systems (Boussabaine, 1996). This system is developed as a structure that is similar to human body; hence it functions in a similar manner. The modelling process will be based on five main aspects: data acquisition, analysis and problem representation; architecture determination; learning process determination; training of the network; and testing of the trained network for generalization evaluation. ANN methodology is a promising alternative modelling technique for the establishment of sound predictive models (Odeyinka, 2012).

Following this, results from both techniques are critically compared and the more economical model / result is selected. The framework (Figure 2) illustrates the procedure to undertake in developing the predictive models, comparing the predictive performance of both techniques, and suggesting the more economical model for the industry. It is expected that this procedure will allow logical conclusions to be reached regarding risk impacts during cost plan production.

CONCLUSION AND FURTHER RESEARCH

This study clarified the need for project information during cost planning. The clarification was employed as a basis to identifying risk factors that are inherent in cost plan development. Based on a review of related previous researches in pre-tender estimating accuracy, a conceptual classification of final tender price forecasting methodologies was developed. A critical evaluation of these methodologies suggested that the MLR and ANN predictive modelling which possess an analytical ability, have the potential of assisting with an objective assessment of risk impacts during cost plan production. Critical comparison of results from both techniques will produce a more economical model/result. The combination of these two tools enhances accuracy and their predictive ability. These ideas were used to develop a conceptual framework that illustrates the procedure to undertake in developing the predictive models, comparing the predictive performance of both techniques, and suggesting the more economical model for application in New Zealand. Similar research is thin in New Zealand and no attempt has been made to develop a model that could assist construction industry practitioners to have a better and reliable prediction of final tender sums from cost plans. Hence, the implementation of this result could yield what others have not achieved in their study areas.

Further development of the work reported here, when data are collected and analysed, will provide more information for the development and validation of the predictive models for application in New Zealand.

ACKNOWLEDGEMENT

The authors gratefully acknowledge the research fund provided by the University of Auckland, New Zealand through its PReSS account to facilitate data collection for this study. The authors would also like to express their thanks to the same university for the award of doctoral scholarship to the corresponding author for his PhD research.

ABSTRACT

A research was carried out titled An Appraisal of Planning in Nigerian Indigenous Construction Companies with an aim of improving construction planning of Nigerian indigenous construction companies. The research collected data through two types of structured questionnaire accompanied by interview which was distributed to 50 construction companies in Abuja. The data were analyzed and result was presented in charts and relative importance index (RII) was used to rank each response among alternatives provided. Key findings from the research indicated that planning process among the surveyed organization was insufficient, this is evident considering 50% of the response indicated there is need for major improvement of planning, 46% of the response indicated that planning needs minor improvement while 2% of the response indicated that planning process in organization needs major over haul. Response from the research further indicated that Planning can be improved through application, adoption of ICT and computerized systems with RII=0.92, Continues monitoring and controlling of project with RII=0.92, Progress meeting / briefing with RII=0.90 and engaging project team members in planning the project with RII=0.84.Research findings was summarized into a model, the model consist of client, communication flat form, project team and the project represented by four phases of a project life cycle, namely initiation, planning, execution and closure. The research proposes adoption of the model which should serve as a basis for developing a frame work for planning construction project in Nigeria.

Keywords: Planning, Construction, Project, Model, Frame Work

INTRODUCTION

Planning was defined by the project management body of knowledge (2004) as the process that is performed to establish the total scope of the effort, time, and resources, refine the objectives and develop the cause of action that is required to attain those objectives. Though, Planning is the process through which the system adapts its resource to changing internal and external conditions, Adebayo (1980) indicated that Planning must create a feasible frame work and method statement for the execution of the works that provide the basis upon which the work will be performed.

The effect of planning on construction success was also studied by Harris and Mc Caffer (2005) who indicated that contractors of the developed countries have embrace planning, this is because performance and profitability of the companies was found to be directly influenced by planning, careful and controlled project delivery. But, Aniekwu and Audu (2010) asserts that many Nigerian indigenous construction companies are unable to meet their contractual requirements because of their in ability to prepare and implement a good plan for a successful project delivery. This according Saleh (2004) has contributed to the inability of the industry in meeting the construction needs of Nigeria.

Benefits of planning was further highlighted by the Project management institute (2003), which confirms that there is no genuine reason to show that a project can succeed without planning. Rather, PM BOK (2004) recommend project managers to invest heavily in planning of their projects, this is because despite the fact that planning alone without careful execution and controlling cannot guarantee success, definitely lack of planning will guarantee failure in the project. Therefore, this paper proposes a model as a way of improving planning in Nigeria.

AbdulAzeez, A.; Umar, B. & Kado, D. (2016). A Conceptual Model for Planning Construction Project in Abuja, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 903-912

David and Elaim (2008) highlighted the confusion that exists in the literature in defining model, framework and methodology. Wong (2005) studied the terms and provided clear definitions for both terms, he defined methodology as an instrument which tends to answer "How to" type of questions, Model answers "What is" type of questions, while frame work seek to provide answers to both "What is and How to" questions. Wong (2005) further shows that both model and methodology are descriptive, while frame work is prescriptive in nature.

The model for effective planning of construction projects would therefore identify all the necessary items that must be considered for efficiency in construction planning, while a framework would not only present such element but would also present ways on how to put them into practice in order to achieve the desired outcome. This study aim at identifying the necessary items required for efficiency in planning construction project in Nigeria, hence, a conceptual model is proposed based on the findings of the study.

STAGES IN THE MODEL DEVELOPMENT

In order to address the question what is construction planning, a review of relevant literature was carried out and also the perception of respondents in the study area with respect to what is construction planning was collected through structured questionnaire accompanied by face to face interview.

Literature was reviewed to uncover the meanings of project planning, construction planning, process of planning in construction and also resources required for effective planning.

Project Planning

Project planning is a wide field of study not only in construction but in other fields of human endeavor. Undoubtedly, early planning impact positively on project, some of such benefits were documented earlier in previous works such as Laufer and Tucker (1987) and also in more recent works such as CORBON and NIOB (2014). Despite such benefits, researches still advocate for more to be done in improving planning such as Inuwa *et al* (2014). This is because, current planning was shown to be inadequate as indicated by Aibinu and Jagboro (2002) while organizations that spent substantial effort in planning, were however discovered to achieve better performance and profitability as documented by Aniekwu and Audu (2010).

PMI defines project as a temporary endeavor undertaken to produce unique product, service or result" (PMBOK 2004). This definition shows that a human endeavor can only qualify to be a project when it is done once to produce a specific product or service, has budget, scope and magnitude. Though, James (2007) believes an endeavor that is repetitive is not qualified to be called project, but if one consider construction activity which appear to be repetitive such as construction of flats in a housing estate, separated by distance in time, space or location, one will see such endeavor has qualified to be called project, since the difference in time or location could alter construction and pricing of the projects significantly.

Planning had undoubtedly generated interest in the past, hence previous works had tried to provide varying definitions which often studying one will see clear similarity among them, this include Islam and Faniran (2005) who define project planning as a conscious effort and process that determines the optimal method, sequence and timing of activities, required resources in order to maximize the chance for a successful project completion, But Ubani et al (2010) defines planning as course of actions taking in advance of performance which defines activities and actions, time and cost targets, performance mile stone which will result into successful project completion.

looking closely at various definitions and explanation of planning, it will be realized that planning involve conscious human effort, resources, time and management, Hence, planning

can be concluded to mean "a conscious management activity that is performed in advance of any action, which define the project objectives, and the most economical way of achieving those objectives with in an agreed and realistic time frame".

Construction Planning

Construction planning is a fundamental and challenging activity in the management and execution of construction projects. This according to Bamisile (2004) involves the choice of technology, the definition of work tasks, the estimation of the required resources and durations for individual tasks, and identification of any interactions among the different work tasks.

CORBON/NIOB (2014) asserts that Planning of construction is generally concerned with completing work of designed quality in a short period as practically as possible which is compatible with economy of production. All future actions of the constructing company in relation to intended construction method, programme of the work, type of materials, labour, plant and equipment must be made known to the project team and more importantly the clients or his representative.

The futurity implication of planning suggests that forecasting is an important part of the whole planning process. Anticipation of the state, nature or the result of alternative courses of actions is an important and crucial phase of decision making process. Conscious effort has to therefore be made to anticipate nature and amount of technology, man power and financial requirement of the project in advance. Political and social climate in the organization, the host environment must also be anticipated, this helps the planning manager to avoid predictable pitfalls that might be disastrous to the project.

Process of Planning In Construction

Planning is a process through which the system adapts its resource to changing internal and external conditions. Hence, Adebayo (1980) indicates that planning must create a feasible frame work and method statement for the execution of the works that provide the basis upon which the work will be performed. Planning must start at an early stage of project, and it progress continues through the various phases of the project life cycle up to project closeout stage or hand over.

planning in construction involve defining all the stakeholders of the project, stating terms and condition of the contract, Identifying resources and constraints in the project, reviewing of all approval and requirements, identification of major activities and their sequence, establishment of time line for activity performance, and a proper management strategy must be selected.

Resources used for Construction Planning

The process of planning construction project requires the use of resources, this resources as identified from the literature include:

i. Planning Techniques

Planning techniques are usually methods of planning that are employed at project operational stage. Planning techniques involves establishing a method of statement for each activity, its relationship with other activities, timing of the projects and how its affect the overall project completion period. Project planning techniques allows for a detailed look at the project's resource requirements, which are not obvious at the strategic level, Harris and Mc Caffer (2005).

The common project planning techniques include the bar charts and linked bar charts, line of balance, network methods, programme evaluation and review techniques as indicated by Chitkara (2012). Graphical representation and review technique has also been identified as an

important planning technique that has been in used in other project management environment such as the military.

ii. Construction Documents

Construction documents are often prepared by recognized professionals and are often legal requirement to a contract. For an efficient planning, it's important to identify all the necessary documents that are required to successfully complete any construction project. The construction documents that should be included in the plan are, the bill of quantity, drawing and schedules, specifications, condition of contract, construction planning report, cost plan and the building production management documents. The building production management document include Construction methodology, Construction programme, Project quality management plan, Project health and safety plan, Early warning system chart and Information requirements schedule.

iii. Planning technology, software, applications etc.

Robson (1997) in CORBON/NIOB (2014) describes information technology to be a collective term that include the hardware (machinery) and software that is concerned with collection, processing, storage and transmittal of the information. Inuwa (2006), Lucey (2005) in CORBON/NIOB (2014) also describe ICT as a general expression covering the use and integration of computers, telecommunications and electronics.

Computers have proving to be a reliable tool in all spheres of human endeavor, Kerzner (2000) indicate the emergence of ICT capability has aided companies to implement project management very fast through the use of computer based software for project planning, estimating, scheduling, and control.

CORBON/NIOB (2014) believe the use of computer applications and ICT to perform core task of project management in project planning, cost data base, cost estimation and document management, have been found to improve project success, project profitability of construction process, and improve bid success ratio of construction companies, but Olaleye and Abdullahi (2014) find out that such computer applications and ICT were found not to be used effectively for planning and avoidance of cost and time overrun.

RESEARCH METHOD

The research aim at studying existing ways indigenous contractors within the study area undertake planning construction project, with a view of identifying methods that yield best result. This makes the research quantitative in nature and hence employed the use of structured questionnaires. Data from each organization was collected using two questionnaires administered each to separate staff of the company; this is design to achieve more factual and unbiased response from each organization. The research assume each contractor undertake planning in one way or the other; therefore seek to examine efficiency of planning in the organizations.

Questionnaire type A was used to determine how organizations plans, who is responsible for planning and instrument that are used for planning. This questionnaire was administered to management staff of Indigenous construction companies responsible for planning in their respective organizations.

Questionnaire type B was used to score the performance of planning in the organization; this questionnaire was administered to production senior staff or site engineers responsible for implementing the proposed plans.

The cooperate affairs commission (2014) provided a list of construction companies in Abuja, a population size of 1920 was determined and used, using Kish (1965), a sample size of 50 companies was used for the study at 90% confidence level.

Data obtain from the questionnaires was tabulated and analyzed using the software, Statiscal products and service solution (SPSS) for descriptive and inferential analysis. Tables, graphs and charts was used for descriptive analysis while Cross tabulation tables ware used for inferential statistics to determine relationship between research Variables.

Relative Importance Index (Rii)

Scott and James (2011) advocate for the wider use of relative importance index as a supplement to multiple regression analysis, this according to Scott and James (2011) is that relative importance indices provide information which is not readily available from indices typically produced from multiple regression. (RII) is determined by dividing the mean response with the highest value on the Likert scale used. Decision relating to most significant factor was taken base on the factor having the highest RII point in the group of the identified variables.

SUMMARY OF RESEARCH MAJOR FINDINGS

Despite identified benefit of planning by the respondents of the research who believe planning can avoid cost overrun(RII=0.88), time over run(RII=0.86) and compromised in project quality (RII=0.86), the process of planning was shown to be inadequate, this is proven by data from the research which show that 50% of the response indicated there is need for major improvement of planning, 46% of the response indicated that planning needs minor improvement while 2% of the response indicated that planning process in organization needs major over haul. This result support the assertion of Basil (2005) who attributed death of new indigenous construction firms with in first five years of incorporation to lack of planning, Idoro (2012) also attributed failure of indigenous construction companies among other things to ineffective and inefficient planning.

Findings in relation to what is planning and how planning should be carried out indicated close conformity with the existing body of knowledge. Example, the activities that defines planning among Nigerian contractors surveyed are ensuring complete, accurate and approved drawings and documents with RII=0.96, then, precisely defining the project with RII=0.92, and establishing exact client requirements with of RII=0.90. This result confirms findings of Adebayo (1980), Ibrahim (2004) who both believe planning should define the project, its objectives, resources and constraint. The result also hold the assertion of Bamisile (2004) to be true who indicated the need for construction managers to ensure complete, accurate and approval of all document while making special emphasis on building production documents.

The study attributed failure of planning to client financial integrity with RII=0.94, inadequate resources budgeted for planning with RII=0.92 and poor communication in the project team with an RII= 0.89. This result has provided more insight and more specific on what causes construction planning to fail by attributing such failures to financial integrity and ethical standards of client rather than to more generalized issue such as lack of finance as adopted in previous works.

Contractors surveyed indicated that Planning can be improved through application and adoption of computerized systems and ICT with RII=0.92, continues monitoring and controlling of project with RII=0.92, progress meeting and briefing with RII=0.90, and by engaging project team members in planning the project with RII=0.84.

Model Presentation

The next step in the model development was to create a schematic diagram of findings from the study. The diagram as represented in Figure 1 considered all the essential items that relate to planning as identified in the literature and from the result of data collected. The method presented two set of complimentary information; literatures information was used as normative means of planning which was tested on the population to test its applicability.

Elements of the Model

The schematic diagram in Figure 1 represents a proposed model for planning construction project in Nigeria. From the top to the bottom of the project as indicated by downward facing arrows, the model consist of project entities identified in the study area namely the client or client organization, a communication means or communication flat form, the project team which comprises every individual concerned or related with the project in one way or the other, and the project represented by the project stages namely, project initiation stage, project planning stage, project execution stage and the project closure stage.

Communication Flat Form

Findings from the research shows that failure of project planning was attributed to poor communication (relative importance index 0.89) among other factors, respondents to the research also believe improve in communication and awareness among the project team has great tendency of improving awareness and avoiding conflict there by improving the chance for successful completion of the project.

The model in Figure 1 identify the respondents perceived importance attached to communication, the flat form which is ICT compliant should be open, accessible, should serve as the nervous system of the project collecting, storing and transmitting information to those who need and when they need it. The flat form is placed between the client and the project team, this is to signify the need for connectivity between client and project team throughout the project duration.

The project team comprises of all professionals, artisans, craftsmen, suppliers and other stake holders in the project. Bamisile (2004) identify that in Nigeria, construction project involve the services of some identified professionals including the architects, builders, quantity survey, engineers, land surveyors etc.

A project can successfully be managed only if all the personnel involve are totally dedicated, project planning requires special skills and wisdom by the management team. The planning cannot be accomplished by one single individual, hence there is need to have a good understanding and relationship between all projects members, all members are required to plan their individual area of responsibility and the collective efforts be delivered uniformly in harmony with the input of others in same project.

In the model as represented in Figure 1, the project is shown to be placed right on top of the project throughout the project. This signify the importance attached with ensuring all the team is carried along through the project, the model also connect the project team with the client through the open communication flat form as indicated by arrows from the communication flat form to the project team.

In the model, it is shown that the full combination of all the project team was completed only at the project planning stage, this is because at the initiation stage, the only member employed is mostly the prime consultants who acts as client representative or together with the client, and hence such combination was considered to be part of the client.

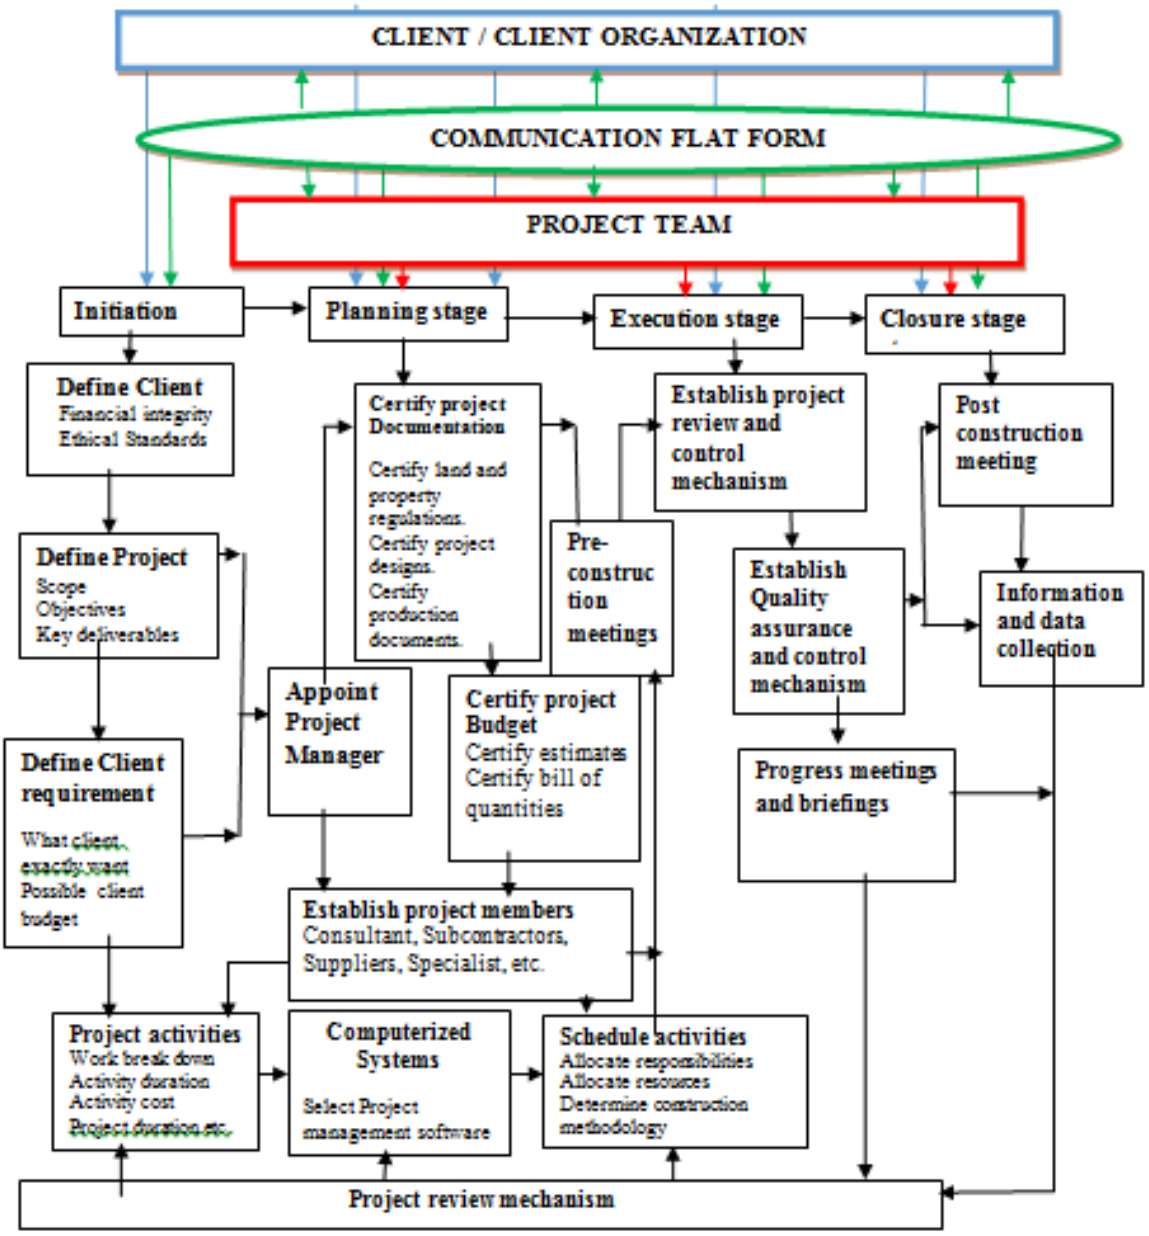

Figure 1: Proposed construction planning model for Nigerian

Project Team

The Project

In the model (Figure 1), the project is represented by the four phases of project life cycle as contain in the project management body of knowledge (2004), these phases are namely, the project initiation stage, project planning stage, project execution stage and the project closure stage. Based on the findings of the research, recommendations were made with respects to each stage of the project. The activities identified with respect to each stage are outline as follows:

i. Project Initiation Stage

Firstly, the model recognized the need for contractor to identify who the client is, client financial and ethical standard in doing business should be assess here, this is as contain in the findings of the research which rank identifying client as the most important planning activity before starting any project with relative importance index

(RII) of 0.91. Findings of the research also rank client financial integrity and ethical standard high among factors that causes project planning to fail with RII = 0.94 and 0.92 respectively.

Next the model identify the need for defining what the project is, the project scope, objectives and key deliverables in the project must all be specified, the model further identify the need to specifically define exactly what does the client need, with respect to quality standards, time of completion and budget capability.

The model also identify the need for contractors to specifically provide details breakdown of major activities in form of work break down structure for the proposed project.

Finally, planning at the initiation stage ends with appointment of project manager who is charge with duty of managing the project from that point onward to completion.

ii. Project Planning Stage

In the model (Figure 1), the necessary planning activities at the project initiation stage was shown to end with appointment of a project manager which could be a single entity or a cooperate body depending on size, complexity and several other project requirements, appointment of the project manager also mark the beginning of the planning stage of the project.

At the planning stage, results of the study shows that ensuring completeness, accurate and approved drawings and documents with relative importance index (RII=0.96) was ranked first among important activities that must be achieved while planning. The research also shows that certifying project budget, establishing exact individual activity duration and overall project duration, use of computerized system for planning, scheduling of the identified activities in the project are all important for an efficiency in planning.

Based on these identified findings, the model therefore placed such activities in order of the respondents' perceived importance and logical order of activity occurrence.

iii. Project Execution Stage

In Figure 1, activities necessary at the planning stage was shown to end with preconstruction meetings and briefings, this also marks the beginning of the project execution stage.

At the execution stage, the model, based on the findings of the study, identified establishment of project review and control mechanism (RII=0.91) to be an important activity the can improve planning. The research also shows that establishing project quality assurance and control mechanism (RII=0.91) and holding progress meetings and briefings (RII=0.90) to be other important activities that can improve planning.

iv. Project Closure Stage

The model based on research findings closed the project by identifying activities necessary for proper closure of the project, these activities as contain in the model are holding post construction meetings and gathering and storing information.

Finally, the model connect all the project stages through an extensive project review which was established as a means of reviewing project should the need arise without negatively impacting the overall project success.

CONCLUSION

Planning was shown to be the system through which a system adapts its resources to changing internal and external conditions. For planning to be effective, previous researches have highlighted the need for planning to create a feasible framework and statement for the execution of the works that will provide the basis upon which work will be performed.based on its findings, the research concludes that, Planning among Nigerian contractors is not sufficient, and hence requires improvement for it to be effective. For planning to be improved, the research advocate for better communication in any project, adoption of information technology in planning and reality check on client financial integrity and ethical standard. Findings, conclusion from the study are summarized into a model presented diagrammatically.

A conceptual model was proposed to aid planning construction in the Nigerian construction industry, the model seek to identify the key areas and activities necessary for an effective planning of construction works which was developed based on the findings of research carried out to appraise planning of Nigerian indigenous contractors.

The key components of the model are the client or client organization, a communication flat form, the project team and the project. The model placed importance to the client, though client is identified first and placed on top of the model. The client interact with the project and the team through a chosen communication flat form, the communication flat form which serve like a nervous system in the project connect every member in the project and is placed between the client and the project team in the model, while the model represent the project by the four phases of a project namely, project initiation, project planning, project execution and project closure stage. A project review mechanism was placed at the bottom part of the model which provide a means of reviewing project at every stage of the project, this makes the model a flexible means of approach to the project execution.

The model is though developed and its constituent components explained, as was explained the model summarizes planning needs of construction project, the research propose adoption of the model which will serve as a basis for developing frame work for planning construction projects can be developed.

An Assessment of Solid Waste Management in Akure, Nigeria

Adebayo, Michael Adedayo[1] & Mbazor, David Ngwoke[2*]

[1&2]Department of Estate Management, Federal University of Technology, Akure, Nigeria
[*] davembazor@gmail.com

ABSTRACT

Solid waste collection is one of the most difficult operational problems faced by many cities in Nigeria of which Akure is not exclusive. This situation has rendered our cities to become the eyesore of the nation and an invitation to health hazards. This study therefore, aims at assessing the methods of managing solid wastes in Akure with a view to achieving the desired environmental sanitation for good health of the people. Data on sources and types of wastes generated, methods of disposal, regularity of disposal, dumping sites and processing were obtained from 368 sampled respondents coupled with information gathered from the Ondo State Waste Management Authority (ODSWMA). Descriptive statistics of frequencies, percentages and Likert scale were used to analyse data got. The results showed that most solid wastes were from residential houses and the refuse were dumped at roadsides waiting for government truck. The study revealed that ODSWMA truck cleared the wastes at least once in a week which the respondents adjudged satisfactory. It is recommended that the authority's refuse disposal trucks are well maintained while modern equipment for collection, recycling, processing, disposal and reuse should be procured for better efficiency.

Keywords: Environmental Sanitation; Refuse Disposal; Solid Waste; Waste Management

INTRODUCTION

Proper management of waste is critical to the health and well-being of urban residents (World Bank, 2003). The volume of waste generated in any city is often a reflection of the intensity of human activities such as increase in population, urbanization and social development, industrial development, resource exploitation and unchecked technological advances (Olanrewaju and Ilemobade, 2009). All these activities generate one form of waste or the other such as garbage, rubbish, ashes, trashes and dead animals. Most of our towns and cities are becoming more populated every day because of migration from rural to urban areas; the volume of solid waste generated has also increased tremendously and this makes solid waste a vital issue among the communities.

The production of waste material incudes the entire variety of refuse generated during domestic, industrial, construction and commercial processes (Bello, 2009). Solid waste is the term used to describe non-liquid waste material arising from domestic, trade, commercial, agricultural, industrial activities and from public services (Aibor and Olorunda, 2006). Solid waste management involves the storage, collection, and transportation of disposed refuse in a manner that is hygienically and aesthetically acceptable to avoid being detrimental to human health (Emeribe, 2000). The disposal of solid waste generated and the rate of evacuation or accumulation is an index of the degree of the effectiveness of solid waste management in an urban environment. Ojolowo (2007) is of the opinion that generation and disposal of waste is an intrinsic part of any developing or industrial society. Solid waste management is also an integral part of property management. It concludes that waste generation as an activity is not problematic per se, but subsequent phenomenal collection, storage and disposal are, in the face of urbanisation, pose challenges in many cities in Nigeria.

A study in Nigeria by Sridhar and Ojediran (1989) showed that municipal solid wastes were produced in the urban areas at a mean rate of 0.43 kg/head/day. Onibokun, Adedipe and

Adebayo, M. A. & Mbazor, D. N. (2016). An Assessment of Solid Waste Management in Akure, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 913-920

Sridhar (2000) also noted that it was not uncommon going through the length and breadth of the country (Nigeria) to find heaps of refuse littering the entire landscape, road sides and commercial centres, even on the premises of primary, secondary and tertiary institutions as a result of poor management strategies. Ossai (2006) discovered that waste generation nationally was alarmingly on the increase with an estimated annual rate of about 0.5 -0.7% and current figures ranging from 0.4 to 0.8 ton /capital /annum. It further stated that complexity in waste was also increasing with biodegradable waste accounting for over 50% amounting to an annual average of approximately 50milion tons per annum of waste burden on the nation with less than 10%waste management capacity. Yusuf and Ojo (2007) were of the view that about 75percent of solid waste collected in Nigeria cities was disposed in open sites thus marginalising the urban environment as a result of negative externalities generated.

The state of domestic solid waste management in Akure is of a serious concern. Wastes of all descriptions find their ways into public places such as open space, drainage channels, and road verges. The body in charge of Waste management in Ondo State is the Ondo state Waste Management Authority (ODSWMA) established in 1999, when solid waste management situation in Akure was chaotic and embarrassing to most of her residents. ODSWMA is solely responsible for the collection and disposal of waste in Ondo State. The desire of the state government to derive value from waste while at the same time effectively protecting the environment also led to the creation of the Ondo State Integrated Waste Recycling and Treatment Project under the Waste Management Authority. Though, waste management by nature is capital intensive and many state governments spend a good percentage of their funds on domestic waste management but what this amount could accomplish is dwarfed by the population it caters for. Moreover, the state of physical environment, especially in urban centres is a major source of concern and it is increasingly confronted with the necessity of developing more capacity to safely dispose of waste. With various strategies tried so far, to improve the situation, the success recorded has not been remarkable enough as noticeable in the heaps of wastes dumped by roadside road divides bus stops and other strategic points on the streets. It is therefore, imperative that an assessment of solid wastes management in Akure, the state capital is made with a view to improving on the existing strategies and exploring new methods as applicable.

LITERATURE REVIEW

According to Benneh, Songsore, Nabila, Amuzu and Tutu (1993), residential domestic wastes form the bulk of all sources of solid waste produced in urban areas. These household wastes were known to have high densities with high moisture content and the organic component of solid wastes, which properly accounts for about 70% to 90%, while tins, cans and paper are probably responsible for about 5% to 10% of the total waste produced. The study noted that because the capacity to handle all the household waste generated was still weak, about 83% of the population dump refuse in either authorized or unauthorized sites in their neighbourhood which creates unsanitary conditions. Ogedengbe and Oyedele (2006) showed that the rate of change in domestic waste quantities and composition in developing and developed countries was unprecedented. It further asserted that, generally the greater the economic prosperity and the higher the percentage of urban population, the greater the amount of solid wastes generated. Akinola and Salami (2001) observed that solid wastes had a lion's share among the total pollution of the earth's surface. Mainly solid waste composed of municipal and solid wastes (MSW), hazardous waste, plastic waste and e-waste. Municipal solid waste also called trash or garbage, is composed mainly of everyday items that are discarded by the public. Municipal solid waste can either be biodegradable (recyclable) and non-biodegradable.

Solid Waste Disposal and Management

Marshal (1995) stated that, waste materials that are organic in nature, such as plant material, food scraps, and paper products, were increasingly being recycled. These materials were put through compost and/or a digestion system to control the biological process to decompose the organic matter and kill pathogens. The resulting stabilized organic material was then recycled as mulch or compost for agricultural or landscaping purposes. Ajadike (2001) observed that most city residence dispose of their refuse either in open gutters, rivers, streets, open dumps, without regard to the environment and associated health hazards.

According to Medina (2002), the major models of disposal of solid waste in the United States were land filling or dumping and incineration. People want their refuse taken away and do not want it disposed of near their habitat, or at least not to where they can see or smell it. However, the European countries have resolved to improving waste disposal practices of solid wastes (including sludge), which may reduce the adverse environmental effects of such disposals and other aspects of solid waste disposals on land. This includes means of reducing the harmful environmental effects of earlier and existing landfills, means for restoring areas damaged by such earlier or existing landfills, means for rendering landfills safe for purposes of construction, and other uses and techniques of recovering materials and energy from landfills.

Solid waste management means the collection, keeping, treatment and disposal of waste in such a way as to render them harmless to human and animal life, the ecology and environment generally (Atsegbua, 2003). A survey conducted in urban centres in Iraq by UNEP (2008) revealed that solid waste management practices were generally very poor and these unsatisfactory practices were found in the collection, transportation, and disposal of wastes of all descriptions. The most serious challenge of the waste management situation in our cities is open dump systems adopted to manage solid waste.

Waste management requires a huge capital outlay. According to Akinwale (2005), Lagos state government spent between 20 and 25% of its funds annually on domestic waste management. The Waste regime in the UK provides a quintessence of a system that makes for effective monitoring of domestic waste prior to disposal and the steps to be taken on disposal. The regime distinguishes between controlled and special waste. Under Section 30 of the EP A, 1990, waste authorities in charge of waste administration have three basic functions: regulation, collection and disposal. Waste disposal authorities are to award waste disposal contracts through competitive tendering and are to make contracts with waste disposal contractors who may be private sector companies or companies set up by the local authority which must be at arm's length from the waste authority. The Waste regulation authority is responsible for issuing a waste management license. Under the regime, controlled waste may not be deposited, treated, kept or disposed of without a license. The licensing method issued as a means of controlling waste.

Malcolm (2005) identified lack of modem technology/lethargy in implementing efficient waste management methods as one of the challenges whereas different efficient ways of domestic waste management had long been in use in many developed countries. Recycling waste is one of the commonest ways of managing waste in developed countries. It involves the production of a useful material from waste garbage almost always has enough value to justify recycling parts of it. Financial instruments are used to encourage recycling and this is supported by environmentalists. In UK for instance, in keeping with the philosophy of introducing market forces into environmental regulation a system of financial credits was introduced by Section 52 of the EPA. It involves the waste disposal authority (the body

responsible for disposing of the waste), making payments to the waste collection authority (the body responsible for collecting the waste), in respect of waste which they have collected for recycling. This means that they would have less waste to take to the landfill site or to the incinerator. If a third party, e.g. a charity association collects waste for recycling they should be appreciated.

Landfill is currently the most common method of disposing of waste in many developed countries. It accounts for the bulk (90 per cent) of waste disposal in the UK (Mowoe, 1990). At its most basic, this involves digging a hole in the ground and filling it with rubbish. The practice usually is to bury different types of waste in the same landfill site (Malcolm, 2005). Usually domestic waste is disposed of with industrial waste; the latter serves to reduce the concentrations of components leached from the former-diluting the industrial leachate. In particular domestic refuse can serve to neutralize acid wastes which arise in considerable amounts in many countries including Nigeria. In the UK, legislation makes it possible for waste regulation authorities to grant licenses subject to conditions relating to the care of the site after it has been filled (Malcolm, 2005).

The other major method of waste disposal is incineration. This means burning waste in an incinerator. In many areas of Japan, France, Germany, Italy and Scotland, such low value recyclable waste (mostly paper and plastics) are incinerated (Mowoe, 1990). The reality is that much domestic waste in these forms i.e. paper and plastics (packaging waste) is a major contributor to the waste stream and to the problem of litter. Incineration could reduce the domestic waste volume by 95% (Atsegbua et al., 2003). When waste is burned, there are two consequences: gases will be emitted into the air and residues in the form of ash and sludge will be left behind. Until recently, disposal of this incinerator waste has been a continuing problem. In the mid-1990's successful experiments in France and Germany used electric plasma touches to melt incinerator waste into rounded glassy pebbles, valuable as concrete filler and they do not dissolve in water (Atsegbua et al., 2003).

Added to the above methods of waste disposal is a new technology for domestic waste collection called pneumatic collection system for domestic waste (Mowoe, 1990). This system conveys waste without the need for trucks driving through towns and is operational 24 hours per day every day of the year. The system was especially suited to the development of new urban areas and for renovation of historic centres. Pneumatic collection is a break away from conventional forms of collection in that it avoids the need to place waste on the public highway and does away with movement of trucks and all the associated nuisances. Running entirely underground, the system contributes to protection of the environment by creating cleaner urban areas that function better and are more environmentally friendly. It is an innovative service with a simple operating principle. Users deposit their waste boxes on the streets on building land or in the garbage disposal areas of residential building and hotels. Each box has an associated "waste value" allowing intermediate storage before transport of the bags to a central collection point.

The bags are then dropped automatically into tanks where the waste is compacted. The air needed to propel the bags is provided by high-power blowers and the system is entirely controlled from a computerized cock pit. Access to the drop boxes is available at any time, every day of the year and without restriction. Pneumatic collection has many economic advantages: designed to last for 50 years, the installation and operating costs are optimized by a high level of automation and energy -efficient processes (Ita, 2000).

THE STUDY AREA

Akure, the study area, became the capital of Ondo State in 1976. Since then, it has been influenced by the influx of people into the town. Akure is located at the centre of the state, approximately within Latitudes $7^0$15'N and $7^0$28'N North of the Equator and longitudes $5^0$6'E and $5^0$21' E East of the Greenwich Meridian. It is bounded in the north by Akure North Local Government in Iju Itaogbolu; in the west, by Ile-Oluji Local Government; and in the South, by Idanre Local Government.

According to the provisional figure of the 1991 national census, Akure had a population of 239,124 people and in 1996, the population increased to 269,207. NPC (2006) puts the population as 353,211 and now over 380,000 people by projection. However, this figure has increased immensely owing to the influx of the people into Akure from other parts of the country due to the various activities in the area.

Trading and civil service are the dominant occupation in Akure. Markets are built by the present administration and this has caused increase in solid waste in the area. There are also some commercial activities and industrial companies. As Akure grows commercially, it is abundantly endowed with well-developed and service oriented industries, insurance, banking, printing, advertising and public relations. These cause increase in solid waste generation in Akure.

RESEARCH METHODS

Survey research design was engaged in this study. The target population were residents of Akure and the officials of Ondo State Waste Management Authority. Structured questionnaires were administered on the sampled residents while interviews were conducted on the top management and actual workers that move from house to house to collect the wastes.

For the purpose of this research, the stratified random sampling method was used. Using this method, Akure, the study area was classified into three strata with each stratum having sub-division. The bases for this classification were location and population density which to a great extent determines the amount of waste generated in any neighbourhood (Agboola, 1999). The pattern of development in Akure is linear along its main roads which are Adesida Road, Arakale Road, Ondo Road and Oda Road. The three developmental strata and their sub-divisions arising from this pattern are:

i. Peripheral suburb: Alagbaka, Ala Quarters, Ijapo Estate and FUTA Area
ii. Newer inner suburb: Hospital Road, Oluwatuyi Quarters, Oshinle Quarters, Ijoka Road, Ilesha Garage, Oke Aro, Oke Jebu
iii. City centre: Oja Oba, Isolo, Oja Oshodi, Eyinke, Ijemikin, Odopetu, Araromi and Odo lkoyi.

A sample size of five hundred was used for this study. This was selected on the basis of administering 25%, 35% and 40% questionnaires in each of the three strata that is, Peripheral suburb, Newer inner suburb and City centre respectively. Using the stratified random sampling method, 125, 175 and 200 respondents from each of the three developmental strata to which Akure was classified were randomly selected. However, 368 returned and well completed were found useful for this study. The data collected were analysed with simple descriptive statistics of frequencies, percentage and 5-point Likert scale.

DATA ANALYSIS AND RESULTS

Table 1 shows the various types of solid wastes generated within Akure, the study area. Respondents were asked to tick the types of wastes generated within their household or business place.

Table 1 shows the type of solid waste generated by respondents. All the respondents i.e 100% confirmed that they generate food waste and nylon, 81.25% of them generates tin as wastes, 64. 67% generates old appliances as wastes while 61.41% generates carton as waste. 48.1% of the respondents generate paper and plastic as wastes, while 35.5% of the respondents generate planks as wastes. The findings conform with the conclusion of Akaninyere and Atser (2001) that the major components of waste are degradable materials (food remnants, paper, and rags) and non-biodegradable plastics, tins, metals, bottles, glass, and bones. The study asserted that in several Nigerian cities, garbage contributes substantially more than other components. This could be explained by the fact that most activities which affect the environment stem from the need for food; its production, processing and preparation. Moreover, the findings of this study also confirm that of Benneh *et al* (1993) in Accra, Ghana and Adewumi *et al* (2005) in Akure.

Table 1: Types of Solid Wastes Generated by Residents

Type of Waste	Frequency	Percentage
Food waste	368	100
Nylon	368	100
Tin	299	81.25
Old Appliances	238	64.67
Cartons	226	61.41
Glass	205	55.70
Paper	180	48.91
Plastic	180	48.91
Plank	131	35.59

Table 2: Waste Disposal Strategies

Method	Frequency	Percentage
Road side (expecting truck)	293	79.61
Dumping in bushes	198	53.80
Controlled dump sites	201	54.61
WMA containers	162	44.02
Burning	122	33.15
Gutters / Streams	72	19.56
Bury within compounds	45	12.22
Cart pusher	89	24.18

Table 2 shows the waste disposal strategies adopted by the residents in the study area. Most of the respondents 79.61% drop their solid wastes by the road side waiting for the Waste Management Authority's truck for evacuation. This method is followed by dumping wastes to controlled dump sites as attested by 54.61% of the respondents. Burning of wastes, dumping in gutters and streams and burying some within the compound are not very common among the residents. Only 33.15%, 19.56% and 12.22% respectively do these. The results of this study show the new orientation of the residents towards a better environmental sanitation. Moreover, the State Government through the Waste Management Authority monitors and penalise offenders of environmental sanitation.

Table 3: Frequency of WMA Collection System

System	Frequency	Percentage
Once in a week	208	56.52
Once in two weeks	102	27.72
Once in a month	35	9.51
No presence	23	6.25

Table 3 shows the frequency of the Waste Management Authority in collecting the solid wastes generated. From the Table, 208 representing 56.52% of the respondents indicate that WMA van comes to their neighbourhood to evacuate wastes, another 27.72% confirms that

the van comes once in two weeks. Only 35 of the respondents (9.51%) say the van only come not more than once in a month while 6.25% say they have never seen any government refuse collection truck in their neighbourhood. This result shows that the Authority in charge covers more than half of the city in a week and much more (84.24%) in two weeks. Perhaps the few areas not covered are due to location and inaccessibility owing to poor roads.

Table 4: Perception of Respondents to Waste Collection Management

	VS	S	N	LS	NS
Adequacy of dump sites	42 (11.41)	63 (17.12)	11 (2.99)	122 (33.15)	130(35.33)
Adequacy of containers	43(11.68)	51 (13.86)	42 (11.41)	120 (32.61)	112(30.44)
Regularity of Waste Collection	117 (31.79)	144 (39.13)	29 (7.88)	52 (14.13)	26(7.07)
Service charge	126 (34.24)	163 (44.29)	2 (0.54)	62 (16.85)	15(4.08)
Attitude of personnel	113 (30.71)	171 (46.47)	47 (12.77)	23 (6.25)	14 (3.80)
Final management of wasters	87 (23.64)	89 (24.19)	59 (16.03)	71 (19.29)	62 (16.85)

Note: VS- very satisfactory; S- satisfactory; N- neutral; LS- less satisfactory; NS- not satisfactory.

Table 4 shows the feelings and thoughts of the respondents towards the general management of solid wastes in the study area. 68.48 per cent of the respondents are not well satisfied with the provision of dump sites. Moreover, 63.05% have the same poor feelings to the adequacy of waste containers located at some points in the town. However, from the Table, 31.79% are very satisfied and 39.13% satisfied with the regularity of waste collection by the Management Authority. In other words, a total of 70.92% of the respondents are satisfied in this regard. The respondents, are also satisfied with the amount being charged for the service rendered; 78.53% of them affirms this. The attitudes of the personnel are also rated high as 30.71% of them show that they are very satisfied while 46.47% are satisfied. The perception of respondents to final management of waste show a sort of dissatisfaction as only 47.83% indicates satisfaction.

Outcome of Interview of Key Staff

The interview conducted on Ondo State Waste Management Authority indicated that the activities of the authority are mainly the collection, disposal and management of waste in the study area. Though there are several factors militating against the management of solid waste by the authority in the study area among them are lack of non-governmental organizations' participation in waste management, low political will to strengthen environmental management agencies and bodies, poor information management, non-compliance by the general public and adequacy of equipment for waste management.

It was further revealed that the state government has taken a step further in the management of solid waste by establishing an integrated waste management plant at Igbatoro road, Akure. It has production capacities of 25 tons of organo-mineral fertilizer per day, 5 tons of scrap metal recycling per day and 50 tons of nylon/plastic recycling per day.

CONCLUSION AND RECOMMENDATION

Generation of domestic solid wastes is a daily affair, though its management ought not to be a problem if correct approaches are employed. Waste management should be given adequate attention by both state and local governments. The study established the important role being played by ODSWMA in solid waste management. The authority is efficient in its services delivery in terms of waste collection and disposal and also the frequency with which the service is carried out in Akure. The authority is adjudged to be living up to its responsibilities according to the findings of this study especially in the regularity of waste collection, pocket friendly service charge and the courteous attitude of the personnel to their customers. However, it is hereby recommended that the state government should increase the annual

budget of environmental management in order to carry out mass repairs, overhaul and maintenance of the Authority's equipment for effective waste collection, disposal and management. For better efficiency, modern equipment for recycling, processing and reuse of wastes should be provided. In addition, more refuse dump containers should be placed on streets within the city to discourage people from indiscriminate refuse disposal.

ABSTRACT

Information Communication Technologies have recently been adopted by transportation systems around the world to improve their services. In adopting these technologies, the stakeholders' involvement and perceptions regarding ICT should be considered. This paper, considering the study area, reflects on the perceptions of different stakeholders of the public transportation system towards the introduction of ICT solutions to the system. The methodology adopted was to understand the expectations of drivers, passengers and operators on integrating ICT solutions into the public transportation system, focusing on mini-bus taxis and Interstate Bus Line buses. The significant results of the study show that ICTs are anticipated and long overdue development to the system but the stakeholders have varying expectations. These results reflect on the priorities of the stakeholders, i.e., passengers yearn for improved service quality; drivers are concerned with their working conditions while the operators' interests are profit motivated. This paper highlights the ICT interests of passengers, drivers and operators. It compares passengers' needs, in terms of technologies, to improve the public transportations system against what the operators are enthusiastic to provide.

Keywords: Information Communication Technologies, Perception, Public Transportation, Stakeholder

INTRODUCTION

Stakeholders' perceptions on technology play a crucial role in the adoption of ICT in the public transportation system. Enabling actions for successful deployment of ICT in transportation should include a consensus amongst the stakeholders (Idongesit & Knud, 2014).The goal of public transportation services is to provide safe, reliable, affordable and accessible public transportation to the public. The main concern of the stakeholders should be that the above factors are met. In the Free State, public transportation is provided by private mini bus taxi operators and bus services which are provided by a private company under government subsidy.

Although public transportation systems in the world have been taking advantage of the current technological momentum to improve their service provision, the Free State public transportation system have not done much yet to exploit the opportunities lying within ICT. Deployment of ICT solutions to improve the public transportations system in the province may however be anticipated by the different stakeholders for solving differing problems in the system and how they may improve their different affiliations to the public transportations system.

The uptake will also depend on how drivers view the development (Zwick, 2002). Innovations render knowledge obsolete, therefore forcing employees to undergo training in order to be able to adapt to the changes. Public transportation drivers will require training in order to use some of the new technologies.

With the public transportation systems facing problems of safety, lack of information, accessibility, and being unreliable; operators should be concerned with eliminating these

Bashingi, N. & Mohamed, H. M. (2016). Perspectives of the stakeholders of the public transportation system on ICT solutions applicability in the Free State, South Africa. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 921-929

problems to satisfy the needs of customers and improve the system for the passengers. The concerns of the operators may not be aligned with those of drivers and operators based on their different needs. The role of the operators, as the service provider is to ensure that the passengers and drivers are safe, they provide regular service for reliability. Service provision, in general, should be inclined with fulfilling customer needs other than protecting the operator's investment.

ICT Opportunities for Stakeholders in public transportation systems

ICT has the ability to improve the efficiency and effectiveness of public transportation systems, therefore improving mobility for the passengers, working conditions for drivers, and service delivery for operators. ICT has improved public transportation through technologies and applications in different scenarios:

Real time information through map and route display screen and trip planning applications

Passengers would use display screens for information on their location, time left to their destination, routes they are travelling on. This would reduce cases of inaccessibility of public transportation due to lack of information on routes in a sense that, a novice would have all the information they need made available through these screens. Studies show that technologies allow real time information transference between travellers and public transportation service providers (Filippi, Fusco & Nanni, 2013),and that usability of public transportation can be improved significantly if good real time traveller information systems are provided (Ferris, Watkins & Borning, 2010). Provision of real time information will enable travellers to enquire about arrival and departure times at locations of their interest, and the availability of this information is a way of increasing public transport ridership as it reduces anxiety of passengers, therefore increasing a sense of reliability towards the public transportation systems (Ferris, Watkins & Borning,2010; Park, Yang &Yi, 2011).

Real Time Tracking and Monitoring of Vehicles

Monitoring of bus stations, stops, and inside the vehicle is important for safety reasons. Currently, the method of payment in mini-bus taxis is such that passengers pass their fare to the person seated in front of them in the vehicle, in some cases money goes missing in the process without any means of tracing how and where it disappeared or identifying a passenger who did not pay. In these cases, the driver, who is the final designated recipient of the money, should be able to see, using CCTV as money is being passed around to solve this problem.

Electronic fare payment (EFP) systems

Electronic fare payments have made payment for journeys by public transportation more convenient and also made it easier for operators and bus conductors; improving public transportation for both passengers and service providers. These fare payment systems operate through electronic communication, data processing and storage techniques that have made manual fare collection an automatic, computerized system (Floridaapts, 2015). They have improved manual labour dealing with handling of cash, safety and security reasons as bus drivers and conductors do not have to be at risk of robberies and hijackings targeting the money collected from passengers. EFP methods include electronic ticketing and smart cards. They have provided a platform for accessibility of information on public transportation, meaning that public transportation has also become more accessible and safer. Information is very important to travellers especially those new to a place (Ben-Elia and Avineri, 2015).

LITERATURE REVIEW

Passengers and drivers' perspectives

Public transportation users have the view that ICT solutions will improve the public transportations system tremendously, by improving accessibility, reliability and safety, and general quality of service. As ICTs can be used by operators or governments to monitor drivers, they can be used to both monitor and mentor drivers. Negative impacts of monitoring such as invasion of privacy and compromising driver behaviour shall be balanced by mentoring. Noting that most operators have shown interest in tracking and monitoring technologies like CCTVs, tracking devices and speed monitoring devices. Operators aims of managing their enterprises through ICT can influence the attitudes can go beyond perceptions of transparency, privacy and fairness to determine the degree of trust in the system (Regan, Horberry & Stevens, 2014).

The Technology Acceptance Model (Davis, Bagozzi & Warshaw, 1989) was adopted to explain possible links between determinants of computer acceptance and user behaviour, can also be adopted to determine acceptance of ICTs by users. The users, i.e. operators, drivers and passengers', perception of how the technologies will be useful to them and how easy to use they will also determine their attitude towards particular technologies or applications. Perceived usefulness and perceived ease of use therefore are seen as the crucial factors determining acceptance. Perceived usefulness of technologies also influences the person's behaviour with regards to their intention to use or not use the technology. This model, based on drivers' perspectives, shows that drivers will accept technologies they assume will enhance their performance (performance expectancy) and improves their working conditions. Behavioural intentions (how the people intend to use the technologies) and their impact on the actual use of the technologies should also be considered. With all the stakeholder's main concern being the usefulness and ease of use of ICT, consideration should be made as to whether those impacts are the same for all the stakeholders, i.e. what the other stakeholders consider useful, will it have the same positive impact on the other stakeholders, and will other stakeholders be able to easily use.

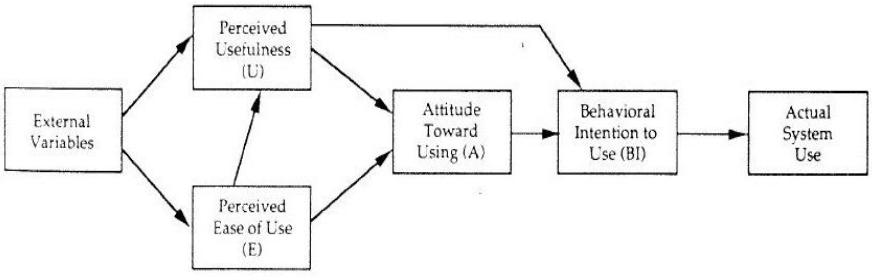

Figure 1: Technology Acceptance Model (Davis, Bagozzi & Warshaw, 1989)

Drivers and operators' perspectives

(Zwick,2000), implied that innovations are brought about to improve service availability, increase productivity, improve performance of employees, and client friendliness, flexibility and satisfaction. Passengers or public transportation users could have positive perceptions towards developments in technology if these technologies would improve service delivery and customer satisfaction, operators would have more interest in innovations that increase productivity, performance of employees, i.e. drivers. These goals somehow put pressure on the driver, as the facilitator between the operator and the passenger to deliver the transportation service in a way that customers will be satisfied and the operator's business.

Table 1: The responsibility of drivers and operators in service provision (Rohani, Wijeyesekera & Karim, 2013)

Items in Quality of service	Bus provider	Bus driver
Reliability	X	X
Responsive	X	X
Competence	X	X
Access	X	
Courtesy		X
Communication		X
Credibility	X	X
Security	X	X
Understanding / knowing the Passenger	X	X
Tangibles	X	

Table 1 shows the responsibility of drivers and operators in service provision as the driver also have responsibilities towards the passengers. (Rohani, Wijeyesekera & Karim, 2013) stressed the point that it is vital for drivers to have good communications with bus passengers and to be service oriented. Drivers in public transportation are in their working environment, therefore the ICT solutions improving the public transportation system should improve their working conditions. (Fourie,2003) listed bad working conditions, lack of skills and appropriate training, as some of the common problems in the public transportation industry.

Table 2: The degree of trust in the system (Regan, et al., 2014)

Monitoring	Mentoring
• Control of driver	• Care for driver
• Reactive advice	• Proactive advice
• Quantitative measurements	• Meaningful feedback
• Strict standards	• Support for improvement
• Comparison with co-workers	• Consider unique characteristics
• Under control of monitor	• Under control of driver
• Unfair standards and evaluations	• Fair and flexible evaluations
• Negative feedback	• Constructive feedback
• Invasion of privacy	• Respect for privacy
• System opaqueness	• System transparency
• Adversarial culture	• Supportive culture

As ICTs can be used by operators or governments to monitor drivers, they can be used to both monitor and mentor drivers, that way out the negative impacts of monitoring such as invasion of privacy and compromising driver behaviour shall be balanced by mentoring. Noting that most operators have shown interest in tracking and monitoring technologies like CCTVs, tracking devices and speed monitoring devices. Operators aims of managing their enterprises through ICT can influence the attitudes can go beyond perceptions of transparency, privacy and fairness to determine the degree of trust in the system (Regan, Horberry & Stevens, 2014).

With the current public transportation system, there is uncertainty these important attributes of the system, safety, accessibility. Uncertainty implies that the decision maker, the passenger or public transportation user does not have the perfect information (Ben-Elia & Avineri, 2015). Information availability and accessibility therefore provide certainty and assurance to the passengers. With journey planning and instant notifications there is an illusion of assurance, passengers can know the time vehicles arrive, departure time and in cases of delays and breakdowns, they can be assured of the next vehicle's arrival time or the exact time the vehicle is delayed by. Passengers avoid public transportation due to safety concerns. Monitoring and tracking technologies perceives safety and also deters crimes such as robberies in public transportation stations, vehicles and waiting areas. Passengers and drivers, unlike operators have relatively similar perceptions on what needs improvement in the public transportation system.

The quality of service provided by the operators determines the customer satisfaction, while the quality of service and driver behaviour also determines customer satisfaction. Driver

behaviour is also influenced by operators' behaviour. Therefore, in order to satisfy all the stakeholders, their needs must be aligned/ synchronised.

METHODOLOGY

Quantitative data collection via questionnaires was undertaken by employing stratified random sampling method to gather information from public transportation users, drivers and vehicle owners / operators. Owners of mini bus taxis and buses operating in the Free State province were asked about the technologies they would like to have in future, if conditions permitted, use in their vehicles. Passengers were also asked about the technologies they are willing to use. The study was carried out in the Free State province between June and August 2015. The questionnaires were given to operators at the Department of Police, Roads and Transportation licencing office where public transportation vehicle owners gather daily. Other questionnaires to passengers and drivers were administered at taxi ranks and Hoffman square where passengers wait for buses and drivers park their vehicles while waiting to leave at their scheduled times.

FINDINGS AND DISCUSSIONS

Passengers and drivers

Figure 2 shows the technologies which passengers and drivers are willing to use. The study looked at the technologies people are willing to use, therefore reflecting on what they think it's useful or will be easy to use. 38% of the respondents indicated that they will be willing to use tracking devices, while 20% indicated that they will be willing to use CCTV cameras. These technologies can be classified as monitoring technologies, which ensures secure and safer working conditions for drivers and perception of safety to the passengers. 25% and 22% of respondents indicated that they will be willing to use map and route display screens and buzzers respectively. Buzzers are a necessity as they will convey the message about a passenger willing to debus to the drivers and are also very easy to use. They will safely send the message to the driver without destructions as currently the passenger has to walk over to the driver and tell him to stop or shout the message across the vehicle to the driver.

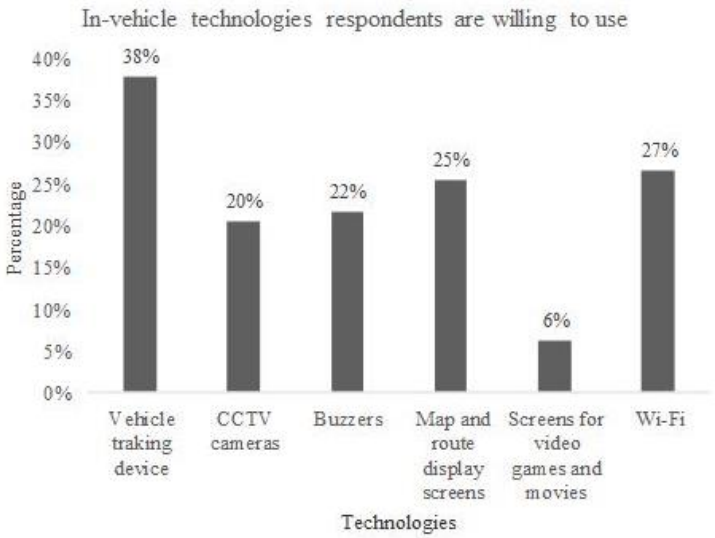

Figure 2: In-vehicle technologies respondents are willing to use

The usefulness of map and route display screens is indicated by the fact that information availability provides assurance and certainty to passengers. Drivers and users indicated that introducing screens for entertainment purposes (TV, gaming) is not a much needed technology as only 6% was willing to use them, these technologies may be easy to use but not

entirely useful as they do not promote accessibility or safety. Reliable internet availability plays a major role in real time information provision and accessibility, for some ICT application to fully function there should be connectivity. 27% of drivers and users indicated that they will be willing to use Wi-Fi if it is provided in the public transportation system. Wi-Fi can be provided at bus stations, bus stops and inside the vehicles for internet surfing, working and social networking. Public transportation users can use it to access the internet while waiting to board vehicles or during trips, as this will also create the illusion of time moving faster when they are kept busy.

Operators

44% of the operators indicated that they are willing to install buzzers in their vehicles for passengers to be able to notify the driver to stop. Buzzers are a way of sending information to the driver without distracting him, that making them useful and are easy to use as they do not require any skill to operate. 34%, 40% and 28% of operators indicated that they were willing to install tracking and monitoring technologies i.e. vehicle tracking devices, Speed monitors and CCTV cameras. Monitoring technologies however raises questions to whether the operator is ensuring customer safety or protecting their investments by monitoring drivers. Many operators would like to add vehicle tracking technologies to their vehicles, in order to monitor the movement of their vehicles and how drivers use the vehicles. As owners of vehicles, operators tend to be more concerned about the safety of their vehicles instead of satisfying the needs of the customers. Monitoring speeds is a way of ensuring the wise use of their vehicles by the drivers. Monitoring drive behaviour through CCTV, this may compromise the freedom of drivers as being under scrutiny all the time may make them uncomfortable.

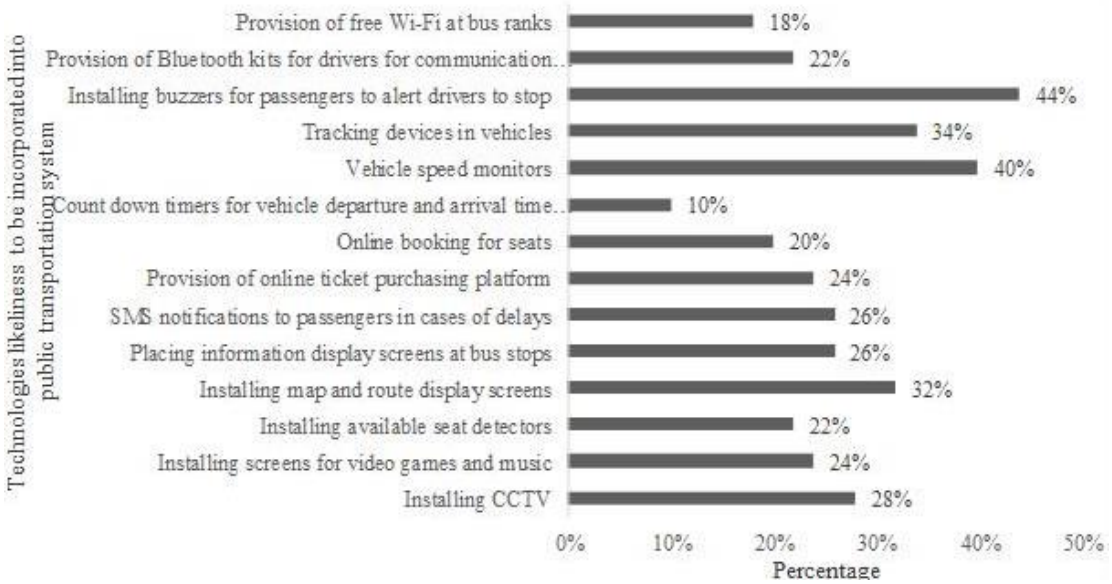

Figure 3: Information Communication Technologies the public transportation operators are willing to provide in future

26%, 26% and 32% of respondents indicated that they would provide SMS notifications to users install information display screens and map and rout display screens respectively. Information may be of fundamental importance to the users, but does it carry the same weight of importance to operators? Only 10% of operators were willing to install countdown timers to provide real time information on status or location of vehicles at bus stations or stops. This indicates that provision of information to passengers may not be a priority to them. Referring to the TAM, these technologies are useful and easy to use, but do not seem important to the operators. 24% of operators indicated that they were willing to provide technologies for

entertainment, by providing screens for TV and gaming, this compared to the passenger and driver's needs.

Drivers, Passengers and Operators

The figure below shows challenges likely to be faced by all stakeholders if ICTs are to be integrated into the public transportation system. These are the factors the drivers, users and operators will hinder the integration process and therefore should be addressed.

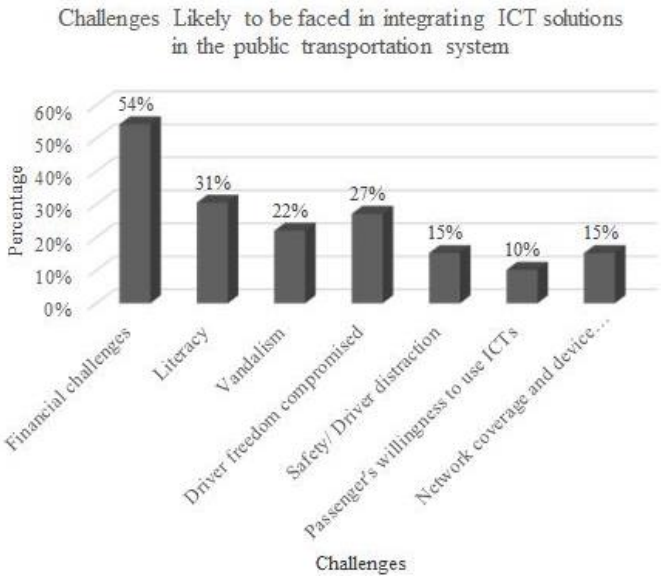

Figure 4: Challenges Likely to be faced in integrating ICT solutions in the public transportation system

Financial challenges: 54% of the respondents cited financial challenges:Installation of electronics and applications will result in financial implications for the operators, and some operators may not be able to install them at all. The passenger' take on financial implications will be the prices of internet connectivity, mobile data for downloading public transportation applications. There is a perception that improved public transportation services will result in increased transportation fare amongst public transportation users. This indicates that people in the Free State think that ICTs are likely to be not affordable.

Literacy: 31% of indicated literacy as a possible problem. This relates to ease of use of technology in a sense that, one should have a certain literacy level to be able to use some applications and technologies and be able to read.

Driver freedom is compromised: With tracking and monitoring technologies, drivers will no longer be free to use vehicles for their personal errands. 27% of respondents indicated that drivers' freedom will be compromised; their privacy will be invaded if they were to be monitored all the time.

Vandalism: 22% of the respondents indicated that vandalism of electronics and applications by users and drivers is also a possible course for concern. ICTs installed in vehicles and bus waiting areas may be deliberately destroyed. With security or monitoring technologies in place, there should be able to monitor any unlawful tampering with the installed applications.

15%, 10% and 15% of respondents respectively indicated that driver distraction, passengers' willingness to use ICTs and network coverage could also be possible challenges. Some technologies especially for entertainment purposes may distract the driver and cause accidents and damage to vehicles. If ICTs are introduced to the public, the people whose travelling experience they are meant to improve, the people should be willing to use them in order for the integration to be successful. Rural areas in the province have connectivity problems and

this may affect the use of mobile applications, web-based platforms such as trip planning and social networking sites.

CONCLUSION ANS RECOMMENDATIONS

The paper investigated the perceptions of Free State public transportation stakeholders towards using Information Communication Technologies in the system. The perceptions of the stakeholders' lean towards their involvement with the public transportation system.We need to remember that the main aim of public transportation service is to provide safe, reliable, affordable and accessible transportation. Within these lies factors such as comfort, certainty and freedom for all the stakeholders. The results the stakeholders have conflicting expectations from integrating ICT solutions into the public transportation system. The ICT solutions for a safer public transportation for instance are not perceived similarly by the stakeholders, they may be safety assuring measures to operators and passengers but not comfortable for drivers.

Drivers and operators should use their responsibilities towards passengers to surpass their personal needs and expectations from ICTs. Their responsibility is firstly to serve the passengers. Considering this, drivers should settle into the idea that monitoring technologies are for the safety of all stakeholders and operators should not abuse the monitoring technologies to make the working environment uncomfortable for the drivers.

Perceptions can also be a result of usefulness and usability of technologies as they are driving forces towards acceptance of technologies. Stakeholders are not willing to accept technologies they do not see useful or they will not be able to use. This should, for implementation in future, prompt decision makers to deploy useful and usable technologies in the transportation system.

Integrating ICT solutions into the public transportation system will have financial impacts on operators and passengers. Operators should provide these technologies in their service provision (installation, maintenance, and operation) while passengers need finances to access and use some technologies, e.g. smartphones, data / airtime. The passengers, taking into consideration the prices of the current transportation services think that improving the system for the better will also result in increased service fees. Generally, the perceptions are influenced by the current state of the system, user acceptance, based on perceived usefulness and ease of use of the technologies as well as the anticipated behaviour of stakeholders towards the technological innovations.

This paper provides more insight and understanding into stakeholders' perceptions to help in decision making concerning introducing new technologies and innovation in the public transportation system. It will therefore improve the decision making process and also help other stakeholders participate in the process and their perspective be taken into consideration.

Impact of Risks on Tendering and Procurement of Building Projects in Lagos State

Dosumu, Oluwaseun Sunday

Department of Building, University of Lagos, Nigeria
osdosumu@unilag.edu.ng

ABSTRACT

The paper examines the impact of risks on tendering and procurement of building projects in Lagos state. The objectives are to investigate the significant sources of risks to tendering and procurement, probability of occurrence of risks in tendering and procurement, level of awareness and adoption of risk management techniques in construction tendering and procurement. The questionnaire for the study was administered on building contractors and consultants. 44 questionnaires were retrieved and used for the analysis of the study through SPSS 20 software. The findings of the study revealed that the significant sources of risk are bad management, errors and omission, unskilled staff and economical regulations. Risk types that have high likelihood of occurrence are safety of works, bribery, inadequate cash flow, insurance, contractor default, inappropriate specifications, and economic pressure and market conditions. In the same vein risk types that have the greatest impact on tender are safety of workers, interest rate, disposal of bad plant and equipment, unforeseen site condition, contractor default, change in scope, defective work and project management. Thus, from calculation, risks that have high probability of occurrence are equipment failure, market condition, financial default by client, insurance, inadequate cash flow, and bribery. The study concludes that in spite of the awareness of respondents of risk management techniques, their adoption are mainly at response level rather than identification and assessment level.

Keywords: Building Projects, Procurement, Risk, Risk Management, Tendering

INTRODUCTION

The construction industry, like many other industries is subject to risks due to its unique features and complexity (Smith, 2003). The industry is one of the most dynamic, risky, and challenging and rewarding fields because it is exposed to both predictable and unpredictable risk (Mill, 2001). As a result of the inherent risk in construction process, researchers (Tipili, & Ilyasi, 2014) concluded that risks cannot be totally avoided, so it must not only be recognised, it must be assessed and managed. Buertney,Abeere-inga and Kumi (2013) noted that risks and construction are not mutually exclusive. Risk is an event that can have a negative impact on project outcome or opportunities that are beneficial to project performance. FAA system (2000) defined it as the probability and severity of accidents or loss from exposure to various hazards including injury to people and loss of resources. Oyewobi, Ibrahim and Ganiyu (2012) described risk as the exposure of construction activities to economic loss due to unforeseen events or foreseeing events for which uncertainty was not properly accommodated. The construction industry is plagued by risks above most industries due to its unique features which include complexity of construction activities, long period of construction activities, complicated process, financial intensity and dynamic organizational structure and these risks which are not adequately dealt with result in overall increased cost, time and reduced quality.

Rezakhani (2012) defined it as the potential for complications and problems with respect to the completion of a project and the achievement of a project goal. Another concept of risk is risk management which is the process of controlling the level of risk and mitigating its effects (Ahmed, Azhar & Ahmad, 2001). As such, it involves a systematic approach for identifying, evaluating, and responding to risks encountered on a project. It was also noted that risk

Dosumu, O. S. (2016). Impact of Risks on Tendering and Procurement of Building Projects in Lagos State. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 930-940

management is a process that involves identifying and assessing managerial resources with a co-ordinated and economic effort to minimize the probability and impact of unfortunate events so as to maximize the realization of poor project objectives. Risk management, according to Zou, Zhang and Wang (2007) is a way of looking at risk areas and determining how each should be treated. Mahendra, Pitroda and Bhavsar (2013) claimed that risk management identifies project risks, analyses them and determines the actions to be taken to avert the threats on any projects.

Risk is a pre-emptive concept rather than reactive and as such if not properly handled can lead to risk effects such as cost overrun, time overrun and poor quality. There are many kinds of risks which include safety risk, social risk, business risk, investment risk, military risk and political risks (Naphade & Bhangale, 2013) but the risks commonly faced by contactors are changes in work, delayed payment on contract, financial failure of owner, labour dispute, labour, equipment and material availability, labour productivity, defective materials, equipment productivity, safety, poor quality of work, unforeseen site conditions, changes in government regulation, political and ordinances, delays in resolving litigation/arbitration disputes, inflation, cost of legal process and force Majeure (Oyewobi, *et al*, 2012).

There is limited research on the effects of risks and risk management on construction tendering and procurement and this may be due to the fact that its importance is underestimated by both practitioners and academia. The concentration of research on construction risks have had efforts mostly being channelled towards effects of risks on construction cost, time and quality (Tam, et al, 2004), risk management at design phase (Chapman, 2001), construction phase (Abdou, 1996). Other people looked at risk from the life cycle perspective (Zou, et al, 2007), construction projects (Radujkovic & Car-pusic, 2011; Calzadilla, Awinda & Parkin, 2012), public private partnership, contingency (Buertney, et al, 2013), organizational performance (Agwu, 2012), Joint venture projects (Adnan, 2008) and insurance in construction industry (Naphade & Bhangale, 2013).

In view of this, it is evident that there is limited research on the impact of construction risks on the tendering and procurement of construction projects in spite of the importance of tender figures and procurement options for construction projects. The tendering and procurement phase is particularly an important stage in the design and construction of projects as it drives the eventual cost, time and quality of the project. Therefore, this study would contribute to the body of knowledge by determining the impact of risks and risk management on tendering and procurement of construction projects.

LITERATURE REVIEW

Sources of Risks

Ultimately, all risk encountered on a project is related to one or more of the following (Flanagan & Norman, 1993): failure to keep within the cost budget/forecast/estimate/tender, failure to keep within the time stipulated for the approvals, design, construction and occupancy, failure to meet the required technical standards for quality, functions, fitness for purpose, safety and environment preservation. For risks to be effectively eliminated, the sources must be identified and properly mitigated. According to Slattery and Bodapati (2001), the sources of risks are schedule, cost, quality, technical, unknown conduction, international, environmental and safety. It was noted in Zou, et al (2007) that cost related risks include tight project schedule, design variations, variations by the client, unsuitable construction program planning, occurrence of dispute, price inflation of construction materials, excessive approval procedures in administrative government departments, incomplete approval and other documents, incomplete or inaccurate cost estimate and inadequate program scheduling. Time related risks involve bureaucracy of government, high

performance or quality expectations and variation of construction programs among others. Quality related risks include low management competency of subcontractors and unavailability of sufficient amount of skilled labour. Environment related risk involve inadequate or insufficient site information (soil test and survey report) and serious noise pollution caused by construction. Safety risks are general safety accident occurrence and unavailability of sufficient amount of skilled labour. Environment related risk involve inadequate or insufficient site information (soil test and survey report) and serious noise pollution caused by construction. Safety risks are general safety accident occurrence and unavailability of sufficient professionals and managers.

The breakdown of the sources of risks is as described in Table 1

Table 1: Breakdown of risk sources

Table 1: Breakdown of risk sources
Source: Radujkovic and Car-pusic (2011: 2)

EXTERNAL SOURCES –outside the project		INTERNAL SOURCES – inside the project	
LEGISLATIVE	1 - Local regulations	CONTRACT	1 – Unrealistic deadline
	2 – Permits and agreements		2 - Unrealistic price
	3 – Law changes		3 – Other contract provisions
	4 – Standards	TECHNICAL DOCUMENT	1 – Delay
POLITICAL	1 – Policy changes		2 – Incompleteness
	2 – Elections		3 – Imprecision
	3 – War		4 .- New solutions as a consequence of 2 and 3
	4 – Existing agreements	ORGANIZATION	1 – Bad management
ECONOMICAL	1 – Economic regulations		2 – Bad organization of works
	2 – Price rises	TECHNOLOGY	1 – Poorly chosen tech. solutions
	3 – Exchange rates		2 – Obsolete technology
	4 – Financing conditions	RESOURCES	1 – Shortage of workers
	5 – Economic policy changes		2 – Shortage of machinery
SOCIAL	1 – Education, culture		3 – Machinery breakdowns
	2 – Seasonal work		4 – Late delivery of materials
	3 – Strike	HUMAN FACTOR	1 - Productivity
	4 – Human fluctuation		2 – Sick leaves
NATURAL	1 – Climate		3 – Motivation
	2 – Soil		4 - Errors and omissions
	3 – Subterranean waters		
	4 – Natural disasters		

Source: Radujkovic and Car-pusic (2011: 2)

Calzadilla, Awinda and Parkin (2012) classified the sources or risks into external and internal. External sources consist of natural/regional sources and the construction industry

while internal sources consist of the project and company. Under the national regional sources, there is political situation (national worker's strike, nationalization of basic industries and labour union), economical/financial (currency exchange control) and social environment (unskilled labour). Construction industry consists of market fluctuation (suppliers bargaining power and shortage of materials and materials and equipment) and laws and regulations (restriction of import or export materials and equipment.

Types of Risks in Construction

There are four types of risks according to Mahendra, et al (2013) and they are (1) technical risks- incomplete design, inadequate specification, inadequate site investigation, change in scope, construction procedures and insufficient resource availability, (2) construction risks- labour productivity, labour disputes, site condition, equipment failures, design changes, to high quality standard and now technology, (3) physical risks are damage to structure, damage to equipment, labour injuries and equipment and material fire and theft and (4) organizational risks- contractual relations, contractor's experience, attitudes of participants, inexperienced work force and communication. The types of risks discovered by Ahmed, et al (2001) are acts of God (flood, earth quake, land slide, fire, wind damage and lighting), physical (damage to structure, equipment, labour injuries, materials and equipment fire and theft), financial exchange rate fluctuation, financial default of subcontractor and non-convertibility), political and environmental (changes in laws and regulations, war and civil disorder, requirement for permits and their approval, pollution and safety rules, expropriation and embargoes), design (incomplete design scope, defective designers and omissions, inadequate specifications and different site conditions), construction related (weather delays, labour dispute and strike, labour productivity, differing site conditions, defective work, design changes and equipment failure.

Risk categories according to Shrestha (2011) are political risk-direct political, political decision making, right of way risk, competing facilities risk, regulatory risk, protectionism and legislation change. There is also economic risk (pre-investment risk, toll revenues, financial risks and cost overrun risk), socio-cultural risks (public opinion, environmental risks, moral hazard, partnering risks and environmental justice), technical risks (project management risks, construction risks, design and latent defect risk, technology risks, force Majeure physical risks). The types of risks mentioned by Oyewobi et al (2012) are design risk (defective design, variation of work, changes of original design and deficiencies in description of work), financial risk (inflation, inadequate cash flow, exchange rates, cost overrun due to schedule delay and contractors default), construction risk (contractors competence, defective material, poor performance of supplier, poor quality of work, productivity of equipment, labour, material and equipment availability and unforeseen site condition) and political risks (political uncertainty, bank policies, changes in government regulations, permits and ordinances and force Majeure). Ritchie (2007) noted from two case study projects that the type of risks include, delay in award of tender, access to site, site conditions, design responsibility, ambiguities in documentation, extension of time, interface risks, fit –out works, subcontracting, scope of works, fit for purpose and cultural heritage. Banaitiene and Banaitis (2012) grouped risks into local, global, economic, physical, political and technological change. PMBOK (2008) categorised it into technical, external, organization, environmental or project management.

Ehsan, et al (2010) pointed out that the categories of risks are technical (inadequate site investigation, incomplete design, appropriateness of specifications and uncertainly over the source and availability of materials), logistical risks (availability of sufficient transportation facilities and availability of resources), management related risks (uncertain productivity of resources and industrial relations problems), environmental risks (weather and seasonal

implications and natural disasters) and financial risk (availability and fluctuation in foreign exchange, delays in payment, inflation, local taxes and repatriation of funds), socio-political (constraints on the availability and employment of expatriate staff, customs and import restrictions and procedures, difficulties in disposing of plant and equipment and insistence on use of local firms and agent).

Risk Management Techniques in Construction Industry

Al-Shilby, et al (2013) classified risk assessment methods in quantitative and qualitative methods, qualitative method involves direct judgment, ranking options, comparing option and descriptive analysis. Quantitative technique includes probability, sensitivity, scenario and simulation analysis. Qualitative assessment involves identifying (1) risks hierarchy which is based on probability of risk occurrence and its impact on the project and employees (2) risks scope and (3) risk occurrence factors. Quantitative risk analysis involves evaluation of the impact of all identified and quantified risk. The results of quantitative are more objective than those from quantitative risk analysis. Risk management is divided into risk identification, risk assessment, risk response and risk treatment. Risk identification involves identifying and applying procedures for identifying opportunities, identification of losses of risk, identify how and why risk arise, analysing process to identify risks, scenario analysis to identify risk, area of risk management, physical inspection to identify risk, risk source, use of questionnaire, interview, brainstorming, SWOT and examination of local/oversees experience to identify the risk.

Risk assessment involves analyses/evaluation of opportunities, SWOT, risk collation, analysis of risk according to likelihood, consequence, quantitative analysis methods, reputation impact, achievement of objectives, financial impact and qualitative analysis method. Risk response involves identification of risk management plan, considering limits to achieve risk management objectives, evaluate cost and benefits of identifying risks, finding out the effectiveness of available controls and risk management responses, prioritising risks that cause great losses and identifying up to rate business continuity plan. Risk treatment involves understanding the risk faced by organizations, regarding communication aboard risk, supporting effective management of risk between staff and management, providing appropriate level of control regarding risks, risk transfer, risk reduction, monitoring the effectiveness of risk management, avoiding risk and accepting/retaining risk. Risk management according to Mahendra, et al (2013) is in four stages – Risk identification, risk assessment, risk response planning and risk control. Risk identification involves brainstorming, Delphi technique, interview/export is categorised into quantitative and quantitative techniques. Quantitative technique involves risk priority numbers and quantitative technique involves sensitivity analysis, scenario analysis, probabilistic (Monte Carlo simulation) analysis, decision trees, Risk, response involves risk avoidance, risk transfer, risk mitigation/reduction, risk exploit, risk sharing, risk enhancement, risk acceptance and contingency plan.

Naphade and Bhangale (2013) noted that the methods of identifying risks are brainstorming, interviews, questionnaire, services specialists and past experience. Risk can be managed by using existing assets, contingency planning and investing in new resources. The risk management strategies are risk prevention (including risk avoidance), impact mitigation, risk sharing, insurance and risk retention. Ritchie (2007) claimed that risk elimination, reduction, transfer and retention are ways of mitigating risk. The risk identification techniques put forward by Kansal and Sharma (2012) are brainstorming, Delphi technique, interview/expert judgment, checklist, influence diagram, flow chart and cause-and –effect diagram. Risk management techniques according to Ehsan, et al (2010) are risk identification, risk quantification, risk response development and risk response control. Risk response is

classified into acceptance, quantification, monitoring the risks, preparing contingency plans, transferring and mitigating risk.

METHODOLOGY

The population for this study is the construction organizations that are involved in project tendering and procurement. Also, the consultants' views were obtained because they are usually involved in the selection process of contractors during the tendering and procurement stage. The construction organizations' list was obtained from the Federation of Construction Industry (FOCI) and construction professional bodies. In the same vein, consultants' firms were obtained from the lists provided by professional bodies such as Nigerian Institute of Building (NIOB), Nigerian Institute of Quantity Surveyors (NIQS), Nigeria Institute of Architecture (NIA) and Nigerian Society of Engineers (NSE). In view of this, organizations that are based in Lagos state were used for the study. A total of 120 questionnaires were sent out to capture relevant information on the study, 44 were retrieved giving a response rate of 36.7%. This response rate is acceptable and not uncommonly low as noted by Takim (2008) that 20-30% response rate is adequate for researches in the construction industry. The sampling was based on convenience as organizations on the lists that are equally willing to provide information were considered for the study. Interview was also used to lighten questions that need further clarifications.

Table 2: Background information of respondents, projects and organizations

Profession of respondents	**Frequency**	**Percent**	**Type of projects handled**	**Frequency**	**Percent**
Architecture	4	9.1	Residential	16	36.4

DATA ANALYSIS, PRESENTATION AND DISCUSSION OF FINDINGS

Table 2 presents information of respondents, projects and organizations. Information covered include profession of respondents, type of service rendered, sector of project involvement, work experience, educational qualification, professional affiliation, type of projects handled and procurement methods used for projects. It can be deduced from Table 2 that builders and quantity surveyors dominate the study and contractors who work on both public and private projects are well represented in the study. Respondents with 1-15 years work experience, B.Sc, M.Sc and appropriate professional qualification are the information providers for the

study. Thus, the respondents of the study are well qualified. Then types of buildings handled by respondents' organization are 36.4% residential, 9.1% institutional, 9.1% religious and 45.5% commercial. Lastly, the traditional procurement method was used on 9.1% of projects, design and build method was used on 45.5% of projects and project/construction management method was used on 45.5% of projects.

Table 3: Sources of risks in construction tendering and procurement

Sources of risks	N	Mean	Std. Deviation	Significance	Rank
Poorly chosen technical solution	44	3.73	.973	Significant	1
Bad management	44	3.64	1.080	Significant	2
Errors and omission	44	3.55	.999	Significant	3
Unrealistic price	44	3.55	1.320	Significant	4
Unskilled staff	40	3.50	1.377	Significant	5
Economic regulations and price inflation	44	3.45	1.247	Significant	6
Education and culture	44	3.36	1.163	Mod. significant	7
Changes in law and standards	44	3.36	1.080	Mod. Significant	8
Climate and soil condition	44	3.36	1.080	Mod. Significant	9
Financing conditions	44	3.36	1.313	Mod. Significant	10
Late delivery of materials	44	3.36	1.163	Mod. Significant	11
Delay in preparation of document	44	3.36	1.313	Mod. Significant	12
Sick leaves	40	3.30	.911	Mod. Significant	13
Obsolete technology	44	3.27	1.370	Mod. Significant	14
Incomplete document	44	3.18	1.352	Mod. Significant	15
Unfamiliarity with local conditions	44	3.09	1.254	Mod. Significant	16
Human fluctuation	44	3.09	.910	Mod. Significant	17
Local regulations, permits and agreements	44	3.09	1.178	Mod. Significant	18
Inadequate contractor experience	44	3.00	1.141	Mod. Significant	19
Risk management planning process	44	3.00	1.294	Mod. Significant	20
Low productivity	44	3.00	1.141	Mod. Significant	21
Shortage of materials	44	2.91	1.326	Mod. Significant	22
Shortage and breakdown of machineries	44	2.91	1.326	Mod. Significant	23
Imprecise specification	44	2.91	1.460	Mod. Significant	24
Season-related work	44	2.91	1.254	Mod. Significant	25
Poor motivation	44	2.82	.724	Mod. Significant	26
Shortage of workers	44	2.73	.973	Mod. Significant	27
Suppliers bargaining power	44	2.73	1.227	Mod. Significant	28
Electioneering process of politicians	44	2.73	.872	Mod. Significant	29
Exchange rates	44	2.64	1.511	Mod. Significant	30

Table 3 indicates that the significant Sources of risks in construction tendering and procurement are poorly chosen technical solution (3.73), bad management (3.64), errors and omission (3.55), unrealistic price (3.55) and economic regulations and price inflation (3.45). Apart from these six sources, other sources used for the study are only moderately and slightly significant. This shows that if risks are to be averted, the significant sources discovered in this study are to be prevented fromoccurring.

Table 4 depicts the total risks and probability of occurrence of risk on construction tendering and procurement. The formulae for calculations are:

i. Total Risk = likelihood of occurrence (L) X degree of input (I)
ii. Probability of occurrence (P) = (Total risk/ cumulative total risk)

It is worthy of note that risks with high likelihood of occurrence and degree of impact are the ones that have high probability of occurrence. Hence, from the calculations in table 4, the risks with the highest probability of occurrence in tendering and procurement are equipment failure (0.022), market condition (0.021), financial default by client (0.023), insurance risk (0.026), inadequate cash flow (0.025), contractor default (0.023), bribery and corruption (0.021), safety of workers and materials (0.031), quality of work (0.021) and unforeseen site conditions (0.0241). The implication of this calculation is that, knowing the risk with the highest probabilities of occurrence will assist construction organizations to guard against them and device appropriate risk management technique to be adopted for them.

Table 4: Total risk and probability of occurrence of risk in construction tendering and procurement

Types of risks	Likelihood of occurence	Degree of Impact	Total Risk = Likelihood x impact	Probability of occurrenc = Total risk/∑ Total risk
Flood, earthquake, landslide, fire, wind	1.09	2.55	2.78	0.0075

Table 5 shows the respondents level of awareness of the risk management techniques for construction tendering and procurement. The respondents are mostly aware of past experience (3.40), interview/ expert opinion (3.20), ranking options (3.09) and risk control (3.0) among others techniques.

Table 5: Level of awareness and adoption of risk management techniques for construction tendering and procurement

Management techniques	Mean	Awareness	Rank	Mean	Adoption	Category	Rank
Risk sharing	2.64	Normal	9	3.55	Normal	Risk response	1
Comparing options	2.55	Normal	15	3.45	Normal	Risk assessment	2
Risk enhancement	2.64	Normal	9	3.27	Normal	Risk response	3
Contingency plan	2.45	Normal	19	3.27	Normal	Risk response	3
Risk transfer	2.45	Normal	19	3.27	Normal	Risk response	3
Descriptive analysis	2.73	Normal	6	3.27	Normal	Risk assessment	3
Interview/expert opinion	3.20	Normal	2	3.20	Normal	Risk identification	7
Ranking options	3.09	Normal	3	3.18	Normal	Risk assessment	8
Flow chart	2.64	Normal	9	3.00	Normal	Risk identification	9
Risk control	2.64	Normal	9	3.00	Normal	Risk control	9
Risk acceptance	3.00	Normal	4	3.00	Normal	Risk response	9
Risk exploit	2.73	Normal	6	3.00	Normal	Risk response	9
Brainstorming	2.64	Normal	9	2.91	Normal	Risk identification	14
Probabilistic analysis	2.64	Normal	9	2.91	Normal	Risk assessment	14
Risk mitigation/reduction	2.45	Normal	19	2.82	Normal	Risk response	16
Scenario analysis	2.45	Normal	19	2.73	Normal	Risk assessment	17
Decision tree direct judgment	2.64	Normal	9	2.55	Normal	Risk assessment	18
Risk priority number	2.73	Normal	6	2.55	Normal	Risk assessment	18
Questionnaire	2.27	Low	27	2.55	Normal	Risk identification	18
Monte-Carlo simulations	2.36	low	24	2.55	Low	Risk assessment	18
Sensitivity analysis	2.64	Low	9	2.36	Low	Risk assessment	23
Cause-effect diagram	2.30	Low	26	2.33	Low	Risk identification	24
Risk avoidance	2.55	Normal	15	2.27	Low	Risk response	25
Delphi technique	2.45	Normal	19	2.18	Low	Risk identification	26
Influence diagram	2.36	Low	24	1.73	Low	Risk identification	27

Also in Table 5, it is clear that the level to which respondents adopt risk management techniques in construction tendering and procurement include to adopt risk sharing (3.55), comparison (3.45), risk enhancement (3.27), contingency plan (3.27), risk transfer (3.27), descriptive analysis (3.27), interview/ expert opinion (3.20), ranking option (3.18), flow chart (3.0), risk control (3.0) and risk exploit (3.0). It is important to note that on top of the table are risk response strategies, followed by risk assessment strategies and then risk identification strategies. This indicates that many of the respondents' organization only do risk response and assessment while risk identification is utterly neglected. There may be less need for risk assessment and response because they would have been averted at the point of identification.

CONCLUSIONS

Based on the findings of this research, the study concludes that the sources of risks are poorly chosen technical solutions, bad management, errors and omission, unrealistic price, unskilled staff, economics regulations and price inflation. Also, safety of workers and material, interest rate challenge, difficulty in disposing bad plant, unforeseen site condition, equipment failure, contractor default, market condition, insurance risk, communication, financial default by client, inadequate cash flow, errors and omission, legislative influence, changes in scope, defective work, contractors and workforce experience, breach of contract by project partner, defects in supervision, project complexity, incomplete design, construction procedure, land acquisition, contractual relations, equipment availability and productivity challenge, differing

site conditions and variation of work have a high degree of impact on construction tendering and procurement.

Risks with highest probability of occurrence are flood, earthquake, inclement weather, design failure, human resource management challenge, equipment failure, project complexity, project management, construction technology, inadequate site investigation, inappropriate specifications, labour and material supply challenges, market conditions and financial default by client. The respondents are aware of the use of past experience, interview, ranking options, risk control, checklists, risk exploit, risk priority number, descriptive analysis, probabilistic analysis, risk enhancement, decision tree, direct judgment, flow chart, risk sharing, brainstorming, risk avoidance, comparing options sensitivity analysis, risk acceptance, risk mitigation, contingency plan, scenario analysis and risk transfer. Therefore, it is recommended that risk management follows the category of risk identification, assessment, response and control. This is against the usually trend of response and assessment that occurs before identification.

ABSTRACT

Health and safety is about the prevention of accident and ill-health among workers caused by their working conditions. Ergonomics is focused on preventing musculoskeletal injuries and illness which is one of the negative effects of construction activities on the human body. This paper addresses the prevention of musculoskeletal injuries through ergonomics adoption among construction craftsmen. The aim of the study is to assess the factors affecting ergonomics practice adoption by craftsmen. Data were collected using a questionnaire and interview administered and conducted with One Hundred and Twenty Five craftsmen (Masons, Electricians, Carpenter, Tilers and Iron-fixers) on construction sites in Abuja, Nigeria. Simple percentage was used to analyse data collected. The Research findings revealed that the awareness of ergonomics among construction craftsmen is very low as only 4% have of craftsmen have knowledge of ergonomics. The study found that training and education (77%), funding and government intervention (72%), involvement off labour unions (70%) and contractor support and commitment to ergonomics are factors that can drive adoption. The study concludes that factors militating against ergonomics adoption are lack of knowledge and understanding of ergonomics by craftsmen, cost of procuring ergonomic equipment, employees reluctant to use safety tools and gadgets and lack of legislation enforcing ergonomics practices. A frame work was developed recommending roles government, craftsmen, trade unions and contractors can play in enhancing adoption of ergonomics.

Keywords: Awareness, Craftsmen, Challenges, Drivers, Ergonomics

INTRODUCTION

The construction industry is labour intensive in nature. While industries like manufacturing have continued to mechanise and automate production the use of human efforts cannot be eliminated in construction. The industry provides a substantial source of employment for professionals, artisans as well as unskilled labour. The construction industry is characterized by the entire spectrum of health and safety hazards, namely physical, mechanical, ergonomic, biological, and chemical hazards (Kayumba, 2013; Muriri and Mulinge 2014).

According to Jabarani (2013) the construction industry has high rates of injuries and illnesses. Complexity of the projects and extensive scope of the works in construction industry make the workers to be exposed to injuries, illnesses, disabilities or even deaths. Ahankoob and Charehzehi (2013) assert that musculoskeletal disorder is the most common ergonomic injury problem in the construction industry. Buckley (2009) adds that strains, sprains and other physical ailments have long been a drain on construction productivity and a risk to overall worker health and safety.

The high prevalence of Musculoskeletal Disorders and the growing urge to improve health and safety in construction has led to introduction of new philosophy such as ergonomics. Ergonomics is one of the strategies in preventing musculoskeletal injuries and improving health and safety in construction (Albers and Estill, 2007; Al-Swaity and Enshassi, 2012; Sass and Smallwood, 2015).

One of the problems facing the Nigerian construction industry is the lack of qualified craftsmen or tradesmen (Ibrahim, 2010). Muhammad, Dodo and AbdulHafeez (2014) also observes that every sector of the construction industry is experiencing some labour shortage.

AbdulAzeez, A. D.; Mustapha T. & AbdulHafeez, I. (2016). Factors Affecting Ergonomics Practice Among Building Construction Craftsmen. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 941-948

Hence, there is need not only to give adequate attention to vocational training to produce commensurate number of competent skilled workforce to counter or ameliorate the menace but to adequately protect the health and safety of the current stock. It would be dangerous to lose the few qualified craftsmen due to illness and injuries caused by lack of a suitable working environment.

Despite the advantage of implementing ergonomics Nigerian building construction craftsmen have not been able to implement it, prompting this research. The objectives are

i. Assess awareness of ergonomic among building construction craftsmen
ii. To investigate factors affecting ergonomics among building construction craftsmen.

LITERATURE REVIEW

Ergonomics and Ergonomics Awareness

Ergonomics aims at avoiding injury and improve health, safety and comfort. The goal of the science of ergonomics is to find a best fit between the worker and the job condition. Too often employees perform job tasks that expose them to potential injuries and illness due to the poor working methods and tool they are using. According to Michigan Occupational Safety and Health Adminstration (2013) ergonomics involves the assessment of job tasks to identify ergonomic risk factors and appropriate engineering or work practices controls to reduce or eliminate the identified risk factors. Ergonomics tries to come up with solutions to make sure workers stay safe, comfortable, and productive (Albers and Estill, 2007).

Ahankoob and Charehzehi (2013) also described ergonomic as adapting the physical environment with physiological, physical, and psychological capability and limitation of the human by considering different discipline such as anatomy, physiology, psychology, sociology, physics, and engineering. There is a strong case for using ergonomic improvements both to reduce workers' exposure to risk factors for Work Musculoskeletal Disorders and to improve their productivity.

The motivation of implementing Ergonomics on the construction site according to Ahankoob and Charenzehi (2013) is to; improve quality, adopt human capability with optimal situation, balance requirement and limitation, increase productivity, make easy the human performance, provide a safe and healthy working environment, reduce disorders, decrease costs, and improve morale of the workers.

Ergonomic Risk Factors

The construction industry entails a wide range of activities, which expose workers to unfavourable ergonomic challenges. According to Al Swaity and Enshassi (2012) ergonomic risk factors are characteristics of a job that facilitate ergonomics stress on the body. The greater the exposure to these risk factors the greater probability of ergonomics injury and this is called work related musculoskeletal disorders (WRMD). Ergonomic risk factors do not affecting the individual immediately it affects the health gradually to the point where the worker cannot perform his daily task comfortably. Therefore, there is sufficient time to prevent occurring injury and cleaning the work environment from all risks by utilizing risk assessment process. Department of Employment and Industrial Relations (2007) mention the main five ergonomics risk factors as forceful exertion, repetition, awkward posture, vibration and duration. While according to MIOSHA (2013) the main ergonomic risk factors in construction industry are as follows: awkward posture, repetition, static posture, vibration, force, contact stress and extreme temperature.

Vedder and Carey (2003) conclude that accidents with construction tools; falling and tripping; manual handling, lifting, and carrying; noise; vibration; dust exposure; and poor

design of tool interfaces are the most important safety, health, and ergonomically related problems in construction. According to Ergonomic Process (n,d) other ergonomic risk factor includes repetition, poor body mechanics/poor posture, force carrying, vibration driving, impact hand tools, acceleration throwing objects, cold working outdoors, working in refrigerated areas and work-rest ratio overtime. Smallwood and Ajayi (2013) associated frequent bending; bending and twisting of the body; working above shoulder height; working below knee level; lifting; manual handling of heavy and irregular-sized loads, and adopting awkward work postures to high prevalence of work-related musculoskeletal disorders (WMSDs) and are a major ergonomic risk factor in construction. Ergonomic risk factors are discussed below.

RESEARCH METHODOLOGY

The Research adopted both the qualitative and quantitative research methods. Data was collected using a questionnaire and interview administered and conducted with Masons, Electricians, Carpenter, Tillers and Iron-fixers on construction sites in Abuja, Nigeria.

The number of craftsmen (Carpenters, Iron-Fixers, Tilers, Masons and Electricians) in the study area cannot be determined; therefore the research adopted an unknown population size. The sample size of 180 (Thirty Six (36) for each of the Five (5) construction craft) in total was determined using Chocrane formula for unknown sample size.

The interview was also used because of the educational background of the craftsmen which might not allow them fill a questionnaire appropriately. One hundred and eighty were interviewed. While One Hundred and Twenty Five responses were found worthy to be included in the study.

In the analysis of data obtained simple percentages method was used.

$$= \frac{Number\ of\ Respondents}{Total\ Number\ of\ Respondents}\ x\ 100 \text{ ---------- } \mathbf{1}$$

RESEARCH FINDINGS AND DISCUSSION

Craftsmen profile

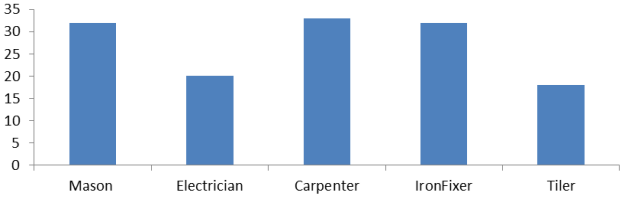

Figure 1; Craft of respondent

Figure 1 shows the distribution of craftsmen who responded to the survey. It can be seen that 25.6% were Masons, 16% were Electrician, 26% of the responded were Carpenter by trade. Other respondents were tilers and iron-fixers representing 16.4% and 17.6% respectively. The response rate were higher among masons, electricians and carpenters because most construction site visited were at the construction stage were these types of artisans are mostly found. Tillers and electricians are mostly found at the finishing stage.

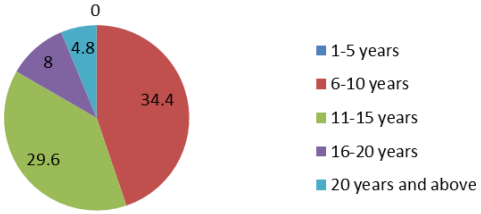

Figure 2 Working experiences of craftsmen

Figure 2 shows the working experience of respondents. It can be seen that 34.4% of respondent have working experience of 6-10 years, 29.6% have working experience of between 11-15 years and the least percentage 4.8% have working experience of 20 and above. Also 29% of the respondents have working experience of 1-5 years. 8% have working experience of between 16-20 years. It could be said that respondents have adequate knowledge and experience in their trades. It could also be seen that there is a blend of both new and experienced craftsmen.

Table 1 Type of Training

Type of response	Frequency	Percentage (%)
College based training	43	34.4
Non College based training	82	65.6
Total	125	100

Table 1 shows the type of training craftsmen went through to acquire their skill. While 65.6% passed through Non-college-based training: Apprenticeship, 34.4% of respondents have college-based training: Primary, Secondary, Technical College, Trade Schools, Polytechnics etc. It is imperative to note that most of the craftsmen in the building construction industry do not have formal education. Most of the craftsmen were trained informally.

After asking questions on the respondent's profile, the interview continued with questions on ergonomics awareness.

Ergonomics Awareness

Table 2: Awareness of ergonomics

Type of response	Frequency	Percentage (%)
Aware	24	80.8
Not Aware	101	19.2
Total	125	100

The study inquired on awareness of ergonomics. Craftsmen were asked whether they know ergonomics. Table 2 shows that 80% of respondents are not aware. Response from this questions included statement like '*I have never heard of it before*' and '*this is the first time am hearing the word*'. 20% of respondents said they are aware.

In ensuring that respondents who claimed to know ergonomics understand understands it. The researcher went further to ask what it means. Out of the twenty four only five gave answers related to ergonomics which included ergonomics as a study of people working, study of people at work, making the worker comfortable while working. Other response was related to economy, economics and studying air. This shows that shows that only 4% of the respondents really know what ergonomics is.

The awareness of ergonomics among craftsmen in the building construction industry is low. This might be due to the fact that most craftsmen were trained informally as shown in Table 1 and they may not been able to come across information on ergonomics. Due to the fact that most employers rarely train craftsmen most craftsmen might not have had the opportunity to come across information on ergonomics.

After the question on ergonomics the researcher chose to educate the workers on the definition of ergonomics and ergonomic interventions. This was done to help the respondents have a better understanding of the subject matter so they would be able to address other questions appropriately.

Factors Affecting Ergonomics Practice Adoption by Craftsmen

Factors affecting adoption of ergonomics practices by construction craftsmen in this study was classified into two, factors militating against adoption and drivers to enhance adoption.

Factors militating against ergonomic adoption among construction craftsmen

Table 3: Factors militating against ergonomic adoption among construction craftsmen

S/N	Factors militating against adoption	Frequency (Nr)	Percentage (%)
1	Lack of knowledge and understanding of ergonomics	99	79
2	Cost of procuring ergonomic equipment	86	69
3	Change can result in loss of jobs,	43	36
4	Employees reluctant to use safety tools and gadgets	75	60
5	Business and financial concerns	50	40
6	lack of legislation enforcing ergonomics practices	72	58
7	Temporary employment	63	50

The research probed into factors militating against adoption of ergonomics practices by craftsmen. Table 3 shows the perception of craftsmen. Lack of knowledge and understanding of ergonomics (79%), Cost of procuring ergonomic equipment (69%). Employees reluctant to use safety tools and gadgets (60%) lack of legislation enforcing ergonomics practices (58%) and Temporary employment (50%) were factors perceived to be militating against adoption of ergonomics.

From the interview it was observed that ergonomics awareness is very low among construction craftsmen. Many respondents haven't even heard of the word before. Many of the ergonomics interventions, working methods and equipments are not known to the craftsmen who are really affected by musculoskeletal injuries. Cost of procuring ergonomic equipments are high. Most craftsmen cannot afford to purchase these equipments. When an iron-bender was told it could take over a hundred thousand naira to purchase a Rebar tying tool. He was astonished. '*I can't afford it'* states an electrician. Carpenters are aware of how the nail gun can make their job easier but most of them complained on how expensive the nail gun is. A tilers also commented that they couldn't afford ergonomic personal protective equipment like the knee guard and kneeling creepers. It is the responsibility of the contractor os Subcontractor to purchase some of these equipments like the motorised screeding machine because of the high cost.

Some employees find it difficult to use the safety tools and equipments even when it is provided. From the interview some respondent an electrician complain of being uncomfortable wearing a helmet, knee guard and leg wedge together. The following statement of an electrician when asked why they don't like putting on safety equipments '*I don't feel comfortable using them, it affects me and I don't work well*'. Some craftsmen even stated that they work better when they are '*free'*. Respondent perceived that some of their colleagues choose not to use this equipment even though they are aware of the importance of using them.

There is absence of legislation enforcing ergonomics practices in the Nigerian construction industry. There is no provision for health and safety plan for construction projects and health and safety practices are not enforced. Currently in Nigeria ergonomics is not even part of the proposed health and safety plan in the National Building code. This notion was echoed during the interview when a mason said '*there is no law to enforce ergonomics'*, therefore implementation is by choice. If it was part of the law contractors and companies could be fined or sanctioned for refusing to implement ergonomic intervention.

Another important factor militating against adoption of ergonomics practices mentioned by respondents was the nature of their employment being temporary. Most craftsmen are employed on project basis and are being paid on either weekly or daily so the contractor and

employee do not provide any form of training. Most of the respondents believed they are employed through recommendation and it is believed that they can do a quality job so they are not given any form of training.

Factor to drive adoption of ergonomics among construction craftsmen

The interview also looked into ways to enhance the adoption of ergonomics by construction craftsmen. The response was grouped and shown in Table 4.

Table 4: Factors to enhance adoption of ergonomic among construction craftsmen

S/N	Factors to enhance adoption	Frequency (Nr)	Percentage (%)
1	Training and education	96	77
2	Funding and Government intervention	90	72
3	Pre-assembly and mechanization to reduce the effects of various ergonomic problems	54	43
4	Involvement off labour unions	88	70
5	Contractor support and commitment to ergonomics	74	60
6	Housekeeping	55	44
7	Changes in tools and equipment	63	50

The research also looked in to drivers to enhance adoption as shown in Table 4. Training and education is ranked highest with 77% of respondent agreed it will enhance adoption. Funding and government intervention (72%) was ranked second, closely followed by involvement off labour unions (70%). Contractor support and commitment to ergonomics (60%) and changes in tools and equipment (50%) was ranked fifth and six respectively.

Ergonomic training and education are very important in increasing awareness. Application of ergonomics is practical; it is achieved through better task design and work procedure and using ergonomic designed tools. Increasing awareness of the danger of Musculoskeletal injuries allows the construction craftsmen know the benefits of applying ergonomics. From the interview it was observed that most of the workers are not aware of the existence of some ergonomics equipment like knee pads, shock absorbing inserts in shoes and the adjustable saw horse. It is also important to note that after the interview and brief education on ergonomics some workers stated implementing some ergonomic practices like stretching before starting their day, during short breaks and after the working day. This shows the importance of training and education.

Respondents have earlier raised concern about the high cost to purchase ergonomic equipments. Most respondents believed if there is funding from organisation in the construction industry and government through grants and subsidies directed to subsidizing this equipment or into training education and research it would go a long way in enhancing adoption. That was why an iron bender speaking of a rebar tying tool said that '*if it was cheaper I will buy the equipment and use since it will make my work easier and faster*'.

It is usually believed that the roles of trade unions are usually to negotiate on wages increase for their members. It is important to note that the trade unions have important roles to play in ensuring the health and safety of their members. In the interview respondents felt trade union should be at the forefront of ensuring employers provide a safe working environment for them. They should also struggle to ensure that employers provide a safe working environment for their member that is free of accident and injury. Trade union roles could also include providing training to members on new working procedures and methods to improve health, safety and productivity.

According to the interviews craftsmen believe contractor and managers who are responsible for construction have an important role to play in enhancing adoption. This was echoed in most comment by respondents that site manager or supervisors consent is required to implement something new to your work process or methods. Without the manager's or

supervisor's consent it might be difficult. Two ways the management support can help in driving adoption. Firstly through education and training and secondly providing ergonomic equipment on site. When these equipments are provided they would use them. Even though they are not permanent staff after the work they would return them to the employer for future use.

Proposed frame work for ergonomics adoption by building construction craftsmen

The proposed frame work involves the following action plan. The framework includes role of professional bodies in the building construction industry, construction contractor and sub contractors, crafts union and the construction craftsmen.

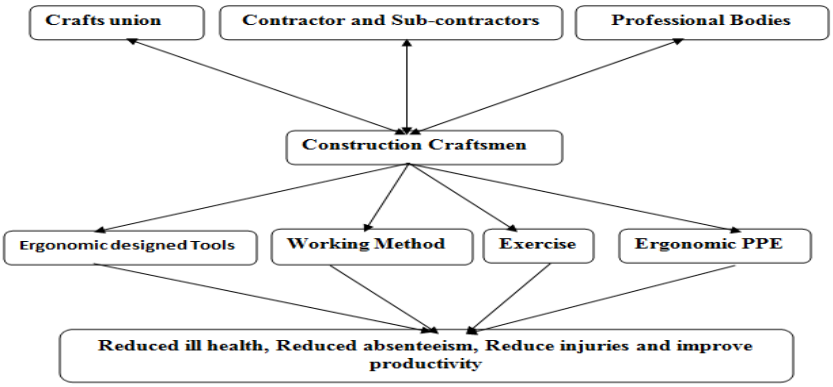

Figure 3: Framework for adoption of ergonomics among construction craftsmen

Professional bodies

The professional bodies in construction industry have many roles to play. They can train both the craftsmen and artisans. They can train both professionals and artisans through continuous professional development (CPD) and conferences and seminars. They can further train artisans during training and certification like the Nigerian Institute of Building artisans and craftsmen training programme.

Crafts union

Crafts union have a role in training their members on health and safety including ergonomics. They should also fight to ensure that employees provide a healthy working environment to their members.

Contractors

Contractors have very important role to play in adoption of ergonomics. One way they can do that is by providing ergonomic equipments for craftsmen like automated screeding machine, rebar tying tool and adjustable saw horse. They can also provide in addition to helmet, reflective jacket and safety boots ergonomic personal protective equipment like leg wedge, knee pads, shoulder pads, adjustable split level scaffold etc. They can also provide lifting equipment (carts and forklift) for lifting materials over the recommended manual lifting weight. Contractors and subcontractors can also take part in educating workers through on the job training of craftsmen this could be during short briefing or training before a project begins. Contractor can also enhance health and safety management through developing and implementing a health and safety plan for each project.

Craftsmen

Craftsmen have the most important role to play because they are the most affected. They have to adopt new working methods and they have to exercise. Craftsmen should use personal protective equipment. While purchasing personal working tools they should consider ergonomically designed tools.

It's important to note that the frame work is not designed from top to bottom but also flows from bottom to top. Craftsmen are also to provide feedback to their Trade unions, Employer (Contractor and Subcontractors) on musculoskeletal injuries and risk factors. Craftsmen should be involved in health and safety planning; they can contribute by making input during safety meetings. Craftsmen ideally should be affiliated to professional bodies like Nigerian Society of Engineers and Nigerian Institute of Building they should be able to share their problems and experience on the site.

CONCLUSION AND RECOMMENDATION

This study investigated factors affecting ergonomics practice among construction creaftsmen. The study concluded that. The awareness of ergonomics among construction craftsmen is very low as only 4% have of craftsmen have knowledge of ergonomics. Factors militating against ergonomics adoption are lack of knowledge and understanding of ergonomics, cost of procuring ergonomic equipment, employees reluctant to use safety tools and gadgets and lack of legislation enforcing ergonomics practices. Factor that could enhance adoption of ergonomics are training and education, funding and Government intervention, involvement off labour unions, Contractor Management support and commitment to ergonomics. The study also developed a frame work to enhance adoption of ergonomics among craftsmen.

ABSTRACT

The literature on User-Initiated Transformation (UIT) of housing suggests the actuality of the phenomenon as a trend in public housing estates in developing countries, despite the legal and planning implications, and the often negative official attitude towards it. Studies also highlight the significance of economic motivation in UIT. This paper therefore examines the resources for UIT in terms of the sources of finance, cost and duration as well as the process and challenges encountered. Systematic sampling method was employed to select 315 housing units from 8938 units in 3 purposively selected low-income estates for questionnaire administration. Findings revealed that the main sources of finance for UIT were individual savings (47.8%) and Cooperative societies' loans (35.8%); while 49.5% of respondents expended between N400, 000 and N600, 000 to transform their housing units. More than 64% of the transformations were completed within 1 year and 34% within the 2 years. Majority of the UIT (65.3%) was by direct labour while 32.3% was by the use contractors. Insufficient finances and unavailable materials were the key challenges encountered in the transformation process. The study concluded on the need to review the legal and planning policies for public housing, to encourage users' participation and incorporate design guidelines that are sensitive to residents' socio-economic realities and aspirations as reflected in UIT. The realistic approach would be to proactively envisage the possibility of UIT and make appropriate design provisions at the conception of public housing programmes.

Keywords: Challenges, Process, Public Housing, Resources, Transformation

INTRODUCTION

User-Initiated Transformation (UIT) has been observed world-wide in many housing settings and particularly in public housing, which represents a notable share of the housing stock in many developing countries (Sengupta and Tipple, 2007). Evidences in the literature show that public housing residents sometimes engage in alterations aimed at adapting their dwellings to better suit their needs or as a means of refurbishing housing that is considered to be inadequate, unsatisfactory or in poor condition (Tipple, Masters and Garrod, 2000; Kallus and Dychtwald, 2010). Tipple (1991:4) defines this tendency as "an alteration or extension involving construction activity and using materials and technology in use in the locality."

The literature on UIT suggests the actuality of the phenomenon as a visible trend in public housing estates in developing countries, despite the legal and planning implications, and the often negative official attitude towards it. It is common for owner-occupiers, through their own initiatives and efforts, to alter their houses in order to improve their housing conditions or meet the changing needs of their households (Salim, 1998). Housing transformation often involves modifications of the external and sometimes the internal parts of dwelling units. Much of the transformation is done either by the residents themselves or by small-scale hired contractors and artisans using locally available materials and labour (Tipple, 2000).

Ilesanmi, A. O. & Morakinyo, K. O. (2016). Resources, Process and Challenges of User-Initiated Transformation of Public Housing Units in Lagos, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. *Procs. of the Joint International Conference (JIC) on* 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 950-957

Studies highlight the significance of economic motivation in UIT. This views the requirement of additional space or conversion of existing spaces for income-generating activities and home-based enterprises (HBEs) as the main reasons for transformation. According to Kellet and Tipple (2000), a house is many things: a production place, market place, entertainment centre, financial institution and also a retreat place. Understanding the resources, dynamics and challenges of UIT from residents' perspectives is therefore essential to initiating policies, plans and programmes that could provide more satisfactory residential environments and improve living conditions. The aim of this paper is to examine the resources for UIT in terms of the sources of finance, cost, and duration; as well as the process and challenges encountered in selected public housing estates in Lagos, Nigeria. The paper proceeds in five sections, namely: the literature review on UIT and related issues; the research method; analysis, presentation and discussion of findings; recommendations; and concluding remarks. The study contributes to the literature on housing transformation and provides information that could inform public housing policy, design and management.

LITERATURE REVIEW

User-initiated transformation (UIT) describes any change to the original spatial configuration of a dwelling unit, by the occupants, in order to meet current needs and future expectations (Salama, 1999). Research in housing transformation is based on the theoretical assumption that people modify their living environments to achieve what they want. This implies that it is an intentional or purposive behaviour that occurs in the human-environment interaction. This conceptual conjecture also infers that UIT of public housing could be perceived as inevitably arising from the need to adjust personal environments rather than simply adapting to them.

Transformation of housing is a behavioural response not only to housing needs, but also to housing satisfaction and socio-economic factors. Through UIT, residents can increase the effective house size to gain more habitable or utility space, transform existing functions, or improve their living conditions (Kallus and Dychtwald, 2010). Manalang, Munemoto, Yoshida and Espina (2002) view UIT as self-built improvement, which depicts how users augmented for the deficiencies in their current residences. Tipple and Ameen (1999) argue for a change in the often negative official attitude to the UIT, while Tipple and Shahidul (1999) disavows the notion that these extensions or alterations helped to create slums.

The conceptual basis for UIT hinges on the principles of 'self-help' as captured in the ideas of: 'freedom to build', 'housing as a verb', 'housing as processes,' and 'housing by people' (Turner, 1976). Although many studies on UIT focus on the more visible phenomenon of 'outward extension,' Popkin, Rich, Hendey, Hayes, Parilla and Galster (2012) posit that it includes activities ranging from the rearrangement of internal furniture and painting a room, to structural amendments such as addition of rooms or demolition of parts of the housing unit.

Aina (2005) observes that transformation of housing was effected by housing speculators for economic reasons in particular. UIT is a major livelihood strategy amongst households in urban formal and informal settlements. Public housing households are motivated to transform their dwellings to provide for new activities, which in many cases were not part of the original concept. It is often carried out outside the established formal planning regulations.

Salama (1999) however observes that UIT by residents in public housing in Egypt not only increased the range of useful spaces within the dwelling units, but also created dynamic multi-functional estates that responded better to the changing needs of households. Tipple (2000) argues that UIT is common in public housing because potential residents are rarely involved in the planning and design of such housing: the houses are neither in tune with their socio-economic, cultural and religious characteristics, nor a reflection of their aspirations.

UIT is highly pronounced in public housing estates because negligible attention is usually given to users' preferences and lifestyles during the conception and design stages. It may thus be viewed as a manifestation of the lack of consultation with public housing occupants in the process of their housing delivery. Tamés (2004) also notes that UIT is pronounced in public housing due to its often uniform and monotonous nature and the limited opportunities for self-expression by the residents.

In addition, the economic motivation for UIT of housing has been variously affirmed. The dwelling is one of the few resources used for generating income. Tipple (1992) posits that, for many households, transformation has the economic potential to provide a better standard of accommodation for those in the low income group. This derives from rents accruable from room or shop tenants, and personal business outlets like shops and other services rendered from home. Spatial elements may be attached to or subdivided from existing structures, shops constructed on perimeter fences and used personally or rented out to others, and parts of the residence converted into office(s), schools, clinics, shops or other outfits. Such businesses which are carried out from places of residence are referred to as home-based enterprises (HBEs): that is, any form of money making venture carried out from the house.

Through UIT, the altered spaces are used for HBEs or let out for renting purposes. The range of HBEs found in housing estates include: tailoring, hair dressing, day-care centre, general trading, and even livestock keeping (Strassmann, 1986). The amount of money made often depends on the extent of transformation carried out. Mahmud (2003) observes the common practice among Asian women in Europe of converting rooms into corner shops for income generation. The Indian Sikh families in England are also known to modify garages into workshops for garments. Such changes are essentially economically motivated apart from the cultural and religious undertones. It is therefore important to better understand the nature of UIT of public housing in Lagos, in terms of the resources, process and challenges involved.

RESEARCH METHOD

This paper reports from a research that was conducted to analyze UIT of public housing in Lagos, Nigeria. The study adopted a survey research method and collected both primary and secondary data. Primary data were obtained through a survey conducted between September and November 2013. This involved the use of questionnaire, complemented by researcher observation and documentation. The majority of the public housing estates in Lagos State were provided by the Lagos State Development and Property Corporation (LSDPC), mainly during the mass housing era of the then welfare-oriented civilian administration (1979-1983). The three (3) largest of twenty (20) identified low-income public housing estates in Lagos were purposively selected, namely: Abesan, Isolo and Iponri housing estates. In addition, the choice of these three selected estates was based on the result of a preliminary survey which revealed that apart from providing housing for the low-income people, they shared similar physical characteristics and also had obvious manifestations of housing transformation. The sample frame from the 3 estates comprised of 1261 blocks of flats with 8938 housing units. Using systematic random sampling, one housing unit from every 4^{th} block was selected amounting to 156 housing units from Abesan, 128 units from Isolo and 31 units from Iponri housing estates giving a total sample size of 315 units as shown in Table 1.

Questionnaire were administered on the household heads to elicit information on their socio-economic and housing characteristics, patterns, process, reasons for and problems of housing transformation. The variables by which residents evaluated their housing transformation contexts consist of a checklist of parameters related to UIT as derived from the literature. These include information on sources of finance for UIT, amount expended to have the work

done to the desired level or taste, how the work was carried out, the duration and the problems or challenges encountered before and during the process of housing transformation.

Table 1: List of Selected Low-Income Public Housing Estates in Lagos

Selected Housing Estates	No. of Units	No. of blocks	One unit in every 4th block
Abesan	4272	624	156
Isolo	3664	512	128
Iponri	1002	125	31
Total	8938	1261	315

Source: Authors' Fieldwork (2013)

Two-hundred and ninety-five (295) questionnaires, representing 93.6% of the 315 units, were retrieved for analysis. The primary data were subjected to descriptive and inferential analysis. Secondary data in the form of drawings, maps and reports, were obtained from the LSDPC and analyzed qualitatively.

.

DATA ANALYSIS AND DISCUSSION OF FINDINGS

Sources of Finance for the Transformation Process

Table 2 summarizes the responses concerning the sources of finance for the transformation process. Sources and means of financing UIT are multifaceted as residents tend to mobilize all manner of efforts to accomplish their aims. The major source of finance revealed in this study is through residents' accrued personal savings. The majority of respondents (47.8%) sourced for funds through savings, while lending money from cooperative societies was the next considered option (36.2% of the respondents). The least proportion (15.9%) sourced their funds as loans from banks that were willing to assist the financially inadequacy.

Table 2: *Sources of Finance for Housing Transformation*

S/No.	What was the main source of finance for the alteration or extension of your housing unit?	Selected Housing Estates							
		Abesan		Iponri		Isolo		Total	
		Freq.	%	Freq.	%	Freq.	%	**Freq.**	**%**
1	Individual saving	53	36.8	10	33.3	81	63.8	144	47.8
2	Cooperative societies	51	35.4	15	50.0	43	33.9	109	36.2
3	Loan from bank(credit)	40	27.8	5	16.7	3	2.4	48	15.9
	Total	144	100.0	30	100.0	127	100.0	301	100.0

Source: Field Survey (2013)

The generally poor saving culture, officious procedures and stringent criteria for obtaining mortgage loans from banks, and inability of the housing finance institutions to keep up with the demand for loans may account for these findings. Mortgage financing institutions tend to remain patently conservative and inflexible when it comes to collateral requirements. Invariably, low-income households are usually disadvantaged in favour of middle and high-income groups. The 'legal status' of UIT relative to the planning rules and regulations for the housing estates may also be a deterrent from sourcing through formal sources like banks.

Costs of the Transformation Process

Table 3 presents results of the responses regarding the costs of the transformation process. The findings showed that the cost of transforming for each household in the surveyed housing estates differed according to the taste, type and the magnitude of transformation. Almost half of the sample of respondents in the selected housing estates (49.5%; 147 of 297) expended between N400,000 and N600,000 to transform their apartments. Those who spent less that N200,000 accounted for a lower percentage of 15.2% and almost equal proportion (15.5%)

spent between N200,000 and N400,000 as transformation expenses. A considerably smaller percentage of respondents spent above N 800,000 to transform their houses.

Table 3: *Cost of Housing Transformation*

S/No	How much did you spend to get this apartment/house transformed to your desired taste?	Selected Housing Estates							
		Abesan		Iponri		Isolo		Total	
		Freq	%	Freq	%	Freq	%	Freq	%
1	Less than ₦200,000	20	13.8	11	37.9	14	11.4	45	15.2
2	₦ 200,000 - ₦ 400,000	35	24.1	9	31.0	2	1.6	46	15.5
3	₦ 400,000 - ₦600,000	54	37.2	6	20.7	87	70.7	147	49.5
4	₦ 600,000 -₦ 800,000	20	13.8	1	3.4	13	10.6	34	11.4
5	₦ 800,000 and above	16	11.0	2	6.9	7	5.7	25	8.4
	Total	145	100.0	29	100.0	123	100.0	297	100.0

Source: Field Survey (2013)

Given that UIT is usually economically motivated, and the low-income economic status of the majority of respondents, it is expected that they would be rational and prudent in their expenses for housing transformation. The minority proportion of respondents who spent the highest (N 800,000 and above), may likely represent the higher status residents of the estates or those who were engaged in housing transformation for purely speculative purposes, and would therefore assume an investment perspective to the whole idea of transformation.

Method of Execution of Transformation Process

Table 4 summarizes the results of responses regarding the predominant method of executing the housing transformation in the selected housing estates.

Table 4: *Method of Implementing Housing Transformation*

S/No.	How did you carry out this alteration most of the time?	Residential Zone							
		Abesan		Iponri		Isolo		Total	
		Freq.	%	Freq.	%	Freq.	%	Freq.	%
1	Self-help (Directly by yourself)	5	3.5	1	3.3	0	0.0	6	2.0
2	Contractor	60	41.7	9	30.0	28	22.2	97	32.3
3	Direct labour (separate tradesman)	78	54.2	20	66.7	98	77.8	196	65.3
	Total	144	100.0	30	100.0	126	100.0	300	100.0

Source: Field Survey (2013)

The direct labour system of execution had the highest patronage of 65.3% as the predominant method. This practice involved the engagement of different artisans and workmen separately under distinct, often informal, agreements. This was followed by those who implemented the transformation by engaging the services of contractors (32.3%). This arrangement removes virtually all burdens from the house owner and ensures a smooth and tidy execution of the project, but requires a steady flow of funds. While most of the 'transformers' engaged others in the transformation process, a small proportion (6.0%) utilised the "do it yourself method." In such cases, personal effort was directly expended without recourse to contractors or separate tradesmen-labourers (Tipple, 1991). Socio-economic and household characteristics as well as knowledge and skills in building construction may be important determinants of the choice of implementers of the extension process. The self-help approach is more common in the informal sector economies; while formal settings such as public housing are more amenable to the direct labour system of hiring separate tradesmen as confirmed in this study. This ensures more flexibility in terms of financial and time resources, which the contract approach may not permit. Public housing residents, especially the low-income, may be limited to methods which they can conveniently afford in terms of finance. Sometimes, time is not a yardstick as they tend to carryout transformation at their own pace – in phases – and as dictated by the inflow of required cash and material resources. The relatively low proportion for self-help transformation in this study may be due to the limited knowledge and skills of building construction possessed by most respondents.

Duration of Transformation Process

Table 5 presents the results relating to the duration of the transformation of housing units in the surveyed housing estates. The results reveal that 64.7% of the respondents spent less than 1 year to get their houses transformed; 33.3 % spent between 1 and 2 years, while lower percentages (1.0%, 0.3% and 0.6%) spent longer durations (2 years and above).

Table 5: *Duration of Housing Transformation*

S/No.	Duration	Selected Housing Estates							
		Abesan		Iponri		Isolo		Total	
		Freq.	%	Freq.	%	Freq.	%	**Freq.**	**%**
1	Less than 1 year	90	61.6	23	76.7	83	65.4	196	64.7
2	1-2yrs	51	34.9	7	23.3	43	33.9	101	33.3
3	2 -3yrs	3	2.1	0	0.0	0	0.0	3	1.0
4	4 - 5yrs	0	0.0	0	0.0	1	0.8	1	0.3
5	Ongoing	2	1.4	0	0.0	0	0.0	1	0.6
	Total	146	100.0	30	100.0	127	100.0	303	100.0

Source: Field Survey, 2013

The duration obviously varied from one household to another relative to issues of funding, extent, type of transformation, method used and quality expected. The majority in the 1-year bracket obscures possible variations in time for saving and planning for the actual work. The lack of a constant cash flow could account for cases that tend to drag over extensive periods.

Problems Encountered in the Transformation Process

Table 6: *Challenges of Housing Transformation*

S/N	Challenges encountered before and during the process of transforming your house.		Selected Housing Estates			Total

Note: Multiple responses were allowed for this research item. Percentages and totals are based on responses

Although housing transformation seeks to obtain a more satisfactory residential environment, it is not without its challenges, which may indicate to what extent the process is worthwhile.

Table 6 summarizes the findings relating to the problems or challenges encountered before and during the process of housing transformation in the selected housing estates. Appreciable proportions of the 'transformers' indicated that lack of sufficient fund/finance (38.3%) and unavailability of materials (29.7%) were the key challenges encountered in the transformation process. Interestingly, 17.4% of the residents indicated the challenge of 'no action' a seemingly "double-edged" problem, as such seasons of inaction may make the project prone to other problems such as the harassments received from 'area boys.' Being forced to make changes in what was built accounted for 13.1%. Even though challenges such as harassment from area boys and government officials, and penalty demand in monetary terms, each accounted for less than 1% of the sample, information derived from interviews revealed instances among the few cases when the problems led to complete stoppage of work or slowed down the pace of work during the transformation process.

RECOMMENDATIONS

Although the phenomenon of UIT has legal, planning and property management implications, which explain the often negative official attitude towards it, this study further confirms its reality and seeming inevitability as a trend in public housing estates. The implications relate to the need to obtain planning approvals for any alterations to the original uses of housing. However, the pragmatic response of many public housing residents (especially the low-income) is to address functional and economic-related needs, rather than the planning or legal considerations. This may be described as the ascendancy of inevitability above illegality.

Institutional and legal impediments to UIT may therefore need to be revisited. Legal and planning policies for public housing should encourage users' participation and incorporate design guidelines that are sensitive to residents' socio-economic realities and aspirations as reflected in the investment of resources of money and time in UIT. The realistic approach would be to take into cognizance the reality of UIT and make appropriate design provisions at the conception of public housing schemes. The concepts of adaptable or flexible design and user-involvement in the housing delivery system could be adopted. While fundamental changes to the form and structure of housing units should be discouraged, non-structural modifications (slight, surface and service) should be envisaged and proactively incorporated from the design stage. This could enhance the character and quality of transformations that residents carry out, which does not preclude their need to obtain official approval.

CONCLUSION

This study evaluated the resources, process and challenges of UIT in selected public housing estates in Lagos, Nigeria, as representative of the context of developing countries. It reported findings from respondents' assessment of the sources of finance, cost, methods, duration and challenges encountered. The extensive investment of finance, time and skilled labour into the transformation process indicates the existence of an informal pool of social capital that may be better channelled into the housing delivery system than is presently recognised by planning and property management. This also points to the actuality and seeming inevitability of the phenomenon of UIT of housing. Transformation shows that people will endeavour to expend resources and make rational changes to enhance the efficiency, functionality, utility or income-generating value of their housing, notwithstanding legal or planning restrictions. It is therefore necessary to review policies related to public housing with a view to encouraging users' participation and incorporating design guidelines that are sensitive to residents' socio-economic realities, needs and aspirations. The realistic approach would be to proactively envisage the possibility of UIT and make appropriate design provisions at the conception of public housing programmes.

ABSTRACT

With the current global challenge of climate change, there is need for professionals in the building industry to attach greater importance to sustainable buildings that are energy efficient, with indoor comfort and in agreement with sustainable home codes. One way to advance the green agenda is through incorporating landscaping into buildings. Apart from having the effect of maintaining the balance of oxygen in the ecosystem, vegetative landscaping materials also act as a source of natural ventilation. However, not many home-owners are aware of this benefit. This paper therefore examines the views of home-owners in a selected residential estate to the benefits of landscaping. Case study was used and data collection was done using stratified random sampling technique to administer close-ended questionnaires to homeowners. Data were presented and analysed using descriptive statistics. Findings show that homeowners are concerned mainly with the aesthetic benefit of landscaping and quite unenlightened about other importance of landscaping to the sustainability of the housing development. The paper recommends the need to make landscaping a requirement for building approval by the planning authorities and enlightening homeowners on the benefits of landscaping. This paper therefore reveals how the sustainability of housing development can be enhanced through landscaping.

Keywords: energy conservation, landscaping, Nigeria, sustainable housing

INTRODUCTION

The need for landscaping in residential properties cannot be over-emphasized. With the globe getting warmer and in tropical countries especially, there is an urgent need to make use of natural means of ventilating homes without further energy consumption. For a housing development to be sustainable, it must be functional in all aspects and use energy minimally. Nyuk and Yu, 2009 has shown that about 25-80% savings on air conditioning can be achieved with proper landscaping. Large trees can provide shading for walls which can reduce outside wall temperatures and also provide shading for windows. This paper discusses the benefits of landscaping and how it can increase the sustainability of housing units especially through reduction in energy consumption on ventilation by adopting natural ventilation through vegetative landscaping. The cost of energy is quite high in most residential neighbourhoods all over the nation as households procure fuel to power generators due to incessant power supply by the Power Holding Company of Nigeria. The need for ventilation and reduced energy consumption cannot be over-emphasized. This paper wants to examine the level of awareness of homeowners to the benefits of landscaping in a residential estate in Akure.

REVIEW OF LITERATURE

Concept of Landscaping

Landscaping can be defined from different perspectives depending on the area of interest and background. Landscape is the art of designing, planning, management of the land, arrangement of natural and man-made elements there on, through application of cultural and

Ajayi, M.; Adegbie, M. & Omole, F. (2016). Landscaping and Sustainable Housing Development in Akure, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 958-964

scientific knowledge with concern for resources conservation so that the resultant environment serves a useful, healthy and enjoyable purpose (Fadamiro, 1998). Landscape deals with the beautification and management of the environment by the organization of space with proper cognizance of the basic principle of design. Landscaping reflects the interaction of the built environment and nature. It is the interaction between man as an individual or part of human society on one hand and nature on the other. It deals with the process of shaping, modifying and creating attractive outdoor scenes in order to effectively express the functional and supportive attributes of the environment of human habitation to enhance the dynamism in city development (Fadamiro, 2001). Landscaping is an expression of the lifestyle and value of the residents which reflects their personality and their attitudes towards the environment. The search for a qualitative, well landscaped environment, proper use of land and its resources are crucial issues for residential development. The environment which people live and how it is organized have profound consequences both for the society and individual. Therefore the need to give permanent solution to the perpetual devastating soil erosion, noise pollution and wind damage in the residential area is very necessary. Through landscaping, sustainable residential environment can be attained.

Landscaping is more than just an arrangement of plants, to be really functional, landscaping needs other items. There are two types of landscaping materials which includes hard landscape and soft landscape elements. Hard landscaping is a term used for the installation of hard or static features in the landscape. It also refers to the use of non-plant materials in the development of landscaping. Examples include walkways, driveways, patio, decks, walls, ponds, fences, steps, landscape lightings, fountain, furniture, containers for potted plants, swimming pool etc. Hard landscaping can be used to compliment the plants component to meet the need of homeowners. Soft landscaping or vegetative landscaping refers to the plant component of landscaping. It entails the use of plants of all categories that are natural in a landscaping. This includes palms, trees, shrubs, grasses, herbaceous plants, flowers etc. The plantings of especially indigenous plants species ensures integration of structure into the natural environment, thus appearing natural in nature. Both soft and hard components are employed to realize a beautiful and functional landscape.

Importance of Landscaping

The benefits derivable from landscaping are varied and accrue to the individual, the house and the environment at large. They include:

Aesthetic: The visual beauty of home and property can be enhanced through creative landscaping. Fadamiro, 2010 stated that constant improvement in the landscape quality of the outdoor environment in housing neighborhoods has direct improvement in resident's perceived quality of living. Moreover, Ayeni (2012) noted that landscaping offer amongst others, environmental aesthetics, seasonal colours and splendour, privacy, break in monotony of views, habitat for animals and security.

Health benefit: Tom (2009) reported that the U.S Department of Agriculture estimated trees in New York City to remove 2,000 metric tons of pollutants each year. It further reiterated that an environmentally- friendly yard, or ecological landscape, needs less chemical treatment and less water; applying fewer fertilizer and chemicals, is much safer for home owners as well as the eco system. The direct health benefits of a "green" landscape come from cleaner air provided by trees, shrubs and grass as they remove pollutants such as Nitrogen oxide, Sulfur dioxide, Carbon monoxide and dust, thus making the environment more conducive for human habitation. According to Massey (no date) one tree can reduce 26 pounds of CO_2 from the atmosphere each year.

Energy consideration: Carefully positioned trees can reduce household energy consumption for heating and cooling by up to 25%. Computer models from the U.S. Department of Energy estimate that three properly placed trees can save an average household between $100 and $250 in heating and cooling energy costs annually. In the same vein, Morakinyo, Balogun and Adegun (2013) investigated the effect of trees on building microclimate, the results shows that trees constitute an excellent passive cooling system for building and conserve energy.

A well designed landscaping reduces heating and cooling cost. It is a well-known fact that garden landscaping by professional can reduce utility bills and conserve the energy. This is because during the winter months, the garden's trees, hedges, grass and shrubs can protect the home from harsh winter winds while capturing the winter sun. On the other hand, in the summer the garden's tree and hedges can absorb heat from the sun to help keep the home cooler.

Enhancement of the neighborhood and increase in property values: According to Associated Landscape Contractors of America reported by Marc (2003) landscaping can add as much as 14% to the resale value of a building and speed its sale by as much as 6 weeks. Landscaping can transform a simple structure into an attractive one. Estate agents and property experts are quick to point that a well-landscaped garden can increase the value of a property dramatically. In some cases, trim and beautiful garden can increase the value of home more than a newly built and decorated lounge or kitchen. In the same vein, a study by Ajayi, Omole, Bako and Ogunleye (2013) revealed that landscaping has an incremental effect of 11% on values of properties in Ijapo Estate, Akure, Nigeria.

Natural Ventilation: Proper landscaping enhances natural ventilation by redirecting wind flow to enter the house, and it was noted by Walker (2010) that natural ventilation has been recognized as a means for sustaining the environment as it relies only on natural air movement and can save significant amount of fossil fuel based energy by reducing the need for mechanical cooling and air conditioning. Reducing electrical energy used for cooling contributes to the reduction of greenhouse gas emission. In favourable climates and buildings types, natural ventilation can be used as an alternative to air-conditioning plants, saving 10% ─ 30% of total energy consumption.

Wind break: Landscaping with coniferous evergreen trees and masquerade trees can provide excellent wind protection to homes by reducing the speed of strong winds. They also reduce heating cost considerably as cool breeze reaches the house rather than a storm. The amount of wind reduction depends particularly on the height and shape of plants and the density and width of planting. A wind break will reduce wind speed for a distance of as much as thirty times the wind break's height. During the raining season, rains may come with strong and catastrophic wind that can blow up the roofs that lie along the direction of operation. Planting trees on its course can deflect such wind while life and property are secured from destruction.

Control of erosion: Planting of grass cover will reduce the rate of erosion. In residential environment water that fall from the roof of individual houses may combine with those that fall directly on the ground to create erosion. Such water is necessary to be drained away from houses environment. Erosion may remove million of tons of soil surface after a considerable number of years.

Other reasons why landscaping is important to homes and environment as a whole include glare reduction, shading, recreational grounds, reduction in noise and environmental pollution, control of vehicular and pedestrian traffic (as flowers can be used to indicate walk areas), source of food and sense of achievement.

Sustainability in Housing Development

Sustainability is the ability of a society, ecosystem, or any such ongoing system to continue functioning into the indefinite future without being forced into decline through exhaustion or overloading of key resources on which the system depends (Gilman, 1992). There is need to consider the sustainability of housing development especially in developing countries such as Nigeria where infrastructures are not usually provided in the housing environment (Ajayi and Omole, 2012).

Using Gilman's definition, Foley, Daniell and Warner (2003) outline that for a system to be sustainable; all of the resources upon which the system relies must be managed appropriately, including natural, financial, social, and man-made (infrastructure) resources. Appropriate management requires knowledge relating to the system boundary, system resources, interactions between adjacent systems and allowable limits, or thresholds, for each resource. Considering a complex urban housing development system, the key resources, processes and interrelations of a housing development can be defined in terms of six interrelated models, namely water, carbon dioxide (CO_2), waste, ecosystem health, economic, and social.

i. the water model incorporates all the water related processes of the development, including rainfall runoff, infiltration, and potable and non-potable water use;
ii. the CO_2 model accounts for both embodied and operational energy use, calculated as an equivalent mass of CO_2, which incorporates the effects of building materials, infrastructure, electricity and gas use, and occupant transport use;
iii. the waste model accounts for all solid and liquid waste, both produced on site, and leaving the site, including sewage, compost, waste to be recycled, and waste sent to landfill;
iv. the ecosystem health model encompasses environmental aspects of the development such as biodiversity and land use changes, as well as air and water quality;
v. the economic model accounts for both the microeconomic processes of each household based on income, expenditure and corresponding levels of debt, as well as the macroeconomic processes which affect the housing development, such as inflation and interest rates; and
vi. the social model incorporates levels of occupant satisfaction relating to comfort, living conditions, access to services (transport, health, education, shopping), employment, as well as equity amongst occupants.

Out of these models of sustainability of the housing environment, the ecosystem health model which encompasses environmental aspects of the development is relevant in terms of air quality which can be enhanced through landscaping. Also, the CO_2 model is relevant as energy requirement to power fans and air conditioning units are reduced.

THE SETTING AND METHODOLOGY

Akure is a city in south western Nigeria and capital of Ondo state. It lies between latitude7^o 13' and 7^o 15' North of the Equator and longitude 5^o 10' and 5^o 12' East of the Greenwich Meridian at an altitude of 370m above sea level. The vegetation of Akure city is equatorial rain forest. Two seasons are experienced by the city - the wet or rainy season from April to October and the dry or harmattan season from November to March. Akure enjoys a moderate tropical climate with maximum temperatures rarely rising above 33°C and minimum temperatures rarely falling below 20°C. Relative humidity is also moderate with maximum relative humidity rarely rising above 86% and minimum relative humidity rarely falling below 40%. The approximate annual precipitation is 1410mm with double maxima occurring in June/July and September/October. There is usually more than six hours of sunshine, even during the rainy season (Ogunsote, Prucnal-Ogunsote and Adegbie, 2010). The population of

the city according to the 2006 Population Census is 353,211 (Federal Republic of Nigeria, 2007).

The case study for this paper is Ijapo Housing Estate located at the periphery of Akure. It was chosen because it is one of the oldest housing estates in Akure and has a lot of landscaped houses. 75% of the total land area is developed while 25% is for planting flowers and trees. Ijapo Estate as a residential area has complementary uses like educational, commercial, recreational and religions properties. The land and properties are sold at affordable prices. Access roads, electricity and other facilities are provided in the estate. It is occupied mainly by medium and high income class. The target population consists of occupiers of landscaped housing units in Ijapo Estate. There are 187 housing units in the estate according to records of the Ondo State Property Development Corporation. Research instrument was a set of close-ended questionnaire administered using stratified random sampling technique. Landscaped houses in the various streets were sampled using one occupant per house. A total of 140 housing units, representing approximately 75% as sample size were sampled. Descriptive method of analysis was used giving rise to the report below.

DISCUSSION OF RESULTS

Data were gathered on the type of landscaping materials, cost of landscaping and the reasons or benefits derived from landscaping. The results are presented in Tables 1, 2 and 3 respectively.

Table 1: Type of materials used for landscaping

Responses	Frequency	Percentage
Flowers	26	18.6
Flowering plants & Trees	32	22.8
Flowers, Shrubs & Trees	42	30.0
Others	40	28.6
Total	140	100.0

Table 1 shows that out of the 140 housing units sampled, 100 houses units were landscaped using vegetative landscaping materials, that is soft landscaping such as flowers, shrubs and trees. This means that a large number of the occupants of landscaped properties in the estate prefer the use of vegetative landscaping to hard landscaping. The study area being in the rainforest belt of Nigeria, tree planting is not difficult to achieve.

Table 2: Cost of Landscaping

Amount ($)	Frequency	Percentage
$300 and below	25	25
$301 - 650	32	32
$651 - 950	28	28
$951 -1250	15	15
Total	100	100

Table 2 shows that the cost of vegetative landscaping ranges from $300 to $1250. Cost of landscaping between $951- $1250 had the least percentage, 15%. ($1= ₦160 as at August 2013). The table shows that the cost of landscaping is not too exorbitant especially when compared to the benefits derivable which is shown in the next table.

Respondents who used soft landscaping were asked to rank the benefits derivable from landscaping and their reasons for landscaping their properties on a 4 point Likert scale of very high, high, low and very low.

Responses on the perceived benefits of landscaping from occupiers of houses who used vegetative landscaping materials were ranked. The most important reason for landscaping by respondents was beautification, followed by increase in property values and wind break. Lowering noise level was ranked least as the estate is a low density area where the noise level is minimal. The other benefits of landscaping such as erosion control, shading and health benefits were ranked low by homeowners. This shows that the level of enlightenment on the contribution of landscaping to sustainability of the housing development is quite low among homeowners in the study area.

Table 3: Reasons for landscaping

Reasons for landscaping	Very high (4)	High (3)	Low (2)	Very Low (1)	Total	Mean score	Rank
Beautification	60	20	14	6	100	3.34	1st
Increase in property values	50	24	14	12	100	3.12	2nd
Wind break	44	26	20	10	100	3.04	3rd
Erosion control	40	30	20	10	100	3.00	4th
Shading	35	35	15	15	100	2.90	5th
Health benefits	40	20	20	20	100	2.80	6th
Lower noise levels	32	30	21	17	100	2.77	7th

Erosion through water run-off could be a menace in the rainforest belt of Nigeria especially in places where the soil structure is loose. Erosion may remove million of tons of soil surface after a considerable number of years. Planting of grass cover and trees will reduce the rate of erosion and prevent the exposure of the substructure of the house, which could have devastating effects. Plants provide shade for houses by absorbing heat from the sun to help keep the home cooler thus reducing the energy cost of air conditioning. In a country like Nigeria where there is erratic power supply, this will also reduce the cost of fueling power generators and consequently reduce the volume of carbon monoxide released into the atmosphere.

CONCLUSIONS

This paper has considered the importance of landscaping to the housing environment. One of the ways to ensure that housing development is sustainable is vegetative landscaping which has benefits of aesthetics, wind break, shading and erosion control among others. The study has revealed that most homeowners use vegetative landscaping in the study area and the cost of landscaping could be as low as $300 and not higher than $1250. Furthermore, the reason or benefit that homeowners consider as most important was aesthetics. Other benefits such as erosion control which protects the building itself and shading which reduces energy cost and pollution were ranked low. Professionals in the building industry need to enlighten clients on the importance of landscaping to the sustainability of the housing environment. This paper recommends the incorporation of landscaping into building design and as a requirement for building approval by the planning authorities.

ABSTRACT

Land use and land cover are some of the many interrelated aspect of a modern nation's activities where adequate information is necessary in order to make decisions. Land use/land cover data are needed in the analysis of environmental processes and problems that must be understood if living conditions and standards are to be improved or maintained. This study has to do with the determination and analysis of land use/land cover (LULC) dynamics within the period of 41 years. Three multidate datasets comprising Landsat satellite images of 1972 MSS as the base map, 1986 Landsat7 TM, 2002 Landsat7 ETM and 2013 Landsat7 ETM using the combined technologies of Remote Sensing (RS) and Geographic Information System (GIS) to determine the magnitude, rate and dynamics of change in land use within the study period. From the satellite images, submaps created were classified by the method of supervised classification based on the following classification schemes: Bare land/cultivated, built-up areas, dense vegetation, light vegetation, exposed soil, rock outcrop, water body. The maps and statistical data obtained were analyzed to infer changes that have taken place within the period of study. The result showed significant 2.5% - 4.3% rapid growth in urban areas annually. The annual rate of change in land use/land cover was determined and used as an index in predicting changes for the future. Adequate recommendations were made for the town planners, administrators and policy makers for land use/land cover development in Akure Township.

Keywords: Land Use, Land Cover, Remote Sensing, Geographical Information System, Environment

INTRODUCTION

A modern nation possesses many complex interrelated aspects. To make quality decisions, nations in these contemporary times must be equipped with adequate information on the activities of its complex interrelated aspects. One of such aspect is the land use and land cover. Knowledge about land use and land cover has become increasingly important to nations in proffering solutions` to various problems of haphazard and uncontrolled development, deteriorating environmental quality, loss of prime agricultural lands, destruction of important wetlands, and loss of fish and wildlife habitat to mention a few. Land use data are needed in the analysis of environmental processes and problems that must be understood if living conditions and standards are to be improved or maintained at current levels.

One of the prime requirements for adequate use of land is information on existing land use patterns and changes in land use over time. Knowledge of the present distribution and area of such agricultural, recreational, and urban lands, as well as information on their changing proportions, is needed by legislators, planners, state and local governmental officials to determine better land use policy, to project transportation and utility demand, to identify future development pressure points and areas, and to implement effective plans for regional development.

The variety of land use and land cover data needs is exceedingly broad. Current land use and land cover data are needed for equalization of tax assessments in many countries. Land use and land cover data also are needed by Federal, State, and Local agencies for water- resource

Ogunlade, S. & Enisan, G. (2016). Mapping and Analysis of Urban Land Use and Land Cover in Akure, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 965-971

inventory, flood control, water-supply planning, and waste-water treatment. Many Federal agencies need current comprehensive inventories of existing activities on public lands combined with the existing and changing uses of adjacent private lands to improve the management of public lands. Federal agencies also need land use data to assess the environmental impact resulting from the development of energy resources, to manage wildlife resources and minimize man-wildlife ecosystem conflicts, to make national summaries of land use patterns and changes for national policy formulation, and to prepare environmental impact statements and assess future impacts on environmental quality.

In change detection and assessment of urban land use and land cover, remote sensing is used to gather information at a distance by detecting and recording electromagnetic radiation from the target areas in the field of view of the sensor instrument. It depends on observed spectral differences in the energy reflected or emitted from features of interest. In an effort to derive information about these features and their distributions, multispectral remote sensing which is the science of observing spectral response of features at varied wavelengths (spectral signature) is used (Campbell and Wynne, 2011).

The aim of the paper is mapping and analysis of urban land use and land cover in an urban center in Nigeria, using Akure in Ondo State as a case study for the purposes of urban development and renewal. This was done by detecting the land use/land cover changes that occurred within the study period, identifying the dynamics of the land use/land cover changes, identifying, quantifying and classifying the nature, magnitude and direction of land use changes and the determination of annual rate of change for all land use classes within the period. Finally the study also assesses and displays the land use change pattern within the period of study.

THE STUDY AREA

The study area (Fig.1) is Akure and its environ which is a sub-mapped portion of Landsat imageries of 1972, 1986, 2002 and 2013 (path 191 row 55) covering Osun, Ekiti and Ondo states of Nigeria. It is covers an area of 917590.68 hectares bounded by top Min X, Y (674894.25, 785987.25) and Max X, Y (803172.75, 857978.25) coordinates.

THEORETICAL APPROACH

Land Use

Land use involves the management and modification of natural environment or wilderness into built environment such as settlements and semi-natural habitats such as arable fields, managed woods. It also has been defined as " the arrangements, activities and inputs people undertake in a certain land cover type to produce, change or maintain it" (FAO, 1997a; FAO/UNEP, 1999 cited in Wikipedia 2015).

Land Cover

Land cover is defined as the physical material surface of the earth. It include grass, asphalt, trees, bare ground, water etc. Earth cover is the expression used by ecologist Fredrick Edward Clements that has its closest modern equivalent being vegetation (Wikipedia, 2015).

Land Use and Land Cover

Concepts concerning land cover and land use activity are closely related and in many cases have been used interchangeably. Land cover is distinct from land use despite the two terms often being used interchangeably (Wikipedia, 2015). Land use is a description of how people utilize the land and of socio-economic activity. The purposes for which lands are being used commonly have associated types of cover, whether they are forest, agricultural, residential, or industrial. Urban and agricultural land uses are two of the most commonly known land use classes (Anderson et, al. 1976).

Remote Sensing and Land Use Land Cover

Remote sensing is used in change detection and assessment of urban land use and land cover, to gather information about features and their distributions, by observing their spectral responses at varied wavelengths (spectral signature) (Campbell and Wynne, 2011). Remote sensing image-forming devices do not record activities directly. The remote sensor acquires a response which is based on many characteristics of the land surface, including natural or artificial cover. The interpreter then uses patterns, tones, textures, shapes, and site associations to derive information about land use activities from what is basically information about land cover (Randall, 2012). Zubair (2006) has observed that a major step forward in the application of Remote Sensing Technologies for environmental monitoring and future change detection studies has been the initiation of consistent land cover / land use (LCLU) mapping and database development efforts at the global, continental and national scales. Orisakwe (2008) observed that land cover and land use patterns are basic data used for physical planning and environmental evaluation. Therefore periodic land use change patterns are needed for many applications including map revision and updating, natural resources inventory and management, urban planning, agricultural land development, forestry and wide life management and demographic studies. Orisakwe (2008) further said that the basic principle in digital evaluation of LCLU changes lies in the fact that there are differences in the spectral reaction of image elements from two or more different periods, if the LCLU have changed within the interval of two or more periods respectively.

Classification

Classification is the process of developing interpreted maps from remotely sensed images.

In LULC classification Supervised and Unsupervised classification are two common methods of classification generally adopted. Supervised classification involves the extraction of the spectral features of some "training areas" of known land cover types from the image. Every pixel in the whole image is then classified as belonging to one of the classes depending on how close its spectral features are to the spectral features of the training areas. Supervised classification procedures require considerable interaction with the analyst, who must guide the classification by identifying areas on the image that are known to belong to each category

(Karen and Zsolt, 1994; Eastman 2012). Unsupervised classification involves grouping the pixels in the image into separate clusters, automatically by the computer program depending on their spectral features. Each cluster will then be assigned a land cover type by the analyst. (Goodchild and Gopal, 1999; Eastman, 2012).

Change Detection

This has to do with the determination and analysis of Land Use/Land Cover (LULC) dynamics within a period. A multi-date datasets comprising a basemap and satellite images of some epochs together with the combined technologies of Remote Sensing (RS) and Geographic Information System (GIS) are used to determine the magnitude, rate and dynamics of change in land use within the study period of an area.

MATERIAL AND METHODS

Three multi-date datasets comprising Landsat satellite images of 1972 MSS as the base map, Landsat 7 Thematic Mapper of 1986, Landsat 7 Enhanced Thematic Mapper of 2002 and Landsat 7 Enhanced Thematic Mapper of 2013 were obtained for the research.

Before information was extracted from the imageries they were first processed and analysed using ILWIS 3.2 Academic and ArcGIS 10.1 software: The images was loaded into the software, the bands one after another, via gateway and in the .tif format. The colour composite was performed in the image processing menu. The area of interest (AOI) was identified. A sub-map of the AOI was created. Coordinate system was created so as to input the Projection, Ellipsoid and Datum parameters (UTM, WGS 1984, Minna Zone 31N). Colour separation was then performed to put the image into its different band of blue, green, red and infra-red. Each of the band/colour was filtered to remove noise or perturbation on the image after which the land use land cover mapping was performed usng the supervised classification scheme.

FINDINGS

From the maps and the statistics obtained, the 1972 map was used as the reference and Akure (red) was the urban focus, the following were adduced:

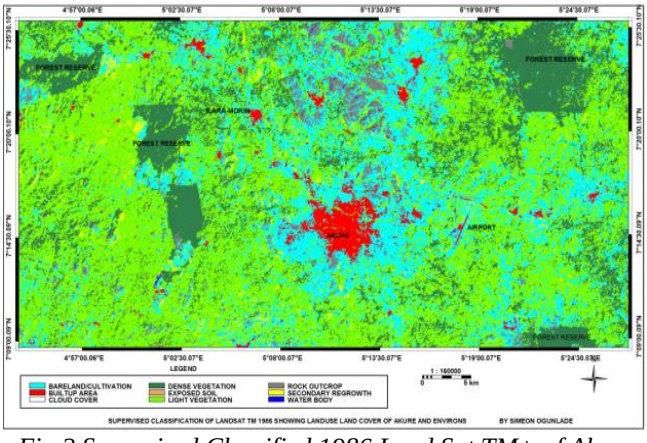

Fig.2 Supervised Classified 1986 Land Sat TM+ of Akure

Fig.2 (1972-1986): Starting from a 328 hectares of land in 1972 there was a sharp increase urban (Akure) growth of 4226 hectares and 1288%. This is expected, because of the change in governments from military to 1st and 2nd republics, creation of Ondo State and making Akure the state capital in 1976 and emergence of various establishments. For instance Federal University of Technology Akure (FUTA) was established in 1981. The Airport by the right

came in. This might have led to a decrease in (37% Dense and 25% Light) vegetated areas and the secondary regrowth (yellow) 11%. Development might have led to a push of the waters hence an increase in the water body (blue) 86 Hectares. The non-existent exposed soil in 1972 has gained about 80ha of land, and the rock outcrop received an exposure of 10144ha. This might be due to exposure coming through turning the forests into farmlands as a result of servicing the developing urban area.

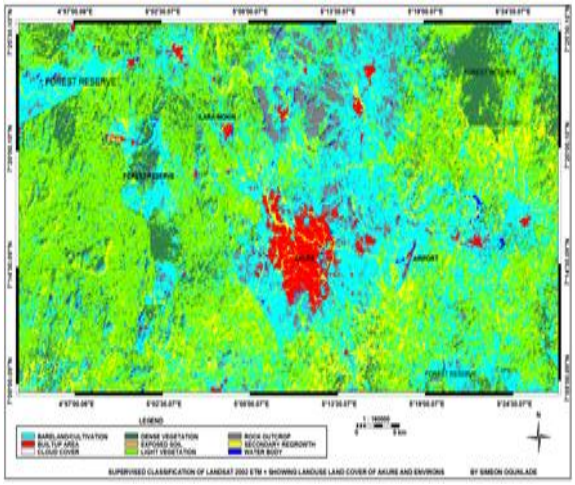

Fig.3 Supervised Classified 2002 Land Sat TM+ of Akure

Fig.3 (1986-2002): There was a 36% increase (1642 hectares, 2.25% per year) in urban growth, lower than 1972-2002. This can be adduced to Ekiti state created out of Ondo State in 1989 but with that, the state capital kept growing. More infrastructures from FUTA, the state government etc. kept rolling in. The effect is seen on the decrease in the vegetation. There is an increase in the secondary regrowth (yellow) which may be as a result of the tree planting campaigns by the government and various horticultural activities within the state. The water body increased from 86 to 905 Hectares. The bare land also increased by 33.3%. The decrease observed in the exposed soil and the rock outcrop might be connected to cleared sites turning to structures and rocks been broken for building and other purposes, a venture still observed till date.

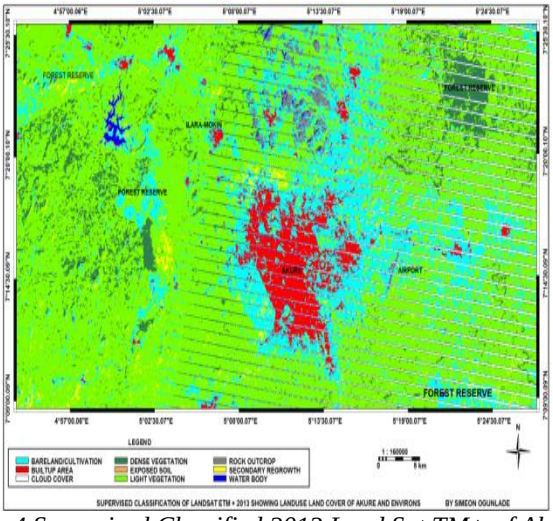

Fig.4 Supervised Classified 2013 Land Sat TM+ of Akure

Fig.4 (2002-2013): A 47.5% increase in the growth of Akure during this period, an 11.5% difference from that of 1986-2002. This is evidenced by lots of estates, nearby villages

merging with Akure as people build their own houses. The influence of FUTA and its staffs toward Eastward (Ilara Mokin) is clearly noticeable. The Dense vegetation kept decreasing due to many farmlands that are undergoing serious conversion to building sites, while an increase in the Water body and Light
Vegetation is noticed. This may be because of the presence of the Owena Dam constructed and various fish farming that suddenly sprung up at this period, which might have caused vegetation growth around the dam and along it channels. Secondary regrowth had a decrease so also is the bare land, which may not be unconnected with stability of the government's horticultural and re-afforestation activities and the fact that many people are leaving the villages for paid jobs. The rock outcrops decreased tremendously and the exposed soil is non-existent in 2013.

FUTURE TRENDS

With particular attention to 1986-2002 (16 years) and 2002-2013 (11years) it is observed that there is a yearly increase of 2.25% (102.64ha) and 4.3% (267.71 ha) respectively that amounts to 2.05% difference for two epochs. The growth is becoming faster as periods rolled by. If the trend in 2013 continues, it can be forecasted that by the year 2023 (10 years) the growth will have increased by an average of 2677.1 hectares per year with all things been equal. This will have an extensive influence on the land cover except if re-afforestation programs are intensified.

CONCLUSION AND RECOMMENDATION

The Land Use/ Land cover mapping and analysis for the purpose of urban development and renewal of Akure and environs has shown a gradual 2.25% and 4.3% yearly increase in urbanization of the study area from 1986-2002 and 2002-2013 respectively and a 2.05% difference between the periods. Akure that started with 328 hectares of land in 1972 has grown to 9141 hectares in 2013, a difference of 8813 hectares in 41 years, at an average of 215 hectares per year. This is about 70% increase per year had all other factors has been kept constant. But an average of 4.3% yearly increase between 2002 and 2013 (11 years) has also been identified. This will be an asset for the town planners, administrators and policy makers for landuse development in Akure Township.

An insight into development in Landuse/Landcover behavior would only be brought into limelight through change detection studies. This fact could be seen in the periodic changes in areal extent of the designated Landuses. This finding however, tells the urban growth in Akure and it's environ. With the outcome of the Landuse/Landcover changes presented according to range and annual changes, it is observed that there is a steady Landuse/Landcover development in the study area apparent in the range period 1986-2002 and 2002-2013. This scenario should be given positive intervention from the concerned authorities such as the Urban Development Board of Ondo State, Ministry of Environment, Ministry of Health and more importantly Ministry of Lands and Housing in synergic collaboration with the Local Government Council so that it will not eventually lead to chaotic situation and a slum development resulting to poor sanitation, absence of land for government projects in the right locations and inevitably persistent socio-economic problems. Therefore, government intervention is hereby necessary and inevitable for sustainable development in Akure Township.

The forecast can be made more accurate if the imageries used are on a yearly basis for the period of 41 years considered. LULC studies using higher resolution imageries will give better assessment and detection of changes not only in Akure Township but in other

neighbouring towns. University-State Government relationship should be strengthened so that researches form the universities can get to the awareness and usage of policy makers.

ABSTRACT

Nature-based tourism is a vital part of the global tourism industry, and its components and features vary considerably from one destination to another. This paper reviews the strength and attractions of tourism potentials in eighteen nature-based sites that spread across the three senatorial districts of Ekiti State, as a framework for sustainability and diversification of her economy from relying on dwindling federal allocation. To determine the viability of these tourism centers, simple random sampling technique was used to select twenty respondents from each of the tourist centres. In all, a total of three hundred and sixty designed questionnaires using larker scale of measurement and analysis were filled by the interviewees who constitute the population. The research revealed that, Ikogosi warm spring, Arinta water fall and Ero river/dam were the three strongest and attractive sites, while Opa Aje was the least attracting site in the state. Bad roads, insecurity, poor publicity as well as shortage of public utilities were major constrains against the expected development of tourism in the state. The study concludes that tourism is an agent of social-economic development only when the huge potential is explored. It further suggests that tourism sector should be strengthened through public- private partnership (PPP) in order to alleviate poverty and attract visitors to the state.

Keywords: Attraction, Ekiti-State, Nature Tourism, Publicity, Sustainability

INTRODUCTION

Nature-based tourism is a rapidly growing phenomenon and has become the largest in tourism industry in the world (Memetoglu, 2006). The impact of nature-based tourism varies extremely. On one hand, it plays an important and certainly positive role in the socio-economic and political development in destination countries by, for instance, offering new employment opportunities. In other to match consumer demand, there must be an increasing need to provide more natured- based tourism attractions to visitors. The term nature–based tourism is generally applied to tourism activities depending on the use natural resources which remain in a relatively undeveloped state, including scenery, topography, waterways, vegetation, wildlife and cultural heritage (Ceballos-Lascurain, 1996). People in millions travel each year to see and experience natural environment, and the scale of such movements leads inevitably, to some disturbance or damage to visited sites. While such damage is attributed directly or indirectly to tourists and their activities, it is often unclear whether their actual behavior is responsible for the major negative impacts on nature and related activities such as the construction and development of infrastructures and facilities. Generallytourism has grown rapidly to become one of the World's foremost economic phenomena. The World Tourism Organization (WTO) estimates that international tourist arrivals in (2020) will reach 1.6 billion worldwide and tourism receipts will exceed 2 trillion US dollar (WTO, 2000). According to the International Ecotourism Society (2000), about 60% of the international tourists can be considered as nature-based tourists. A study done by the World Resources Institute also claimed that this type of tourism is increasing at an annual rate of 10% to 30% and will continue to play an important role in international tourism (Reingold, 1993).

Adeyemo, A. & Bada, A. O. (2016). Assessing Nature-Based Tourism Potentials for Socio-Economic Development in Ekiti State, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 972-979

There are many western nations such as U.S.A, United Kingdom, and Canada that have utilized the benefit of tourism to sustain their economy. However, over the years, tourism sector has been experiencing disdain in Nigeria. The Nigeria economy solely relies on crude oil with total neglect of other sectors such as tourism and agriculture which are the mainstay of a good economy (Ojo 2014). Over– concentration on oil sector has a great implication for the survival of Nigerian economy. The nonchalant attitude of government towards the development of the tourism sector has been major challenge facing the sector in Nigeria. In other for Nigeria State to be a beneficiary in the tourism prospects come year 2020, a lot still need to be done. While Ekiti State is blessed with abundant tourism (Ecotourism) potentials such as waterfalls, spectacular rock formations, beaches, hydrological bodies, springs and games reserves, only Ikogosi warm spring has been converted into tourism resorts (Bankole, 2002). Others are left fallow without any conscious efforts either by the government or private organizations towards its development.

According to Munn (2003), in order to design aMaster plan for realistic tourism development, tourism potentials of town, villages and their environment need to be evaluated.The evaluated factors need to relate to natural conditions, existing facilities and tourism performance as well as to environmental factors. Based on the present states of the nature-based tourist centres in Ekiti State, the study will therefore assess their strength, attractions, accessibility and amenities to see how they can turn around the dwindling fortunes of the state in particular and Nigeria in general.

THEORITICAL FRAMEWORK

Tourism is of central importance to social, cultural and economic lives in the twenty-first century. Goeldner, Ritchie and Mclntosh (2000) identified three operating sectors within the tourism industry: (1) the transportation sector, (2) the accommodation sector and (3) the attraction sector. According to Gunn (1988) attractions are described as the “first power”, “Iodestones for pleasure” and the real energizer of tourism in a region. Pigram (1983) takes a more pragmatic approach by stating that without attractions, tourism would not exist. Attractions are a central component of the tourism industry and Gunn (1988:37) states that “without develop attraction, tourism as we know it could not exist; there would be little need for transportation, facilities services and information system”. Attractions are important to the tourism production system as they often as the reason to visit specific destinations or places. This emphasizes the importance of tourism attractions and highlights the need to understand the range and the type of attraction that exist. According to Swarbrook (2000), visitor attractions are the heart of the tourism industry; they are the motivators of that make people want to take a trip in the first place”. In opposition, Richards (2001) points out that it can be argued that attractions do not always literally attract visitors, however, they certainly do provide a focus for much tourist activity, and are essential weapon in the arsenal of tourist destinations engaged in a competitive struggle for tourist business.

There have been many attempts to explain the multitude forms in which visitor attractions exist (Holloway, 1995; Smith, 1998). Visitor attractions range from very small to enormous size, from free entrance to expensive fees, and include both natural and built features or a combination of these two (Prideaux,2002). Laarman and Durst (1987) define Natural Based Tourism Attraction (NBTA) as type of tourism activity that combines three specific elements, namely education, recreation and adventure. Valentine (1992) also incorporates the recreation element in his definition, and state that NBTA is primarily concerned with the direct enjoyment of some relative undisturbed phenomenon of nature. He suggested that there are three types of activities that come under his definition: experiences that are dependent on nature, experiences that are enhanced by nature and experienced for which a natural setting is

incidental. According to Jenkins and Pigram (2003), nature-based activities may be defined as all forms of leisure that rely on the natural environment and include many activities, ranging from sitting under a tree to hiking in the wilderness. Due to the diversity of activities and the variation in styles, there is a plethora of expressions for NBTA. According to Newsome, Moore and Dowling (2002) NBTA may be labeled as adventure, wildlife and ecotourism while Mckercher (1998) expands it further to alternative tourism, educational tourism, sustainable tourism, responsible tourism and other forms of outdoor-oriented non-mass tourism.

Furthermore, Manwa (2012) argued that for tourism to be sustainable the community has to benefit directly from it, this will enable them to protect and conserve the resources upon which it is based. This is further emphasized by Smith (2007) that apart from the type of tourism, the extent to which tourism confers economic benefits on any country also depends on the expectations of the tourists and the host country's ability to provide appropriate and adequate facilities. Unless economic policies to promote tourism remain a focus in developing countries, tourism will not be a potential source of socio-economic growth (Ekanayake and Long, 2012). This has been a problem for the developing countries like Nigeria with inadequate infrastructure generally and tourism supporting infrastructure in particular. There is nowhere the problem of inadequate infrastructure is most pronounced than in Nigeria where the dearth of infrastructures is compounded by the inability to maintain the few existing ones and replicate infrastructures to areas lacking in amenities usually outside of the capital and major cities. In Nigeria, poor state of infrastructures is most pronounced in the rural areas where incidentally most of the tourist sites are also located. Nevertheless, efforts at developing infrastructure to support tourism in Nigeria paltry as they may be happen only in the urban areas (Briedenhann and Wickens, 2004). This is where and how tourism is expected to have its most impact on socio-economic development given the infrastructure and income it can attract to rural Nigeria to spur socio-economic growth and development in rural areas and the regions (Yang, 2010). In this regard, tourism can facilitate the replication of infrastructure to the regions and the rural areas of Nigeria, which are usually the areas that lack amenities (Hawkins and Mann, 2007; Yang, 2010).

CASE STUDY AREA PROFILE

There are strong indications that Ekiti State which is located in the southwestern part of Nigeria derived its name principally from its hilly environment and as such the name when pronounced in its original form, it is *'OKITI'* meaning mountain area (Afolabi, 1992). The state is situated entirely within the tropics with diverse and variegated ecosystem of flora and fauna most of which remain uninterrupted. The state lies between longitude $4^{0}45^{'}$ and $8^{0}5^{'}$ north of equator and occupying an area of about 7000sq.km,The state is bounded in the north by Kwara and Kogi States, on the west by Osun State and on entire south and east by Ondo State. The state according to Afolabi (1992) is mainly an upland zone rising above 250 metres above the sea level. It lies within the area underlined by metamorphic rocks of the basement complex. Generally, the state has an undulating land surface with a characteristic landscape that consists of old plains broken by steep-sided outcrops dome rock that may occur singularly or in group of ridges.

Like some states in Nigeria, Ekiti State with sixteen local government areas parades some of the world's most exciting and fascinating tourist centres. With most of the physical areas in the state is still untouched, Ekiti State is famous for its natural environments and cultural heritage which when fully harnessed will influence the development of the tourism industry to generate local economy. Based on the potentials of the state to be developed as natural tourism destination, sixteen destinations (fig.2) were selected for natural assessment as

follow: *Ureje River/Dam, Ado- Ekiti, OkeAyoba Hill, Ado- Ekiti, Olota Hill, Ado-Ekiti, Ikogosi Warm Spring, Ikogosi-Ekiti,Arinta Waterfall, IpoleIloro-Ekiti, Kosegbe stone, IpoleIloro-Ekiti, Sacred fish River, Erinjiyan-Ekiti*0, *Orole Hill, Ikere-Ekiti,Olosunta Hill, Ikere-Ekiti,Forest/Game Reserve, Ikere-Ekiti, Efon- Alaaye Hill, Efon-AlaayeEkiti,Obalu Drinking Place, Efon-AlaayeEkiti, Elemi Lake, Igede-Ekiti, Esa Cave, Iyin-Ekiti, Ero River/Dam, Ikun-Ekiti, Egbe River/Dam, Egbe-Ekiti, Forest/Game Reserve Aromoko-Ekiti* and *OpaAje, Emure-Ekiti.*

RESEARCH METHODOLOGY

Eighteen natural tourist attraction sites which fall within nine local government areas but spread across the three senatorial districts of Ekiti-State were selected in carrying out this study. Data were collected through mixed method approach involving household self-designed questionnaire using larker scale of measurement and field observations. Questionnaire was used to collect raw data because it involves the collection of data in its natural state; since the phenomena cannot be directly observed and obtains the desired results therefore people's opinions are needed for the study.

Twenty (20) questionnaires per attraction centre were administered using simple random sampling technique representing a total of 360 respondents. Only those who were keen to complete the questionnaire were selected based on their perceived educational level. Furthermore, aside personal observation, data were also collected from various secondary sources, staff of the resource centres and community heads as means of exploring background information of the study area. Collated data were analyzed using simple statistical tools such as frequency and percentage. Each tourism attraction was weighted and calculated based on Sedai (2006) postulation by multiplying the total responses about a tourist attraction with each grade and summing them all up i.e. total respondents that choose very attractive x 4 (Its grade) + total respondents that choose attractive x 3 (Its grade) + total respondents that choose fair and finally + total respondents that choose low x 1 (Its grade).

RESULTS AND DISCUSSION

The findings of this study were explained based on four categories which are: Strength, Attraction, Accessibility and the public utilities of the tourist destinations .In table 1, the strength of the eighteen nature-based tourists attraction centres were determined through the responses of the 360 respondents interviewed. All the tourism attractions were strong enough to attract visitors from near and far as 265 respondents (73.6%) agreed that the sites are in good positions to attract tourists to them. Only 25 respondents (6.94%) viewed the sites as very poor to lure visitors to them. By implication, all the sites stand a good chance to grow and develop because Sedai, (2006), avers that a strong tourism attraction is a prerequisite for any destination to be considered by tourists.

The visited tourism attractions were ranked (Table 2) to actually know those that can attract more visitors based on the existing facilities, location and accessibility. Here, the result confirmed that Ikogosi Warm Spring was the most ranked among them all with 78 total weights. Arinta waterfall came second with 77 while Ero River/Dam was ranked third with 73 total weights. However, OpaAje was considered to be the least attractive with 47 total weights. The reason for the results obtained from this ranking could be as a result the present developments in these sites. While the first three most ranked could have been enjoying some positive touches from government at various levels, virtually nothing has been done to improve the least ranked sites.

According to Hawkins and Mann (2007), the tourist attraction sites that have strong attraction will continue to move tourists than those that are less attractive. It is therefore necessary to

develop both more attractive and less attractive sites together so that those that are more attractive can help pull tourists to those that are less attractive in the same area since visitors always love visiting as many sites as possible within the same location.

Table1: Strength of the tourist sites as perceived by respondents

Tourism attraction	Very strong	Strong	Weak	Poor
Ureje river/ Dam	04 (20)	07(35)	06(30)	03(15)
OkeAyoba Hill	10 (50)	06(30)	04(20)	00(00)
Olota Hill	04(20)	06(30)	07(35)	03(15)
Ikogosi warm spring	18(90)	02(10)	00(00)	00(00)
Arinta water fall	17(85)	03(15)	00(00)	00(00)
Sacred fish river	03(15)	15(75)	01(05)	01(05)
Orole hill	12(60)	06(30)	01(05)	01(05)
Olosunta hill	08(40)	08(40)	03(15)	01(05)
Forest/game reserve (Ikere)	03(15)	05(25)	10(50)	02(10)
EfonAlaaye hill	05(25)	07(35)	06(30)	02(10)
Obalu drinking place	02(10)	08(40)	07(35)	03(15)
Elemi lake	04(20)	14(70)	01(05)	01(05)
Esa cave	07(35)	08(40)	03(15)	02(10)
Ero river/dam	17(85)	03(15)	00(00)	00(00)
Forest/game reserve Aramoko	05(25)	06(30)	07(35)	02(10)
Egbe river/dam	14(70)	05(25)	01(05)	00(00)
Kosegbe stone	04(20)	12(60)	03(15)	01(05)
Opaaje	03(15)	04(20)	10(50)	03(15)

Notes: Figures in parentheses are percentages

Table 2: attraction of the tourist sites as perceived by the respondents

Tourist attraction	Very attractive (04)	Attractive (03)	Fair (02)	Low (01)	Total weight	Ranking position
Ureje river/Dam	04	07	06	03	52	14th
OkeAyoba hill	10	06	04	00	66	5th
Olota hill	04	06	07	03	51	15th
Ikogosi warm spring	18	02	00	00	78	1st
Arinta water fall	17	03	00	00	77	2nd
Sacred fish river	03	15	01	01	60	8th
Orole hill	12	06	01	01	69	4th
Olosunta hill	08	08	03	01	63	6th
Forest /game reserve (Ikere)	03	05	10	02	49	16th
EfonAlaaye hill	05	07	06	02	55	12th
Obalu drinking place	02	08	07	03	49	16th
Elemi lake	04	14	01	01	61	7th
Esa cave	07	05	03	02	60	8th
Ero river/dam	14	05	01	00	73	3rd
Forest/game reserve (Aramoko)	05	06	07	02	54	13th
Egbe river/dam	07	08	03	02	60	8th
Kosegbe stone	04	12	03	01	59	11TH

It was not a fair result on the path of accessibility (Table 3) as most of the sites had no good roads. Worst still, two of the tourist centres, Orole and Olosunta hills both in Ikere-Ekiti have no access and were both culturally shielded from tourists. Okoko (2001) opined that transportation is the live wire of any country's economy and if by chance the roads were in deplorable states, such country's economy will be millions of miles away from countries who parade excellent road networks. Many more tourists, according to the interviewees would have visited these sites repeatedly only if the roads leading to them were good and spiritual barriers placed on some were removed.

Table 3: Accessibilities of the tourist sites as perceived by the respondents

Tourism attraction	**Good Road**	**Fair Road**	**Poor Road**	**No access**
Ureje river/ Dam	04(20)	15(75)	0(05)	00(00)
OkeAyoba hill	16(80)	04(20)	00(00)	00(00)
Olata hill	08(40)	11(55)	01(05)	00(00)
Ikogosi warm spring	10(50)	08(40)	02(10)	00(00)
Arinta water fall	08(40)	10(50)	02(10)	00(00)
Sacred fish river	05(25)	08(40)	07(35)	00(00)
Orole hill	00(00)	00(00)	00(00)	20(100)
Olosunta hill	00(00)	00(00)	00(00)	20(100)
Forest/game reserve (Ikere)	01(05)	02(10)	17(85)	00(00)

Table 4 vividly showed that the entire state is ravaged by poor electricity. All but one tourist sites (Oke Ayoba Hill) had poor electricity rating and this singular factor has serious implication on tourism development in the state. Tourists' security is compromised in the dark and tourists especially the foreigners may refuse to visit these sites if their enquiries reveal that most sites lack electricity. On the state of accommodation in the selected sites, though, not too excellent, but tourists according to the interviewees are assured of average accommodation

These hotels and other rest houses should be improved upon to meet international standards. This will go a long way to persuade tourists to spend more days than they may have earlier bargainedfor. Table 4 also revealed that virtually all the sites and their environs were served with good or fair telecommunication network. This could be a plus for them as tourists can effectively communicate with families and friends any hour of the day. On the aspect of security, information from table 4 showed that only Oke Ayoba Hill and Ikogosi Warm Spring had good security. This is worrisome because when tourists visit and purchase artifacts and souvenirs, they need sufficient protection from robbers in order to prevent them from being attacked. In addition, the security of their hotels is important. Ikogosi Warm Spring enjoys fair patronage as a result of adequate security, while Oke Ayoba Hill benefited from the state security because the government house is situated on the peak of the hill.

CONCLUSION

Undoubtedly, Ekiti State remains a land of stupendous potentials and all the government need to do is to get its act together and lure private organizations to participate and partner the state government towards the development of these astonishing and fascinating sites in the state. According to Ojo, (1978), Aref et al.(2010) and Pongponratk, (2011) Tourists come from far and near sources to enjoy the areas of outstanding natural and artificial beauty, plants and wild animals as well as cultures and traditions. It is therefore quite expedient to the private sector in the management and reorganization of tourism and rural areas in the state.

This research confirmed that the state is adequately blessed with a large concentration of natural tourist attractions which are still at low level of development. Some of the identified odds against the expected development of tourism in the state are lack of publicity, insecurity, bad roads as well as shortage of or non-availability of public facilities. It is expected that findings from this work would enhance the interest of the government, private individuals and policy makers in the development of rural tourism potentials. Finally, based on the strength of the tourism potentials of the state to attract both local and foreign visitors, who says Ekiti State will not be economically and socially viable through tourism?

Geospatial Analysis of the Distribution of Health Facilities in Peri-urban area of Ifedore, Nigeria

Olusola Popoola[1]; Yusuph Adekoya[1] & Tayo Obasanmi[1]

[1] Department of Urban and Regional Planning, Federal University of Technology, Akure, Ondo State, Nigeria
[*]oopopoola@futa.edu.ng

ABSTRACT

Growth of peri-urban area is a consequence of high rent, need of individual dwellings and employment opportunities. Hence, many social services like housing, education, transportation, infrastructures, and healthcare are relatively inadequate owing to unplanned growth. The distribution of most public facilities in peri-urban area of developing countries is characterised by locational disparity. Often time, facilities are concentrated in one location than the other. This has given rise to geographic inequality. This study examined the level of accessibility of peri-urban population to health facilities in Ifedore Local government area of Ondo state while analysing the efficiency of location of the facilities and suggesting recommendations on how to increase the utility of inefficiently placed facilities. The study also assessed distribution pattern through spatial analysis operation using ArcGIS. Nearest neighbour technique was explored to determine current pattern of the distribution at Ifedore. The value of the spatial operation was 1.24 associated with z score of 2.3 and p-value of 0.02. This indicates that facilities were dispersed across the study area. Buffer analysis was carried out to enhance graphic comprehension of the shortfall in location of the facilities. Thus, it was established with the value that facilities are not evenly distributed in the peri-urban area. Results indicate that a facility is presumed serving 9,481 people as against 1:5,000 people recommended by World Health Organization. The study recommends mapping of health facilities and establishing GIS for all health facilities in the country as well as developing criteria for siting of new health facilities at all levels. In addition, the study recommends rehabilitation of some substandard facilities that are in deplorable state.

Keywords: Health facilities, spatial analysis, nearest neighbour analysis, peri-urban, distribution pattern

INTRODUCTION

Peri-urban areas are zones of transition from rural to urban land uses located between the outer limits of urban and regional centres and the rural environment. The boundaries of peri-urban areas are porous and transitory, as urban development extends into rural and industrial land.

Accessibility coverage measures how health-care facilities are physically accessible to the teaming population. Often time, facilities might be available but inconveniently located, therefore hindering physical access. Leapfrogging growth of physical development and disordered distribution of health facilities may have likely imposed an undesirable consequence on the access to qualitative health-care service and the environment at large. According to Haggertya *et. al.* (2014), the issue of equality of access to health care has become a research priority in many countries. As a broad principle, Aregbeyan (1992) reported that the greater the distance between two points, the lower the probability of these points being functionally related. He further expressed that most studies maintained that there is a regular decline in accessibility to health facilities with increasing distance on the trip to hospitals. The significance of using GIS in site selection and distribution of health care centres is to enhance decision-making. The use of GIS for measurement of physical distribution is well established and has been applied in many areas including retail site analysis, transport network planning and analysis, emergency services, and health care services (Wilkinson, 1998).

Popoola, O.; Adekoya, Y. & Obasanmi, T. (2016). Geospatial Analysis of the Distribution of Health Facilities in Peri-urban area of Ifedore, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 980-987

Every year, governments work with other Non-Governmental agencies by allocating substantial part of their annual budgets to improve health sector. Despite this financial commitment, many citizens are denied easy access to good health care services mainly, because of the inability of the government to respond quickly to increasing demands for health facilities to catch up with the rate of urbanization (Olawuni, 2007; Adetunji, 2010;). Adewara (2011) opined that distribution of primary healthcare services in Nigeria is characterized by substantial disparity. He added that such disparity is obvious in the ways some medical facilities are concentrated in one geo-political region at the expense of others. This often resulted in spatial inequality that typifies Nigeria's socio-political landscape. Though government has shown serious commitment towards addressing these inequalities, much is still expected in the areas of technical expertise. Many households in the urban area in developing cities do travel over long distances and spend significant proportion of their income in order to procure healthcare services elsewhere (Adetunji, 2010).

Spatial analyses of location and distribution of health care facilities are important as suburban expansion influences the way health care facilities are located and accessed. Spatial expansion of suburb area is partly influenced by population dynamics. Therefore, investigation of distribution of public health care facilities in relation to demographic characteristics forms an important scope of concern in research.

Several models have been developed for locating static and mobile facilities. They include health care delivery models and nearest neighbour analysis model. Three typical models are evident in health care delivery models. Firstly, politically driven healthcare delivery operates five levels of health care facilities, provided in a hierarchical order of dispensaries at village level; health centres at ward level; district hospitals at district level; regional hospital at regional level; and national hospital at national/zonal level (Msami, 2011). Its organisational structure forms a pyramidal like structure where dispensaries are at the bottom, health centres at the middle and hospitals at the apex. Secondly, the centralised model of healthcare operates on specified standards for locating and distributing community facilities such as health and education, which are provided in master plans on a threshold of population and planning units, on neighbourhood, community, district, and central business levels (Msami, 2011). Thirdly, the Public-Private Health Care Service Delivery Model driven by neo-liberalism theory and decentralization notion. It is an effort to bridge the gap of health care delivery left by the first two models (Msami, 2011).

Nearest neighbour analysis as reported by Taleb and Uddin (2012), is concerned mainly with the spatial pattern of various species of plants and trees on the earth. The analysis compares the existing distribution with the expected distribution that might occur under random conditions. The Average Nearest Neighbour tool measures the distance between each feature centroid and its nearest neighbour's centroid location. It then averages all these nearest neighbour distances. If the average distance is less than the average for a hypothetical random distribution, the distribution of the features being analysed is considered clustered. If the average distance is greater than a hypothetical random distribution, the features are considered dispersed. The average nearest neighbour ratio is calculated as the observed average distance divided by the expected average (Environmental Systems Research Institute-ESRI, 2012).

Average Nearest Neighbour (ANN) has five values: the observed mean distance, the expected mean distance, nearest neighbour index, z-score, and p-value. If the index (average nearest neighbour ratio) is less than 1, the pattern exhibits clustering. If the index is greater than 1, the trend is toward dispersion. The equations used to calculate the average nearest neighbour distance index and z-score are based on the assumption that the points being measured are

free to locate anywhere within the study area (for example, there are no barriers, and all cases or features are located independently of one another). The p-value is a numerical approximation of the area under the curve for a known distribution, limited by the test statistic (ESRI, 2012).

Health Care Institutions in Nigeria

The three healthcare structures in Nigeria include primary, secondary and tertiary health institutions. Primary Health Care (PHC) by policy arrangements is within the purview of the Local Government. They are known within the system by the context of a health centre, maternity home/clinic and dispensaries (Ademiluyi & Aluko-Arowolo, 2009). Secondary health centres include comprehensive health centres and general hospitals and are usually within the control of state governments (Ademiluyi & Aluko-Arowolo, 2009). Tertiary health institution, also called specialist/teaching hospitals, handles complex health problems/cases either as referrals from general hospitals or on direct admission to its own. The present lopsided distribution of health facilities between urban and rural areas in Nigeria is inherited from colonial era as the urban areas where the educated, the rich and the powerful live, received the lion share of infrastructure (Ademiluyi & Aluko-Arowolo, 2009).

This study examined the level of peri-urban household accessibility to health facilities in one of Nigeria's rapidly developing region in Ondo state. It explores spatial limitations of public health care service delivery, which enlightens areas for effective interventions by the government institutions. It also highlights on the policy issues that need urgent responses in the area of equity, access and hierarchy issues persistent in the location and distribution of health care facilities in the public health institution. The study tested a hypothesis, which explains the relation between the distribution pattern of healthcare facility and willingness of residents to patronise such healthcare facilities.

MATERIALS AND METHODS

Study Area

Ifedore Local Government Area is located in Ondo State, Nigeria as shown in Figure 1. It occupies 295 sq.km area of land. Its total population figure projected from 2006 population census to year 2016 at 3% growth rate is 237,029 . It lies on 732061.27, 823043.63 to the North while 739975.24, 812467.11 to the East. It is bounded by Ikeji in Osun State, Igbara Odo, Ikere in Ekiti State, Iju-Itaogbolu, Ipinsa and Apomu in Ondo State. It has three primary towns namely; Igbara-Oke, Ilara Mokin and Ijare (see Figure 2). It has its headquarters located in Igbara-Oke town. Igbara-Oke is a Yoruba town in Ifedore Local Government Area (LGA). Educational institutes in the LGA include St. Paul Anglican primary school – the first primary school established in Akure and Elizade University. Facilities available include 18-Hole Golf Course and Abiye Safe-Mother-Hood project.

Materials

The study utilised both spatial and attribute data from the field to answer research questions, which led to understanding and explanation of the pattern of healthcare facility distribution. Spatial data was acquired from satellite images including Google Earth imageries while attribute data were collected from the respondents of the study area and the National Population Commission. The health care facilities were treated as point data obtained through the use of geographic positioning system (GPS) for which feature data set were created. The study was targeted at residents of the study area, including members of the household, in the study area.

Methods

The population frame for the study is estimated to be 8465 buildings with an average of 7 people per household and 4 households to a building. The study made use of the cluster sampling technique. The study area was delineated into twenty-five clusters, being the total number of public health care facilities in Ifedore local government. Buffer analysis was conducted for 250 meters radius of the health facility in accordance to World Health Organization (WHO) standard. Likewise, buffers of 500 meters and 1 km were included in the analysis in recognition of the possibility of variation in the size and capacities of the facilities. The number of buildings that fall in the stipulated buffers with the aid of ArcGIS and Google Earth Imagery is 2504. This thus forms the target frame for the study. In determining the sample size, 10% of the target population was used which gives a sample size of 250 and hence, forming the number of questionnaires administered. The study then used a systematic sampling technique to determine the buildings for questionnaire administration. Neyman Pearson approach was adopted for testing the stated hypothesis. The null hypothesis for this study is "there is no significant difference in the distribution of health facilities in Ifedore Local Government Area. The hypothesis suggests that facilities are evenly distributed in the study area. Nearest Neighbourhood Analysis (NNA) was calculated based on the average distance of one facility to the other, which was expressed in ratio (index).

RESULTS AND DISCUSSIONS

Socio-Economic Characteristics

Findings reveals that the larger percentage of the respondents were females with a 51.6% while males were 48.4% with 61.2% of the sampled population married while 27.6% are single, 6.0% divorced and 5.2% widowed. Results revealed that 60.4% of the respondents are self-employed while 19.2% are unemployed; government employed 10.8% of the respondents whereas 8.4% were engaged by private sector. A review of the nature of job for most of the self-employed residents reveals that farming and trading are preferred alternative for livelihood in the study area. This agrees to the fact that the area is peri-urban, and supports agricultural activities. A sizeable 74% of the respondents are permanent residents while 24% are temporarily living at Ifedore.

Results revealed that 96% of the residents do patronize government owned facility, among which a significant portion, 68.0%, maintained that they chose the government health facility because of good quality of services offered by health workers while 14.8% held that it is due to closeness to their abode. Apart from this, 12.8% of the respondents submitted that service cost is not high in comparison to private clinic while 4% gave varying reasons for their patronage. It was further realised that the main reasons for preference to government health care include affordability, free maternal child health, availability of diagnostic equipment in a selected primary health centre, a coordinated referral system, skilled and competent medical staff. Affordability is considered as there is low cost of treatment in government owned facilities, free advisory services in relation to reproductive and child health (RCH) and availability of limited drugs. Thus, patients consider government health facilities accessible without recourse to the additional cost for consultation, diagnosis and certain medicines. Referral system is coordinated such that it paved way for patients whose case cannot be handled in the receiving health centre to higher order centre.

Income is one of the basic determinants that affects access to healthcare service. Access to qualitative healthcare is connected to income level of the household in a developing country. It is believed that high-income earners do have unequal access to better healthcare than their counterpart whose monthly income is relatively low. It is important to state that travel cost is an inclusive cost to the overall healthcare cost.

Spatial Analysis of Health Facility Distribution

There were twenty-five public health facilities in Ifedore: twenty-one basic health centres, two comprehensive health centres, one primary healthcare centres and one general hospital. Nearest neighbour analysis (NNA) was adopted in determining the pattern of the distribution. NNA outcome is mostly expressed as a ratio or index. The index ranges from 0 to 2.15. Spatial operation of the facility means showed that observed and expected mean distances were 1942.51 meters and 1566.38 meters respectively. This was further computed into a ratio or index making up 1.24. The index indicates that the pattern of distribution is dispersed. The derived NNA index was accompanied with z-score (standard deviation) of 2.3 and p- value of 0.02. Hence, the null hypothesis is rejected. Result of NNA index establishes that facilities were not evenly distributed. Furthermore, facilities were not sited consistently on a prescribed pattern. Presently, the distribution pattern depicts scattering, which indicates that efforts have not been intensified by government to coordinate planning of healthcare facilities in Ifedore local government area.

Buffer Analysis

WHO (1997) suggested a catchment area of 0.25 km as adequate for health care facilities. These could be further extended, in relation to the size of the facility. As a confirmation of the observations inferences drawn from output generated from the NNA, a buffer analysis

was carried for the facilities. The catchment size (250 meters radius) suggested by WHO was adopted. Also in recognition of the possibility of variation in the size and capacities of the facilities, 500 meters and 1 km were also considered. Although it must be stated that these are inadequate especially in case of emergency considering that emergency services are not at the desired operation level in most developing countries. It could be inferred from the output of the buffer analysis that the developed (inhabited) portion of the study area are largely outside the catchment area of the concerned facilities. The Ifedore region is a rapidly growing region in socio-economic terms and physical developments. The implication of this is that with increasing physical development activities and growing population of the region, the available facilities will not only be insufficient, but also inefficiently positioned, hence, the need to ensure effective planning before the provision of additional facilities.

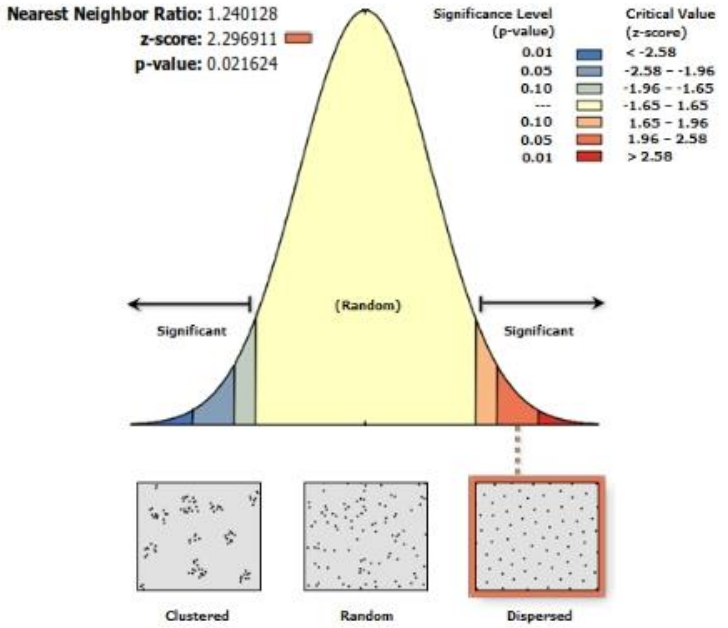

Figure 2: Nearest Neighbour Analysis Output

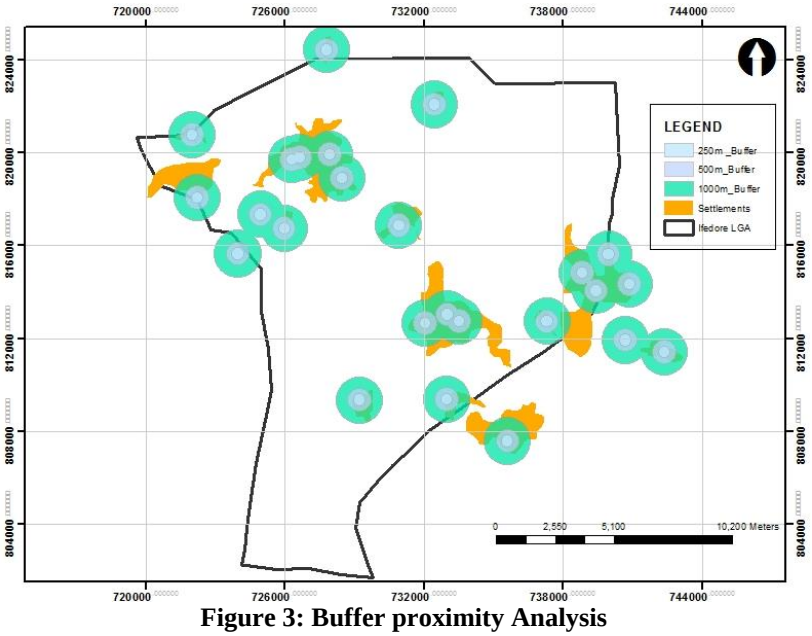

Figure 3: Buffer proximity Analysis

Healthcare Facility – Population Ratio (HFPR)

Population is a fundamental input and an imperative element in planning for the healthcare facility. It defines the number and level of facilities to be provided. The relationship between health services and population is an important area in the public health practice. Facility-population ratio is a fraction adopted to measure present capacity of a facility with a given population. The specification of WHO is that for every five thousand population, one healthcare facility is required for efficient service. Ifedore population is approximately 237,029. Presently there are twenty-four facilities with one general hospital. Thus, the ratio is 1:9,481. This simply means that a health facility is expected to serve a population of 1:9,481. This is grossly inadequate, should there be a need to attend to several patients at the same, for instance in times of natural disaster or epidemic. This inadequacy and insufficiency is in stark contrast to the goal of health-for-all as envisioned by WHO.

SUMMARY OF FINDINGS AND CONCLUSION

Summary of Findings

Facility-population ratio is one of the key parameters to measure the efficiency of healthcare delivery system. It attempts to measure supply of facilities to a required population. It is established from this study that the present healthcare facilities in Ifedore LGA is not sufficient to meet the standard of WHO concerning population. A wide gap exists between recommended and expected facility-population ratio. Though efforts were not made to ascertain the ratio of health workforce to anticipated population, yet it can be presumed that there are insufficient numbers of public health officials in the study area.

Location of facility is fundamental to health facility planning and a well-located facility does enhance accessibility. It was discovered that location of the facility strongly relied on the availability of space, physical accessibility, and government policy. It is agreed that nearness to facility strongly influence low-income earners' access to healthcare. However, this is not so for high-income earners who can find their way out to far distance for qualitative healthcare.

Spatial planning is connected with the spatial arrangement and service population in order to achieve convenience. There are various suggested standards in the aspect of health facility distribution. It is imperative to state that any recommended standard must define such facility capacity that is required for such. However, the present condition of the said facility is not up to the standard of World Bank assisted project specification.

Policy Implications

This study analyzed the spatial pattern of health service delivery system in Ifedore LGA. A major objective of government is to improve geographical equity and access to quality care. This is suggested to involve mapping of health facilities, establishing GIS for all health facilities in the country as well as developing criteria for siting of new health facilities at all levels. However, it is evident that this is not the case in the study area. The fact that facilities are scattered shows that geographic equity has not been achieved and some facilities appeared substandard. The Ondo State government has made a bold effort in achieving universal healthcare coverage. This is noted with Abiye Caring Heart Motherhood Programme financed by Ondo state and the World Bank. However, efforts need to be intensified to address present shortfalls. These will necessarily include the rehabilitation of existing and substandard health facilities in deplorable state.

CONCLUSION

It is evident in the locations of the existing facilities that proper consultation and analysis were not carried out. This error can be pardoned, in light of the fact that most of these

facilities were developed at a time when planning as an activity and profession was still taking root in Nigeria. Although application of sophisticated tools such as GIS and its affiliated wares are still evolving, there are numerous GIS tools, methodologies, and models (both mathematical and symbolic), that have been developed, which are available to help in decision making for efficient facility location. It is therefore important for policy makers and government agencies to ensure proper consultation before making these decisions. Hence, it is suggested that government agencies should consult relevant department and scholars in Nigerian universities for support and calculated and professional advice before decision-making.

ABSTRACT

An Average income earner living in Ikeja experiences basic shelter issues that includes high accommodation cost, insufficient space to build, and high cost of buildable land among many others. Most of them could not afford adequate space required of their family size. The present housing situation in Ikeja is therefore investigated and space utilization method is induced as supportive option in mitigating the problem of interior space congestion with the use of transformable interior furniture in residential spaces.Three hundred 300 questionnaires were administered in the study area and Simple table, percentages and explanatory paragraph were used to analyze the results. A comparative study was also carried out on cost implication of the use of transformable furniture to the habitually used interior furniture in the area. The results shows a promising outcome as room congestion and cost constraint could be annulled with the use of transformable interior furniture design in the study area. The study concludes that the use of the transformable interior furniture should be encouraged as increase in demand of the transformable furniture will increase the number of manufacturers thereby reducing the product cost through market competitiveness.

Keywords: Housing, Nigeria, residential spaces, space utilization, transformable furniture

INTRODUCTION

Housing remains in a deplorable state over time mostly in the urban environment of less developed countries as a result of an ever rising population caused primarily by rural-urban drift. The situation is even worse in places like Lagos, Nigeria that is short of buildable land spaces. Housing the "surplus population" of the city has long been an acute problem and a competitive exercise of multi-dimensional implication manifested in the political, socio-economic and environmental processes (Olayiwola, Adeleye and Ogunsakin, 2005). The urban poor constitute the vast majority of urban dwellers and they are in a disadvantaged economic position to build for themselves and are generally unable to make effective demand of existing housing (Olotuah and Taiwo, 2013).

An Average income earner living in urban cities like Lagos, Port-Harcourt, and Abuja experiences basic shelter issues that includes high accommodation cost, insufficient space to build, high cost of buildable land among many others (Olotuah and Aiyetan, 2006). Many effort had been made to improve the level of housing provision for the urban poor from government policies for a goal of achieving adequate housing to extensive mass housing development employing indigenous materials and methods, and involving the target population from policy making through programme execution. These methods of approach involved the participation of the grassroots user population to ensure the sustainability of the housing development in Nigerian cities, yet little of the effort have been felt so far. Despite the fact that they were mainly low income earners, they have household size of four persons and above, and most of them live in one bedroom apartments (Aduwo, Ibem and Opoko, 2013). They have improvised by altering their houses arrangement because they needed to

Onanuga, O. A.; Folorunso, C. O. & Adeyanju, A. (2016). Adoption of Transformable Furniture for Space Utilization in Residential Spaces in Lagos, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 988-996

provide more and better spaces to accommodate their growing families. This has resulted into interior overcrowding and spread of diseases.

Several studies that have been done on resident's satisfaction, quality and adequacy of housing, have reported that the quality is generally poor and level of satisfaction is very low (Ukoha and Beamish, 1997; Olatubara and Fatoye, 2007; Fatoye and Odusami, 2009; Jiboye, 2009; Ilesanmi, 2010; Clement and Kayode, 2012; Ibem and Amole, 2011; Ibem and Amole, 2012). Meanwhile, to improvise, over 89% of the open space around each of the buildings have been used up in the course of transforming the dwelling units. This has invariably reduced the available open space needed for adequate circulation of air and human traffic as well as outdoor activities (Aduwo et al, 2013). Despite this, it has been observed that there are still some space that are not well utilized even in the course of transformation.

Most researchers have concentrated on design specification that avoids excessive space provision, while much work have also been done as regards proficient land-use for more housing provision. However, research as regards the effective optimal use of provided space round the clock is still grossly scarce. This can be explained better considering the living room serving as a space to accommodate visitors, but its' effective use is limited to daytime therefore remain unutilized at night. This study therefore aims to investigate how the provided spaces in the interior can be adequately utilized to provide the required space that will accommodate the household size without altering the design of the space, a move to mitigate overcrowding of a part while some other parts of the interior are underutilized. The subsequent discussion shall focus on the result of housing delivery achieved so far by different strategy employed to solve housing matters in Lagos, Nigeria.

LITERATURE REVIEW

Housing Situation and Effective Responses in Lagos, Nigeria

Lagos is the smallest state in Nigeria in terms of land area with only 0.4 percent of the Nigeria total land space, but remains the most populace city in Nigeria (UN-Habitat, 2004). The state accounts for about 9.7 percent of national population and stretches 180km along the Atlantic Coastline having 17% of its total land area made up of Lagoon and water. At the Northern and Eastern sides lies Ogun State and the Western side is bordered by Republic of Benin. The increasing rate of population growth of over 9% per annum, resulting to additional 1.4 million persons annually (Bamgbose, 2009; Lagos State Government, 2004) and about 4,000 people per day with population density of one person per square kilometer is about 16 times the national average (Ibrahim, 2014).

The population explosion in Lagos is attributable to significant economic, commercial and political changes that made Lagos the fastest growing city in Nigeria as it accounts for nearly 50% of the total value added by the manufacturing sector of Nigeria and increasing capital intensive than other parts of the country. The large population which accounted for more of urban poor engage in irregular, low-income employment making them poor that they cannot afford conventional housing that will accommodate their family size (Ibrahim, 2014).

Since the late 1960s, the intervention of government in housing in Nigeria has covered provision of staff quarters, staff housing loans to government workers, direct house construction in public schemes, and site-and-services schemes (Olotuah et al, 2013). Government have responded in their own way to solve the problem of housing right from the military era to date. Government efforts in providing public housing during the first and second policy plan period (1962-68, 1970-74) were concentrated in Lagos. From 1973 to 1979, 10,000 housing units were constructed in Lagos and about 24,000 units in the rest of

the states. The civilian administration, before the 1983 military coup executed 20% of its housing programme (about 30,000 housing units) (Olayiwola et al, 2005).

The Lagos State civilian government constructed 10,428 units out of the planned 50.000 units whereas it completed about 70% of the housing units meant for the high-income groups (Alaka, Opebi, and Alapere estates). The 1984 military administration of Lagos State completed 200 housing units out of the programmed 8000 housing unit proposed to be built between 1983-1986 (Olayiwola et al, 2005; Olotuah et al, 2013). Many other strategies have been put in place by different government bodies between 1986 to date, and Federal Government involvement in housing within the last six years shows that government has a significant contribution (olayiwola et al, 2005).

The National Housing Fund, another government policy, which is supposed to be the source of housing finance is itself, faced with the difficulty of mobilizing contributions from the informal sector compromising self-employed workers. The formal sector has not been forthcoming, either, in its contribution to the Fund as the financial institutions (notably the Commercial Banks and Insurance Companies) and have not been participating in the scheme. The private sector, been essentially profit-oriented, cannot as well ensure an equitable distribution of housing resources. This is inevitable in a country with high unequal income distribution. The poor majority are thus subjected to unending housing poverty in the absence of decisive intervention with respect to direct construction of low-cost houses; meanwhile, the quantitative housing needs of the populace, though staggering, have to be met for all Nigerians to have access to adequate housing.

Space Planning and Its Limitation

Space planning involves optimum utilization of available buildable space in an efficient and effective manner that meet the users' needs and requirements. Space planning gives an effective total use of an available buildable space, a method that has involves vertical development at areas where horizontal development are impossible. Space planning strategy have been an alternative sought by governmental organization in other countries to tackle the issue of housing inadequacy, and in developing countries like Nigeria, vertical development of high rise buildings and condominiums has been fully harnessed. Nigeria, been one of the developing country, her building practice is still grappling with a lot of challenges, ranging from inadequate technical and managerial know-how to insufficient financial, material and equipment capital base (Oluwakiyesi, 2011). This is made evident by the threats it imposed on the building practice in Nigeria that varies from importation of costly building materials and professionals from foreign countries, to diminishing opportunities for indigenous professionals cum low local contractors' growth due to competition from their more capitalized and better equipped foreign counterparts. The cost of imported building materials (Onibokun, 1985) and construction techniques involved usually make acquiring accommodation more cost unbearable. However, increasing household size imposed a limit to space planning methods as space requirement keeps increasing to accommodate the household size, hence, changing the original form and spatial configuration of a dwelling unit by the occupants in order to meet current space need arises. In lieu of this, a guideline for space utilization strategic approach was developed (SMG, 2006).

Space Utilization Scheme

Space utilization is a measure of whether and how space is being used. The utilization rate is a function of a frequency and occupancy rate. The frequency rate measures the proportion of time that space is used compared to its availability, and the occupancy rate measures how full the space is compared to its capacity (SMG, 2006). The household size of an average family keeps increasing once a marital relationship starts, and the size of a family determines the

space required to accommodate them. Meanwhile, increasing the space in a home lead to higher prices for the end purchaser (Luke, 2014). The inability to afford new houses or expand the existing one resulted in overcrowding thus, aggravating what is originally a convoluted situation. Most families resolve to a confined space they can possibly get due to financial constrain, therefore keeps transforming the interior partitions and overloading existing spaces. Meanwhile, it has been observed that it is only a part of the space that is been overloaded while some other part are limited in use (Freeman, 2004). In other to achieve balance in the use of interior space for the household need is the target of space utilization approach.

Reviews on issue of residential management approach, the German Bauhaus movement produced an analysis entitled; 'Existenzminimum' (McGrath, 2011). The project focused on setting minimum standards for elements such as floor space, density and fresh air amongst other items in response to the then German postwar housing crisis (McGrath 2011; Luke, 2014). The rooms were designed to be multifunctional; to easily change between uses throughout the day. Research has affirmed that a rented apartment allows dwellers to act only on partition wall level and utensil level and that the tenants cannot operate beyond the furniture level according to the context (Khan, 2014). Since most of the tenure category affected by housing issues are the tenants, the design of multipurpose furniture becomes necessary as movement of different furniture for different interior use can also be wearisome.

Furniture, an essential companion of human lives and work, and an important/inevitable constituent of the indoor environment is a basic component in achieving a compact, yet functional and comfortable interior spaces. Space saving concept with the use of multifunctional furniture has been in existence for decades. However, it was not until recently that its importance and convenience was recognized, particularly in this time of increase urban population growth which is associated with limited living surface area (Kilmer et al, 1992). The space management technique through the use of multifunctional furniture involves either the use of a dual function furniture that can serve two purposes (like a sofa can be converted to a bed in figure 2) or furniture design that relate with space (that is a bed can be hid into a wall or ground or raise to the ceiling as part of design - figure 3). It is assumed that space saving furniture, multifunctional design and tiny transforming spaces are a new idea, however people have been looking for ways to make their homes more space efficient and products more versatile (Ching & Binggeli, 2012).

METHODOLOGY

The study utilized both secondary and primary sources of data. The secondary data sourced for relevant information from journals, articles, and research reports from government agencies, and parastatals. Primary information was collected from both personal observations and questionnaire. The area concentrated on in Ikeja are the Ikeja G.R.A, Allen Avenue, Awolowo way, and Alausa. A total of 300 questionnaires were administered to the government workers residing in the study areas. These areas have a large concentration of government workers in Lagos. Seventy five (75) apartments were randomly chosen from each area and the questionnaires was administered to the head of the family of one household in each apartments. The comparative study of cost difference in the use of transformable furniture in a one bedroom apartment against the regular furniture setting in a two bedroom apartment was also analyzed.

Study Area

Lagos State is the economic nerve center of Nigeria. It would be the fifth largest economy in Africa if it were a country. At the inception of Lagos state in 1967, Lagos Island was both the state capital as well as the seat of the Federal Government. However, when Nigeria's federation was restructured into 19 state in 1976, the capital of the state was moved to Ikeja. Lagos state is also made up of five administrative divisions in which Ikeja was one, the administrative division were further divided into local governments. Ikeja division consist of six local government authorities namely: Agege, Mushin, Alimosho, Oshodi/Isolo, Somolu and Ikeja. Ikeja serves as the seat of government and also as the division's headquarters. Prior to the emergence of military rule, Ikeja was a well-planned, clean and quiet residential environment with shopping malls, pharmacies and government reservation areas. It now boasts of a large shopping mall "Ikeja City Mall" which is the biggest mall in the Lagos mainland and also has a cinema. The investigated areas for the purpose of this research cut-across G.R.A., Allen Avenue, Awolowo way, and Alausa.

Ikeja is one of the many parts of Lagos mainland constrained by space consisting of many residential apartments, government offices, commercial centers, and industries among others. The research examines the impact that transformable furniture will make on dwellers in disadvantage economic position who cannot afford to rent adequate space required of their family size.

Plate 3: *Showing a map of Lagos State and the study area.*

RESULTS AND DISCUSSIONS

Effect of Income on Choice of Accommodation

The income of the residents living around the Ikeja areas is presumed to be a predominant factor that determines the types of apartment that they live in. To justify this, the income classification in relation to the type of dwelling of the respondents was analyzed. In the questionnaire, the income was classified into low income earners (range between those of no regular income to lowest rank government worker collecting #280,000 per annum), middle income (income class range between #280,000 to #700,000 per annum), and high income (class earning above #700,000 per annum) earners. The study showed that about 56% (168) of the respondents were of low income classification, 36% (108) are of middle income and 8% (24) are in high income class. The result of the dwelling units tallies with expectation. About 22% out of the total 56% in low income class lives in rooming apartments, 24% lived in one bedroom apartments, while only 10% in low income category lives in two bedroom apartment. The table gives a summary of all responses by the respondents for all the classes of income, and percentages shaded for clarity.

The result therefore proves that the urban poor were limited to the confined spaces due to their disadvantaged economic position. This situation can be attended to if the available space that they can afford are been properly utilized and strategically managed. The concept of transformable furniture bring about the achievement of a reduced square area required to accommodate a unit family in an urban environment. This will create more space to accommodate more urban dwellers thereby reducing the crowdedness in the provided spaces and housing need of the people.

Table 1: showing the relationship between the apartment type and the income classification

Apartment		Income classification			Total
		Low income No regular – 280,000	Middle income 280,000-700,000	High income Above 700,000	
Rooming apartment	count	66	6	0	72
	percentage	22	2	0	24
1 bedroom apartment	count	72	18	0	90
	percentage	24	6	0	16
2 bedroom apartment	count	30	30	0	60
	percentage	10	10	0	20
3 bedroom apartment	count	0	30	18	48
	percentage	0	10	6	30
4 bedroom apartment	count	0	24	6	30
	percentage	0	8	2	10
total	count	168	108	24	300
	percentage	56	36	8	100

A Comparative Analysis of Two Dwelling Spaces

A comparative analysis was carried out of two different apartments of an average income earner in the study area. The cost of the furniture put in place in the interior space of the two bedroom was compared with cost implication using transformable furniture for a one bedroom apartment (table 2). The cost of a minimum annual lease for both one bedroom apartment and two bedroom apartment at Awolowo way was noted, and also the cost of necessary furniture the spaces could require. The one bedroom apartment contains a living room and a bedroom with other facilities such as kitchen and toilet, while the two bedroom apartment contains a living room and 2 bedrooms with other facilities such as kitchen and toilet.

Table 2: Cost comparative study using transformable furniture in a studio apartment against the orthodox furniture setting in a two bedroom apartment

	Studio apartment Transformable furniture		**2bedroom apartment orthodox furniture**	
	unit	**Price (#)**	**unit**	**Price(#)**
Minimum annual lease	1	200,000	1	300,000
Bed	1no platform bed (HDF) first room	210,000	1no platform bed (HDF) first room	210,000
			2no average size bed second room	260,000
Sofa	2no dual use sofa (convertible to queen size bed) – HDF	840,000 (at $2000 each)	1 living room caret fabric sofa set	200,000
Total cost		#1,250,000		#970,000

Source: Authors field work

Table 2 shows the details of cost incurred by the residences in both apartments. Transformable furniture was considered for use in the one bedroom apartment and the orthodox furniture was used for the two bedroom apartment. With the use of the transformable furniture, the dual sofa is convertible to two numbers queen size bed, thereby providing additional two bed spaces for comfortable night rest for a household that could only afford one bedroom apartment. Therefore, it can be said that the bedroom is copiously utilized round the clock. It can also be deduced that the tenant occupying the two bedroom will be paying more as cost difference will take effect after the first year as the dweller in the two bedroom will annually be paying #100,000 more, yet harnessing same comfort level as the other dweller.

The implication of using a transformable furniture is that a great deal of space is saved and the use of a space can be multi-functional. The sample above show a one bedroom apartment that employs the strict use of transformable space saving product. The one bedroom apartment eventually provide a satisfactory two bedroom apartment accommodating a double bed for the converted living room space.

CONCLUSION

Most of the respondents prefer the transformable furniture to the local furniture, although large percentage of them have neither the idea nor have seen the product. It is affirmed through comparison that a one bedroom apartment can serve the function of a two bedroom in a situation where a transformable type of furniture is used. A transformable sofa can be converted to a bed and changes the use of the lounge space during the day to bedroom at night. With this scheme put to use, it can be assured that problems associated with overcrowding of space and indecent housing condition can be averted. The implication is that those that can only afford one bedroom apartments, with the use of the transformable

furniture, could have a satisfaction that can be compared to those dwellers in 2 bedroom/3bedroom spaces using the common furniture.

The transformable furniture is an imported product which significantly affect the cost of purchase as none of the company producing is established in Africa. The cost of this transformable furniture varies according to material and what it is to be converted to. The price range of a queen sized transformable bed with a bookshelf according to Resource Furniture (a leading brand of this type of furniture) is from #800,000 to #3,000,000 ($4000 - $21000 CAD) when converted to the local currency, and a simple transformable sofa bed costs only around #200,000 (Shiyao Wang 2013). The government can therefore help in this regard to put a strategy in place in attracting the product companies into Nigeria. Doing this will merit in two ways; it will bring about job opportunities and also reduce the cost of purchase of the product. The supply for a commodity has an inverse effect on the price because the higher the supply the lower the price and this will give enough purchasing power especially to the low income earners.

The main reason why the ordinary furniture may be cheaper is because it is locally available in the market, therefore if the transformable furniture is made available in local market in large quantity, its price will become reasonable as the locally available ones. However, as much as this paper was able to expose this products existence taking into consideration the people that the questionnaire was administered to, the preference of peoples' changed and a larger percentage opted for the transformable space saving furniture. Therefore, government could focus on the production of housing type having more of one bedroom apartment as this will increase the number of housing unit in the study area thereby greatly impacting housing need of the people, hence, the housing challenges in the urban environment is reduced, enough space is created out of existing space and shelter provision is adequate enough for the city dwellers.

A Critique of the Implementation of Abuja Tourism Development Master Plan

Idris Isah Iliyasu

Department of Urban and Regional Planning, Faculty of Environmental Design, Ahmadu Bello University, Samaru-Zaria
urbanist2005@gmail.com

ABSTRACT

The objective of the preparation of any tourism development master plan is to provide a guide for a short, medium and long term development framework of the sector. Hence the viability of the plan is explained by the success of the implementation programme and by extension, describes the performance of the industry. In this study, a critique of the implementation of the Abuja tourism development master plan was carried out. Observations have indicated that, important components of the plan have not been implemented. This was explained by the outcome of the assessment which shows that, physical development and upgrading has scored 0.23, marketing and promotion has scored 0.19 and events products has scored 0.20, while the overall score of the implementation programme was 0.62 points and this indicates failure of the plan implementation. Several factors were identified explaining the reasons for the failure of the plan implementation; these include: poor identification of potentials, lack of private sector involvement, inadequate funding, technical shortcomings, shortcomings associated with planning and implementation strategies, institutional constraints of policy and laws, inadequate publicity and poor advertisement. The study concluded with recommendations which include: the need to review the tourism master plan, provision of adequate funding, formulation of Abuja tourism policy and enactment of tourism laws; these would further enable tourism planners, policy makers and private sector contribute immensely to the improvement of the planning and development of tourism sector in the F.C.T.

Keywords: Assessment, Implementation, Master planning, Tourism development, Programmes

INTRODUCTION

Tourism is defined as the short term movement of people from their usual place of residence (origin) to other places (destination) for the purpose of leisure and recreational activities without any intention of securing a permanent resident or job at the destination; Christopher Cooper and Brain Boniface (2006). In 2007, the European commission on tourism and travels (ECTT) adopted a definition that included among others; persons traveling for pleasure, for family reasons or in a representative capacity of any kind and persons traveling for business reasons (ECTT, 2005).

It is also seen as the science, art and business of attracting and transporting visitors, accommodating them and graciously catering for their needs and wants; Mentosh and Gupta (2008). Since the early 70s, tourism has grown to become one of the fastest growing economic sectors in the world, ranking only after petroleum and auto trades (UNWTO, 2010). Tourism today plays a significant role in the balance of payment of many countries both in the developed and developing worlds. Tourism therefore, brings huge economic and social benefits to many nations, especially those that carefully plan and manage their potential attractions or resources (UNTWO, 2010). It has become the world's largest growing industry, statistics by the world Tourism organizations shows that there are no signs of this growth slowing down in the next Millennium. To benefit from this global trend, tourism is been adopted by governments as a vehicle for poverty alleviation, employment generation and wealth creation. It is also seen as a veritable tool for the realization of the Millennium Development Goals (MDGs).

Iliyasu, I. I. (2016). A Critique of the Implementation of Abuja Tourism Development Master Plan. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 997-1005

In recognition of these prospects of tourism, the defunct Ministry of Federal Capital Territory (FCT), Abuja prepared a comprehensive tourism development master plan in 2000. The tourism master plan is a strategic document, report or plan prepared to serve as a blue print or guide in harnessing the varied potentials i.e. National and Cultural attractions of the FCT for tourism development. The plan intends to provide a plat form through which tourism potentials could be develop in the territory. The ten (10) year plan was with the mandate of establishing short, medium and long term development programmes, such as high quality leisure and recreation facilities, accommodation and transportation within the framework of the Abuja city (F.C.T) master plan for attracting domestic and international tourists and visitors. The implementation of the plan was observed to be poor and unsuccessful in meeting the designed goals and objectives; therefore, this paper carried out a critique of the plan implementation programmes with the view of establishing the factors responsible for the poor implementation outcome of the plan.

Method and Materials for the study

The data used in the study were sourced from opinion surveys. The review of secondary data which includes; the master plan document, legal documents and policy reports that were meant to guide the implementation of the programme, were also carried out. Purposive sampling method was adopted for the selection of respondents for the opinion survey to ensure a wide coverage of all agencies responsible for the implementation of the projects and programmes of the master plan in the FCT, Abuja for the actualization of the objectives of the study. In conducting assessment that would be free from ambiguity, subjectivity and biasness, the Kergs scoring criteria (expressed levels of project or programme implementation achievements in percentages (%) and to a defined score values ranging from 0% to 100% and a score values of 0 point to 3.0 points) was used. The overall scores is acquired by summing up of all the points of the implementation projects or programmes divided by the score points; this is mathematically expressed as:

$$\boldsymbol{K} = \frac{\sum \boldsymbol{x}}{\boldsymbol{n}}_{\boldsymbol{t=1}} - - - - - - - - - - - - (\mathbf{1})$$

Where: K = constant value meaning the mean of the Kergs points

$\sum x$ *= Summation of all points of individuals projects scores*

n = total number of scores in Kergs index

The relationship between outcomes is also expressed mathematically as: $\boldsymbol{0 \leq \emptyset \geq 3.0}$**----------** ***(2).***

The Study Area

Abuja, the Federal Capital Territory is located in the geographical Centre of Nigeria, occupying an area of about 8,000sq.km. It is bounded to the north by Kaduna State, to the west by Niger State to the east and south by the new Nassarawa State (formerly part of Plateau State) and to the south-west by the new Kogi State (formerly part of Kwara State). On the world map, FCT lies between latitude 80' 25°, north of the equator, and longitude 60' 46°, and 739, east of the Greenwich meridian. The central geographical location of Abuja makes it easily accessible from all parts of the country, especially by road. The administrative composition of Abuja is made up of six area councils and eleven districts.

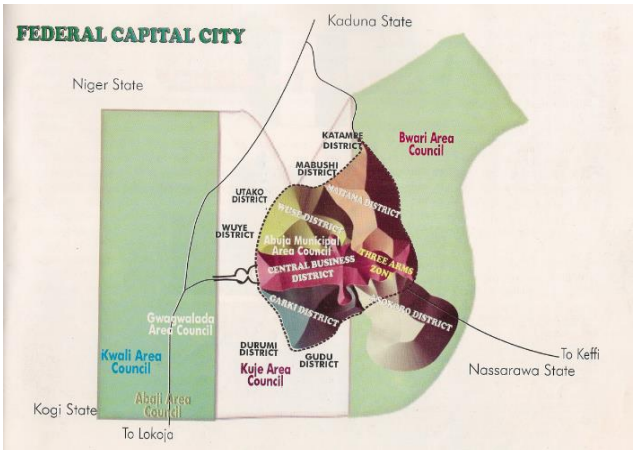

Figure 1: Administrative Districts in the F.C.T Abuja

The main occupation of F.C.T's local communities is farming. Manufacturing sector has also grown quite substantially especially in respond to the demands of the building and food industry. Local handicrafts especially; poetry, blacksmithing, basketry and leather work. The population of F.C.T is about 8.0 million. The major indigenous groups in the territory are the Gwaris followed by Koros, the Ganas, the Gwandaras, the Bassa and the Egbiras. Most of them live in the rural areas of the FCT and are somewhat related in their culture, language and tradition. Presently, the main city of Abuja, administratively called Abuja Municipal Council Area is inhabited predominately by the Hausas, Igbos and Yorubas and a minority of the indigenous tribes.

THE TOURISM MASTER PLAN OF THE F.C.T ABUJA

The master plan proposals for the development of the sector are anchored around three issues. These are the development potentials which include:

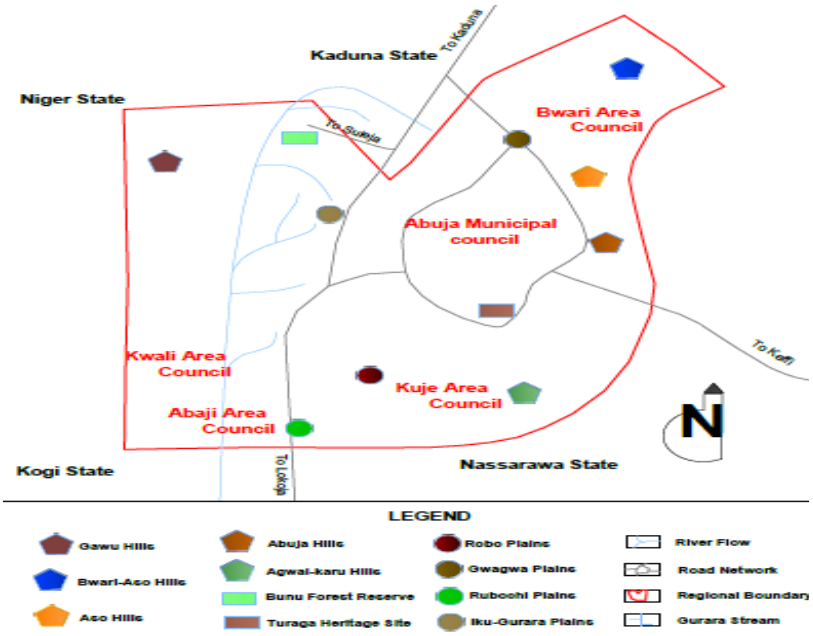

Figure 2: Proposed Physical Development Potentials

The Natural Elements

These involve the natural features or bounties of Abuja such as Hills and Rock outcrops, the geomorphology and topography, climate and hydrograph of areas. For the purpose of the

master plan; the following natural potentials of the areas are considered for the development of tourism sector of the F.C.T; Aso or Asokoro Rock, Strabag Hill (or the National Center), The Zuma Rock, The Twin Mountains of Abuja City Gate, Gurara Falls, Jabi Dam Resort, Lower Usuma Dam, The Republic Garden/Abuja Garden, Abuja Plant Nursery, Julie Useni Park, Abuja Zoo, FCT Game Reserve and The National Arboretum.

The Cultural Elements

The cultural elements refer to historical and traditional artifacts of areas. For the purpose of the master plan the following existing tourist cultural potentials of the F.C.T were adopted or development of a robust tourism destination in Abuja. These include; handcrafts, music, traditional buildings or settlements, signature architectures, cuisines, religious places, palaces, theatre and performing arts, festivals, events and fairs, museums and monuments, traditional games and sports, fashion and textiles as well as traditional medicine (curatorial services).

The supporting facilities

Tourism largely depends on the numerous existing supporting or complementary facilities to thrive. For the purpose of the master plan the following existing tourist attractions and facilities have been integrated into the master plan for the development of tourism in the F.C.T; Hotels, Restaurants, Conference Facilities, Transport Facilities, Sports and Recreational Facilities, Shopping Facilities, Tourism Information Posts, Tour Operators and Travel Agencies.

FINDINGS AND DISCUSSION

Assessment of the plan Implementation

In the assessment, out of 22 physical development projects proposed, only 2 were fully implemented representing 9.1%, about 9 projects were partially implemented representing 40.9% of the projects. Also out of 8 physical upgrading projects proposed, only 1 was fully implemented representing 12.5%, while 2 projects were partially implemented representing 25% of the proposed projects.

The assessment of marketing and promotion programmes, indicate that out of 6 programmes proposed, only 2 were partially implemented representing 33.3% of the programmes.

The events product assessment also, shows that only 2 events products were partially implemented out of 5 products proposed, representing 40% of the proposed products.

Overall Assessment of Plan Implementation:

The sectoral assessment carried out above was further examined. First was to enable comparative assessment of the implementation levels of the sectors; and second to enable appreciation of implementation at the aggregate plan level. In the study, the aggregate scores of the plan components obtained indicates that, Physical development and Upgrading projects has the highest aggregate score of 90 points, marketing and promotion has the moderate score of 18 points, while event products have the least score of 15 points. Outcome of the overall assessment shows that, the implementation of Physical development and Upgrading projects did better than the other components obtaining the best aggregate score of 20.95 points, while implementation of events product was poor with the score of 3.0.

Inference form the study established that, the total implementation scores indicates poor implementation of the master plan. This has been established by the results of the overall assessment scores outcome of the plan implementation which shows an overall score points of less than 1.0 (0.62), this indicates failure of the implementation of the master plan. This implies that the critical components of the tourism master plan have not been implemented as established in the assessment of the various components of the plan. Therefore, it has become

necessary for the study to further provide explanation on the factors that are responsible for the failure of the plan implementation towards actualizing the F.C.T Tourism development mandates. Table 1 shows the detail of the overall assessment scoring.

Table 1: Scores of the overall assessment of the plan implementation

S/No	Variables	Maximum scores	∑x	n t = 1
1.	Physical development and Upgrading	90	20.95	0.23
3.	Marketing & promotion	18	3.5	0.19
4.	Events Product	15	3.0	0.2
	Total			**0.62**

Note: 0-1=Failure, 1=Poor, 2=Moderate, 3=High,

FACTORS EXPLAINING THE POOR LEVEL OF PLAN IMPLEMENTATION

Poor Identification of Tourism Potentials

The results obtained from the study have shown that poor implementation is partly accounted for by wrong choices of tourism potentials made by the Master Planners. The proof of this comes by comparison of chosen potentials in the plan and the perceptions of the public, determined based on an opinion surveys. Table 2 shows the various user perceptions.

Table 2: User Perception on Tourism Potentials in Abuja

S/No	Users / stakeholders	Tourism Potentials in the F.C.T						Total
		Architectural elements & monuments	Hotels	Catering services	Conference centers	Parks, Recreation & Resorts	Cultural elements	
1.	Domestic tourism	20%	22%	12%	11%	30%	5%	100
2.	International tourists	12%	25%	2%	53%	6%	4%	100
3.	Day visitors	28%	20%	15%	21%	13%	3%	100
4.	CATA	36%	12%	11%	20%	6%	15%	100

Poor Private Sector Involvement

The analysis established that, the various projects and programmes that were ear marked for implementation, over 70% of the project tasks implementation was made the responsibility of the government which are yet to be implemented. Government were supposed to create enabling environment for the private sector participation such as economic incentives (tax holiday, free registration and accessibility to serviced land), but such environment does not exist in the F.C.T. However, this explains the poor outcome of private sector involvement in tourism industry of the F.C.T, and further explains the non-implementation of the three basic components of the master plan.

Inadequate Funding

At the F.C.T level, the study has established the lack of effective private sector involvement in the tourism sector. Problems of funding were found to be one of the major reason for the unsuccessful implementation of the tourism master plan. Table 3 shows the various outlays of funds proposed for the implementation of the master plan.

Table 3: Funds allocated between 2000-2010 for Tourism development in the F.C.T

SN	Agency	Phase I (2001–2004)		Phase II (2005-2007)		Phase III (2008 – 2010)	
		Spent (#)	Budgeted (#)	Spent (#)	Budgeted (#)	Spent (#)	Budged (#)
1.	Public sector	12.2m	1.5b	14.6m	2.2b	120.5m	2.56b
2.	Private Sector	120m	1.8b	240.34m	2.6b	406.84	3.52b
	total	132.2m	3.3b	254.94m	4.8b	527.34m	6.08b

Source: Abuja Tourism Master Plan, (2000), NTDC (2011) and FCT, Tourism Development Department. (2013)

Technical Shortcomings

In the context of Abuja tourism sector, the analysis on table 4 has established that, the organizations responsible for the implementation of the master plan were poorly staffed.

Table 4: Manpower for Tourism Development in the F.C.T.

S/No	Bodies	Senior cadre		Middle cadre		Junior cadre	
		Available	required	Available	Required	Available	Required
1.	NTDC	4	8	6	10	8	16
2.	Abuja Tourism Development Department	2	6	3	15	7	18
3.	Abuja Art and Culture Bureau	3	8	4	12	6	16
4.	Tourism Area Councils	-	4	-	6	-	12
	Total	9	28	13	43	21	62

Sources: Abuja Tourism Development department, 2011 & Field Survey, 2013.

Poor Implementation Strategies

The study has established that poorly articulated strategies existed for implementation of the tourism master plan. Table 5a and figure 5b examined the various views and opinions of stakeholders who directly or indirectly influenced the implementation of the plan. Stakeholders opinions were sorted out and their views and opinions indicated that, implementation of tourism development programmes in the F.C.T is poor.

Table 5a: Stakeholders Perception on the implementation of the Tourism Master Plan

Respondents	Responses				Total
	High	Moderate	Low	Poor

3.	F.C.C. Residents	*	√	*
4.	Tour operators	*	√	*
5.	Financial institutions (Banks, Insurance Companies)	*	*	√

Lack of Tourism Development Policy

The provision of adequate and functional policies, laws and administrative structures is key to the effective implementation of development programmes including programmes for tourism development. At the F.C.T, such policy was established from the study to be non-existent,

and its absence has constituted a major hindrance to the effective implementation of the plan. In its absence, the National Tourism Development Policy of 1990 (reviewed in 2004) appears to be the only guiding instrument for tourism development in the F.C.T and without reference to the tourism needs of the F.C.T this policy in effect has been of limited value. Table 6 shows the conflicting roles among different agencies responsible for Tourism development in the FCT as a result of absence of the policy.

Table 6: Conflicting roles of Tourism Development Agencies in the FCT

RECOMMENDATIONS

Based on the outcomes of the assessment; the study made the following recommendations with the purpose of improving on the implementation of both the tourism master plan and the tourism activities towards delivering the mandates of the Abuja tourism development visions and goals. Thereby, help in improving on the general performance of the tourism sector.

Review of the Tourism Master Plan of the F.C.T

In view of the outcome of the assessment, the tourism master plan should be reviewed with emphasis on revising assumptions, selection of viable potential resources, evaluating methodologies of tourism elements, explore the city significant architecture, culture and landscape elements as well as adoption of an appropriate tourism circuit for strategic development of the sector.

Provide improved funding

A system of exploring the appropriate models of Public-Private Partnership (PPP) should be designed and implemented, so as to augment government efforts towards actualizing the tourism mandate. Public sector should be more proactive towards creation of enabling environment in the provision of basic infrastructures for tourism, while the private sector is to provide funds for developing the industry.

Strengthening of the existing institutional framework

The Abuja tourism development policy should be gazette, and laws related to tourism development should also be enacted. Also, synergy should be created among the various agencies of tourism in the FCT for effective implementation of development programmes and projects, as well as re-strengthen them towards actualizing the FCT tourism master plan.

Strengthen the technical component of the Tourism Development Board

The sole implementing agency of the Abuja strategic tourism plan and development to be re-strengthen to reflect the ideals for effective tourism development in the territory. This includes the provisioning of adequate staffing, office equipments, communication gadgets, vehicles for monitoring, improved salaries, wages and welfare packages for the staff and conducive office space for operations.

Establish the Abuja Tourism Development Board (ATDB)

The national assembly should be solicited to pass the Abuja tourism development policy and law bill, this is to enable the establishment of the board, which would serve as the state apex for coordinating and monitoring of tourism development.

Create Adequate Publicity

the Abuja tourism programmes should be given popular publicity and awareness drive such as TV Jingles, Newspaper Advertisement and participation in tourism Events and Fairs, and also should be made available on the internet and also an effective web site for the board should be created to enable contributions in form of suggestions and opinions to be expressed in meeting the designed goals of the tourism development of the F.C.T.

Develop Political will for tourism

Government should commit effectively towards actualization of the Abuja tourism mandate. This should take the form of provision of supporting infrastructures such as; water, electricity, roads and public transport systems, etc, economic incentives such as tax holiday, free investment portfolio from the C.B.N, insurance companies, development and commercial banks, investment houses and other financial institutions in the country; policy regulations such as visa holiday, immigration lifts, trade tariffs and improved security system.

CONCLUSION

It has become clear from the assessment that Abuja is rich in tourism attractions and potentials but the implementation of the programmes have been unsuccessful, constrained by the identified factors. This hindered the effective development of the tourism sector of the F.C.T as established by the study. The outcome established that the basic components of the tourism master plan were not adequately implemented, while others are yet to be carried out. These were attributed to the identified factors that resulted to the outcome. Recommendations were made for transforming the Abuja tourism sector to a more viable sector and also for future tourism planning process and programmes for the actualization of the National Tourism Development Master Plan and the National Tourism Development Policy with regards to Abuja and the country at large.

Mapping For Community Development: A Case Study of Apatapiti Community North East, Akure-Nigeria

Ogunlade, S.[1*] & Tijani, S.[2]

[1&2]Department of Surveying and Geo-Informatics, Federal University of Technology, Akure, Ondo State, Nigeria
[*]soogunlade@futa.edu.ng

ABSTRACT

This project aimed at carrying out the detail surveys of North Eastern part of Apatapiti community. The 2-D geospatial data of the features existing on the study area were acquired using the Total Station instrument to determine their planimetric positions in space. The planimetric positions were plotted using the AutoCAD 2007 software on a scale of 1:1500 to obtain the layout plan. Charts were produced from the analysis made to the variation in the sizes of plots and blocks, road lengths and the land use activity characterised with the layout, using Microsoft Excel software. Findings revealed poorly constructed temporal and permanent features in the community for appropriate attention. Results obtained from the analysis of the land use showed that the layout is 61% residential with commercial (29%), agricultural (7%), social (2%) and educational (1%) sharing the remaining space. The proof of Geomatics method as a tool for effective mapping, the achievement of the aim based on the results obtained and the plan produced was the conclusion of the project work. The sufficiency of the project work for Land Information System (LIS) applications and database creation, further work on the project area, archival in the department for record and research purposes were recommended.

Keywords: Detail Survey, Geomatics, Planimetric positions, land use activity, geospatial data

INTRODUCTION

Mapping survey are made to determine the locations of natural and cultural features on the Earth's surface. Once located, these features can be represented on maps (Ghilani & Wolf 2012). The results are used for planning, policy making and quality decisions for development. Detail mapping helps in the production of a plan (to scale) of an area of land showing all detail, natural and man-made. It helps to provide a record (in coordinate form) of detail within an area. It also aids in taking measurements to allow earthwork areas and volumes to be calculated.

Problem of the Study

Apatapiti, is a community characterized by various dilapidations and poor living infrastructural conditions. It lacks adequate information on what type of natural and artificial features exists therein. There is no record of comprehensive detail mapping (in large scale maps or geospatial data) available for decision or policy making for the development of the community. the North Eastern part of the community is seen as the fulcrum of the community with the lion share of the problem. Hence, the pursuit of this project to help in solving these problems.

Purpose of the Study

Considering detail mapping as being essential to the study area, the study aims at carrying out the detail mapping surveys of the North Eastern part of the community through the following objectives:

i. Locate existing property boundaries.
ii. To fix all the existing details within the project site.
iii. To provide the geospatial data.
iv. To produce corresponding plan and charts

Ogunlade, S. & Tijani, S. (2016). Mapping For Community Development: A Case Study of Apatapiti Community North East, Akure-Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1006-1010

v. To proffer various recommendations to help the authorities concerned.

STUDY AREA

North Eastern part of Apatapiti community is located at Akure South Local government area, Akure, Ondo State, Nigeria. It is bounded by Min. [050 08' 45''E, 070 17' 21''N] Max.[050 09' 03''E, 070 17' 29''N] geographic coordinates, and has FUTA south gate area to the North, FUTA main campus to the West, Aule community to the South and Alaba layout to the East. (Figure 1).

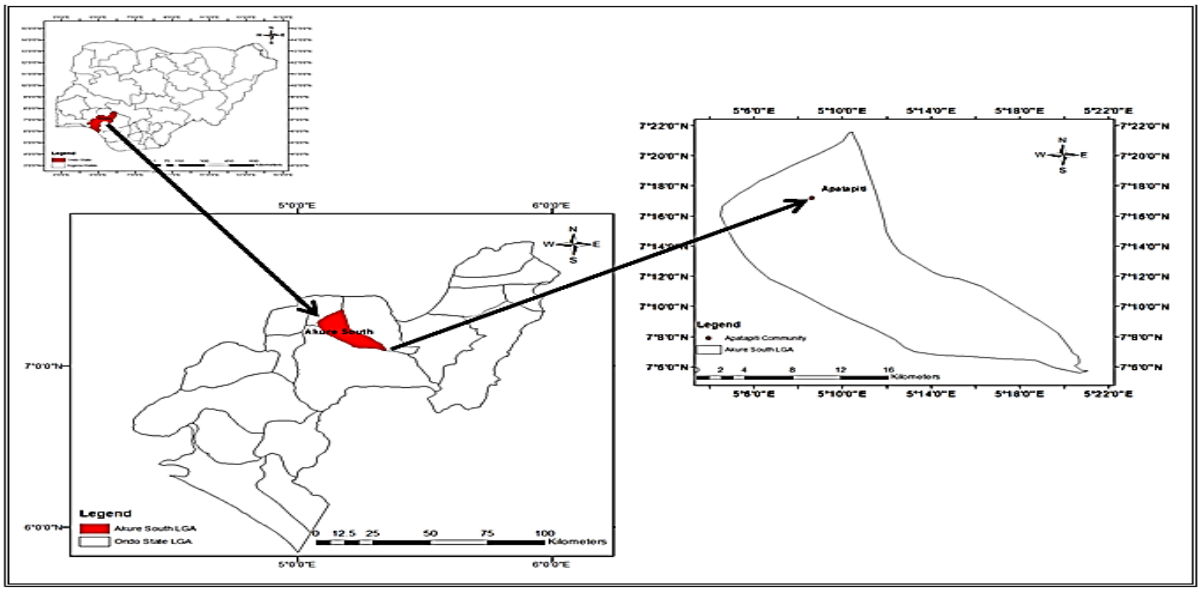

Fig. 1 Map of the study area

METHODOLOGY

Data

i. Downloaded coordinates from Leica (TCR 307) Total Station.

Software

i. AutoCAD 2007 software
ii. Leica Downloading Office Software
iii. Microsoft Excel.

Hardward

i. Laptop computer (Intel PIV DualCore, 500GB HDD,4GB RAM)
ii. Hewlett Packard Deskjet 9600 series and Laserjet 1120w
iii. Leica (TCR 307) Total Station and its accessories.

Data Acquisition

The data acquisition was achieved by carrying out the survey of the perimeter (boundary) of the study area, and the survey of the included details. These were performed sequentially using a Leica (TCR 307) total station instrument. The Total station instrument is equipped with a combination of Electronic Distance Measurement (EDM) and Digital Theodolite making it capable to combine angular measurements with distance measurement simultaneously.

The pillars used as control for the survey were checked and confirmed to be in correct angular and linear positions. A total of fourteen boundary stations were selected and a closed traverse was carried out on the stations to determine their planimetric coordinates.

All the details within the study area were fixed using the radiation method. Using the boundary pillars as reference, the edges/corner points of the objects/features in the study area were coordinated.

Data Processing

The 2-D geospatial data of the boundary points and the features existing in the study area were acquired to determine their planimetric positions in space. The planimetric positions were downloaded from the Total Station instrument using Leica downloading office software and these data were exported into AutoCAD 2007 software. These data were plotted on a scale of 1:1500 to obtain the layout plan, and thus the area of the study area was determined

Result Presentation

The results were presented in Tables (Table 1-3), Charts (Charts 1- 2) to explain the land use analysis of the community, and a large scale map (Figure 2).

Table 1: Features that were detailed

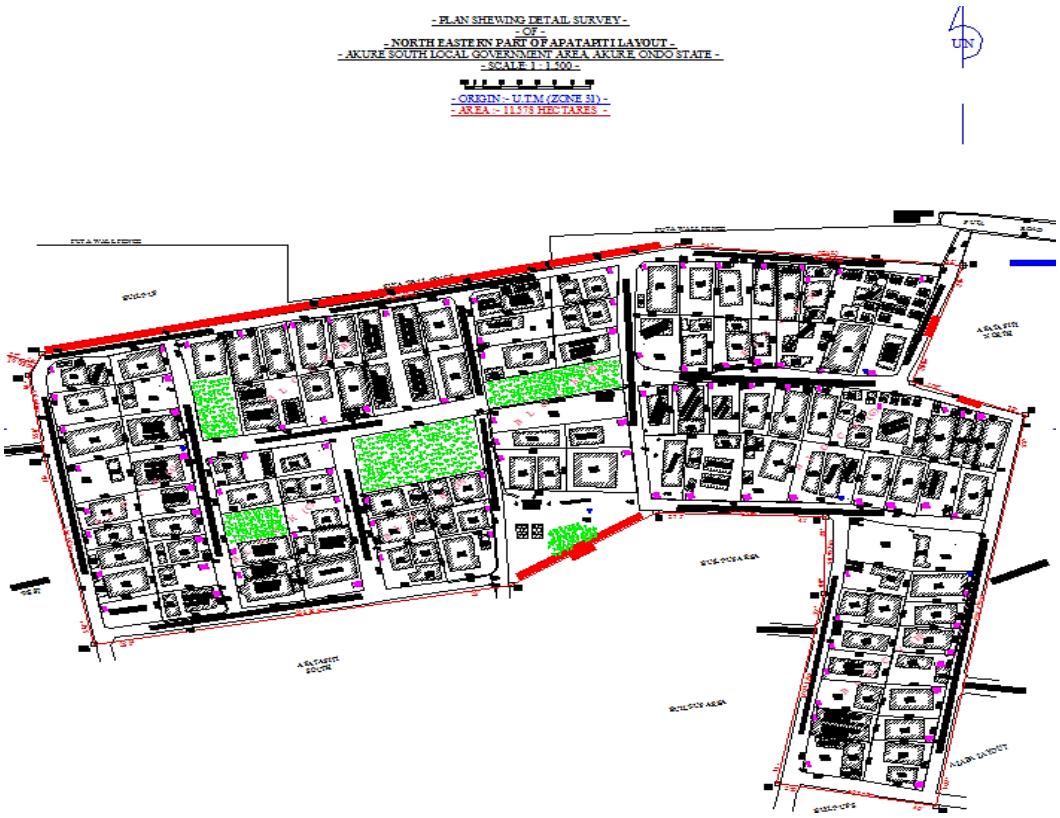

Figure 2: Produced Plan of the Community (Source: Authors' Work, 2015)

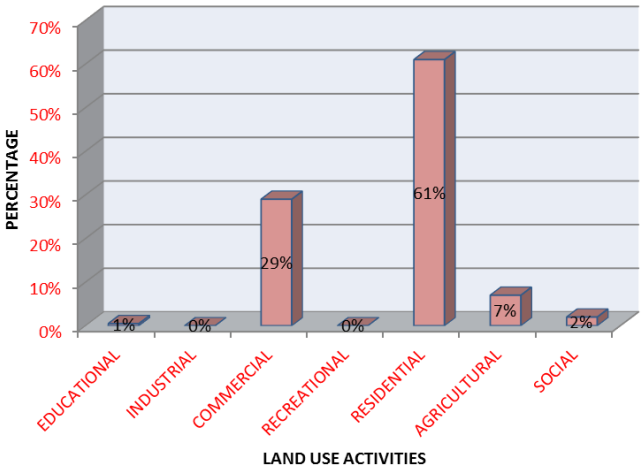

Chart 1: Land Use Analysis of the Community

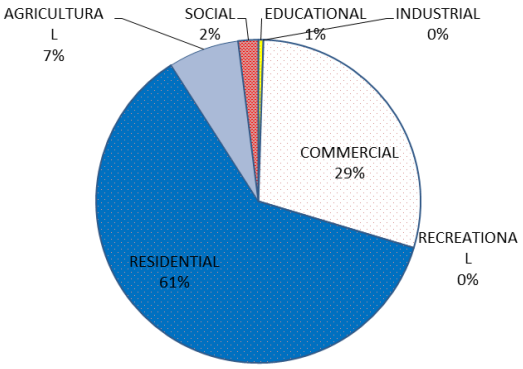

Chart 2: Land Use Analysis of the Community

Analysis of the Results

The result obtained from the study (Table 3, Chart 1 and Chart 2) showed that the total area covered in the study was 11.587 Hectares, the community is characterized with Residential (61%) as the major land use activity, Commercial, Agricultural, Social and Educational takes 29%, 7%, 2% , and 1% of the entire land use activities respectively, while the community has no Industrial (0%) and Recreational (0%) land use activity.

FINDINGS

The community is occupied by civil servants, students and commoners in descending order

i. Fish farming is common in the households
ii. There is incessant refuse dumping especially at the fish farming area which is a threat to health, fish farming and flooding/erosion.
iii. The community is full of poor conditioned roads and insufficient drainage system which can aid accidents, flooding and erosion.
iv. There is the absence of Street lights, which threatens the security of lives and properties of the community.
v. There is the absence of recreational activities in the community which is not too good for the health of the people and productivity.
vi. The absence of industries in the community is commendable due hazards to health which the presence can threaten.

CONCLUSION

Geomatics has proven to play an important role in the mapping of the study area mapping of the of the study area to reveal the prevalent condition therein and aid quality decision making for its development. From the findings, it is clear that the community is not in good infrastructural conditions, hence the need for serious and urgent attentions. From the analysis of result it is shown that the study area is majorly residential. The absence of industries in the community is adjudged to be commendable while the absence of recreational activities is not a welcome idea to the good living and productivity of the people.

RECOMMENDATION

The study has revealed the condition of the study area. It is recommended that the study be adopted as sufficient for a Land Information System (LIS) applications and database creation for the community.

Being a community mostly residential, provision of social amenities such as good roads, drainage system, street light, recreational activities etc., are very germane and need serious attention as a matter of urgency. Concerned authorities and agencies in various sectors: the Environment, Health, Town planning, Security etc. should through mapping survey (and various Geomatics methods) look into the conditions/problem of the community and other communities to proffer lasting solution for better living. The resultant Map is a tool to achieve this purpose

The study is also recommended for further research on communities for further development. The resultant geospatial data be archived for record and research purposes.

ABSTRACT

Nigeria has vast tourism components that could make her the leading tourism provider and compete with other tourist destinations globally. Numerous tourists' attractions spread across the length and breadth of Nigeria, ranging from places of natural attraction to historical heritage. In this paper, the research on the socio-economic impact of architecture on tourism development was conducted using Idanre Hills as a case study. Furthermore, the paper evaluates the socio-economic contribution of architecture on Idanre Hills and critically analysed the potentials of Idanre Hills; focusing on the impacts of architecture on the host community. The study adopted the quantitative approach of data collection, using questionnaires. Data collected were analysed using the Statistical Packages for Social Sciences tool. Results revealed that architecture and tourism are related and can contribute significantly to the host community by creating unique spaces using traditional materials and styles that preserve the cultural, social and environmental values.This in turn will help attract tourists and on the long run improve the economy of Idanre. The paper concludes that architecture will improve the economy as well as the life style of the people by attracting more tourists, as well as create a sense of place for the host community.

Keywords: Architecture, Nigeria, Tourism Development, Socio-Economic

INTRODUCTION

Tourism is identified as a fast growing activity all over the globe (Basu, 2003, Jennie, 2012) and widely acknowledged as a key driver of socio-economic progress. Over the years, tourism has become one of the largest and fastest growing economic sector of the world (UNTWO, 2015) with the assertion supported by the statistical data from regional, national and international tourism of United Nations World Tourism Organisation. Tourism, as defined by World Tourism Organisation, is an activity of persons travelling to and staying in places outside their usual environment for not more than one consecutive year for leisure, business and other purposes. Also, tourism is the study of people away from their usual habitat of the establishment that responds to the requirement of travellers and of the impacts that they have on the economic, physical and social well-being of their host (Wall and Mathieson, 2006).

The impact of tourism fall into three categories that include the economic, social and environmental impacts and these categories could be positive or negative (Mason, 2003, Cook, Yale, Marqua, 2006). Socio-economic impact is designed to assist communities in making decisions that promote long-term sustainability including a healthy community and social wellbeing (Chadwick, 1995).

Architecture comprises one of the unique opportunities that have affected major economic development in cities across the world, Olanusi (2015) opines that the impact of architecture in tourism is to create a friendly environment that attracts and appeals to the sensory-emotional instinct in man to want to see, appreciate and belong. Thus, this process will

Ola, O. A. & Ayeni, D. A. (2016). Socio-Economic Impacts of Architecture on Sustainable Tourism Development in Nigeria: Case Study of Idanre Hills, Ondo State. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1011-1018

generate and monumentally contribute to the social and economic development of man and the society.

Nigeria as a nation is endowed with both natural, historical monuments that can be tapped to aid the economic development of the country but according to Ayeni, Ebohon, and Taki (2009), the Nigeria tourism industry is" beset with numerous problems", which include lack of tourism supporting and enhancing infrastructures. Saheed (2012) argued that, the provision of tourism infrastructure is important to ensure proper tourism development and Nigeria need to consider quickly this to create a commitment to sustainable tourism developmentAs often said and to be effective, it needs the attention of all- the architect, planners and the society. However, Long (2012) pointed out that tourism development without proper planning and integration with local values and environment can lead to socio-cultural, environmental and economic damage. A more complete point of view can be provided by the concept of architecture and sustainability because it can help to ensure the development of the tourism sector and determine that the quality of life of future generation is not at risk.

Hence, the study explores the impact of architecture potentials in tourism development of the socio-economic base of Ondo State using Idanre hills as a case study.

LITERATURE REVIEW

Relevance of Architecture to Tourism Development

Architecture is defined as the practice of building design and its resulting products. Amole (2004) refers to architecture as being concerned with planning, design and production of buildings either existing or new and its role in which the Nigerian state seeks her rightful position in emerging 21st global economy cannot be overemphasized. Architectural elements are one of the categories demanded by tourists. However, care must be taken to protect the architectural and historical monuments of the region. Tourism is widely acknowledged as an effective tool for socio-economic development, because of the possible backward and forward linkages with the rest sectors of the economy, which allows it to facilitate employment opportunities, income, local economic development, and enhance the quality of life (Hall, 2007). Architecture and tourism are closely related activities that can be said to depend on each other. However, architecture regarding tourism is an integral element of the planning of any region, whether it is of cultural heritage or contemporary architecture. For the development of any destination, adequate and efficient infrastructure and access to tourist destination are of great importance.

As noted by Bullen et al(2011)), tourism development deals with infrastructural investment stimulation and as such, social amenities like road, airports, communication network, electricity, portable water and other social facilities should be improved in some of the communities where the tourist attraction facilities are situated. Since architecture is concerned with planning, Itayemi (2012) views that both the public and private sectors involved in tourism should depend on planning to achieve a tourism development that respects the host community, maintains the natural environment and delivers a quality tourist experience.

Planning is necessary for tourism to develop in a way that is beneficiary to the host community. The destination regions must have many values ranging from cultural, historical and even environmental in which it is necessary to be maintained to attract tourists. The majority of tourists are concerned about the destination in which they will spend their holiday. So, the natural environment of the host regions, their buildings and tourist institutions, their people, culture and history and other forms of tourist elements are what the tourists want to experience in the destination, (George, Mair and Reid, 2009).

Architecture and Sustainable Tourism development

The term sustainable development has been used by various individuals, researchers, organisations, forums and conferences and it all attempts to contribute to the quality of life and services, as well as, economic and social welfare for the future generations. The platform of Architecture in Tourism (2007) stated that high-quality architecture stands for sustainability and if well planned can be easily adapted to changing demands over time. Architecture has the talent of defining spaces and, therefore, has a powerful influence on the human behaviour and understanding, and this is exactly what is always taken into account in sustainability, maximizing economic benefit and preserving the ecosystem. Architecture acts through its qualities to achieve function and well-being Orientation, functionality and quality of space are hygienic factors indispensable for guest satisfaction Sustainable architecture with respect to indigenous cultural traditions and minimizing the negative impacts on the environment can unite the natural and built spaces and create a sense of place for the tourists. Also providing aesthetics, culture and special attractions can seriously save the technological and cultural aspects of indigenous environment. The idea of sustainable architecture is to cover tourism development and economic activities.

The World Commission on Environment and Development (WECD) defined sustainable development as ‘‘development that meets the needs of the present without compromising the ability of the future generations to meet their needs’’ (WECD, 1987). Hunter (2002) and Veneeva (2006) noted that although the concept of sustainable tourism is derived from the sustainable development, it is one of the pre-requisites of achieving sustainable development. According to the UNWTO (The World Tourism Organization), sustainable tourism can be defined as: "Tourism that takes full account of its current and future economic, social and environmental impacts, addressing the needs of visitors, the industry, the environment and host communities Also, London School of Economics and Political Science (2009) defines sustainable tourism as tourism development that avoids damage to the environment and cultures of the locations where it takes place. Sustainability principles refer to the environmental, economic and socio-cultural aspects of tourism development, and a suitable balance must be achieved.

Mowforth and Munt (2002) has argued and challenged the notion of sustainability and its relationship in the developing world that the growth of tourism offers a means for third world countries to escape the confines of underdevelopment. Sustainable tourism development meets the need of the present tourist and host regions while protecting and enhancing the opportunity for the future. It was envisaged by WTO (2002) as the management of all resources in such a way that economic, social and aesthetics needs can be fulfilled while maintaining cultural integrity essential processes, biological diversity and life support systems. Planning to promote human welfare, derived in part from the stock of economic, human and social capital and to maintain and enhance ecosystem services (Buckley, 2009).

Johnpaul (2013) has identified certain factors that need to be considered in order to achieve a successful tourism planning and sustainable development, and includes integrated planning by involving the stakeholders; Community Participation of the host community by bringing in their social, cultural values and economic problems; Proper funding by the federal or state government in order to improve the standard of living of the host community; Provision of tourism infrastructures such as electricity, pipe borne water, good road, good communication systems and accommodation, that enhance the sustainability of life, and sustainability in resource usage making sure tourism does not increase pressure on local resources. Idanre hills have great tourism potentials that can attract local and foreign tourists. Tourism in Idanre hills, Ondo state according to Itayemi (2012) is undergoing a total revamping and

transformation and this will contribute to the socio-economic development of the community, state and the country at large if well and properly developed.

STUDY AREA

The study was carried in Idanre hills in Ondo State. Ondo State generally referred to as the sunshine state is located in the south-western zone of Nigeria and was one of the seven States created on 3rd February 1976 by the then Federal Military Government of Nigeria. The state lies between latitudes 5°45′ and 7 °52′N and longitude 4 °20′ and 6 °5′E. The state is made up of 18 Local Government Areas, and is bounded in the north by Ekiti and Kogi States, in the east by Edo State, on the west by Osun and Ogun States and in the south by the Atlantic Ocean (Ogunbodede 2007, Francis 2012).

Background of the Study Area

Idanre hills (Oke Idanre) which is about 24 kilometres away from Akure the capital city of Ondo state has been the home of the Idanre community for almost 100 years. Idanre hill is one of the awesome and beautiful natural landscapes in Ondo State and Nigeria (Itayemi, 2012). According to UNESCO (2007) Idanre hill consists of high plain with spectacular valleys interspersed with inselbergs of about 3000 feet above sea level and the vegetation has diverse and variegated ecosystems of flora and fauna. Its physical attributes include the great 660 steps, guest chalets, Omi Apaara (thunder water), Aghagha hill (Orosun peak), old court, burial mounds and ground, Owa's palace, shrines, belfry, Agboogun foot print on the rock, strange inscriptions on one of the gigantic rocks, Arun river, and Ark of Noah. As narrated by Adisa (2010); Itayemi (2012); Adeniran (2012) and Oluwole (2013) the great 660 steps laid in concrete along the sides of the hills lead to a pleasurable adventure to the intriguing wonders of the hill, the ancient king's palace is believed to have been built in the seventieth century. The palace commands unique features, which possesses architectural value. Within the palace are the ancient clangs and designs of various types which symbolize customs and culture of ldanre people and the Yoruba at large.

The footprint of a great ruler of ldanre (Oba Agboogun) is also on the top of the hill. The Oba then invoked his power into the foot on soft eruption (Lava flow). This left behind a footprint on the rock. It is widely believed that any size of foot, either big or small is bound to be accommodated by the print. It is believed that the footprint changes invisibly in shape and size but anyone whose foot could not be accommodated in the footprint are either a witch or wizard. The position of this print on the hills is not easy to locate. The writing on the rock is strange and clumsy that no one has ever understood it's meaning, even when it is conspicuous. In the recent time, those letters are becoming invisible to the naked eye. It was also gathered that Archaeologist believed that the writing must have taken place before the eruption. This is a symbol widely believed by the people of Idanre to be the famous Ark of Noah in the Bible. History is yet to ascertain or denies the authenticity of this believe. However, the awe inspiring object is fascinating enough to attract first time visitors for a second visit to the tourist centres. The traditional Idanre people have a rich cultural heritage.

Till present day, the Idanre people in their different ages still go up to the hill to celebrate some traditional festival where traditional intercessions are rendered for the peace and progress of the community. One of the notable festivals include the Orosun festival which is the remembrance of one of the heroines or historical figures in Idanre and is one of the major factors for Idanre's consideration as a UNESCO Heritage Site and the Mare festival which is a recent creation of the Ondo State Government that involves mountain climbing annually. According to Okong-Ekong (2015) and Obinna (2015), the newly built hills resort at the foot of the hill is an eco-friendly blend that amplifies the heritage of Idanre. Amongst the facilities built at the foot of the hill are the resorts traditional welcome (Ekaabo), tree houses, houses

on the rock (Ile oriota), food sheds, children's playground, wadii(for plaiting hair), swimming pool, office complex and fully serviced apartments (three and two bedrooms ensuite). The hills resort has hosted a number of guests during the 2014 Mare festival and has continued to attract patronage from the town's residents and tourist.

METHODOLOGY

The study adopted the quantitative method of data collection and used the survey research design. Copies of the questionnaire designed for this study were administered by the researchers between the months of May to July 2015. They were duly completed and collected from the respondents.

Close ended questionnaires divided into five sections A, B, C, D, E were used for the study. Respondents were chosen by random sampling from the study area and some parts of Akure and were required to respond to a four-point scale ranging from 4 strongly agree to 1 strongly disagree. A total number of one hundred and fifty (150) copies of the questionnaire were distributed to randomly selected respondents comprising of tourists, the staff of Idanre Resort Hill, the residents of the case study area and other respondents in some parts of Akure. This method enabled each of the respondents to have an equal chance of being selected as a representative of the total population. The one hundred and fifty (150) questionnaires were duly completed and returned. These responses, however, constituted the source of data used for this study and data analysed using the Statistical Packages for Social Sciences (SPSS) and results expressed in simple percentages and standard deviation.

FINDINGS AND DISCUSSION

Respondents Characteristics

Analysis of data using the SPSSx shows that 59.3 percent of the respondents were male while 40.7 percent were female and implied that majority of the respondents were male. The majority of the respondents were within the age bracket of 18 to 50 years accounting for 85.3 percent of the total sample size while those above the age bracket of 50 years accounted for 14.7 percent. Furthermore, 36.7 percent of the respondents were single, while 59.3 percent were married, 3.3 percent were widowed and 0.7 percent of the sample size did not respond.

Also, the educational status of the respondents showed that 2.0 percent of the respondents had no formal education and needed assistance with the questionnaire, 5.3 percent were primary school holders, 22.0 percent were secondary school holders, and 64.0 percent were well educated to be tertiary holders, while 6.7 percent of the respondents held other professional qualifications. A total of 44.0 percent of the respondents were government workers; 28.0 percent were private workers while 19.3 percent were students and 8.7 percent were farmers and artisans. The range of income accounted that 52.6 percent of the respondents earned between N18,000 and N100,000, 42.7 percent earned between N100,000 and N250,000, and 4.7 percent did not respond to the questionnaire. The respondent's characteristics revealed that all stakeholders are represented in the sample.

The role of Architectural Facilities within Idanre Hills

Respondents were asked on their perception generally on architectural facilities. This was asked to find out if they were adequate and whether or not improvements are needed. From the literature review, according to Bullen et al (2011) provision of adequate or improvement in the architectural facilities is important in a tourist attraction. As revealed in Table 1, about 16.0 percent (24) of respondents strongly agree that architectural facilities of Idanre Hills are not well developed and if improved will make the attraction unique and attract more tourists. Also, 52.0 percent (78) agree. Also, 2.0 percent (3) strongly disagree while 4.7 percent (7)

disagrees and 25.3 percent (38) did not respond. It implies that 68.0 percent agree that architectural facilities are of great importance in a tourist destination.

Creating a lasting impression on tourists

The respondents' view in line with the above was asked to know if the building types and recreational facilities would create memories for them to visit the tourist destination again. Ascertaining the findings from the literature review, the host regions buildings and facilities are the important elements tourists want to enjoy and experience. From the analysis in Table 2, 12.0 percent (18) strongly agree that type and quality of the building and recreational facilities will create a lasting impression on tourists, also, 60.0 percent (90) agree. Also, 2.0 percent (3) strongly disagree while 1.3 percent (2) strongly disagrees and 24.7 percent (37) did not respond. The total respondents that agree to this notion, therefore, are 72.0 percent, and this reveals that tourist wants to appreciate what attracts their sensory emotions to visit any tourist destinations.

Table 1: Showing the Role of Architectural Facilities within Idanre Hills

	Frequency	Percent	Valid Percent	Cumulative Percent
Strongly agree	24	16.0	16.0	16.0
Agree	78	52.0	52.0	68.0
Disagree	7	4.7	4.7	72.7
Strongly disagree	3	2.0	2.0	74.7
No response	38	25.3	25.3	100.0
Total	150	100.0	100.0	

Table 2: Showing Creating a Lasting Impression on Tourists

	Frequency	Percent	Valid Percent	Cumulative Percent
Strongly agree	18	12.0	12.0	12.0
Agree	90	60.0	60.0	72.0
Disagree	2	1.3	1.3	73.3
Strongly disagree	3	2.0	2.0	75.0
No response	37	24.7	24.7	100.0
Total	150	100.0	100.0	

Socio-economic Impact of Architecture on the Host Community

Again respondents were asked to know whether architecture impacts on their socio-economic wellbeing or vice versa. Table 3 revealed that 36.0 percent (54) strongly agree that architecture is a strategy for socio-economic impact on the host community and 32.0 percent (48) agree. Also, 2.7 percent (4) strongly disagree while 4.0 percent disagrees and 25.3 percent (38) did not respond. It therefore implies that a total of 68.0 percent of respondent agree that architecture development in Idanre Hills will contribute immensely to the Idanre community. The findings from the respondents revealed that the presence of accommodation and catering facilities within the Idanre Hills will impact greatly on the socio-economic activities within the community.

Table 3: Showing Socio-economic Impact of Architecture on the Host Community

	Frequency	Percent	Valid Percent	Cumulative Percent
Strongly agree	54	36.0	36.0	36.0
Agree	48	32.0	32.0	68.0
Disagree	6	4.0	4.0	72.0
Strongly disagree	4	2.7	2.7	74.7
No response	38	25.3	25.3	100.0
Total	150	100.0	100.0	

Tourist Centres Should Be Maintained To Ensure Sustainability and Continuity

Also, questions were posed to the respondents to know if the use of sustainable local resources and proper planning or maintenance of infrastructure would enhance tourism continuity and development. Table 4 revealed that 41.3 percent (62) strongly agree that

tourist centres should be maintained to ensure sustainability and 58.7 percent (88) agree. It, therefore, implies that a total of 100.0 percent of respondents agrees to the data in the table that sustainability and continuity of the tourist centres will be ensured through maintenance. Also, the views of the respondents validate the fact that tourism and sustainability deal with adapting to change over time and it also requires constant maintenance to ensure its growth.

Table 4 Showing: Maintaining of Tourists' Centres to Ensure Sustainability and Continuity

	Frequency	Percent	Valid Percent	Cumulative Percent
Strongly agree	62	41.3	41.3	41.3
Agree	88	58.7	58.7	100.0
Total	150	100.0	100.0	

Based on the analysis, findings shows that sustainable tourism can be achieved through architecture if there is proper planning, maintenance, enhancement and provision of tourism infrastructure to improve the social, economic and cultural well-being of the community in which historical monuments is sited.

The Findings generally revealed that there should be more provision, rehabilitation and maintenance of tourist chalets, and other infrastructural facilities on the Oke Idanre to make it habitable to tourist and develop tourism within the host community. Furthermore, the government should ensure provision and maintenance of these infrastructural facilities to allow for full exploration of the touristic value of Idanre Hills. This corroborates the findings from the literature review that provision of accommodation and other tourism facilities is a key factor that impacts on the economic, environmental and social development of the host community.

As also observed from the analysis, the type of buildings and recreational facilities create an overwhelming impact the tourist wants to experience and share. It creates repeated memories the tourists would like to experience. As noted in the literature review, tourists love to explore and experience the destination tourism environment, monuments, culture, and other elements found within the tourism sites. However, there should be proper maintenance of recreational and building elements to ensure sustainability and promote tourism and improve on the tourist's visits within the host community

Furthermore, tourism has conserved the local cultural heritage, architectural traditions and ancestral heritage of the host community and allows cultural interaction with the tourists. Also, the development of tourism has provided employment opportunities such as tour guides, restaurants, transportation, since tourism is known to be a labour intensive industry and to improve the living conditions of the people of the community and also generate revenue to the government. This was revealed from the literature review that tourism development is seen as an important aspect in regards to the improvement in the quality of life. Therefore, the government should encourage and contribute immensely to tourism development in the community.

Findings from the literature review, reveals the use of sustainable local resources, planning and maintenance of these facilities would be of great benefit as it acts to meet the needs of the present and future generation. Therefore, sustainable tourism and promotion of tourism development through management and maintenance of the tourism infrastructure and sector should be encouraged. As further discussed in the literature, architecture through the efficient planning of resources and spaces, provision of adequate infrastructural facilities will minimize the negative impacts of tourism in the environment and ensure sustainable tourism development to meet the needs of the host community and future generations. Thus, sustainable architecture acts to preserve the tourist environment by influencing the use of

available resources to improve the socio-cultural heritage and economic values to promote and facilitate tourism development.

CONCLUSION

Based on the discussions in this study, it could be deduced that architecture can be considered as an effective means of connecting sustainable tourism through strategic planning, provision of infrastructure and local use of local sustainable materials since design and planning of spaces in the tourism industry are built by architects. Architecture will impact positively through the creation of skilled and unskilled jobs in areas of accommodation and catering facilities. As such will be a valuable source of employment and will serve as additional source of revenue and foreign exchange for the state and community in general. Furthermore, the relationship between sustainable tourism and architecture attempts to create unique spaces using traditional materials and styles, and it preserves the cultural, social and environmental values. The government needs to support and develop the tourism sector to achieve a fulfilling future of sustainable tourism.With this in mind, it would be highly essential to consider the effects of architecture in creating opportunities in the tourism industry to attract more tourists and create a sense of place for the host community.

ABSTRACT

Major damages and gradual annihilation of the natural landscape have resulted from continuous human settlement and interaction with the natural environment. This has also had an enormous catastrophic effect on the existence of both the built environment and the natural landscape. This paper examines the use of recreational open spaces either publicly or privately owned through questionnaire administration in LSDPC Estate, Lekki in Lagos Nigeria. It affirms that the use of these spaces in planned residential estates is fast becoming an increasingly important part of people's lives thus demanding more free time and greater prosperity to enable them extend their free time activities. It further explores the awareness of respondents' to the effects of the existence of these spaces on city aesthetics. It opines that if well managed, these recreational open spaces will go a long way in improving the general aesthetics of the city and will prove sustainable where various policies are put in place. Expected outcomes of these policies implementation would include the encouragement of relaxation activities, communal interaction and organization, encouragement of active and healthy lifestyles, preservation and use of leftover land which otherwise would have developed blight. It asserts that the need for an improvement in the built environment can be reasonably achieved through effective collaboration between stakeholders in the building construction industry, the citizens and government agencies, and proffers ways in which recreational open spaces can be made an integral part of a sustainable, aesthetically pleasing and healthy environments in Nigeria.

Keywords: City Aesthetics, Blight, Open Spaces, Stakeholders and Sustainable

INTRODUCTION

A number of the low-cost housing estates built by the Lagos State Government in the 1980s have gradually deteriorated to the extent of becoming nightmares to their occupants and people who toured the estates. Varied findings have shown that lack of maintenance and failed infrastructures have eroded the foundation of many of the buildings which should be awaiting demolition but are still being occupied. The Government of Alhaji Lateef Jakande in Lagos State initiated the low-cost housing scheme in 1980 to cater for housing needs of the populace especially workers in the state. As a result, many people grabbed the opportunity to become home owners at a take away price of N3, 000 with repayment plan of 15 years, not knowing the houses would become a source of headache to them many years after. Not left out of this deterioration are the recreational open spaces within them.

Goudie (2000) articulates that; "*Open space is a tribute to the commitment of residents and professionals to an excellent environment and the natural legacy of increasing value."* Recreation activities are those carried out with leisure, usually chosen voluntarily by the participant either to derive satisfaction or pleasure. It can also be a creative enrichment based on the perception of one's personal or social values. Recreation deals with important matters of many and varied leisure- time activities, including development of skill in recreation activities, participation in competitive and non-competitive games, free play, improvement in health and social interaction, to name a few (Ulrich, R. (1983); Riley, (1992); Malakoff, (1995). These phenomena have resulted in several situations that will be subsequently discussed in this paper.

LITERATURE REVIEW

Recreational Open Spaces in Planned Housing in Lagos state, Nigeria

With a very diverse and fast-growing population of 13,427,000 (2000 census estimate) and as a result of unending migration from the rest of Nigeria and neighbouring countries, Lagos, is characterized by its mostly unfettered and fast growth. However, Obia 2010 states that Lagos is already a megalopolis (Urban Planet: Collective Identities, Governance and Empowerment in Megacities, 2010) with a projected population of 24 million persons by 2015. Metropolitan Lagos became the pre-eminent city in Nigerian system, functioning as the political and administrative capital of Nigeria following the amalgamation of the Northern and Southern provinces of Nigeria in 1914 through political independence in 1960, until the federal capital officially moved to Abuja in 1990. This change in seat of power notwithstanding, the continued astronomical population growth lent credence to the decision of several past governments to make housing provision for the citizenry priority of sorts (lagosstate.gov.ng 2009).

The use of recreational and communal spaces either publicly or privately owned is fast becoming an increasingly important part of people's lives both locally and globally thus demanding more free time and greater prosperity that has enabled them extend their free time activities. However, a challenge in creating and maintaining successful public spaces is how to achieve an integrated approach, which includes design and management set within the broader context of urban policy (Shaftoe, 2008).

Going by the aforementioned, one can decipher that the terms green space, open space, open public space and recreation space all refer to spaces that are left for the purpose of leisure, relaxation and or recreation which have environmental benefits for the public wellbeing of the citizenry. In this study, these terms will be used interchangeably throughout this thesis and they refer to those reasonable larger open spaces not limited to children's play spaces, public open areas and green areas within residential neighbourhoods. The implementation and subsequent sustainability of the environmental benefits and their management of these spaces in the future is the focus of this research.

The Human Desire to Enhance the Living Environment

It is very significant that for over 11 centuries, humans have chosen to devote time and resources, including water to establish and maintain turf grasses in landscapes for a better quality of life. While this desire to enhance the living environment may exist worldwide, it has not been attainable in those regions where people must spend all of their waking hours in pursuit of food, fibre and housing to survive.

Countries that have industrial as well as agricultural employment can generate sufficient financial resources, enabling individuals to afford to improve their living environment with landscape plants. Studies around the world have consistently observed that countries with extensive urban landscapes, including lawns, trees and shrubs, also have associated with them a dominant population with a relatively high productivity rate. In addition, people in these places interact more harmoniously than people who live in areas that are seriously deficient in using landscapes to improve the quality of life.

Unlike the prevailing circumstances in advanced countries, the urbanization process as studied by Aluko (2011); Jiboye (2011) resulted from rapid industrialization which consequently altered the physical makeup of the cities, while in Nigeria, it is consequent upon the rural – urban migration between the village and the city. These have inadvertently posed the challenge of different socio-economic, cultural and environmental problems which have necessitated efficient and superior governance in a bid to surmount the problems. Daramola and Ibem, (2010) opine that, several factors have been traced to the pitiable condition of the Nigerian environment, prominent among them is poor environmental management practice

which have led to poor quality of the environment in urban areas. However, Arigbola (2008) maintains that adequate planning and control is needed to ensure harmonious development considering the rapid rate of urbanization and constant demand for land for different purposes.

City Aesthetics and Urban Blight

In the absence of any significant affordable housing strategy by the State government, citizens have continued to explore different approaches to accommodate themselves. The urban poor, who are dominant in Lagos, are transforming the city to meet their needs, often in conflict with official laws and plans. They reside in the slums and squatter settlements scattered around the city and are predominantly engaged in informal economic activities which encompass a wide range of small-scale, largely self-employment activities. 60% of residents are tenants and have to pay rent as high as 50-70% of their monthly income since most of the existing accommodations are provided by private landlords (Aluko, 2011). Most housing decay and deterioration comes in various forms and their existence is more evident in densely populated parts of the city. Some of the characteristics of slum include inadequate and deficient facilities obsolete buildings, filthy environment, etc. Much concern has been shown about the problems of the slum areas particularly on the level of decay exhibited by such areas and the plight of the low income households which dwell in them, this put lives and health of the residents in danger.

METHODOLOGY

Data and information collected from both primary and secondary sources were adopted for the study. Primary data were collected through physical investigation of the estate. The intention of this study is to assess the existing situation in the selected areas of Lagos and produce a model for future research on the use of sustainable urban open spaces. For this study on city aesthetics and sustainable recreational open spaces in the planned residential estate, questions were drawn up to appraise the aesthetic impact of these spaces on the estate while the general information on the study area was collected from literature.

The Study Area

The study area, Lagos, is in the South-Western Geo-political zone of Nigeria (Fig. 1). It is known for the sub-equatorial climate and receives a high annual rainfall of over 1,520mm (Adelekan, 2010). Lagos State is located approximately between longitude 2^0 42`E and latidudes 60 22`N and 60 52`N.

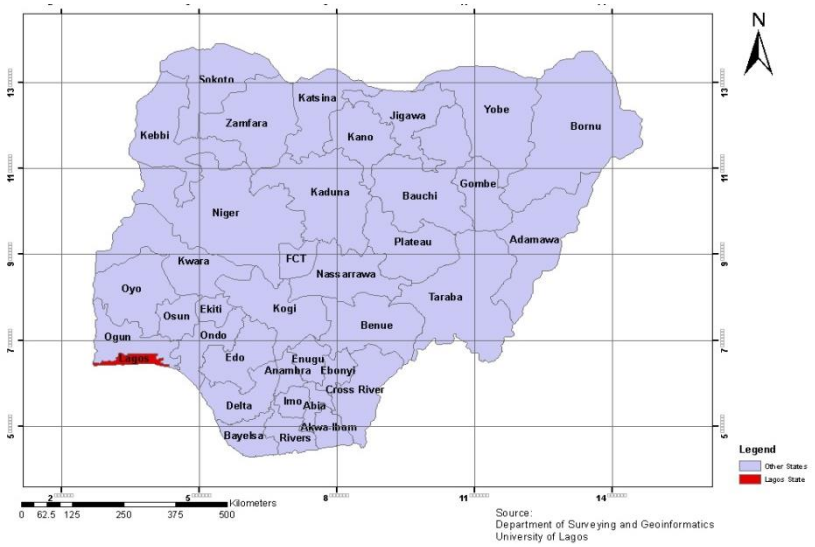

Fig 1.0: Nigeria highlighting Lagos State
Source: Department of Surveying and Geoinformatics, University of Lagos.

Though the smallest in the country, the state has an annual population growth rate of about 13.6% (about 5 times as fast as the national growth rate of 2.8%) (Adelekan, 2010). It is Africa's second fastest growing urban centre after Cairo, being a focal point for regional, national and international trade and served by significant and often overloaded road, rail, ocean and air transport facilities (Aluko, 2011).

Secondary data relied heavily from the LSDPC office as well as relevant information from related studies that had been carried out previously on the estate. The data were presented in tables on the state of the recreation spaces within the estate, their aesthetic properties as well as their impact on property value of the estate. Implications of blight, slum development among others were addressed in this section.

The low-cost housing estates built by the Lagos State Government in the 1980s have become nightmares to their occupants and people who toured the estates, reports that lack of maintenance and failed infrastructure have eroded the foundation of many of the buildings which should be awaiting demolition but are still being occupied. One of these, the LSDPC, Lekki Estate is the focus of this study.

FINDINGS AND DISCUSSIONS

Population and Structure: Settlement at the LSDPC low cost housing estate scheme Lekki is nucleated. The buildings are divided into various sections, each of which has the buildings in clusters. The estate consists of 125 blocks of 6 units all housing 4080 people on the average. The building types in all other sections are all similar except the ones in the Q-block which are of a different type. No single recreational open space could be found to still exist in its original form.

Social Economic Characteristics: After several visits to the site, the study found that the community has become an eye-sore and above all, the dangers posed by the delicate appearance of these buildings, recreational open spaces and the general estate atmosphere is better imagined. However, if information that the government is planning relocation for residents of the estate is anything to go by, the Lekki Jakande Estate might just be one of Alhaji Lateef Jakande's legacies of low cost housing to fall.

Plate 1.0: Showing state of road and conversion of recreational open space to other use.

The study reveals that residents of the estate comprises of construction workers that work on the Lekki-Epe Expressway, several members of staff of the Lagos State Government among others. However, over 70% of respondents are not the owner occupiers and could not provide some questions pertinent to the study. Majority of the womenfolk are petty traders who run small scale businesses within and outside the estate. Other trades such as barbing, shoe making are common in the estate. These small businesses form the hub of activities within this estate.

Table 1: Recreation participation level of LSDPC, Lekki residents based on a 5-point scale (Most frequent, Frequent, Indifferent, Infrequent, Never)

Socio-economic Activity	Cumulative Mean	Valid Percentage (%)
Outdoor		
Gardening	28.2	13.252
Walking	67.1	31.537
Driving for pleasure	16.2	7.614
Jogging	19.4	9.118
Bicycling	16.7	7.849
Ball games (football, handball, volleyball)	24.6	11.562
Resource Based		
Picnicking	12.2	5.734
Swimming	20.0	9.400
Community School Programs	14.1	6.768
Going to Movies	1.90	0.893
Indoor		
Reading for Pleasure	59.2	27.824
Watching Television	46.2	21.714
Visiting Friends	**35.2**	**16.344**

The above data in Table 1 clearly shows that indoor activities have the highest rating for recreation and this is closely followed by walking, the outdoor activity chosen by 31.537% of the respondent population. This indicates that level of participation in resource based activities is not as high as both outdoor and indoor activities. During the interview, respondents were asked the reason for this and they all cited the non-existence of such recreational open spaces in the whole of the estate. They further stated that the efforts of the resident association to appeal to the estate authorities had proved abortive.

Plate 2.0: Showing conversion of recreational open space to other uses.

However, a gross mismanagement of the estate roads, infrastructure and facilities are evident and as attested to by respondents and the site visits see plate 3.0 and 4.0 below. Refusal to comment by officers of the LSDPC as at the time of questionnaire administration contributed to a dirge in information retrieval.

Plate 3.0: Showing indiscriminate waste disposal along perimeter wall of a commercial facility

The above plate 3.0 shows how the environment is being defaced by indiscriminate and unlawful dumping of refuse. The residents further substantiated that the most of their efforts at sanitation had proved abortive especially without the backing of the estate management.
During the interviews that were conducted, respondents identified several causes of slum and blight in the estate. They are the following:

i. Overcrowding
ii. Neglect
iii. Unplanned development
iv. Lack of infrastructural facilities
v. Improper disposal of waste

Plate 4.0: State of open space being used as refuse dump disfiguring the aesthetics of the landscape

Commercial activities are the main hub of the estate. They provide much needed income for the residents and give support to the community's development by paying their levies to the Community Development Association (CDA) albeit unwilling but they and a few residents are the only people keeping the estate from total degradation. However, the presence of many dump sites defeats the input of commercial activities. In addition to this is the conversion of the open and recreational spaces within the estate into shoddy accommodation for the very low income earners in the estate.

Plate 5.0: High congestion of poor building structures (shanties) on undeveloped estate land

The estate has a variety of commercial activities that take place as well as petty trading. The popular Lekki beach in Lagos which draws tourists from far and near and is one of the symbolic sites in Lagos is located right behind the estate; it thus doubles as a recreation resource for the people of the area.

The state in which the estate is in prompts one to ask questions about the activities, efficiency and relevance of the Lagos State Property Development Corporation (LSPDC), the developer of the Jakande estates. Interestingly, it is gathered that rents in the estate are not too far from

the Lekki standard. A Landlord in the estate, who chose anonymity revealed that, depending on location, rents still dangle between N100, 000 and N150,000. According to him, areas that are not prone to flood rent rooms as high as N200, 000.

Table 2: Effect of age and Number of Children at Home on Average Participation Level in Recreation. (1-Never, 2-Sometimes, 3-Often)

Number of Children at Home	Below 25	Age group(years)		
		26-45	46-65	65 +
0	0.90	31.70	8.20	3.25
1	13.9	57.40	16.10	2.20
2	7.53	75.70	18.30	1.15
3	3.90	91.80	31.70	1.00
4	**9.60**	**12.20**	**19.60**	**0.83**

Table 3: *Effect of Educational status or Attainment on overall recreation participation (1-Never, 2-Sometimes, 3-Often)*

Education Attainment	Number of respondent	Average Participation	Valid (%)
Primary School	21	0.140	14.00
Secondary School	36	0.255	25.50
BS.c /H.N.D	45	0.319	31.90
Higher Degree	15	0.106	10.60
Other-Trade, Skill.	**24**	**0.170**	**17.00**

Table 2 showed clearly that presence of children could affect recreation patterns in families. The family with the lowest and highest number of children had a higher participation level. Table 3, show that most respondents are averagely educated and belong to the middle age, who actively participate in outdoor recreational activities such as walking, playing organized sports and the likes, although facilities for these outdoor recreation activities are not available in the area yet people still found means of recreating themselves.

The "rereation orientation" analysed in this study represents a mid point between the analysis of specific activities and that of overall participation, for LSDPC Lekki Estate residents. The study found that indoor recreation activities generally was the second most popular, no doubt becuse they can be practiced through out life and without regard for seasons. Participation in recreation can be heightened by increasing the educational status of people, creating their awareness to the importance of recreation and its health benefits on the human body.

CONCLUSION

This report describes the existing situation at the LSDPC Low Cost Housing Estate, Lekki. It has highlighted the absence of recreational open spaces within the estate. It describes how to go about selecting and protecting recreation space areas. It suggests employing a variety of tools and resources to fully accomplish the job. It also notes that there are issues that local communities will face as they struggle to build a recreation system.

To be effective, the report emphasizes that recreation spaces must be an integral part of the overall planning effort. Equally important is the concept of linking together a variety of recreation space types into a coherent system of open space. Such a system of open space takes on a greater value than just the sum of its individual parts. The recreation space system will succeed in meeting the needs of community residents when it is based on a vision that they helped to shape.

Acquiring or protecting open space areas and constructing facilities represent only the first step in the conservation and protection of land and resources. It is a community's ongoing commitment to land stewardship that ensures its continued enjoyment of recreation space benefits.

Sequel to the foregoing, the government, individual property owners, and the town planning authorities should play their individual and constitution role under to eradicate their slum development in the study area, hence put a stop to nuisance and environmental degradation and other circumstance associated with it, so that the area can develop into an environment free from dirt and blight and that brings rise to the saying "A healthy environment, a wealthy people".

RECOMMENDATION

For any housing estate to have sustainable recreational open spaces that would improve city aesthetics, several facilities and management strategies need to be put in place. The use of development plans have tended in the past to emphasize detailed quantitative standards, but there is now an increasing focus on the quality of public open space, which ensures that the reasonable expectations of users are more likely to be fulfilled. Qualitative standards include:

• Design: The layout and facilities should be designed to meet a range of user needs, including both active and passive recreation, as identified in the planning principles above. Users should feel safe at all times within parks; adequate supervision, passive surveillance, boundary treatment and public lighting contribute to creating a sense of security. Public open spaces should be suitably proportioned; narrow tracts or 'left over spaces' which are difficult to manage should not be acceptable. Materials should be chosen for their durability.

• Accessibility: Estate recreational areas should be located to be within not more than 10 minutes' walk of the majority of homes in the area; the parks should be on public transport routes as well as pedestrian/cycle paths. Playgrounds should be carefully sited within residential areas so that they are both easily accessible and overlooked by dwellings, while not causing a nuisance to nearby residents.

• Variety: A range of open space types should be considered having regard to existing facilities in the area and the functions the new spaces are intended to provide. A balance will be required between the provision of active and passive recreational facilities.

• Shared use: The potential for maximising the use of open space facilities (such as all-weather pitches) should be explored, for example, by sharing them with nearby schools.

• Sustainable Urban Drainage Systems are often used to reduce the impact of urban runoff on the aquatic environment.

Most planning authorities include quantitative standards for public open space in their development plans, generally in the range of 2 -2.5 hectares per 1,000 population, and allocated according to a hierarchy of spaces. Assessing open space requirements on a population basis can be difficult due to the unpredictability of occupancy rates where often larger houses and apartments are occupied by fewer persons than the number of bed spaces would indicate.

ABSTRACT

Access to a secure, safe and sufficient source of fresh water is a fundamental requirement for the survival, wellbeing and socio-economic development for all humanity. The challenges face by the Lagos State Water Cooperation (LSWC) is to ensure continuous water supply for her citizen. In spite of this effort to rescue the situation, a substantial proportion of the city's population are yet to be served with water from the main source. One of the major challenges in water supply is the provision and management of the pipe network and the associated assets. Effective functioning of these assets is necessary for distributing water continuously and efficiently. The methodology for this research work was data acquisition, geo-referencing and digitizing, data integration, data analysis and manipulation, data display as maps, charts and tables. Analysis and result for this research works shows that LSWC is made up of 22 Project Control Units (PCUs), from which analysis shows that population is higher than water supply in Lagos West, Owode, OluteKirikiri, Ajegunle, Victoria Island, Itire among other. Water supply as regard to population ranges between 0 – 0.94 g/c/d whereas on the other hand, water supply is higher in Iseri Oke, Isolo, Shomolu, Surulere, Yaba and Lagos/Ikoyi ranging from 1.09 – 8.71 g/c/d. The study shows that water is in short supply and with the use of a GIS software has showed the expected water supply within Lagos Metropolis. Some of the factors that have been identified as important controls on water demands in the study area include increase in population, increase standard of living and purchasing power, changes in social tastes and policy decisions. Unfortunately, LSWC is unable to meet the growing water demand of the people due to: inadequate water facilities such as network distribution, water works (reservoirs), inadequate power supply, poor state of some of the equipment, reckless over-consumption and misuse of water amongst others.

Keywords: GIS, Water Pipeline and Primary and Secondary Network

INTRODUCTION

A Geographic Information System (GIS) is a system designed to capture, store, manipulate, analyze, manage, and present all types of spatial or geographical data. GIS applications are tools that allow users to create interactive queries (user-created searches), analyze spatial information, edit data in maps, and present the results of all these operations. GIS is a broad term that can refer to a number of different technologies, processes, and methods. It is attached to many operations and has many applications related to engineering, planning, management, transport/logistics, insurance, telecommunications, and business. For that reason, GIS and location intelligence applications can be the foundation for many location-enabled services that rely on analysis and visualization.

Water is very important to the world, is a precious natural resource, vital for life, development and the environment. It can be a matter of life and death, depending on how it occurs and how it is managed. When it is too much or too little, it can bring destruction, misery or death. Irrespective of how it occurs, if properly managed, it can be an instrument for economic survival and growth (Niyi and Felix, 2007).

According to Kofi Annan (former United Nations Secretary General), "access to a secure, safe and sufficient source of fresh water is a fundamental requirement for the survival, wellbeing and socio-economic development for all humanity" (Awake, 2009). For more than 30 years there has been remarkable growth in the need for quality water purification by all

Ariyo, T.O.; Tata, H. & Omogunloye, O. G. (2016). A GIS Approach in Spatial Distribution of Water Pipeline through Primary and Secondary Network in Lagos State. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1028-1036

categories of users - municipal, industrial, institutional, medical, commercial and residential. The increasingly broad range of requirements for water quality has motivated the water treatment industry to refine existing techniques, combine methods and explore new water purification technologies (Pure Water Handbook by Osmonics).

Water covers 71% of the Earth's surface, and is vital for all known forms of life. On Earth, 96.5% of the planet's water is found in oceans, 1.7% in groundwater, 1.7% in glaciers and the ice caps of Antarctica and Greenland, a small fraction in other large water bodies, and 0.001% in the air as vapour, clouds (formed of solid and liquid water particles suspended in air), and precipitation. Indeed only four million cubic kilometer of water is obtainable for man's use. From this inventory, it is clear that water though appear abundant in nature only a small fraction can be exploited for man's use (Linsley and Franzini, 1972).

Earth's water is always in movement, and the natural water cycle, also known as the hydrologic cycle, describes the continuous movement of water on, above, and below the surface of the Earth. Water is always changing states between liquid, vapor, and ice, with these processes happening in the blink of an eye and over millions of years (According U.S Geological Survey, 2013). Today, access to safe drinking water has improved over the last decades in almost every part of the world. Water distribution systems have existed since the Minoans constructed the first piped water conveyance system (Michael S. A., Saviour M. and Naa D. T. 2011).

Currently, water distribution systems effectively serve municipalities of all sizes worldwide. A water supply network consists of engineered hydrologic, hydraulic mechanisms. It also includes water resources, pumps, treatment plants, reservoirs, pipes and their accessories (Babovic et al., 2002; Chin, 2006) and other equipment for operation and management. One of the major challenges in water supply is the provision and management of the pipe network and the associated assets. Effective functioning of these assets is necessary for distributing water continuously and efficiently.

According to United Nation's projections, by 2050 almost half of the world's population will be experiencing either water scarcity (<1,000m^3 of renewable water per capita per year) or water stress (between 1,000m^3 and 1,700m^3 per capita per year). It is estimated that 1 billion people in developing countries do not have access to portable water and unsafe water is implicated in the deaths of more than 3 million people annually and causes 2.4 billion episodes of illness from water-borne diseases each year.

The world urban population was projected to increase from 6.7billion in 2007 to 9.2billion in 2050 (United Nations, 2008). 90% of this global entire population growth will take place in urban areas of developing economies (Lunqvist et al, 2003, United Nations, 2004). The forces identified for this explosive growth include industrialization, mass transportation and the telecommunications revolution (Hall & Pfeiffer, 2000).The management challenges posed by the growth on a mega scale are substantial (Jones & Visaria, 1997) coupled with rapid urbanization (Paddison, 2001).

The location of water supply assets is vital to its effective management. Geographical Information Systems (GIS), with extensive spatial analytical capabilities have become widely applied in the infrastructure sector since its introduction in the 1960s. GIS is applied in four sections of the water infrastructure sector: asset management, distribution management, customer and outage management (Brussels, 2005). It is ideal to manage infrastructure by integrating all the information systems within these sections. However, lack of data is often a serious limitation. Consequently, a GIS application in the operations and maintenance section

of water utilities is a first stage approach to integration and optimization of all sections of water supply systems.

The Significance of Global Water Crisis

Lagos, for example, the commercial centre of Africa's most populous country, is a city with a current population of almost 14 million, about half that of Kenya and larger than most African countries. It is the most populous city in Africa and Europe, the sixth in the world, and could jump to number three in the world in another 20 years. This would require expanding water access and provision of other basic services and infrastructure to several more million inhabitants. As in many other African countries, Lagos is a city on the verge of a water crisis (Omogunloye&Ayeni 2012).

In spite of huge fund being expended on water related projects in Lagos in the last few years, very little success has been achieved in eradicating water crisis in the city. Financial & Operating Statistics of Lagos State Water Corporation shows that Investment expenditure on water projects in Lagos state in the year 2000 was put at ₦24,458,000, about ₦10,358,000 was expended on water production and treatment, ₦3,000,000 was spent on water distribution while ₦11,100,000 was spent on operational support. In spite of this investment the impact of water shortage is still stronger in Lagos metropolis. Thus this implies that a multidisciplinary approach from planning stand point would be required for the problem to abate. In view of this, this research intends to use Geographic Information Systems (GIS) as a planning tool for evaluating the impact of water crisis in Lagos metropolis with the view to identify area of needed attention.

THE STUDY AREA

Lagos State is located on the south-western part of Nigeria on the narrow coastal flood plain of Bight of Benin, to the South. It lies approximately on longitude 20 42'E and 30 22'E respectively and between latitude 60 22'N and 60 52'N. The Lagos Lagoon is to the East, Ogun State to the North and North-West and the Ologe Lagoon to South-West.It is situated on an area characterized by creeks, lagoons and tributaries of major rivers, such as River Ogun and Owo with large catchment areas which present difficulty in drainage due to high water table and near flat marshy terrain. The water area and marshland represent about 40% of the total area of the Metropolis. However, territorially, Lagos State encompasses an area of 358,862 hectares or 3,577sq.km, see Figure 1

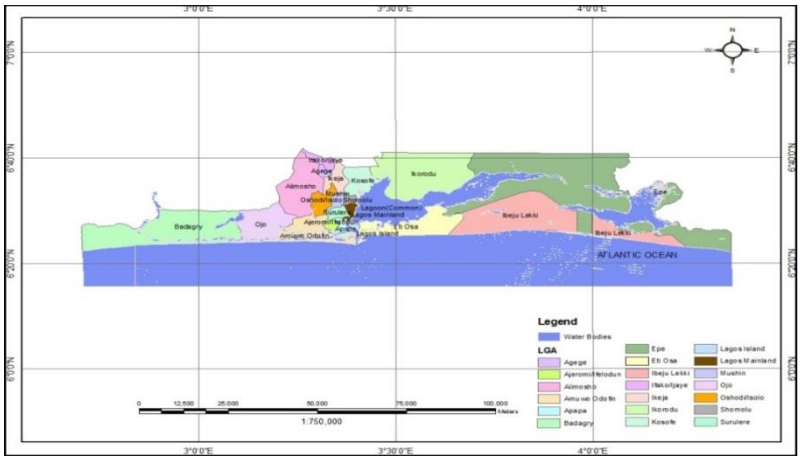

Figure 1: Administrative Map of Lagos State

Population

Although Lagos state is the smallest state in Nigeria, with an area of 356,862 hectares of which 75,755 hectares are wetlands, yet it has the highest population, which is over five per

cent of the national estimate.The state has a population of 17 million out of a national estimate of 150 million. The UN estimates that at its present growth rate, Lagos State will be third largest mega city in the world by year 2015 after Tokyo in Japan and Bombay in India.

Of this population, Metropolitan Lagos, an area covering 37% of the land area of Lagos State is home to over 85% of the State population.The rate of population growth is about 600,000 per annum with a population density of about 4,193 persons per sq. km. In the built-up areas of Metropolitan Lagos, the average density is over 20,000 persons per square km.

Current demographic trend analysis revealed that the State population growth rate of 8% has resulted in its capturing of 36.8% of Nigerian urban population (World Bank, 1996) estimate at 49.8 million people of the nation million populations. The implication is that whereas country population growth is 4/5% and global 2%, Lagos population is growing ten times faster than New York and Los Angeles with grave implication for urban sustainability.

Water Distribution in Lagos Metropolis

Due to the fact that Lagos is surrounded by water, many people assumed that it would be easy to provide the people with the required water; however the present situation is far from this. The water in the lagoon and ocean surrounding Lagos are not fit for human consumption. The large expanse of water around Lagos is not potable and does not meet World Health Organization standard. Hence, the public authorities in Lagos had to search far and wide to get water for the people of Lagos to drink and for other domestic use.

Lagos State comprises of capacity of three Primary Trunk Mains "A", "B" and "C" which cater for the transmission of water about 159,000m³/d (35mgd) since 1973, (Lagos State Water Corporation facts data, 2002). Since 1910 to date, the main concern of the authorities managing water supply to Lagos has always been how to increase the supply of water due to the ever increasing population of Lagos as a commercial nerve centre of the nation's economy.

At present, Lagos has a population of about 15 million. Over the years, therefore, the supply from Iju was no longer enough to meet the demands of Lagosians and a second waterworks had to be constructed at Ishasi, deriving its source from River Owo having a capacity of 18,000m³/d (4mgd).

Mini Waterworks are waterworks that can provide water supply up to 3 million gallons daily, (Agenda 21, 1992; Barth, 1993; Black, 1990; East Bay municipal Utilities district, 1991; Engelmann and LeRoy, 1993; Bulletin 160-93, Sacramento, CA, U.S.A., 1994; Brooks and Peters, 1988). Seven of the mini waterworks in Lagos metropolitan; had a combined design output of 82,000m³/d (18 mgd) while the remaining three in the semi-urban areas have a combined capacity of 38,000m³/d (8.4 mgd).

The Mini Waterworks were designed to feed directly into the networks laid in their various locations, to give immediate effect in these areas. Along with the installations of the Mini Waterworks, additional tertiary distribution networks have been laid on a continuing basis, to improve access to consumers (Lagos State Water Corporation facts data, 2002).

METHODOLOGY AND RESULT

Data Collection

Data used for this research work were gotten from Lagos State Water Corporation (LSWC) Ijora, Google earth and various Internet wide searches. The various methods that were used in acquiring data can be seen in the flowchart of research design below Figure 3.1. The initial steps taken before the adopted method was to acquire data used for the research work which were not limited to the following:

i. Administrative Map of Lagos State.
ii. Water facility Map.
iii. Population Data
iv. Water Demand
v. Production Analysis

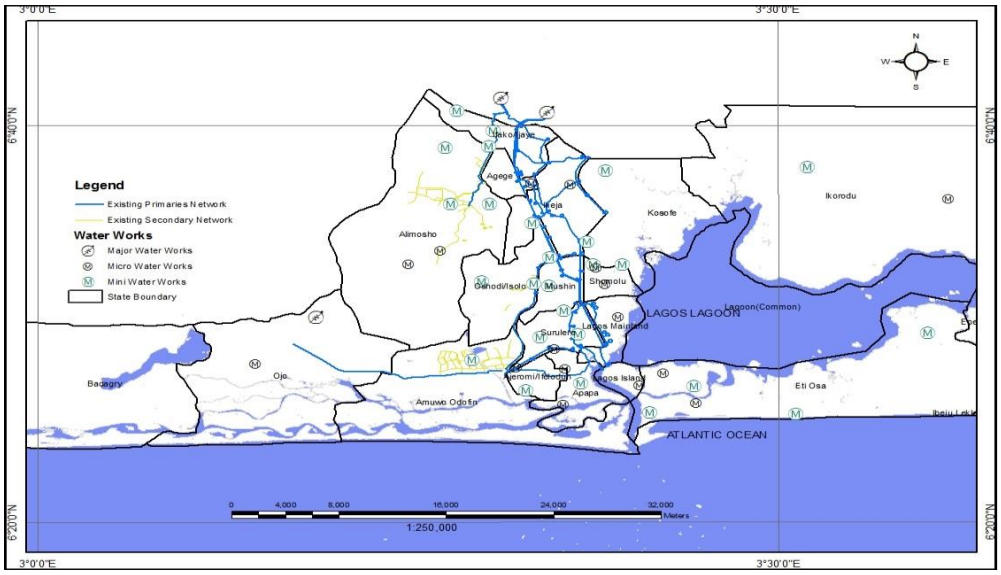

Figure 2: Water Facilities Map in Lagos State (source: Lagos State Water Corporation)

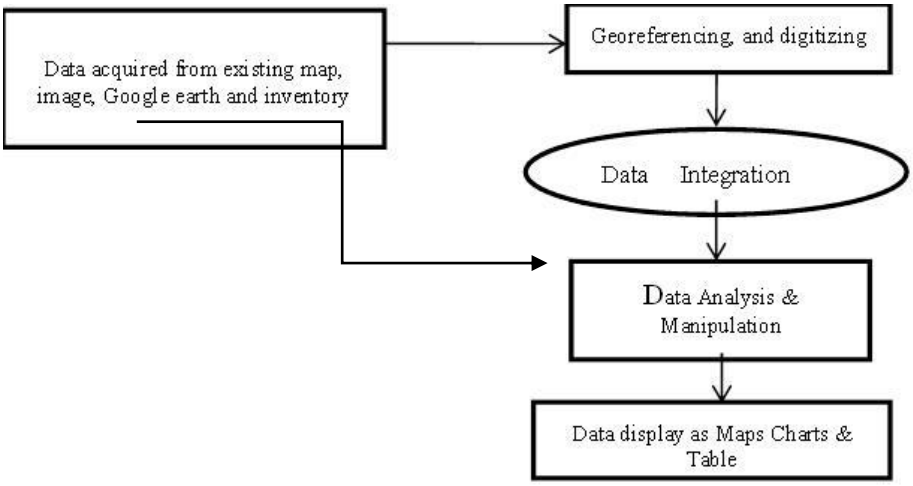

Figure 3: Flow chart Research Design

Chart and figures

Result generated from Chart and Figure are shown from Figure 4 – 6 below.

Figure 4 – Figure 6 gives a further analysis of water supply in the state. However, Figure 4 shows analysis of water production with the design capacity (mgd) of water work against average production (mgd) for year 2012. From this, it is observed that Adiyan has the highest

design capacity of 70 (mgd) with an average production of about 48.61 (mgd). It also observed that the likes of Mosan-Okunola and AbuleEgba water works are currently not producing.

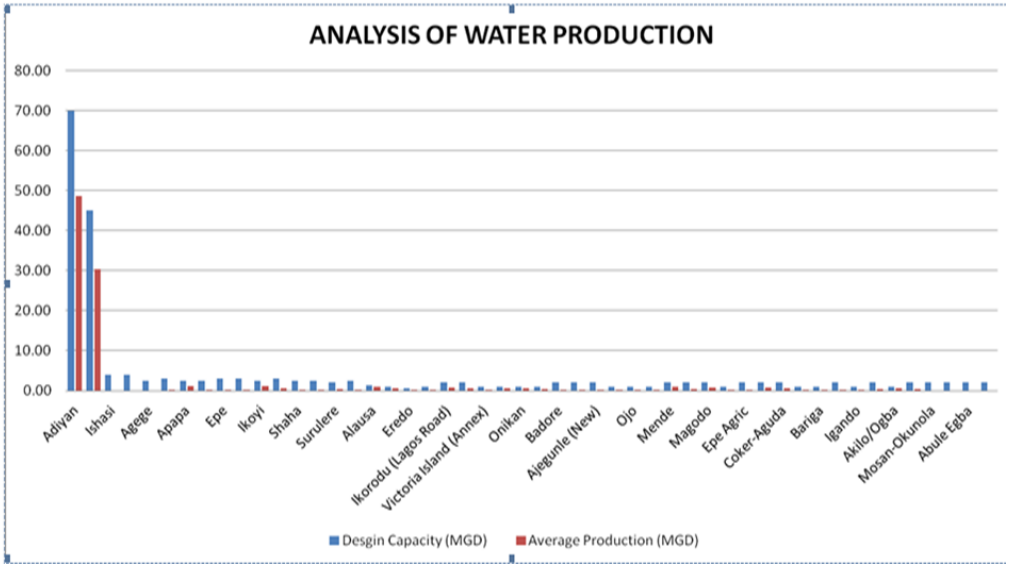

Figure: 3 Analysis of Water Production Chart (Lagos State Water Corporation Water Works Design Capacity and Average Projection)

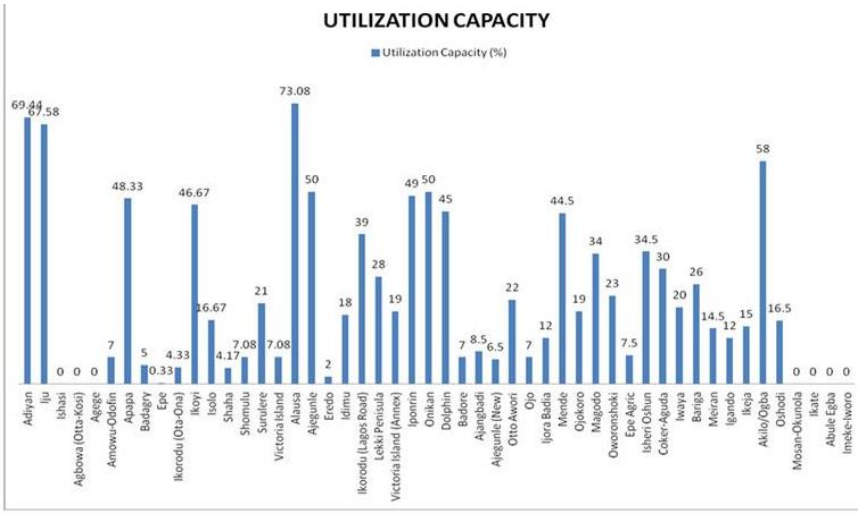

Figure 4: Utilization Capacity Chart (Lagos State Water Works)

Figure 4 depicts utilization capacity of water works in the state, with Adiyan, Iju and Alausa water works having the highest percentage based on performance, while Epe, Eredo, Shaha Badagry among others shows very low performance.

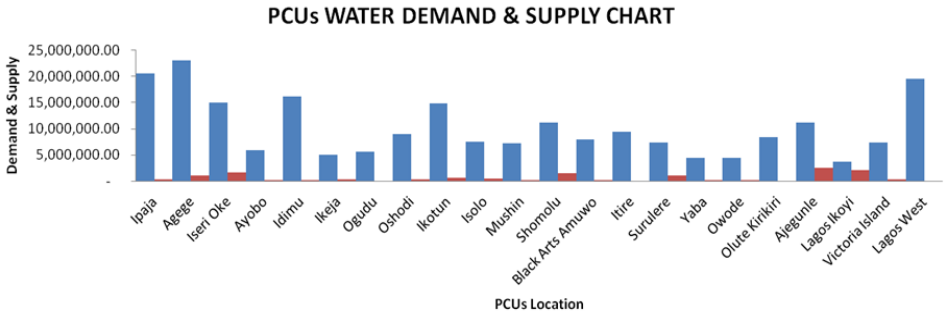

***Figure 5**: Project Control Units Water Demand and Supply Chart, Lagos State Metropolis*

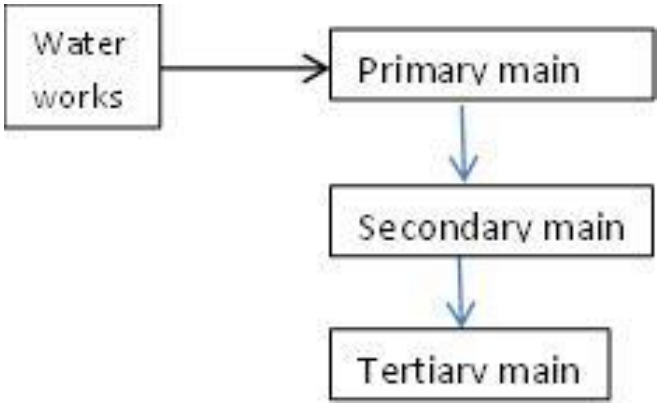
Figure 5 above shows analysis of water demand and supply within Metropolitan Lagos in the 22 Project Controlling Units. From the chart it is evident that water demand is far above water supply. Hence, the chart highlights shortage of water supply within PCUs. The Chart equally shows that there are no supply within Ogudu, Itire, OluteKirikiri and Lagos West PCUs. Lagos West PCU lack of water supply could be as a result of the rehabilitation work that was currently ongoing while the factor identified for lack of supply at Itire PCU, is that water work is currently under construction. No water work identified with Ogudu and OluteKirikire.

Water Distribution Network

Figure 6 and Figure 7, shows the spread of primary and secondary pipeline as well as water works in Lagos Metropolis. However, the spread of pipelines within the metropolis are not evenly distributed. The primary pipeline is characterised running from north (Ogun State) to south- Olute Ikirikiri PCU (Amuwo Odofin LGA) without any considerable extension to the east and west of the state. The secondary pipeline can be observed to have its spread along Ipaja, Idimu, Isolo, Agege,Ikeja, Mushin and Black Arts Amouwo PCU and took to a more central position base on the spread of the primary pipeline.



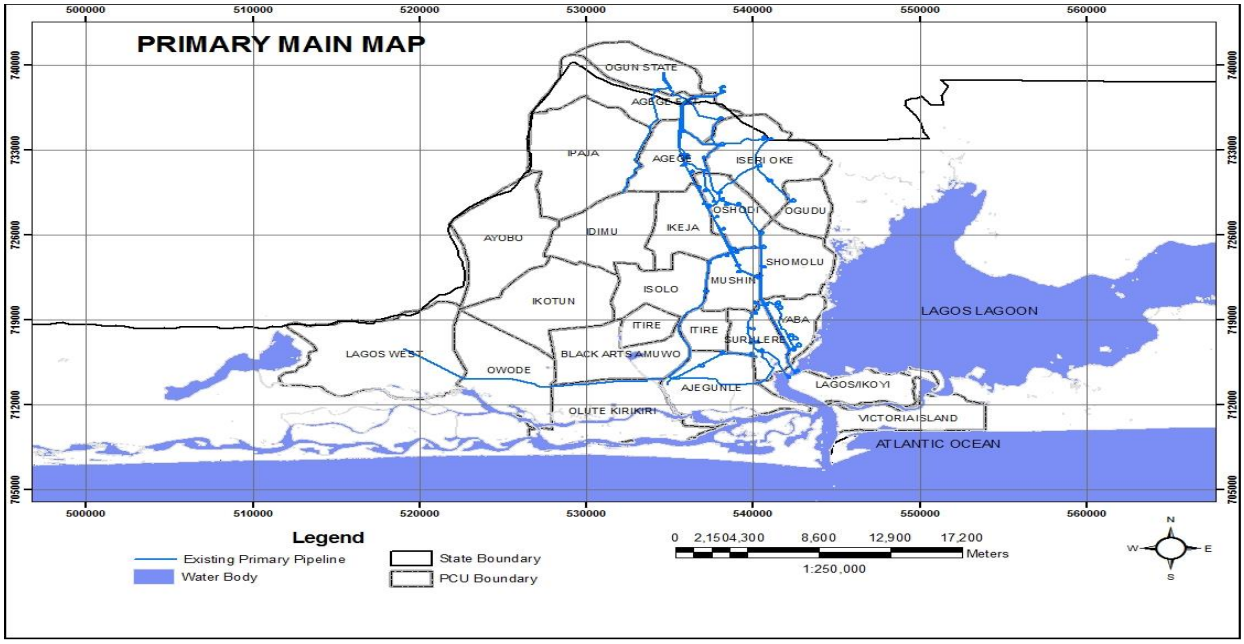


Figure 6: *Map showing primary main across Project Control Units in Lagos Metropolis*

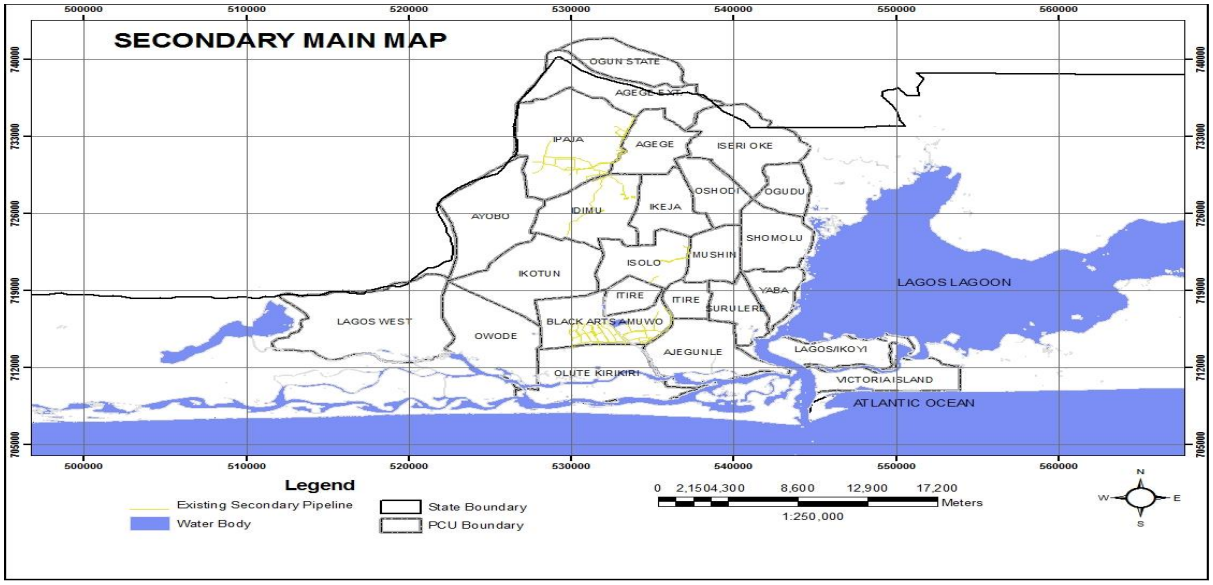

Figure 7: Map showing secondary main across Project Control Units in Lagos Metropolis

CONCLUSION

The role of portable water in modern society such as the Lagos Metropolis cannot be over-emphasized. People depend on its good quality-and quantity-for drinking as well as maintaining personnel hygiene. This research work has highlighted the following:

i. The spatial distribution of water pipeline through primary and secondary network in Lagos State. Despite the considerable attention paid to water supply in the study area over the years, inadequate water supply remains one of the major problems. Findings revealed that most of the water works are performing below average while in some cases there was no water supply/production as the case maybe.

ii. There are situation where people that have the network connected to their houses are left unsatisfied with the supply; and whenever the water is pumped, it does not last more than 2 hours in a day and as such the people within the metropolis are left with no choice than to find alternative sources of water to meet their daily consumption.

iii. Proper delineation of PCUs was not done, there were few discrepancies between PCUs and LGAs boundaries. However, reason for these discrepancies could be that the delineation was not done by geographers or surveyors. And as such, assumption was used in some cases in merging PCUs population for each LGA population.

iv. Some of the factors that have been identified as important controls on water demands in the study area include increase in population, increase standard of living and purchasing power, changes in social tastes and policy decisions.

v. Unfortunately, Lagos State Water Corporation is unable to meet the growing water demand of the people due to: inadequate water facilities such as network distribution, water works (reservoirs), inadequate power supply, poor state of some of the equipment, reckless over-consumption and misuse of water amongst others.

vi. Finally, the use of GIS should be employed for effective management, since overtime it has been proven to be very useful for effective planning and cost efficient.

ABSTRACT

Nigeria is endowed with abundant natural resources of which petroleum resources play a dominant role in the economy. These resources can be effectively harnessed and managed for the benefit of all Nigerians. Unfortunately, the distribution of petroleum products in the Nigerian economy is fraught with complex problems resulting sometimes in petroleum products outages, inflated prices of products and contentions on the pump price of products. The aim of this paper is not only to evaluate the distribution of petroleum products in the country but to apply Geographical Information System (GIS) to highlight distribution weakness in the country. The research work was carried out using data acquired from NNPC, PPPRA and NEITI. These data was processed using GIS. The findings from the study show that the distribution system of petroleum products in Nigeria is ineffective and inefficient due to a number of factors which have been identified. To meet all this demand for these products without provoking market imbalances, the right supply levels are needed. Measuring this is always a challenge for the experts who work in the oil industry. Thus, the use of GIS should be employed in the downstream sector of oil industry.

Keywords: GIS, NNPC, Petroleum Consumption and Distribution

INTRODUCTION

Nigeria's economy is dominated by the oil and gas sector. In 2004, this sector accounted for about 80% of all government revenue, 90-95% of export revenues, and over 90% of foreign exchange earnings (Aluko, 2004). The country is Africa's leading oil producer and at a global level, ranks among the top 10 oil producers (Olokesusi, 2005). Most of the oil and gas is produced in the Niger Delta Region, presently defined by the political boundary of nine states: Abia, Akwa-Ibom, Bayelsa, Cross-River, Delta, Edo, Imo, Ondo and Rivers.

The Nigerian oil and gas operations comprises of assets and infrastructure including 5,284 oil wells, 10 gas plants, 275 flow stations and 10 export terminals (Joab, 2004). All of these are connected by a network of pipelines that crises-cross the country. These developments often require a large chunk of the wetland to be reclaimed/ dredged. Oil and gas production has come at a great environmental cost to about 1,500 communities in the Niger Delta where the Nigerian National Petroleum Corporation (NNPC) oil venture partners operate.

However, marketing of these petroleum products in Nigeria could be traced back to 1907, when kerosene was imported with an agency agreement believed to be the first was concluded by Secony Vacuum Oil Company (now Mobile) to market its ''sunflower'' kerosene. Thus, kerosene was the first petroleum product marketed in Nigeria and Mobil had the privileged of being the pioneer in this business (Nigerian National Petroleum Corporation, 1985).

Distribution problem in general, is not a recent problem. The extractive/mining sector in Nigeria have, for the past decades shown comparatively slow rate of growth and have been, in the main, predominantly foreign-dominated. This reflects a fact that the sector is both

Tata, H., Ariyo, T. O. & Omogunloye, O. G. (2016). Mapping and spatial distribution of petroleum products by marketers in Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1037-1044

technology and capital intensive, requiring a high level of sophisticated, expensive equipment and expertise, which are in short supply in Nigeria.

Consequently, business features, irrespective of all glamours, gains and aspiration have their attendant problems as well. These problems associated with the business come in varied ways and takes different dimensions. The attendant problems may arise from logistics activities, inefficiency and mismanagement of the marketing mix. These problems plague the Nigeria oil sector in its effort to market petroleum products.

These products are marketed by the multinational oil companies like Exxon Mobile, Total Finas etc. Despite the effort of government aimed at efficient distribution of petroleum products; the problems of inadequate and uneven distribution among others still threaten the marketing of petroleum products today in the country.

As a result, these problems gave birth to independent marketers that served as panacea to the prevalent economic situation occasioned by inadequacy in petroleum products distribution in the country

Independent marketers therefore were granted right to be involved in the industry as to bridge the gap created by distributors logistics, to ameliorate the suffering of Nigerians. Entry of independent marketers became welcomed and justified, in the oil industry. Prior to the birth of the independent marketers, petroleum product distribution was epileptic and unreliable.

The Nigerian Petroleum Industry

The petroleum industry can be classified by type of actors or by sector. The actors in the Nigerian industry consist of both private and public organizations. The public actors are the government agents and functionaries such as the Nigerian National Petroleum Corporation (NNPC) and its subsidiaries, the Department of Petroleum Resources pricing regulatory authority (PPPRA), among others. The private segment consists of both indigenous and foreign actors.

The indigenous sector consists of private independent marketers. As far back as 1978, the concept of independent petroleum products marketing was introduced with a view to bringing indigenous independent marketers to that sector of the industry. According to Edoreh (1997), in 1979 a year after the scheme of independent marketers was introduced, there were not more than 20 (twenty) "independent marketers". By 1993, the number had risen to 1,000. Today, the indigenous independent marketers are well over 7,948 (Petroleum Product Pricing Regulatory Agency, PPPRA, 2010). As a measure of the growing involvement of the indigenous petroleum products marketers in the economic development process of Nigeria, it is interesting that in 1981, they accounted for less than half – percent in terms of volume of petroleum products marketed in Nigeria. By 1998, they had captured about 25 percent of the market. Today, they account for nearly 40 percent of the volume of products marketed in country (NNPC, 2010). In terms of outlets, the major marketers have 2218 while the Independent marketers have 7948 outlets. The NNPC has 18 mega stations nationwide as at June, 2010 (Table 1.1).

These indigenous independent marketers are competing with the established big (foreign) multinational enterprises usually referred to as the major oil marketers comprising:

i. Mobil Oil Nigeria Plc
ii. MRS Nigeria Plc
iii. Total Nigeria Plc
iv. Con Oil Plc
v. Oando Nigeria Plc
vi. African Petroleum Plc

These six major oil marketers control about 60 percent of the market. There are two major classification of petroleum industry by sector. These are the "Upstream" and ''Downstream'' sectors.

Table1. 1: Nationwide retail outlets 2009 census-summary distributed by zone

Geo-Political Zone	Marketer Type Major	Marketer Type Independent	Total No of Outlets
North Central	355	1318	1673
North East	163	726	889
North West	265	1023	1288
South East	194	1227	1421
South South	224	1519	1743
South West	1017	2135	3152
Total	**2218**	**7948**	**10166**

Source: Petroleum Products Pricing Regulatory Authority Available at www.pppra-nigeria.org

In the downstream sector, activities are progressively falling within the control of private entrepreneurs, especially the indigenous independent marketers. It is the policy of the Federal Government that petroleum products be distributed by private companies. To this end, government divested a sizeable portion of its interest in oil marketing companies by selling some of its share to the public through the Technical Committee on Privatization and Commercialization (Christopher E and Adepoju A., 2012).

The study looks at the various methods employed by the various marketers in Nigeria to distribute petroleum products from the refinery to the final consumers and types of channels involved. This reveals the extent to which the shortage of petroleum products as well as their adulteration could be traced to the distribution system.

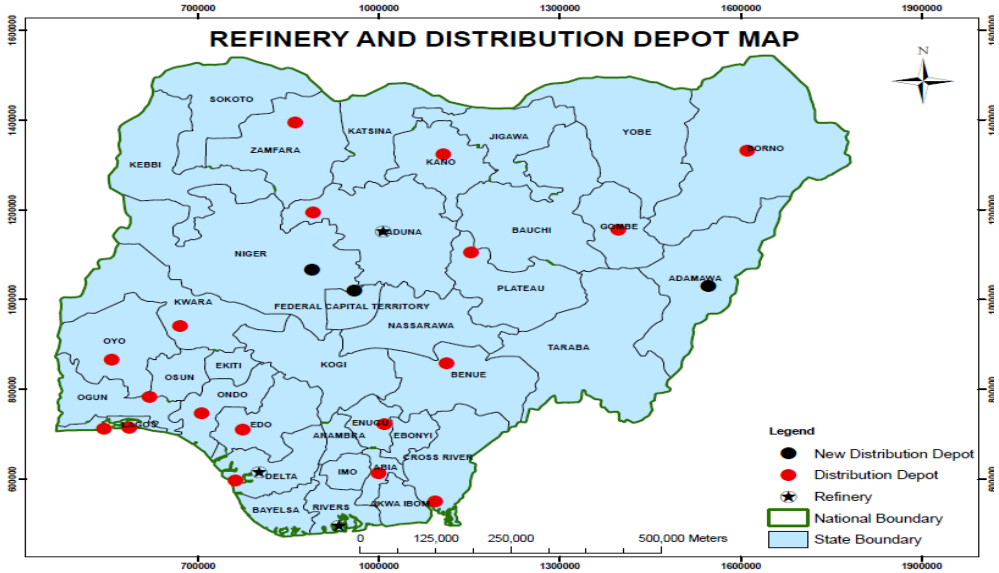

Figure1. 1: Map showing the distribution of Depot in Nigeria (source: Pipeline product marketing company of Nigeria)

METHODOLOGY

Data Collection

Data used for this research work was gotten from PPMC (Pipeline product marketing company of Nigeria), NNPC (Nigeria National Petroleum Company), PPPRA (Petroleum Products, Pricing Regulatory Agency) NEITI (Nigeria Extractive Industry Transparency Initiative) and Internet wide searches. There were various methods that can be used to acquire data; the method adopted can be seen from the flowchart below Figure 1.1.

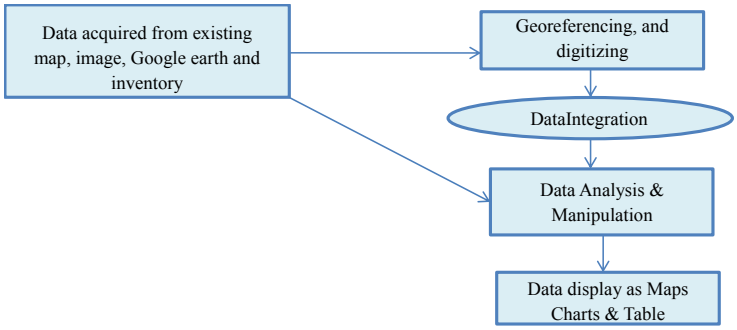

Figure 1.2: Flow chart for the research

PRESENTATION OF RESULT AND ANALYSIS

The zonal petroleum product Consumption/distribution for year 2011 as seen in Figure 4.7 shows that South West has the highest consumption with 3,520,949 million litre consumed during the year, with the lowest consumption being South East with 254,437 million. Table 4.6 and Figure 4.8a below equally buttress consumption/distribution for the year. South West been the highest consumer, thus, could be as a result of the huge industrial activities taking place in this region while Southern East having the lowest supply of product shows that the level of industrial activities could be low. It is observed that the PMS and ATK product are consumed mostly in the South Western zone which again defined the kind of activities that can be identified in this region. South South region has the highest consumption of HHK and Brake Fluid in the country while North Central has the highest consumption of special products. However, Figure 4.15b show that South West 39% of the distribution, seconded by South South with 24%, North Central 17%, North West 7%, North East and FCT 5% and South East has just 3%.

Table 1.2: Show the zones distribution of petroleum products in Nigeria (Petroleum Products Pricing Regulatory Authority Available at www.pppra-nigeria.org)

Products	South West	South East	South South	North West	North East	North Central	FCT	Total

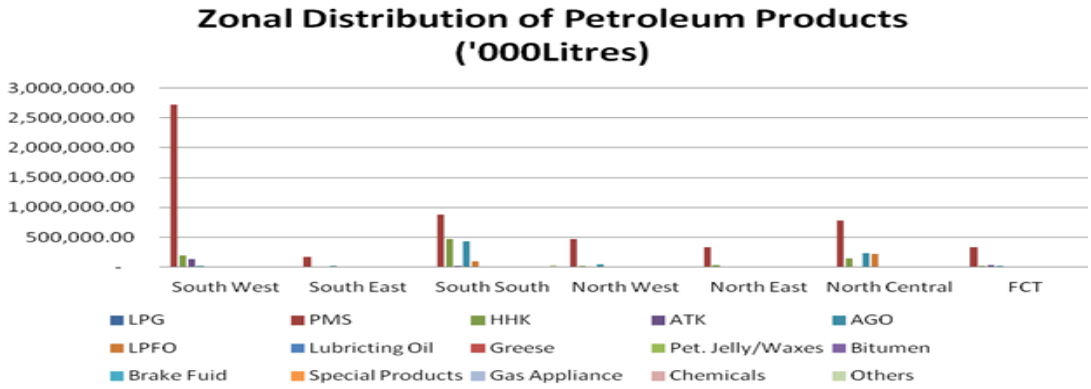

Figure 1.3: Shows distribution/consumption of Petroleum Product by zone for year 2011 in Nigeria

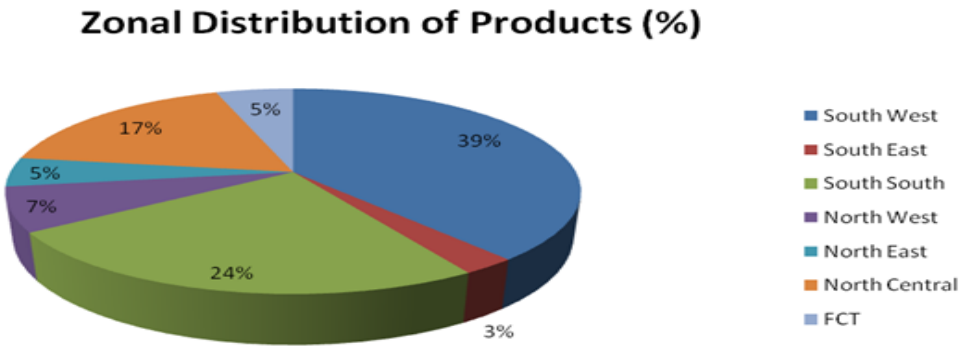

Figure 1.4: Shows percentage of distribution/consumption of Petroleum Product by zone for year 2011 in Nigeria

Table 1.3: Shows the contribution of major and independent marketers to the distribution of petroleum products distribution in Nigeria

Marketers	LPG	PMS	HHK	ATK	AGO	LFPO	Lub Oil
Forte Oil	2,584.46	652,654.93	54,075.74	59,841.20	-	-	-
Conoil	-	934,743.04	68,551.31	169,180.21	-	-	-
Mobil	-	-	-	-	-	-	-
NNPC Retail Outlet	-	1,536,286.98	192,524.15	193,924.60	-	-	-
MRS	-	-	-	-	-	-	-
Total	-	-	-	-	-	-	-
Oando	-	-	-	-	-	-	-
Independent Marketers	29,257.15	2,564,764.58	585,555.79	-	-	-	-
					-	-	-
Total	**31,841.61**	**5,688,449.53**	**900,706.99**	**422,946.01**	**-**	**-**	**-**

Table 4.7 and figure 4.10 below shows the contribution of major and independent marketer to the distribution of petroleum products in Nigeria. From the available data, both the major and independent marketer did not contribute to the distribution of AGO, LFPO and Lubricating Oil. This however, could imply insufficient supply of product to the Nigeria citizen. It also observed that independent marketers have contributed measly to the distribution of products in the country.

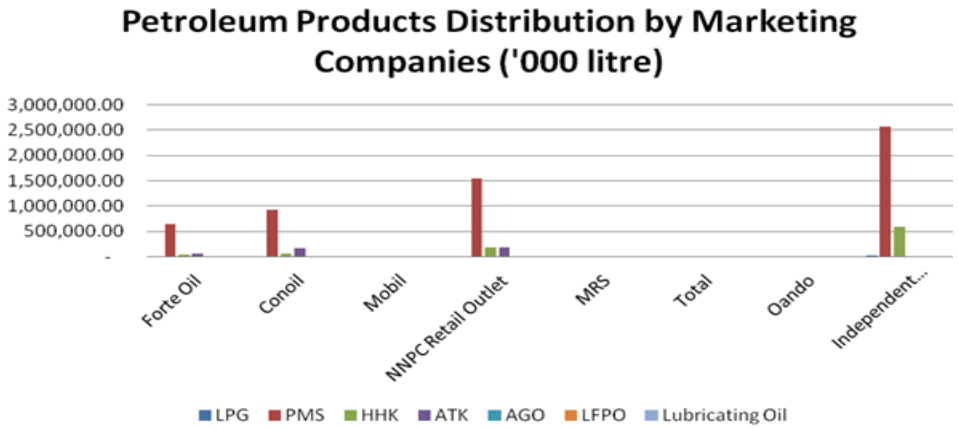

Figure 1,5: Showing petroleum products consumption/distribution by marketer in Nigeria for year 2011

Furthermore, Figure 1.6 below shows the trend movement of petroleum/consumption by state for the past 3 year from 2009 – 2011. The trend shows that the consumption of petroleum products is higher in 2009 than 2010 and 2011.From the movement it is observed that the consumption is slightly higher from Edo to Kebbi State in year 2011 than in year 2010. Many factors could be responsible for this gap in consumption. However, one of the factors that might be able to result to this gap is change in price of petroleum products which could reduce the purchasing power of the people within the states and the country at large which is in conformity to Law Demand and Supply. Supply and demand is perhaps one of the most fundamental concepts of economics and it is backbone of a market economy. Demand is how much quantity of a product or services is desired by buyers. The quantity demanded is the amount of a product people are willing to buy at a certain price; this shows the relationship between price and quantity demanded (demand relationship). Supply represents how much the market can offer. The quantity supplied refers to the amount of a certain good producers are willing to supply when receiving a certain price. The correlation between prices and how much of goods or services is supplied to the market (supply relationship). Thus supply is a reflection of supply and demand which implies that more quantity of petroleum products will be demand if the price is reduced.

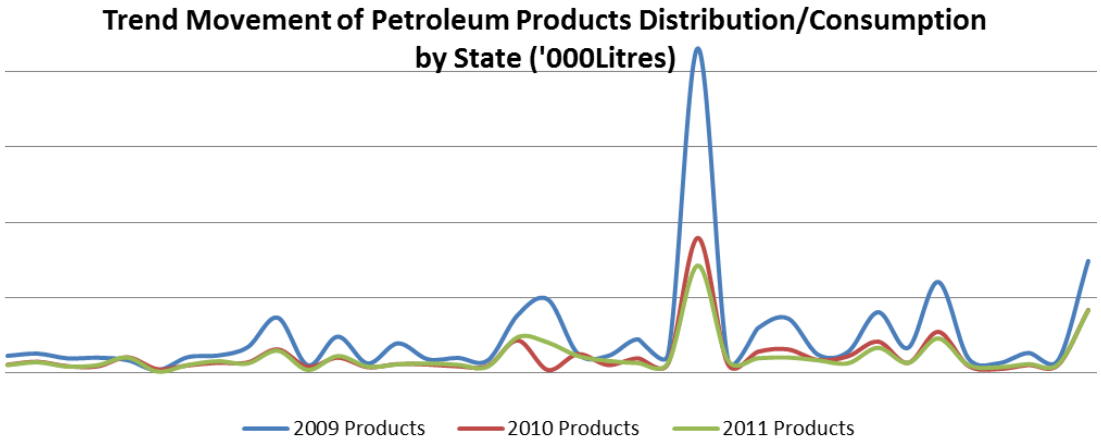

Figure 1.6 shows the trend movement of petroleum/consumption by state for the past 3 year from 2009 – 2011

DISCUSSION OF FINDINGS

From the available data, the local refineries received a total of 40,405,605 barrels (5,284,675 mt) of (dry) crude oil and condensate and processed39,408,108 barrels (5,088,208 mt) into various petroleum products. The total production output by the refineries was

5,379,854metric tons of various petroleum products. The combined average refining capacity for year 2011 was 24% as against 22% in the previous year.

PPMC evacuated 5,208,930 mt of petroleum products from the refineries and it also imported 759,681 mt of PMS,AGO and HHK for distribution. Total value of imported products was $0.802 billion. PPMC sold a total of 13.21 billion liters of various grades of petroleum products through depots and coastal lifting. During the year, 1.37 billion liters of petroleum products worth about ₦141.13 billion was exported.

A total of 8,199.02 million liters of petroleum products was distributed nationally giving an average daily consumption of 15.58million litres of PMS, 2.68 million litres of AGO and 2.47 million litres of HHK. The total petroleum products distribution of8, 199.02 million litres is about 3% lower than 2010 total volume of 8,476.99 million litres. This is due to non-availability offigures from major retail companies namely MRS, Mobil, Total and Oando. The quadruple usually account for more than 50%of total petroleum products distribution.

The distribution by zone shows the South-West with the lion share of 40% followed by the South- South with 24%, North Central with 17%, North West with 7%, FCT with 5%, North East with 5% and South East with 3%. Thus, scarcity of petrol has continued to prevail in the country, despite this significant increase in importation.

Conclusively, with government claims that the landing cost of a litre of imported petrol put at ₦152.44, making it to pay about ₦55.44 on every litre of petrol as subsidy since the control price for her citizen is put at ₦97 per litre. When the ₦55.44 per litre is multiplied by a daily consumption of 40.32 million litres, it amounts to a daily subsidy expenditure of ₦2.235bn. The figure adds up to ₦69.29bn monthly.

CONCLUSION

i. With the current trends at which Nigerian economy is growing, the Country needs more pipeline distribution network.
ii. From the analysis, trend movement of petroleum/consumption by state for the past 3 year (2009 – 2011), shows that the consumption of petroleum products is higher in 2009 than 2010 and 2011.
iii. Finding also shows that South West has the highest zonal petroleum product Consumption/distribution for 2011 with 3,520,949 million litres while South East has the lowest consumption with 254,437 million litres (Figure 1.3).
iv. Further findings from this research work, shows that depot within the country are not evenly distributed (Figure 1.3).
v. Finally, the use of GIS should be employed as planning tools for proper and effective distribution.

Graphic Communication for Sustainable Development: Eliciting Desired Response from Target Audience

Ebigbagha Zifegha Sylvester

Department of Fine and Applied Arts, Niger Delta University, Wilberforce Island, Bayelsa State
[*] *herbertvella@yahoo.com*

ABSTRACT

This paper focuses on eliciting desired target audience response pivotal for sustainable development. Toward this end, it utilized the Critical-Historical-Analytical Examination, and Content Analysis methods to assess conditions and response to media. It started with the need to understand target audience perception when making graphic messages for development. Furthermore, it examined the perception process of graphic messages using the Aaker and Myers Model. And it discussed audience responses to graphic messages in Africa, based on the analyses of secondary data of the conditions pivotal for decisive response, and found that neglect of target audience conditions resulted in the production of ineffective stimulus conditions as well as communication failure. The paper recommends that communication actors should understand conditions that determine responses to development messages and integrate Target Audience during media production. This would create stimulus that elicit desired response from target audience.

Keywords: Development, Eliciting Desired Response, Graphic Communication, Perception, Stimulus/Audience Conditions

INTRODUCTION

Eliciting desired response from target audience is the primary objective of graphic communication campaigns. These campaigns often employ pictorial images and verbal signs to share messages about development in agriculture, health and education, to mention a few.

The response of target audience to these messages is largely determined by the way the graphic messages are created and distributed. A positive or negative response largely depends on the reactions elicited by the typographic and graphic elements selected to produce graphic messages. This is because both form and content attributes produce emotional reactions that affect behaviour (Ebigbagha, 2010, citing Garland, 2005; and Watt, 1979). For this reason, the media is the message (Baran, 2009). So, both graphic form and content immensely impact on target audience perception.

In order to produce graphic media with salutary effect, it is necessary to understand target audience perception. Media generated without necessary and sufficient consideration of audience conditions usually is ineffective, and with grave consequences. An example is the 'Dress Code Campaign' in Ahmadu Bello University, Zaria, Nigeria by the Dress Code Action Committee, in 2005. The media produced were rejected and destroyed by the target audience. This would have been prevented had adequate consideration been given to target audience conditions during production of the stimulus conditions (the billboard posters). For instance, had the draft of the posters been pre-tested with the target audience and recoded based on the pre-test result, a suitable, likeable and modest dress code, which reflected the interest of the target audience would have been depicted and the time, money, energy and resources wasted saved.

A thorough consideration of target audience conditions is indispensable to creating

Ebigbagha, Z. S. (2016). Graphic Communication for Sustainable Development: Eliciting Desired Response from Target Audience. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1045-1052

appropriate, accurate and vivid stimulus. It helps the graphic encoder to satisfactorily resolve uncertainties, which are bound to occur as development ideas are encoded into graphic messages. These uncertainties (Technical, Semantic, Syntactic, Arousal/Aesthetic and Response) are ruinous and could pose formidable barriers to effective communication of stimulus conditions.

A diligent consideration of the conditions that determine target audience perception of graphic messages is essential to effective graphic media production. Towards this end, the Aaker and Myers model of the perception process, which lends itself as a veritable guide, is examined. Also, discussed are variables for generating graphic messages with particular focus on target audience conditions. And audience responses to graphic communication campaigns, which considered or neglected target audience perception during media production process, are adequately highlighted.

THE PERCEPTION PROCESS OF GRAPHIC MESSAGES

The way target audience perceive graphic messages is lucidly described in the Aaker and Myers(1981) model of the perception process (figure 1).The model shows how stimulus flow through attention and interpretation to cognition. It also suggests how this flow of stimulus is determined by stimulus and audience conditions.

The model identifies four elements in the perception process, these are: (i) Stimulus - the content of the message the audience is exposed to in a given environment. (ii)Attention - the careful notice focussed on a given stimulus, which essentially controls the amount of information the audience processes at any given time, whether he/she engages in Active search, Passive search, or Passive attention. (iii) Interpretation - the explanation or meaning the target audience makes of the content of any given stimulus, which he/she could Simplify, Distort, or Organise; and (iv), Cognition - how target audience see, recognise and understand a given stimulus.

In addition, the model also identifies two principal types of variables that determine the attention and interpretation of a given stimulus, these are: (i) Stimulus conditions, which are all the things that could affect or make up the stimulus itself, these include: Intensity, Size, Message, Novelty, Position, and Context. (ii) Audience conditions are all the things that could affect the state of being of the target audience, these include: Information needs, Attitude, Values, Interests, Confidence, Social context, and Cognitive style.

The model shows the information seeking pattern of target audience. It holds that information provided by a given stimulus are first screened at the attention stage, whereby attention, which acts as a filter, controls the amount of information the receiver processes; whether he/she is involved in active search, passive search or passive attention. This screened amount of information is then organised into explanations/meanings the receiver could make out of it, which conforms to his/her image of reality. At this stage, the target audience could simplify, distort or organise the content of the stimulus into a suitable cognition. All these activities are influenced by stimulus conditions and audience conditions.

The stimulus and audience conditions that determine attention and interpretation target audience give to graphic messages are of prime importance in communication development process. This is particularly salient in our society today, where mass production and distribution of information have flooded the environment and create problems for the individual who desires to sort out or seek for relevant information to meet his or her needs.

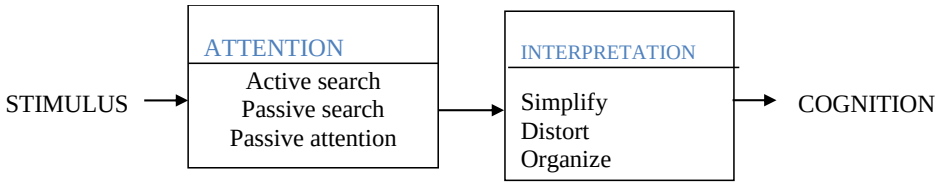
More importantly is the awareness and necessary application of these stimulus conditions in the creation of graphic messages, bearing in mind target audience perception. It is important

to know that there are attention filters, which determine the amount of information processed, and affect the attention given to a particular message when target audience are exposed to it. So, unnecessary information/content in the stimulus must be eliminated to avoid 'noise' that repels.

In addition to the above, the element of interpretation is essential. It shows that target audience match information to their image of reality. As a result, when encoding graphic messages, all that concern the audience should be considered. Otherwise the message would often not achieve the desired response.

Therefore, when determining messages and making media production plans, it is important to consider: the intensity of colours of the graphic and typographic elements, the size of design elements in relation with one another within the picture plane and the overall size of the media itself in comparison with similar ones in the same vicinity. In addition, what portion of the message need be emphasised, the syntax/arrangement order, and the novelty, uniqueness or unusual presentation should be planned. Also, the position where the graphic message would be mounted in relation with other messages displayed, and the context should be taken into serious account.

Finally, the information needs, attitude, values, interests, the socio-cultural environment and the cognitive style of the target audience should be considered because they greatly impact on target audience response.



Some Suggestive Determinants of the Perception Process

Stimulus Conditions	Audience Conditions
Intensity, Size, Message,	Information needs, Attitudes
Novelty, Position and Context	Values, Interests, Confidence and
	Cognitive style

Figure 1: A model of the Perception Process, influenced by two principal types of variables: stimulus and audience conditions (Aaker and Myers, 1981)

TARGET AUDIENCE RESPONSES TO GRAPHIC MESSAGES

Target audience responses to graphic messages in development communication are immensely determined by the conditions of the stimulus presented. A diligent consideration or careless neglect of target audience conditions during communication development process would either produce stimulus conditions that afford or hinder desired response respectively. This is evident in the graphic media produced for three nationwide campaigns (The ORT Campaign in Egypt, The Delayed Sexual Debut Campaign in Nigeria, and The Use Condom Campaign in Nigeria) on health issues.

The ORT Campaign in Egypt

The ORT Campaign in Egypt (Ebigbagha, 2010; citing World Health Organisation, 1987) is an example of effective media production that elicited desired response. It emphasises the need for draft of graphic communication to be pre-tested with audience before final production for campaign. This is salient to avoid rash decision-making and the production of ineffective media.

The first Executive Director of the Egypt ORT Project was to decide on and adopt a logo for the project. Having examined many logo ideas submitted by different artists/designers, he liked one more than the others (see Plate I). The director was tempted to adopt the logo he

liked without further deliberation. However, he withheld his opinion until all logos had been tested.

Plate I: Logos Pre-tested for the ORT Campaign in Egypt,

The logos were tested with a sample of the target audience, mothers, and the result shows that, the logo the director preferred was the one least favoured by the pre-test respondents. It also shows that the logo chosen needed be modified to be more effective. A large number of the respondents opined that the colour be modified and the mother pictured in the logo should put on a wedding ring.

The logo selected by the pre-test respondents was adopted for the ORT campaign. The experience so impressed the first Executive Director that he often recounted the story, to emphasise the need to pre-test draft with target audience for successful communication in development programme.

Had the director not involved the target audience in the development process through pre-test, the necessary improvements made on the logo would have been missed. The introduction of a wedding ring on the hand of the pictured mother in the logo is very significant and instructive. It is a staple on the socio-cultural influence on the interpretation of graphic language. Significantly, it points to the socio-cultural interpretation of motherhood as a product of legality in marriage. Also, it points to the fact that very crucial idea could be omitted when making initial draft of the stimulus, which can be corrected during pre-test/evaluation process. The omissions, if not corrected could significantly thwart the realisation of desired target audience response.

The Delayed Sexual Debut Campaign in Nigeria

The Delayed Sexual Debut Campaign is another rare example of the production of target audience-based stimulus that produced desired target audience responses in Nigeria (SFH Corporate Presentation 2006, Ebigbagha 2010, 2012).Stimulus produced include posters, pamphlets and stickers, to mention a few. The examination of the media production process showed that there were series of collaborative efforts and integrated planning between the source, graphic encoder, and the target audience during the media production process. Of these stimulus materials that were produced, two billboard posters: "Sex is worth waiting for ZIP UP…" and "Yana Da Daraja KU KAMA KANKU (it is respectful to hold yourself) (Plate IIa and Plate IIb) respectively, would suffice to relate how the quality of the graphic media produced elicited desired target audience response.

a b

Plate IIa and IIb: (a) A billboard poster on Sex is worth waiting for'ZIP UP'(b) Hausa Version: Yana DaDaraja KU KAMA KANKU (it is respectful to hold yourself). By the Society for Family Health.

The two billboard posters carried the same prime messages and supporting information in Pidgin/English, and Hausa but with different configuration based on diligent cultural considerations, knowledge, aptitude and practice of target audience. Using the English version (Plate IIa) "Sex is worth waiting for ZIP UP…" for analysis, which equally holds for the Hausa version; the prime message is 'Sex is worth waiting for'. It is executed in white lettering on high intensity blue background. This makes it legible when juxtaposed with 'ZIP UP' that is emphasized in size and depicted in gold/yellow ochre hue. The letter 'l' in the 'ZIP' is the iconic sign of a zip that is done up - a ploy that visually re-emphasized the main idea of the ZIP UP campaign. The supporting information 'Delay sex now, unwanted belle or HIV/AIDS fit spoil your life' also, appears in white but smaller in size in comparison with sex is worth waiting for', and italicized, which makes it an important warning slogan but not in formal terms as the prime message.

The pictorial element consists of four youths (two males and two females), a female and a male, a male and a female alternate juxtaposition. The youths are in trendy cloths, with captivating smiles that attract attention and arrest interest in the poster.

The relation in size and space between the typographic and graphic elements are well thought of and excellently articulated. The colours in the poster in terms of hue, value and intensity are superb, and the colour of the lettering 'ZIP UP' was balanced by similar colour of clothes worn by a male and a female in the group following the organisational principle of Harmony, involving rhythm repetition. Also, the pose of the two youths not wearing yellow-based cloth produced a diagonal movement that is countered by the other two. This creates dynamic forces that enlivened the stable typographic elements.

In addition to the above, the whole design consists of colours that have symbolic connotations. The red and black colour symbolise danger and death respectively, which could result from HIV/AIDS, other sexually transmitted diseases and unwanted pregnancy. Attention then moves from the grey colour to the yellow, which depicts the burning passion of youthful exuberance. The blue background and the white lettering is symbolic of peace, and purity respectively, which seem to suggest that if the target audience adopts the development message, peace is guaranteed in relation with sex.

The spatial relationship in terms of surface division followed the established principle of the 'golden mean'. This is suggested by visually extending an imaginary line from the hand of the female in red shirt to the bottom of the billboard poster, which produces a ratio of three to five (3:5) that as well conforms to the Fibonacci theory of harmonious surface division. Furthermore, the background is free of any distraction. The edges of the blue background colour into the figure created a vignette at the bottom of the poster that allows for gradual and peaceful transition of view into the picture, which a hardedge demarcation would have destroyed, and permits the eye to seamlessly move within the picture frame.

The Delayed Sexual Debut Campaign produced and employed suitable stimulus conditions that effectively elicited the desired responses from target audience. As a result, the campaign was a colossal success (Ebigbagha, 2010, 2012; citing the Nigerbus Research Group evaluation in 2004; and the National HIV/AIDS Reproductive Health Survey - NARHS evaluation in 2005; as cited in SFH Corporate Presentation, 2006).

The Use Condom Campaign in Nigeria

The Use Condom Campaign is an example of the prevalent production of ineffective graphic messages for development in Nigeria. Its goal was to sensitize audience to use condom as a preventive measure against HIV/AIDS. Stimulus produced includes posters, pamphlets and stickers, to mention a few. An examination of the media production process showed that there

was extremely low level of collaboration between the source, graphic encoder, and the target audience during the several stages in the media production process (Ebigbagha, 2010). Of these stimulus materials produced, a poster: "No Condom No Sex" and a Sticker "Female Condom Does Not Promote Promiscuity Use It" (Plate IIIa and Plate IIIb) respectively, would suffice to be examined in order to relate whether or not the quality of the graphic media produced elicited desired target audience response.

Plate IIIa and IIIb: (a) A poster on "No Condom, No Sex" and (b)A sticker on "Female Condom Does Not Promote Promiscuity Use It" by Society For Women and Aids in Africa

The poster "No Condom, No Sex" (Plate IIIa), warns against unprotected sex as a measure to stem the HIV/AIDS epidemic. The emphasis is on the use of condom. It depicts a man approaching three ladies in front of a building (brothel). The man is in attire commonly worn by Western and Northern Nigerians. The three ladies, each in front of a door to a room wore seductive attires and seem to communicate with the man. The illustration in the poster is fair but contains elements that could destroy the essence of the campaign because of semantic uncertainty. Some interpretations that could be inferred from it include the following: (i) only those who go to the brothel are at risk to contracting HIV/AIDS and need use condom. (ii) Only those who patronize prostitutes are at risk to contracting HIV/AIDS and need use condom. (iii) Only those who are from the Western and Northern Nigeria are at risk to contracting HIV/AIDS and need use condom; and (iv) Only those who want to prevent HIV/AIDS need use condom.

A consideration of these misleading interpretations would have been made at the draft stage, and proper decisions taken had the media draft been properly pre-tested with target audience. The attire of the man would have been revised because of the socio-cultural implication. Also the attention to brothels and prostitutes would have been revised because the most liable group to HIV/AIDS who are in the age group of fifteen to twenty-five years (SFH Corporate Presentation, 2006) are predominantly in the school and out-of-school environment, particularly on the street rather than in the brothel. Today, prostitution along the street is common and fashionable than the brothels.

The Sticker, 'Female Condom Does Not Promote Promiscuity Use It' (Plate IIIb), is a potent example of a stimulus that woefully failed to elicit the desired response from target audience (Ebigbagha, 2010).

The stimulus condition is a misleading misrepresentation of the message purported. The word 'Promiscuity' is emphasised with red colour and boldly written in capital letters. The prime message 'Female Condom' is de-emphasised with green colour though boldly written in capital and low letters. The supporting information 'Does not promote' and 'use it' are written in slim italics and further de-emphasised with black colour. The iconic image of the condom and the container are placed on both sides separately and further de-emphasised with

green colour in half tone. Each set of words are expressed in a different typeface and in all, there are four typefaces, which are too many for the given space.

On the whole, the haphazard placement of both the graphic and typographic elements defies any existing described/prescribed layout for the production of effective graphic language. At a distance, one is confronted with these three words 'Female Condom Promiscuity' The IEC materials seem to encourage promiscuity, which is against its real communication goal.

Besides, it is unattractive, uninteresting and loaded with uncertainties. The iconic image was paled to the point that it was insignificant and target audience asked for real representation for the purpose of clarity because they could neither understand it nor identify what it was.

From the foregoing, the campaign was a huge failure. It was found that proper evaluation (pre-testing, and summative evaluation) with target audience was neglected; and as a result, the stimulus produced was unable to elicit the desired response from target audience (Ebigbagha, 2010, 2013).

FINDINGS

Eliciting desired responses from target audience requires generating graphic messages that are target audience-based. A key way to achieving this is pre-testing media draft with target audience, as exemplified by The ORT Campaign in Egypt and The Delayed Sexual Debut Campaign in Nigeria. This provides needed knowledge of the two major determinants (Stimulus and Audience Conditions) of audience perception and response to graphic messages.

The pre-testing of media draft provides panacea for technical, semantic, syntactic, arousal/aesthetic, and response uncertainties that characterize most graphic communication campaigns in Nigeria, as shown in the Use Condom Campaign. Its neglect during the communication development process, usually result in the production of ineffective stimulus conditions that often leads to communication failure and create formidable barriers to effective graphic communication that is counterproductive.

The foregoing findings are hinged on a triangulation of methods (the Critical-Historical-Analytic Examination, and Content Analysis). The Content Analysis was employed to examine the graphic and typographic elements in the campaign media. This is in order to assess the stimulus conditions described/ prescribed in the Akar and Myers model of the perception process, which is salient for eliciting desired target audience response.

Furthermore, the Critical, Historical and Analytic Examination approach was utilised. This was to evaluate the consideration of audience conditions during the media production process and target audience response to the graphic media produced for campaign. These were achieved by critical and analytic examination of existing secondary data (related literatures, models and reports, to mention a few).

CONCLUSION

Making graphic messages based on target audience conditions is a key to eliciting desired target audience response in development communication. So, a diligent consideration of the knowledge, aptitude and practice (KAP) of target audience is indispensable to generating stimulus that attracts attention, stimulates interest, correctly interpreted and easily committed to memory and recall.

A prerequisite of effective target audience-based stimulus is pre-test of the media/stimulus

draft; which requires integrated planning and the collaboration of all communication actors including the target audience in the communication development process. This facilitates the understanding for the proper use of the element of design according to the principles of organisation within the context of the target audience KAP. In addition, satisfactory resolutions of uncertainties that usually occur in the graphic encoding process that are potent hindrances to achieving desired response are occasioned.

RECOMMENDATION

From the forgoing:

i. The graphic encoder, other communication actors, and the target audience need be embedded in the communication development process.

ii. The media team should be conversant with target audience conditions by thorough consideration of receivers' knowledge, aptitude and practices; and

iii. The Source should adopt strategies of evaluation, particularly pretesting media draft with target audience.

The Economic Impact of Ikogosi Warm Spring on Its Immediate Environment

Olanrewaju, D. O. & Adedeji A. A.

Federal University of Technology, P.M.B 704, Akure, Ondo State, Nigeria
* *dejgok986@gmail.com*

ABSTRACT

Ikogosi warm spring is an important tourism resort in Ekiti State, Nigeria for which little has been known of its contributions to the development of its immediate environment. This study thus attempts to provide synthesized information on the impact of the tourism centre. Data for the study were collected using both primary and secondary sources. Specifically, 191 households being 10% of the total households of Ikogosi settlement were randomly and systematically selected for questionnaire administration. In the same way, questionnaire was also administered on 10% of the tourists found at the tourist centre. Apart from collecting information from the staff of the tourist centre using focus group discussions the officers of the State Tourism Board, useful data were gathered from relevant National and State publications. The findings showed that the tourism centre is an important resort for which the immediate past government had invested on though, the facilities so provided are underutilized. A significant impact in terms of improvement in the social life of the population, their occupation, particularly, trading activities and transportation were identified. The tourism Centre is not without its disadvantages which include destruction of fauna and adverse social behaviour by youths. The study recommends private – government partnership for effective management and effective publicity to raise the number of visitors to the tourism centre.

Keywords: Economic Impact, Ikogosi, Immediate environment, Tourism, Warm spring

INTRODUCTION

The contributions of tourism to the economic development of the Nations are widely acknowledged. No wonder the world tourism organization (WTO) argued that exports of tourism service generated $1,093 billion in 2010 and 30% of the total world exports of service accounted for $ 2670 billion. Ogunberu (2011) pointed out that tourism is the largest and fastest growing industry in the world. According to him, tourism accounts for about 7% of world capital investment with revenue predicted to rise up to 1.550 billion dollars by the year 2015. Akintude (2011) had elucidated that international tourism has been a major source of foreign exchange earnings in countries such as Saudi Arabia, United Arab emirate, United States and Spain. The contribution of tourism to employment generation cannot be over emphasized. The international labour organization (ILO) estimated that tourism generated 253 million jobs worldwide in 2010. A study of Vella (2011) in T20 countries confirmed the high rate of employment generation in those countries. Nigerian has several capacities that have not been used. Ikogosi warm spring in Ekiti west local government area of Ekiti State Nigerian is one of those tourism resources which are known but largely unexplored. Ekiti State Nigerian is not an oil producing state but has the warm spring which is a unique tourism resort. It is well known that tourism if well-developed could generate numerous opportunities for diversification of local economy, by attracting economic resources to areas where there are few opportunities for alternative (Vella, 2011).

Ogbuewu (2003), also argued that if tourism sector is developed has potentials in addition to to generate foreign exchange, encourage even development, promote tourism based rural enterprises, generate employment, and accelerate rural and urban integration and cultural exchange**.** This study is therefore aimed at assessing the impact of warm spring in Ikogosi town on his immediate environment with a view to assess the economic impact of the tourist centres on the host population and immediate communities. The paper takes off from this

Olanrewaju, D. O. & Adedeji, A. A. (2016). The Economic Impact of Ikogosi Warm Spring on Its Immediate Environment. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. introduction to look at relevant literature to put the whole study in properly theoretical perspective. The literature search is followed with a view of the study area and the research methodology which is followed by analysis and discussion of findings. The findings will be followed with appropriate recommendation and conclusion.

THEORETICAL FRAME WORK AND LITERATURE REVIEW

Tourism has been described as a bundle of goods and service combined together with a fixed proportion (Ardahaey, 2010). According to Zaei and Zaei (2013), tourism is not limited only to activities in the accommodation and hospitality sector, transportation sector and entertainment sector with visitor's attraction, such as theme parks amusement parks, sports facilities, museums and others. But tourism and its management are closely connected to all major functions, process and procedures that are practised in various areas related to tourism as a system. Tourism is therefore, an economic sector which can significantly affect the economic growth of a region. Economic impacts associated with tourism arise as a result of the demand and supply relationships in the industry, the associated visitor and investment expenditure patterns that they stimulate, and the structure of the economy (Ardahaey, 2010). Ardahaey (2010) further argued that the demand and supply factors influence the number of visitors, their length of stay, and their expenditure patterns.

While the economy's structural characteristics determine its propensity to re-circulate that expenditure internally, tourism influences different categories of impacts, economic, physical and social. It is however argued that the links between the different categories of impacts, economic, physical and social are close and thus interpreted and indicated complex and difficult to measure and plan (Ardahaey, 2010). Economic impacts can be categorised into direct, indirect and induced impacts. Stynes (1997) defined direct effect as production change associated with the immediate effects of change in tourism expenditure. Impacts include payment for accommodation in hotels, travel cost and food and drinks. Direct impacts are related to issues directly affecting the tourism workers and the resorts environment. Indirect effects according to Stynes are production changes resulting from various round of re-spending of the hotel industry receipts in other backward linked industries.

The benefits include industry supply products to hotels and those who benefits from the expenditure of tourism workers. On the other hand induced effects are the changes in economic activity resulting from household spending of income earned directly and indirectly by tourists, spending their income in the local and the region for housing, food, transportation, array of household products and service need (Stynes, 1997).This paper will not attempt to differentiate these categories of impacts in its assessment. There are a number of techniques to assess tourism economic impacts. The economic impacts of tourist's expenditure can be calculated by using the multiplier analysis (Ardahaey, 2011). It is argued that economic features of tourism industry are that an income earned in places of residences, is spent in places visited (Holloway & Robinson, 1995).

According to Zaei and Zaei (2013) tourism is an instrument in transferring a vast sum of money from income generating countries to income receiving countries. The money spent by tourists in Zaei and Zaei's words does tend to percolate through levels. They further said that tourism as a source of income is not easy to measure with any degree of accuracy , nevertheless , the most common method for estimating income generated is to determine the ' multiple effect' in a destination. Multipliers may be expressed as ratio of sales income or employment, or as ratio of total income or employment changes relative to direct sales, multipliers express the degree of interdependency between sectors in a region's economy and therefore vary considerably across regions and sectors (Stynes, 1997).

The flow of money generated by tourist spending multiples as it passes through various segments of the economy. Referring to Holloway (1998), Ardahaey (2011) argued that there are four ways of measuring economic impacts of tourism, that is, the effect on income, employment, the area of balance of payment and finally the effect of investment and development. As much as possible this study will cover most of these areas particularly as revealed and limited by local factors

THE STUDY AREA AND RESEARCH METHODOLOGY

Ikogosi-Ekiti in Ekiti State is located in Southwest Nigeria which is situated between lofty, steep-sided and heavily wooded, north-south trending hills of about 27.4 km east of Ilesha (Osun State), it is also located about 10.5 km southeast of Effon Alaye (Ekiti State). Ikogosi warm spring is located north of the 7^{o} 35'N latitude and slightly west of the 5^{o} 00' E longitude. The elevation of the general area is between 457.0- 487 metres above sea level. Temperature ranges between 21° and 28°C with high humidity. The south westerly wind and the northeast trade winds blow in the rainy and dry (Harmattan) seasons respectively. Tropical forest exists in the south, while savannah occupies the northern peripheries. Ikogosi Warm Spring is selected as a case study because it is one of the most popular recreational centres with the highest recreational potentials in the State (Afolabi, 2006). The 1991 national population census puts the population of Ikogosi –Ekiti at 6,984 with 3,314 male and 3,670 female. And its estimated population in 1996 was 7,863. At present using a population growth rate of 2.5 percent, the town is estimated to have over 13,386 people.

The type of research design employed in this particular study is survey design. Data was collected from both primary and secondary sources. Data were collected from tourists and the people living around the tourist centre by the use of questionnaire. Also a focus group discussion was used to gather information from staff of the tourist centre. In addition to observation photographs of the tourists and the study area were taken. Information from the secondary source includes data on the number of visitors in the previous years from records of workers and recent policy of government from Ekiti state tourism board. The total number of questionnaire administered amounted to 10% of the total population and a figure of (191) people. Also 10% of the population of tourists, the researcher came across were randomly selected for interview. In order to analyse the data that were collected in the course of the research; both descriptive and inferential statistics were used. Tables and chart were employed to present the magnitude of occurrences of the variables that were obtained.

ANALYSIS AND DISCUSSION

As earlier mentioned most of the analysis and discussion were limited to direct impact, due to constraints of appropriate data in other areas of impact measurement. The employment issue is presented in table 1. Majority of the respondents that is, over 58% agreed that the presence of the tourism centre creates employment for the residents of the town. There is no doubt that the presence of the tourism centre has created employment opportunities because most of the staff of the tourism centre are residents of Ikogosi town. It was also noted that a lot of the youths in the town were engaged in transportation business, particularly motor cycle (okada) moving from the town to the tourism centre. In addition, there is the goosy bottle water company owned by UAC, this is located very close to the warm spring, majority of the staff of the company live in the town. This section on employment went further in its analysis by enquiring if the tourism centre had provided desirable jobs in the community. As indicate in table 2, 42.4% of the resident's disagreed that the tourism centre had provided the desirable job while 15.7% strongly disagreed. In other words more than 58% were of the opinion that the centre had not provided the desirable jobs. It was argued that the jobs provided were

seasonal, unskilled and low wages by this group. While about 15% of the residents were neutral on the job creation, up to 26% agreed that the right and desirable job were created.

Table 1: Creation of employment opportunities

Employment opportunities	Frequency	Percent
Strongly disagree	20	10.5
Disagree	10	5.2
Neutral	50	26.2
Agree	91	47.6
Strongly agree	20	10.5
Total	191	100.0

Table 2: Provision desirable jobs in the community

Provision of Desirable jobs	Frequency	Percent
Strongly disagree	30	15.7
Disagree	81	42.4
Neutral	30	15.7
Agree	21	11.0
Strongly agree	29	15.2
Total	191	100.0

Authors actually varied in the argument on value of tourism as far as job creation is concerned. Zaei and Zaei argued that tourism industry is high labour intensive service industry and hence a valuable source of employment. They argued it provides employment several times more than normal manufacturing industries. Ardahaey (2011) on the other hand believed that tourism employed more people in less developed countries and people employed are at lower performance level in order to keep their salaries low. Tourism effects are often invisible or covered as tourism might employ people from other sectors or people that would not otherwise be considered to belong to the available workforce. Therefore it might be difficult to measure and see the real impacts tourism has on employment.

The Result of the survey as shown in table 3 reveals if the price of goods and services in the community has increased as a result of the resort. As much as 63.9% of the residents sampled agreed that price of goods and services in the community have increased because of tourist resort. Also 5.3% strongly disagreed, 9.4% of the respondents disagreed while 20.9% strongly disagree. This section went further in its analysis by enquiring if the local businesses have benefitted from the tourists. Table 4 shows that 41.9% of the residents sampled agreed that their local businesses have benefited from the tourist while 20.9 % of the respondents disagreed. Also 20.9% were of neutral view, 10.5% of the respondent's strongly agreed while 5.8% strongly disagree. The local businesses that thrive as a result of the tourists include the petty trading and the motor cycle riding business (okada).

The major problems of the tourist centre were also examined so as to examine the impact of the problems on the economic development of the host communities. Table 5 shows that like most Nigerians, the host community blames the government for inadequate facilities at the centre with 42.9% choosing this as one of the main challenges of this site. Everyone seems to opine that the majority of the responsibility of the site rests with the government. Next to that 22.0% of the respondents were of the opinion that the problem of the tourist centre is as a result of lack of awareness of the centre. This presupposes that the government did not do enough publicity to attract visitors to the site. In other words, there was no enough publicity concerning the existence of the tourist centre, 13.1% of the respondents confirmed that the

level of patronage is low because the resort are mostly patronised during festive period. Also 6.8% of the host community respondents confirmed that the centre lack development which leads to massive emigration of the youths that they believed are much needed for the promotion and every day running and maintenance of the centre. They ascribe the emigration movements to the State capitals around the communities such as Akure and Ado Ekiti .Other problems includes; difficult topographical terrain with 9.9 % and there was more or less no blame on the tourist themselves with just 6.8% of the respondents putting the blame on bad usage by the tourists.

Table 3 Increase in price of goods and services

Increase in price of goods and services	Frequency	Percent
Strongly disagree	40	20.9
Disagree	18	9.4
Agree	120	63.9
Strongly agree	11	5.8
Total	191	100.0

Business Benefit from Tourist	Frequency	Percent
Strongly disagree	11	5.8
Disagree	40	20.9
Neutral	40	20.9
Agree	80	41.9
Strongly agree	20	10.5
Total	191	100.0

Table 5. *Major problems of the tourist centre*

Major problems of the tourist centre	Frequency	Percent
Inadequate government intervention	82	42.9
Difficult terrain	25	9.9
Lack of awareness	42	22.0
bad usage by the tourist	13	5.2
emigration of youth	19	6.8
Low level of patronage	10	13.1
Total	191	100.0

CONCLUSION

This study has tried to assess economic impacts of Ikogosi tourism on its hosting environment. While there have been some significant impacts, the impact have not been enough. They are not outstanding enough because opportunities that are supposed to be available have not been fully tapped. Majority of the respondent were of the opinion that the centre had not provided the desirable jobs. It was argued that the jobs provided were seasonal, unskilled and low wages by this group. Also only 41.9% of the agreed that there business as benefited as a result of the resort the study thus recommends that some of those opportunities be fully utilized. Information from the tourists and observation show that the tourist centre has not attracted enough international tourists. This is evidence that there has not been a satisfactory level of publicity.

RECOMMENDATIONS

It is well known that tourism generate numerous opportunities for diversification of local economic by attracting economic resource to area where there are few opportunities (Vellas, 2011). Ekiti state is not an oil producing state, both the government and individual should take the advantage of the resource available with Ikogosi resorts to come up with economic enhancing opportunities. Apart from Ekiti state government provided chalets there are no hotels and standard restaurants in Ikogosi, this is among the area where private investors should come in. Government need to provide the enabling environment to attract private investors in tourism development in the region. In relation to the above is the relatively unknown of Ikogosi warm spring internationally as found in this study. This due to lack of publication, Both the Nigeria and Ekiti governments need to embark on high profile publication to make the resorts recognised nationally and internationally.

Preference of Visual Aesthetic Architectural Features amongst Practicing Architects

Omale, Reuben Peter

Department of Architecture, Federal University of Technology, Akure. Ondo state, Nigeria
reubenomale@gmail.com

ABSTRACT

This study entails assessment of the approach façade of some selected public buildings in Akure, Nigeria for visual aesthetic quality. The study sought to find out if preference for certain aesthetic building features were common in architects or if individual divergent choices existed. Twelve buildings were assessed for visual quality and five architectural features were considered as the variables for the study. They include: entrance design, façade colour, roof design, fenestration design, and innovation in overall shape of the buildings. Previous studies have shown that there are divergent views on preferences for aesthetic features between laypersons and building professionals. Therefore, this study concentrated on building professionals in the assessments-particularly practicing architects. Preferences for visual features in buildings are based on what people like or dislike, hence a level of subjectivity is allowed in peoples' choices within the study. Digital photography was used in capturing the images of the twelve building samples and these images were used alongside questionnaires as first hand visual data so as to elicit information on preferences for aesthetic features. Some results indicated that though some of the buildings were visually appealing, they were lacking in other aesthetic appeal and other buildings that were not so visually appealing had some striking aesthetic features. Recommendations from this study will assist designers especially architects in creating buildings that are more visually appealing and more public friendly.

Keywords: architecture, architectural features, assessment, buildings' façade, visual aesthetics

INTRODUCTION

To prefer a thing to another means having more likeness for the preferred object compared to other objects. In nature generally, humans continuously process visual information either consciously or unconsciously, thereby making visual processing the most processed data in humans. Ware (2008) affirm that the visual sense is an exceptional human quality required in perception in many disciplines including art and architecture while Leone (2013), opines that scientists have confirmed that half the human brain is devoted to processing visual images, and 80 percent of learning is based on visual inputs. Visual aesthetics means the perception or appreciation of objects that are appealing to the sense of sight. The environment in which we live, work and play contains and emits features that portend and evoke stimuli in people. The built environment which architecture is a subset of contains visual features that creates an interaction with observers when visually perceived. According to Sanoff (1991), buildings have certain qualities that give them a high probability of evoking a strong image in any given observer. Characteristics like shape, colour, or arrangement enable the making of vividly identified mental images of the environment. Buildings are also objects with features that can transmit non verbal messages and can be subjected to visual experience of an observer for aesthetic judgment. Buildings can be judged based on their physical features especially along how pure the lines are, colour, texture, form, size etcetera. Goldman (2001) suggests that applying aesthetics to buildings and related architectural structures is a complex phenomenon, and aesthetics in buildings can be studied from either of two or both vital factors. These are extrinsic and intrinsic factors to visual design. Extrinsic factors comprise structural integrity, cost, nature of building materials, and functional utility of the building,

Omale, R. P. (2016). Preference of Visual Aesthetic Architectural Features amongst Practicing Architects. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1059-1067

while the intrinsic factors are elements of visual interests that are perceptible and sensory and can be evaluated in buildings.

Despite the fact that architecture can be considered as visual art, assessment of building facades for visual aesthetic quality and post occupancy evaluations especially of public buildings are rarely done in this part of the world thereby making studies around visual quality difficult. However, this creates a huge research gap by making the visual field a virgin area of research in architecture especially in the tropics where housing affordability and quality still remains a mirage for the teeming populace. Researching visual aesthetics in buildings can be a difficult task as agreed by Goldman (ibid), but this is an attempt to close the existing research gap a little and to open up channels for further studies. Onsite field observation checks reveal that low visual aesthetics exists in most of the building samples for this research. This research work aims at assessing public buildings facades to study preference for architectural features among practicing architects with a view to developing a framework towards higher visual quality standards in public buildings.

REVIEW OF LITERATURE

Previous studies have shown that visual aesthetic quality in buildings has been understudied Nasar, (1994), and (Zhang 2009). This phenomenon according to (Fuerst, McAllister and Murray, 2011), could be attributed to the high level of subjectivity involved in the assessment of visual properties. In particular, the distinction between experts and lay persons can be a crucial variable. For instance it is notable that surveys have found that there tend to be significant differences in the ratings of design quality between the public and design professionals (Brown and Gifford, 2001). Delvin and Nasar, (2004) further showed that even among professionals, significant differences still exist within and across professionals. Despite these difficulties, this should be a challenge and an avenue for further studies towards opening up more researches into the visual aesthetic field, especially among building professionals.

Ulrich and Gilpin (2003), noted that generally speaking on studies of visual environments including urban architecture and interiors as well as natural environments, there appears to be a strong preference for natural scenes compared to urban scenes for different population groups around the world._Tonio & Leder (2009), studied familiarity of simple and complex stimuli in observers and findings indicate that preference for complexity showed strong contrast effects with more familiarization. Observers familiarized with simple stimuli preferred more complex stimuli, while those familiarized with complex stimuli later preferred simpler stimuli. Bar and Neta (2006), recently found that people tend to prefer objects with curved contours to similar objects with sharp contours. This is an indication that sharp contours are more threatening and could be harmful than curved ones. Preferences for colour in gender as indicated by Chiu et al (2006) also discovered that girls within the ages of 3-12 tend to prefer pink and purple, while boys of the same age group show more preference for red and blue. Products experts especially in kids toys have taken advantage of such discoveries from the results of such studies to develop gender-specific toys that follow such colour patterns. However, these colour preferences within gender changes with age as children mature.

Other studies with features of the built environment as direct predictors of aesthetic appraisals reveal that in building interiors, unusually high ceilings, presence of windows and squares rooms as opposed to rectangular ones are associated with high preference (Kaye& Murray, 1982). Other studies about abstract variables such as cognitive constructs show greater preference for buildings that have moderate complexity, and buildings that appear more orderly or coherent (Herzog, 1992). Ghomeshi, Nikpour and Jusan (2012), found out in

a study on 'architects perspective of identifying different aesthetic quality of buildings', that building attributes have different values and meanings among architects, and while some cues are very important for architects, some were not so much important. Using an instrument called 'TACS' The Architectural Coding System, the study indicated that architects prefer glass cladding, bricks and colour uniformity among others, and had a strong dislike for circular windows. Gifford et al (2000), found out that architects preference for buildings with more railings, fewer arches and more metal cladding elicit more pleasure and buildings that had more triangular elements and more rounded edges and corners were fancier and elicit feelings of arousal within architects. The study also found that a combined feeling of pleasure and arousal was noticed within architects as it appears that metal-clad buildings excite architects. Gifford and friends attribute this perception and preference in architects to their training and experience compared to non architects. However, he concluded that it has become clearer that not all observers appraise buildings in the same way and that it is necessary to learn how appraisals within different groups vary.

The issue of taste and experience becomes key when an aesthetic experience is judged. Joshi *et al* (2012), attributes this to the highly subjective nature in aesthetic experience explaining that it is the reason why same photographs can be appreciated by some observers and not appreciated by others. Other important factors that come into play when judging an aesthetic experience include exposure by observers to previous works to be judged, cultural differences, emotional evocations and other personal attributes. Aesthetic opinions/judgments have been found to be dynamic as human observers aesthetic feelings can change over time.

METHODOLOGY

This study was carried out in Alagbaka area of Akure in Southwest Nigeria. The study employed a quantitative methods approach and a survey and observation method was adopted while a questionnaire was structured to elicit relevant quantitative information from respondents. It was necessary to measure visual aesthetic quality by quantitatively assigning values to several building features that can be visually assessed through two-dimensional graphic representations using digital images. The building features should have the characteristics that can be evaluated through direct observation of the captured building images. The views captured, as much as possible show the building features that were assessed. 50 respondents were targeted for the full scale study. On that account, 10 respondents representing 20% of participants were administered questionnaires for the pilot survey. The target group was strictly architects as only professional assessments of experts were sought within the study. The intention of the study was to get opinions of experts and not lay persons as a huge gap has been shown to exist between perceptions and preferences between architects and non-architects.

This necessitated the need to carry out the study using architects alone. This method was adopted so as to find reliable, objective and simple straight-forward means of measuring visual aesthetic quality in buildings that can also be applied to other types of buildings as well. To stimulate visual interests, 12 modern urban building images were captured using digital camera and the digital images of the buildings were included within the questionnaire so as to elicit aesthetic responses from the target group. According to Groat 1988, Nasar 1998, & Stamps 2000) a strong correlation was found between preferences expressed in 2D representations in photographic forms and preferences indicated onsite, although a negative correlation was found when original paintings and sculptures were assessed onsite than online (Joshi *et al*, 2012).

A five point Likert-like scale was used to generate numeric values within the survey questionnaire that was developed for quantitative analysis. The questionnaire was designed

around the five variables to be studied and was refined to maximize the time limit spent on responses. This type of method of enquiry is commonly used among researchers in environmental aesthetics as it is a method of qualitative interview which involves using digital camera to capture first hand visual data of the physical appearance of the building images as existing on site was adopted and corresponding questions were directed to respondents on the photographed buildings using quantitative measures. The research assistants took snapshots of the buildings from different positions, while the best snapshots that showed more visual features were chosen for the study samples. 5 research assistants were co-opted into the research team and were effectively utilized during the field study and questionnaire administration.

FINDINGS AND DISCUSSIONS

Perception of Visual Aesthetic Quality of Public Buildings among Design Professionals

Five variables were assessed in twelve building images for visual aesthetic quality among practicing professional architects, while the five building characteristics include: roof design, entrance design, fenestration design, façade colour and innovation in building shape. The calculated mean scores were very useful in making comparisons within the ordinal data provided. However stronger comparisons could be achieved using percentage scores for each variable within the 12 building images. Joshi *et al* (2012), posits that when a photographic scene is rated by observers on a merit scale on the basis of its aesthetic qualities, the average score can be thought of as an estimator for its intrinsic aesthetic quality. Descriptive summary for the twelve buildings are as presented in table 1. It shows the mean distribution of the roof design, fenestration design, façade colour, entrance design and Innovation in building shape, including the appropriate ranking for all 12 buildings.

Table 1: shows the mean values of individual buildings against the five respective variables within the study.

Building images	**Roof design**		**Fenestration des.**		**Façade color**		**Entrance des.**		**Inn. in shape**		***Overall***	
	Overall Mean	Rank	Overall Mean	Rank	Overall Mean	Rank	Overall Mean	Rank	Overall Mean	Rank	Overall Mean	Rank

Building 7	3.36	6	3.29	9	3.54	6	3.61	4	3.36	6	*3.43*	6
Building 8	2.72	9	3.68	6	3.27	7	2.54	11	2.77	9	*3.00*	8
Building 9	2.02	12	3.29	9	2.00	12	2.02	12	2.40	11	*2.35*	12
Building 10	3.45	5	4.04	3	3.56	4	2.97	9	3.38	5	*3.48*	5
Building 11	3.56	3	4.27	1	3.88	2	3.52	5	3.97	2	*3.84*	2
Building 12	3.77	2	4.06	2	3.93	1	4.15	1	4.52	1	*4.09*	1
Average	*3.17*		*3.58*		*3.29*		*3.23*		*3.20*		*3.29*	

From the average of the mean values shown in table 1, it can be deduced that fenestration designs for the building features ranked 1st in terms of perception among professional architects with an average of 3.58. This indicates that fenestration designs are ranked high in

public buildings. This can be attributed to a common design trend in the tropics where weather situations can be very hot amidst poor power supply. Large symmetric fenestration designs, especially for windows allow natural cross ventilation thereby reducing the effects of hot weather and thereby cooling the building interiors. Façade colour ranks 2nd-3.29. This could be an indication that architects use colours well for a sense of appeal in building facades. Entrance design ranks third with an average score of 3.23. However, innovation in building shape ranks 4th among the five variables studied with an average of 3.20. This result could be an indication that innovation in building shape in public buildings should be given more attention. Roof design ranks 5th with an average of 3.17. This is a clear indication that roof designs have least visual appeal in public buildings in Akure.

The table also shows an estimation of the average of all the five building attributes assessed for visual quality. On the overall average, building 12 was ranked 1st in terms of visual aesthetic quality with an average of 4.09. Building 11 ranked 2nd with an average of 3.84, building 2 ranked 3rd with an average of 3.79. 4th is building 6, 5th-building 10, and 6th is building 7. Others are: building 5 ranked 7th, building 8 ranked 8th, building 4 came 9th with an average of 2.99, while building 3 ranked 10th position in visual quality. Surprisingly, building 1 ranked 11th with an average of 2.71 and building 9 ranked last position with an average of 2.35.

Interestingly, some of the buildings, especially the last ranked 3 positions, were ranked relatively high in some of the building features assessed compared to their total average. For example, building 3 ranked 10th overall position, but still showed some strength in entrance design- 3.18, facade colour-3.02 and roof design-3.11. Also, building 1 ranked 11th position overall, but showed some strength in fenestration design-3.30. And building 9 too, showed some strength in fenestration design with an average of 3.29.

A closer look at table 1, show that the best 3 ranked buildings (i.e buildings 12, 11 and 3) have the highest average score in innovation in building shape, fenestration design and roof design. This could be an indication why the three buildings were ranked as the best three amongst other reasons. However, innovation in building shape and roof design ranked 4th and 5th positions in the assessments of building features, showing that less attention is given to innovation in building shapes and roof designs.

Preference for Building Features of Public Buildings among Professional Architects

Within the study, preference for five building features which include roof design, fenestration design, façade colour, entrance design and innovation in building shape was sought on the facades of the 12 building samples among professional architects. In some building facades, some features are more striking and therefore dominate other features and are therefore preferred to others. Following the most dominant score concept of Joshi *et al* (2012) as used for aesthetic emotions, the most dominant score concept was employed for preference voting for each of the five building feature within the 12 building images, and the most dominant score or single majority vote for each building feature was accepted as the true reflection of observers preference. It should also be noted that where no most dominant score exist for any building, the closest option will be to accept the one-third majority vote. Table 2 shows respondents' preferences for the five building features in percentages.

In building 1, fenestration design is most preferred with 44% compared to roof design and façade colour with 20% each. Entrance design is ranked 4th and only 2% of respondents like the shape of the building. In building 2, 44% of respondents prefer the building's roof design, while 24% believe its innovation in shape is interesting. Both façade colour and entrance design for building 2 have 12% each and its fenestration design poorly preferred with only 6%. Roof design is most preferred in building 2. For building 3, 32% of respondents prefer its

façade colour, while an average of 21% was voted for three building features, namely: roof design, fenestration design and entrance designs. Only 2% believe there is innovation in its building shape. This makes façade colour most dominant of its building features.

Table 2: Shows the percentage of respondents that chose the five building attributes under study among the 12 building images.

Building images	Roof design	Fenestr. Des.	Façade colour	Entrance Des.	Innov. In bldg shape
Building image 1	20	44	20	10	2
Building image 2	44	6	12	12	24
Building image 3	22	20	32	20	2
Building image 4	4	44	24	24	2
Building image 5	10	16	18	50	4
Building image 6	22	30	20	18	8
Building image 7	6	32	22	36	4
Building image 8	12	38	22	12	12
Building image 9	10	54	12	12	2
Building image 10	22	28	24	18	6
Building image 11	4	22	28	20	24
Building image 12	2	6	8	16	68

For building 4, fenestration design was most preferred with 44% response rate. 24% each chose façade colour and entrance design, while roof design and innovation in building shape were poorly voted with 4 and 2% each. For building 5, half the number of respondents representing 50%, prefer its entrance design. 18% prefer its façade colour, while its roof design and innovation in building shape are 10 and 4% respectively. For building 6, 30% prefer its fenestration design while its roof design, façade colour and entrance design are almost evenly preferred with 22%, 20% and 18% respectively. Innovation in building shape is least preferred with 8%.

Table 3 is a summary of table 2 showing only where most dominant feature/score occurred.

Building images	Most dominant feature	Percentage score
Building image 1	Fenestration Design	44%
Building image 2	Roof design	44%
Building image 3	Façade colour	32%
Building image 4	Fenestration Design	44%
Building image 5	Entrance Design	50%
Building image 6	Fenestration Design	30%
Building image 7	No most dominant feature	-
Building image 8	Fenestration Design	38%
Building image 9	Fenestration Design	54 %
Building image 10	No most dominant feature	-
Building image 11	No most dominant feature	-
Building image 12	Innovation In bldg shape	68%

For building 7, 32% prefer its entrance design, closely followed by fenestration design-32%, façade colour-22% and 4th and 5th place were roof design and innovation in building shape. In Building 8, 38% of respondents prefer its fenestration design. Closely followed by 22% façade colour. Roof design, entrance design and innovation in building shape were all rated 3rd with 12% each. Building 9 however has over half of respondents prefer its fenestration design with 54%. 54% is the second highest preferred score for any building feature. An average of 11% prefer three of its features, namely: roof plan, façade colour and entrance design. The least preferred building feature for building 9 is innovation of building shape with 2%. Despite building 9 ranking 12th position (table 2) it has the 2nd highest score among the five building features investigated and the highest score for fenestration design (54%).

Building 10 has an almost even distribution for four of the building features namely: roof design, fenestration design, façade colour and entrance design with 22, 28, 24 and 18% respectively. The least preferred building feature for building 10 is innovation in building shape. Building 11 has a similar distribution like building 10 except for that the choice of building features are slightly different. In building 11, the even distribution are for fenestration design, façade colour, entrance design and innovation in building shape with 22, 28, 20 and 24% respectively, except for roof design with the lowest preference of 4%. Building 12 has the highest percentage (68%) for innovation in building shape. This possibly explains why it ranks 1st in overall building features in table 1. Entrance design ranks 2nd while the other features: roof design, fenestration design and façade colour rank low- 2, 6 and 8% respectively.

In all the building images investigated, it is obvious in the percentage scores that all the building features were preferred by observers in all the buildings represented, though some features were scored very low while others very high, yet some others were moderately preferred. It appears that preference for building features is highly subjective and is relative from person to person. This statement is further corroborated with the Pearson Chi-square test below to check individual difference among the professional architects.

Pearson Chi-Square test was used to analyze quantitative data. Five building features where assessed within the 12 building samples among 50 professional architects. The results for the Chi-Square tests are presented in table 4 below:

Building images	Value count	df	Asymp. Sig. (2 sided)	min. expected
Building image 1	2.917	10	.983	.12
Building image 2	7.617	10	.666	.12
Building image 3	10.762	10	.376	.12
Building image 4	12.460	10	.255	.12
Building image 5	8.956	10	.536	.12
Building image 6	13.748	10	.185	.12
Building image 7	5.443	8	.709	.24
Building image 8	15.818	10	.105	.24
Building image 9	7.708	10	.657	.12
Building image 10	5.956	10	.819	.12
Building image 11	13.485	10	.198	.12
Building image 12	9.542	8	.299	.12

The asymptotic significance level calculated for all the building features within the 12 building samples among the professional architects were all greater than 0.05. Therefore this is a clear indication that no significant difference was found in individual architects' preferences for aesthetic building features in the 12 building samples tested.

CONCLUSION

Practicing architects are challenged to create an all-inclusive and well balanced aesthetic façade design especially for public buildings, bearing in mind that aesthetic features of buildings constitute and trigger aesthetics responses in observers. Innovations in building shape and roof design were played down in samples of public buildings façades studied, yet they play an integral and key area in making building facades worthwhile aesthetic experiences.

This study did not consider the emotional evocations of professional architects and that of other design or building professionals within its scope. It also did not study aesthetic

emotional responses of users and Clients of buildings. These are areas of further research that can throw more light into aesthetic perceptions and preferences of observers, thereby enhancing architects aesthetic appeal for public buildings and other building typologies. The policy recommendation for this paper is for architects to continue being very aware in their aesthetic appeal and to create more innovative buildings with appealing roof designs especially in public buildings.

Synopsis of Washed and Unwashed Eucalyptus Ash Treatments on Formulated Ceramic Glaze Properties

Ajala, Adewale Oluwabunmi

Department of Industrial Design, Federal University of Technology, Akure, Nigeria
adewaleajala@yahoo.com

ABSTRACT

Art and science share a fundamental convergence, especially in applied arts; this is the field of Ceramics. Ceramics does not stop only at the art of pottery and aesthetics but goes further into the material science of the organic and inorganic constituents of a body or glaze while their qualitative and quantitative analyses are also brought to the fore. The objective of this paper was the formulation of high quality ceramic glazes from 100% locally sourced and treated materials to solve the problem of current dependence of Nigerian potters, and the extant Ceramics Industry, on foreign glazes and materials for compounding them. Eucalyptus leaf ash, from the eucalyptus forest of Rafin Zurfi, of Bauchi LGA; Ball clay, from Gubi Dam, Bauchi LGA; and Granite, from Julius Berger Construction Company quarry, at Miri, on Jos – Bauchi Express, Bauchi LGA; were sourced, processed, chemically analyzed and used as the three main materials for ceramic glazes, in a Tri-axial blend at 1100^{o}C. The formulation batch and glazing were subjected to two separate tests. The first with washed Eucalyptus leaves ash and the second with unwashed. The research produced a variety of fused Earthenware glazes. The chemical constituents of each of the elements had particular characteristic effects on the resultant glazes, according to their percentage content in the materials used. The percentage difference in the effects of the two treatments on Eucalyptus ash on the glazes produced was 51.52% washed to 57.58% unwashed.

Keywords: Batch, Earthenware, Eucalyptus, Glaze and Tri-axial

Introduction

As the name implies, ash glaze is derived from ashes. The earliest such glazes can be traced back to the Shang period in China (1500 B.C.), and it is thought they were produced accidentally, the result of white-hot wood ash being carried through the kiln with the draft of the fire and settling onto the pots, where the searing white heat melted it to a glass. Three thousand years later, ash has remained an important and immensely popular feature of pottery glaze making, (Edmund, 2015).

Ash glaze has glasslike and pooling characteristics which puts emphasis on the surface texture of the piece being glazed, the final result is mostly from dark brown to green. Pieces with ash glaze resemble the earth in color and texture. As the ash percentage decreases, the artist has more control on the color and the final glaze color differs from light to dark shades of brown or green. (Rogers, 2003).

For the modern potter, the satisfaction of working with ash glazes comes from following an ancient tradition as well as from using materials that occur naturally. The results of different wood ashes often vary dramatically, making it possible to achieve a wide range of unique finishes. Even wood from the same species of tree garnered just miles apart can produce subtly different results, (Lombardo, 2003). Current ash glazes usually contain less than 50% wood ash compared to before when the majority of the glaze was ash. The decrease in ash percentage is to give some control over the chemical makeup and result of the glaze. Ash glazes are mostly used by artists as a decorative tool, but some still use ash glaze ware.

In Korea, the traditional ash glaze composed of only ash and water is used to make functional pottery such as bowls, cups, and teapots. To create the ash, the wood needs to burn completely in a kiln. Wood-ash is around 1% the mass of the original wood; therefore, a lot

Ajala, A. O. (2016). Synopsis of Washed and Unwashed Eucalyptus Ash Treatments on Formulated Ceramic Glaze Properties. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1068-1076

of wood is necessary to produce the ash. The ash is then put through a sieve to eliminate the excess clumps from the ash. At this point artists can process the ash further to create a more uniform mixture or leave it unprocessed so there are more random final results. To process the ash, water is first added to the mixture and left to settle for a couple hours. The solution is drained and dried and the result is ash containing less harmful chemicals like some soluble alkalis, (Svoboda, 2010).

LITERATURE REVIEW

Ash Glazes

The practice of incorporating ashes into glazes is a long tradition, and the qualities imparted to such glazes are appreciable. Although ash can hardly be classified with rocks, its constituent materials/minerals too derived from the earth. It has the general formular: $Al_2O_3.SiO_2.CaO.Fe_2O_3$, (Ajala, 2007). Ashes are non-combustible remains of animals (bones) and plants, it also contains or provides fluxing and other oxides. The main ores concerned are calcia, phosphorus peroxide, potash soda, alumina, silica and many trace oxides. Although the original matter is organic (that is, with carbon being the most important element and hydrogen, nitrogen and sulphur also involved) the potter is seeking the inorganic content. Thus from a large bulk or wood, the potter collects a relatively small amount of ash. Even so, the ash is only a halfway stage between the original matter and the required oxides.

Vegetable ashes contain carbon, sulphur, fluorine and chlorine. Bone ash contains carbon and fluorine. The burning of the original matter is not intended to, and in fact cannot completely, create non-volatile compounds. The burning is a preparation, controlled calcination, which removes the bulk of unwanted carbon, hydrogen, and sulphur and renders the material to a useable form. The elements involved have reached stable states for dry conditions as oxides, carbonates, sulphates, phosphates, chlorides and fluorides. Some unwanted compounds can be removed by washing the ash but most will be removed during the forming when the presence of silicates will cause decomposition of the compound oxides and volatiles, (Frank & Janet, 1991).

Chemical Constituents of Organic Ash

Wood ash is primarily made up of calcium carbonate, which is used in many glaze recipes. The ash also contains potassium carbonate, phosphates, and other metals; however, the ratio of these chemicals depend on the location, soil, and type of wood the ash came from, (Ajala, 2010). The different chemical compositions make the glaze to produce different results from batch to batch. Furthermore, two pieces with the same glaze batch can even have different results. If the ash is not cleaned or mixed thoroughly, some parts of the glaze mixture can have more of one chemical and others could have more of another making each part of the glaze to actually have varying concentrations of chemicals.

A few contain sufficient silica to fuse to a glass alone, but the majority of ashes are therefore considered as fluxes especially for glazes, (Frank & Janet, 1991). They also introduce colouring and crystallizers, which give textures. Many wood ashes contain a large proportion of monovalent oxides, which give strong fluxing action at stoneware temperature. If sufficient as is used, and it is the glaze's only flux, it creates the decorative effect known as stinging, (Marshall, 1993).

As opined by La Meridiana International School of Ceramic Art in Tuscany, (Notes on Ash Glazes, 2004), most ashes will melt to a fluid glass at around cone 10. When ash is used alone as a glaze, it will usually result in a rather thin, watery-looking glaze. Ashes vary rather widely in composition, and even the ash of a given variety of tree will vary, depending on the soil in which it grew. The use of ash in glazes depends, therefore, on testing and

experimentation with the material at hand. It may be difficult to locate a reliable source of ash which will be uniform in composition, but some potters have successfully used the ashes from the burning of waste in sawmills or fireplaces. The ashes from burned corncobs, rice hulls, or other agricultural wastes such as fruit pits offer possible sources. Volcanic ash has been successfully used as a glaze material. In small quantities, of say 10% or less, it is not a dominant ingredient and can usually be replaced with feldspar or even omitted without noticeable effect. But in amounts over about 25% it usually contributes distinct colour and texture. Recipes which simply specify 'wood ash' usually mean from a general mixture of woods. The particular qualities of ash are better exploited in reduction than in oxidation, although interesting results can be achieved in electric kilns.

Preparation of Ash for Glazes

To prepare plant ash for use, one must first ensure that it is well-burnt. For practical work the ash must also be available in sufficient quantity, at least half a bucket, and preferably more. A careful initial sieving through a garden sieve will remove the rough stuff. It is then soaked in plenty of water and passed through a 30 mesh. As the ash settles, the surface water will contain a considerable concentration of soluble alkalis and will be caustic. This liquid can be poured or siphoned away and replaced with clean water. The ash is well-stirred and again left to settle then passed through 80 mesh. Ash is caustic, it is therefore advisable to carry out these operations in a well-ventilated area with a respirator, and wear safety goggles and chemical resistant gloves. Dry wood ash, whether in the raw or prepared state, is a potentially hazardous material. It contains light particles of silica and, in the raw state, caustic material. When ash is handled in the dry state this should be with due care, avoiding the creation of airborne dust, (Lombardo, 2003).

Table 1: Standard Analysis of a Sample Ash Glaze

Ingredients	Granite	Wood Ash	Fusible Clay
SiO_2	71.9	52.0	52.7
Al_2O_3	14.6	4.0	18.2
Fe_2O_3	1.4	2.7	6.2
CaO	0.9	23.1	4.7
MgO	0.7	2.6	3.4
K_2O	5.3	6.7	3.2
Na_2O	2.9	1.0	0.5
Others	2.3	5.2	1.8
Total	**100.0**	**100.0**	**100.0**

Source: (Department of Industrial, Ceramics Section, ABU, Zaria. 2002)

The 'washing' process can be repeated two or three times, during which fluxes will be removed and the ash will become progressively more refractory. Reasonable washing is essential for ash which is to be added to tableware glazes, but for purely decorative purposes a totally unwashed ash can give entertaining results (Beth, 2015).

After the final settling and decanting, the sludge is spread out to dry. When dry it is stored and weighed like any other ingredient, care being taken not to raise too much dust. Some potters prefer to wash the ash several times by soaking it in water, then sieving the mixture through a mesh. They may repeat the procedure four or time times. The washing process removes the soluble salts from the ash and often produces a better-behaved glaze. (The Saint John's Pottery, 2015). But there are also other potters who argue that the washing removes some interesting qualities of the ash. They prefer simply of sieve, the ash, dry, through a mesh to remove all the large particles. Once prepared, the ash, if wet, should be dried. It can then be weighed out in the same way as other glaze ingredients. Tony H. (2008)

For washed ash, after burning, the procedure is to mix the ash with plenty of water in a container and to remove the charcoal and scum, which rises to the surface with a coarse sieve. Then the mixture is promptly decanted, leaving any grit or sand at the bottom of the first container. The next step is to run the liquid through a 60 – 100mesh sieve and presence what will not pass through it, together with the coarse charcoal, for drying and further burning. Finally the ash is passed through 100 – 200 mesh, according to the requirement of the glaze. After the ash has settled for a few hours the brackish surface water containing the greater part of the soluble alkalis is powered off. Fresh water is added and the decanting repeated until the water is clear and tasteless. The ash is then dried and stored or used (Ajala, 2002).

METHODOLOGY

The materials used were locally sourced from Bauchi State, Nigeria. They are eucalyptus leaves, ball clay and granite. Bauchi is one of the six states in the North-Eastern geo-political zone of Nigeria. It experiences about 6 to 7 months of rainy season in a year and about 5 to 6 months of dry season. Temperatures are generally high, where mean daily maximum temperature ranges from 29.2^{0}C in July and August to 37.6^{0}C in March and April. The mean daily minimum ranges from about 11.7^{0}C in December and January to about 24.7^0 C in April and May. The sunshine hours range from about 5.1 hours in July to about 8.9 hours in November. The monthly rainfall ranges from 0.0mm in December and January to about 343mm in July. Onset of rains is often in March while they end in October. Bauchi State has two distinct vegetation zones: the Sudan savannah in the southern part and the Sahel savannah in the northern part. It is generally characterized by undifferentiated (mixed) woodlots particularly mixed acacia. Bauchi State is also endowed with different types of mineral resources. The following minerals are found in its administrative region, they are Gold, Cassiterite (tin), Haematite, Granite, Precious Stones, Galena, Coal, Limestone, Gypsum, Wolframite Silica Mica, Corundum, Graphite, Zinc oxide, Clay, Tungsten, Wolframite and Molybdenite, (Ajala, 2010).

Sourcing of Materials

Eucalyptus leaves were used as raw material for the production of ash that was used. The eucalyptus forest in Rafin Zurfi, near Gwallameji, Bauchi L.G.A was ear-marked as the location where the leaves were sourced. The trees were planted in 1990 (25 years ago), by the one-time Director of Forest Management, Bauchi State, Abdul Leeman. The trees cover about 100 by 300meters. Bauchi L.G.A was the source of the ball clay that was used for the purpose of this study. Granite was sourced from the Julius Berger Quarry Site along Jos – Bauchi Express. Since granite is hard and may not be easily crushed, granite dust was collected from the quarry site instead.

Ball Clay Processing

After the ball clay had been collected from site, it was blunged and then passed through the ball milling machine, sieved and water milled again. The resultant product was then dried and made ready for use.

Granite Dust Processing

Owing to the hardness to crush of granite, granite dust was collected instead, from the quarry site was collected, sieved and used.

Laboratory Tests

Tests were carried out on the 3 materials used. Chemical analyses were carried out on the ash (washed and Unwashed), ball clay and granite, at the National Metallurgical Development Centre, Jos.

Table 2: Results of Chemical Analyses of Eucalyptus Leaf Ash, Ball Clay and Granite

SAMPLES	PARAMETERS (%)							
	Al_2O_3	SiO_2	Fe_2O_3	CaO	MgO	K_2O	Na_2O	Others
Eucalyptus Ash (Washed)								
	5.87	56.29	2.49	19.99	10.48	4.12	0.43	0.33
Eucalyptus Ash (Unwashed)	6.39	56.60	2.39	20.01	9.98	4.12	0.32	0.19
Granite	19.32	64.90	3.96	1.86	1.71	4.88	2.61	0.76
Ball Clay	22.09	60.80	5.32	6.22	1.92	2.47	0.36	0.82

Source: (Certificate of Analyses, NMDC-Jos, 2006)

Test Tiles

As a body on which the blends were test-glazed, test tiles were produced from ball clay. Slabs were made out of already prepared plastic ball clay. The tiles were measured ($25cm^2$) and cut out. At leather hard stage, each tile was marked with numbers behind, dried and bisque before administering batches on them for the tests.

Firing

Firing consist of heating to a temperature high enough to cause a physical and chemical changes which converts the green body into a hard, strong and chemically resistant product, without causing it to melt completely to change form. (Budworth, 1970). Firing is done in two stages; bisque (or biscuit) firing and glaze firing. The former is achieved from 900^0C and below, whereas, the later from 900^0C and above. For this test the glaze firing was done at 1100^0C.

Test Blend Methods

Riegger (1978) proffered some models in which different experiments and tests could be carried out to achieve a goal in either body or glaze formulation. These models will help to determine the proportion or composition of materials that will be considered suitable and acceptable for the production of desired body or glaze.

They include:
a. The Bi-axial Test Blend Method
b. The Tri-axial Test Blend Method and
c. The Quadri-axial Test Blend Method

In the same vein, to get a standard blend of 2 and 3 glaze or body materials in all possible blends of proportions, the bi-axial blend and tri-axial blend, respectively, is best, (Ajala, 2010).

Tri-axial Blend Method

The tri-axial blend is a series of tests of mixtures of 3 materials, in which proportions are systematically varied until all possible combinations are tried out, (Ajala, 2002).

In the case of this research project, 6 x 66 (6 lines, 66 combinations) was used for the 3 raw materials – eucalyptus ash, ball clay and granite.

FINDINGS AND DISCUSSIONS

Tri-axial Blend Test Results

Two tests were carried out, the first with washed ash and the second with the unwashed ash.

Chemical Contents/Behaviour of Materials

Each of the parameters qualified in the sample materials were determinants of their behaviour in the tests. The ash was divided into two; washed and unwashed. From the Table 2 above, highest in the ranking among the constituents of the ash was silica, as traditional of ashes. The washed ash had 56.29% while the unwashed had 56.60% of silica. This infers that the unwashed ash was a better glass former. Second to silica is calcium oxide with an average of about 20%. Alumina content of the washed ash was 6.13%. Magnesium oxide had an average

of 10.23%, potassium 4.12%, iron oxide 2.44% and sodium oxide 0.36%. Other untested constituents measured an average of 0.26%.

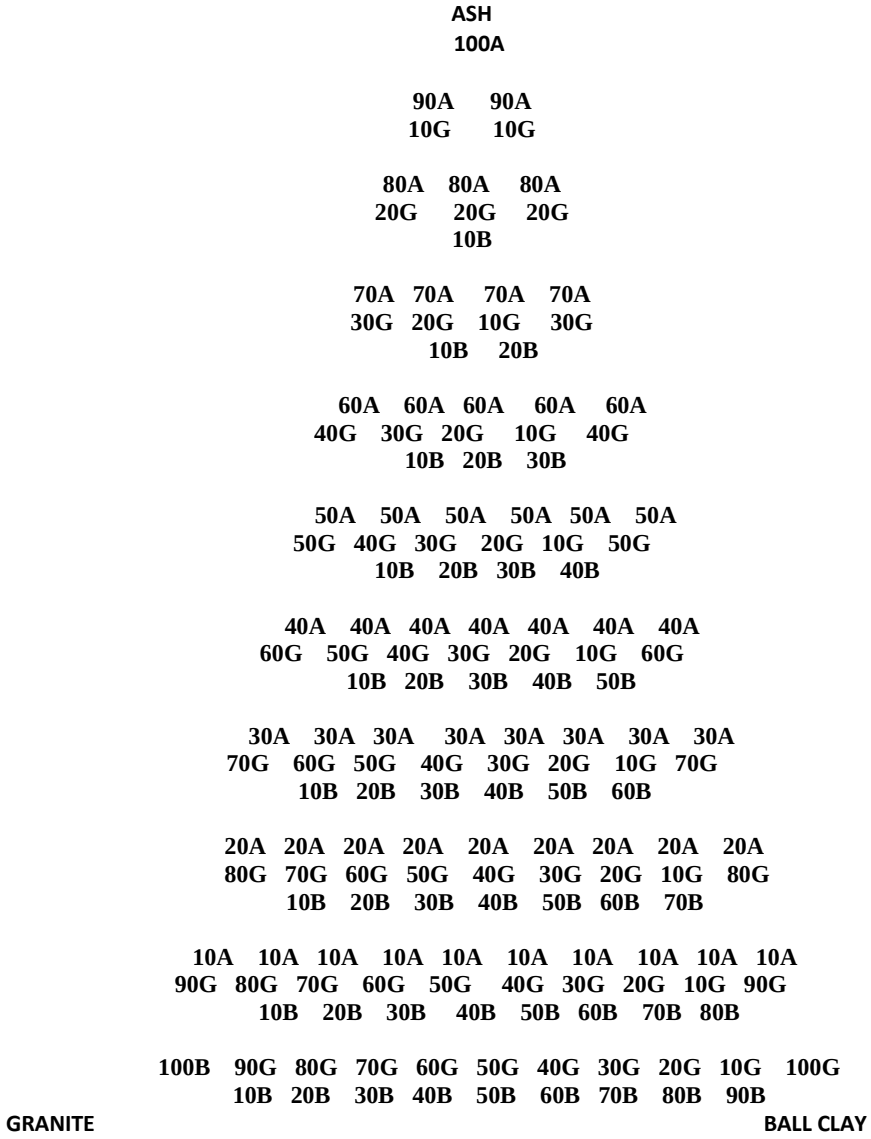

Fig.1: Percentages of Batch for Tri–Axial Blend

The silica content of the washed ash was slightly less than the unwashed as obvious in the result. More glaze fuses was recorded in the unwashed ash result. The average silica content of the unwashed ash was 56.36%, alumina with average of 5.92%, iron oxide had 2.68% (more than that of the washed ash), while calcium oxide averaged 11.11%. Magnesium, potassium and sodium oxides had average3s of 10.29%, 4.12% and 0.42% respectively.

Ball Clay

Next to granite, ball clay had the highest silica content of the three (3) materials used with 60.80%. It fused alone in the tests having alumina content of 22.09%. the brown and tan colours that characterized some of the test results was due to the 5.32% iron oxide content of ball clay, which ranged highest of the materials used. Calcium oxide, magnesium oxide potassium oxide and sodium oxide contents were 6.22%, 1.92%, 2.47% and 0.36% respectively.

Granite

Bauchi granite is quite rich in alumina with about 19.32%, which is next to the ball clay that was used. Of all the materials used in this research, granite had the highest silica content. The silica and alumina contents therefore was responsible for it fusing alone as glaze in the tests. The granite contains 64.90% silica, the 3.98% iron oxide it possessed informed the brown colouration of the results. Bauchi granite contains 1.86% calcium oxide, 1.71% magnesium oxide, 4.88% potassium oxide and 2.61% sodium oxide. Other untested trace elements made up the remaining 0.76%.

CONCLUSION

From test tiles #1 to #10 (100% Ash to 70% Ash and 30% ball clay on the one side and granite on the other) produced highly vitreous glazes. This is obviously because of the high silica content in the batches due to the amount of ash involved. As in the washed ash test, results of the unwashed tri-axial test gave highly vitreous glazes in the first ten (#1 to #10) tiles. This inferred that the blends needed more binder/stiffener to yield better results.

From test tiles #11 to #21 produced fused glazes that were less vitreous than the ones above. As the blend went down the line, the amount of ash decreased while, concurrently and arithmetically, those of ball clay and granite increased. More alumina and the refractory strength, of ball clay and especially granite, accounted for the increase in the stability of the glazes. Transparent, green and dark green glazes abound from tile #11 to #21.

Test tiles #22 to #66 produced fused glazes. There were some with pinhole and boiling effects, which may have been due to improper homogenization of the batch while blending. #22 to #66 proved feasibly for matt, gloss and Temmoku glazes. Except for #56, #57 and #58, which appeared under fired in the unwashed ash test.

The glaze types produced in this tests were Transparent, Green, Speckled green, Brown, Speckled brown and Temmoku. The washed ash test was about 96.96% successful; with 10.61% matt, 15.15% highly vitreous, 18.18% vitreous, 51.52% Stable and 1.50% under fired results. In the same vein, the highly vitreous outcome, for the unwashed ash test, was about 15.15%, the vitreous 15.15% too, matt 6.06% under fired 4.55% and the stable fused glazes make up 57.58%. The ash alone and granite alone fused. The ash(s) gave green effects, the ball clay brown and the granite some speckled effects.

The research produced a variety of fused Earthenware glazes. The chemical constituents of each of the elements had particular characteristic effects on the resultant glazes, according to their percentage content in the materials remaining before and after washing respectively. Therefore, the tested eucalyptus ash treatments had a significant effect on the formulated ceramic glazes.

Evaluation of Pre-Consumer Textile Waste Treatment Practices and its Potential for Economic Sustainability in Akure, Ondo State

Adiji, Bolajoko Esther[1*] & Fagbenro, F. Moyo[2]

[1 & 2]Department of Industrial Design, Federal University of Technology, Akure, Ondo State
[*] preciousdiji@yahoo.com

ABSTRACT

Municipal Solid Waste Management (MSWM) and Sustainability have become a global concern especially with relevance to its impact on the environment. Textile has great potential for reuse and recycle and is currently being practiced in developed counties, however, In Nigeria, reuse and recycling is generally at its developing stage. This study was carried out to examine the current practices of pre-consumer textile waste (fabric scraps) treatment by tailors and fashion designers and also to determine potentially the commercial value of products made from such waste. One hundred tailors and fashion designers within Akure, were administered with questionnaires which were collated and analyzed using descriptive statistics such as pie charts to be able to establish the awareness of reuse of textile waste as cross referenced with the educational qualification of the tailors and fashion designers thereby checking their level of independence. About 77% of the sample population were aware that fabric scraps could be reused, 89% still prefer to dispose of their textile waste using the public waste management service and only 6% actually reuse their textile waste. It was also observed that there was a correlation between the educational qualification of the sample population and their awareness of the reuse of fabric scraps. Design can incorporate the concept of environmentally responsible and sustainable products by focusing on reinvention i.e. reinvention of materials and materials use to give value to waste textile products. This is important for future change in attitude to the current environmental waste disposal.

Keywords: Sustainability, Textile Waste, Waste Management, Municipal Solid waste, recycling

INTRODUCTION

Sustainability as explained by Clifford (2010) and Udeh (2010), is a concept that endeavors to fulfill the needs and aspirations of the present without compromising the ability to meet those of the future. He goes further to state that "It is a process in which the exploitation of resources, the direction of investments, the orientation of technological development, and institutional change are all in harmony and enhance both current and future potential to meet human needs and aspiration" (Clifford, 2010). Sustainability has become a global issue in recent years mainly as a result of the rapid and constant population growth in developed and developing worlds which has led to a massive increase in waste generation (Awopetu et al., 2013). In Nigeria, waste generation and management is a major challenge because the amount of waste generated especially from urban areas within the country cannot be efficiently managed by the facilities and practices currently in place (Babayemi & Dauda, 2009; Ogwueleka, 2009; Uwadiegwu, 2013). Municipal solid waste (MSW) is a major part of the waste produced and it includes refuse from residential, commercial, institutional, industrial and construction sites, and consist of various materials such as food waste, wood, plastic, textiles, metals, glass and special wastes (electronics, batteries, oil, tires etc.) (Abur, Oguche, & Duvuna, 2014). Municipal Solid Waste Management (MSWM) involves the collection, sorting, transportation, storage, treatment and disposal of solid waste, however, in Nigeria, priority is placed on collection and disposal which poses a challenge for the principle of waste Reduction, Recycling and Reuse (Achi, Adeofun, Gbadebo, Ufoegbune, & Oyedepo, 2012).

Adiji, B. E. & Fagbenro, F. M. (2016). Evaluation of Pre-Consumer Textile Waste Treatment Practices and its Potential for Economic Sustainability in Akure, Ondo State. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1077-1082

Originally in developing countries, recycling and reuse was generally practiced out of necessity, but with the onset of globalization, developing countries like Nigeria have adopted the waste management methods of the developed countries which favour landfill for waste disposal. The increased awareness of the impact of waste management practices have on the environment have convinced more countries (especially the developed countries) to focus more on sustainability and view "waste management" more as "resource management" thereby creating more efficient means of waste disposal and establishing policies and laws that encourages a culture of waste reduction and supports the development of recycling and reuse infrastructures (Abur et al., 2014; ISWA, 2010; Zavodska & Uhuo, 2011).

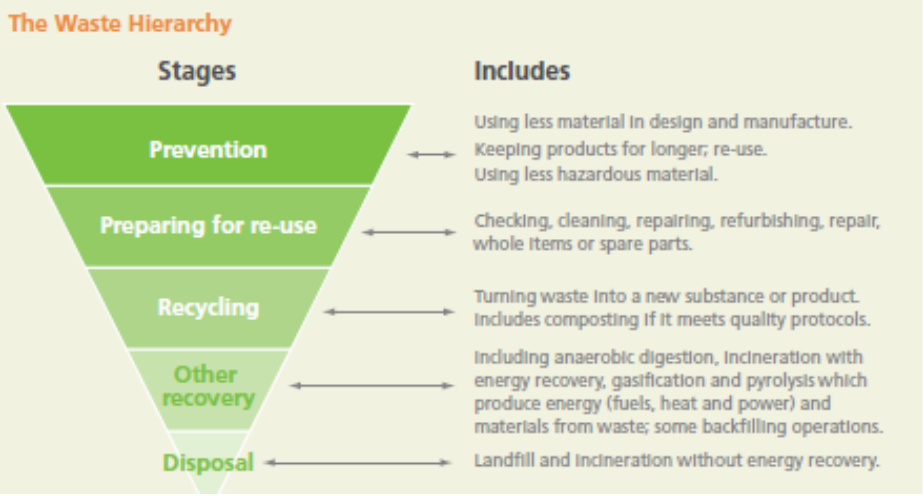

Figure 1: The Waste Hierarchy Pyramid formalized in the 2008 European Union (EU) (Defra, 2011).

Waste reduction, recycling and reuse is environmentally more desirable as it reduces the amount of waste needed to be collected and disposed of, as well as helping the economy by recovering and reusing valuable materials. The application of this principle ensures that only 'true waste' is disposed of (waste which is impossible to recycle or reuse), which invariably suggests that what is reusable should be prepared for reuse what can be transformed into a reusable resource may be used as such (recycling) (Awopetu et al., 2013). With regards to textiles, a lot of work has been done to reduce the environmental impacts of the production and use which has helped to establish industrial standards which promote sustainability. However, until recently little attention has been given to sustainable ways of textile disposal (McGill, 2009).

Textile waste is created in two broad categories, Pre-consumer and Post-consumer textile waste. Pre-consumer textile waste is created during manufacture of fibre, yarn, fabric and garments, it includes fabric off-cuts or scraps created during the cutting phase of clothing manufacture. Post-consumer textile wastes is created by consumers and is made of garments or household textiles the consumer decides to dispose of either due to damage, wear, change in size/fit or the item may be out of vogue (Caulfield, 2009). Good quality garments in this category are usually sold as second-hand clothing while damaged fabrics are generally shredded into fibres and used to produce other materials such as carpet underlays and fillings, pre-consumer waste can also be treated this way but in the developed world a large percentage is still being dumped into landfills(Caulfield, 2009; Defra, 2011; Kozlowski, Bardecki, & Searcy, 2012; Miraftab, Rushforth, Horoshenkov, & Swift, 2004)

The predominant method of making clothes involves cutting fabric and assembling the pieces through sewing, fusing, welding and other techniques of making garments (Rissanen, 2013). The marking and cutting of the patterns is a major area of pre-consumer textile waste generation in Nigeria. According to Antonucci & Stein (2012) , the average efficiency for a

garment is 80%, and a minimum 10-15% of each garment produced is waste. Despite the known desirability of reusing resources and the known recycling of textile products for many years, attempts to reclaim and reuse fabrics from old garments, scraps and rags have encountered large obstacles which have prevented the development of a practical, commercial approach. Consequently, there is a dearth of information on textile recycling and reuse in Ondo state. This study was put together to provide data with regard to the current trend of textile waste disposal practices of tailors and fashion designers in Akure town, It will validate the feasibility of the reuse of fabric scraps to produce products that are functional and commercially acceptable, which will ultimately encourage the reduction in waste disposal and creating entrepreneurship.

METHODOLOGY

Using random sampling method, one hundred (100) tailors and fashion designers located in various areas in Akure, Ondo State were involved in the research and questionnaires were administered individually. Ninety-seven (97) were recovered and Scale values were assigned to the responses to enable computation as follows: yes – 1, no – 2, not sure – 3. The method adopted for the analysis of the data was descriptive statistics using pie charts and the non-parametric chi-square test of independence using SPSS version 16. The awareness of the reuse of fabric scraps was cross referenced with the educational qualification of the tailors and fashion designers to check the level of independence.

RESULTS AND DISCUSSION

It is very important for fashion designers and tailors to be aware of the impact of waste generation on the environment, and from the results obtained from the survey, about 72% of the sample population are aware of the issues associated with waste generation as shown in figure 2 and 77% are know that the textile waste generated from their studios can be reuse or recycled (figure 3). However, 90% of the sample population still prefer to dispose of their textile waste using the available government public waste management service while only 7% recycle/reuse their textile waste as shown in figure 4. The recycle/reuse percentage is very low and some of the reasons given for this is the labour intensive nature and considerable of amount of time involved in collecting, sorting and reusing the waste. Some also expressed concern that customers may be displeased to see pieces of their quality fabrics being used for other purposes.

When the sample population was asked if they will be willing to donate their textile waste if a system was created specifically for textile reuse and recycling, 65% were willingly to be cooperative while about 25% refused due to suspicions and fear that customers who owned/bought those fabrics may be exposed to some sort of spiritual harm. This shows that cultural beliefs and practices are still relevant and can influence the mind set individuals regardless of their educational qualification,

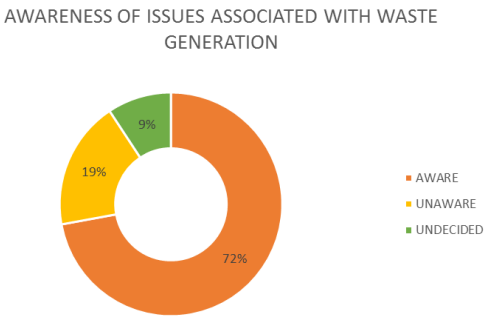

Figure 2 Pie Chart showing sample populations opinion on their awareness of issues associated with waste generation

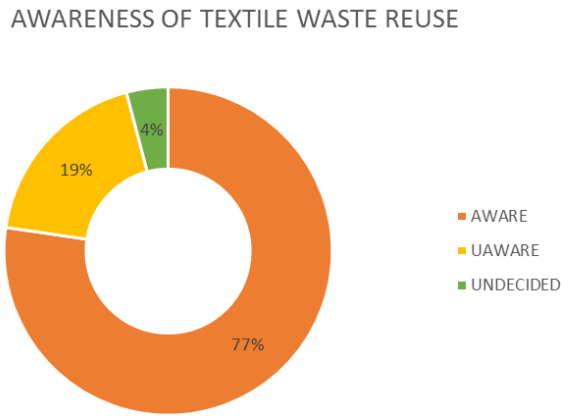

Figure 3 Pie Chart showing sample population's awareness of pre-consumer textile waste reuse

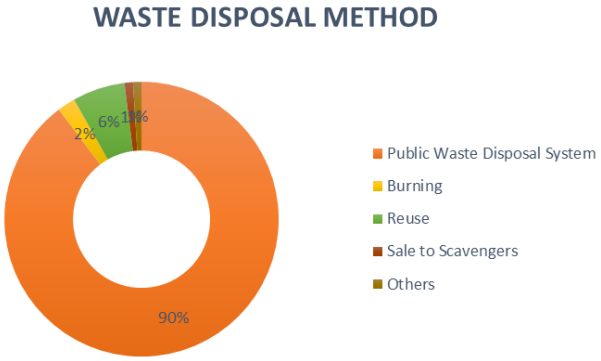

Figure 4 Pie chart showing sample population's preferred method of textile waste disposal

To validate the feasibility of textile waste reuse, some fashion design and interior design items were made from some of the textile waste collected from various tailor and fashion designers studios. The products made include handbags, laptop bags, duvet and a braided rug. It was observed that a great deal of time was spent sorting the textile waste which supports the reasons given by the sample population for not reusing their textile waste, however, it is an avenue for job creation. Based on the products that can be produced from textile waste, the sample population was asked to access the commercial value of the products and the consumers' response to the products. The results garnered showed that while it was agreed that products made from textile waste have good commercial value (figure 6), consumers may have a lukewarm reaction to the products. This is because products made from waste aren't viewed to be of good quality and so they may not be willing to pay good money for the value even though the products made may be standard.

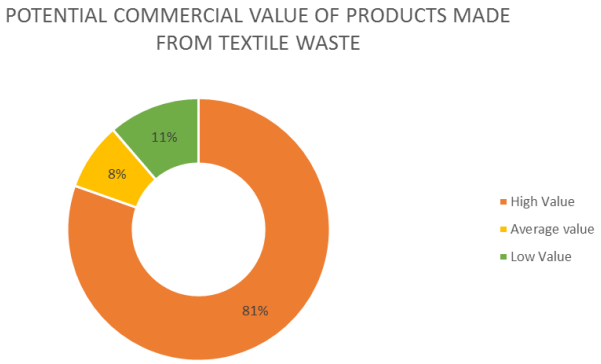

Figure 5. Pie chart showing the sample population's opinion on the potential commercial value of products made from textile waste

Figure 6 Bags made from pre-consumer textile waste (fabric scraps)

Figure 7 A braided center rug made from fabric scraps

A relationship was discovered to exist when the educational qualification of the sample population was cross referenced with their awareness of the reuse of textile waste. The bar chart in figure 6 clearly shows that 100% of those who had tertiary education were aware of textile waste reuse while 75% of those who had no formal education had no awareness of this fact. This suggests that education is very important and relevant to vocational practices and their impact on the environment. It also brings about development and innovation to the industry when practitioners are aware of new and sustainable methods involved in waste management.

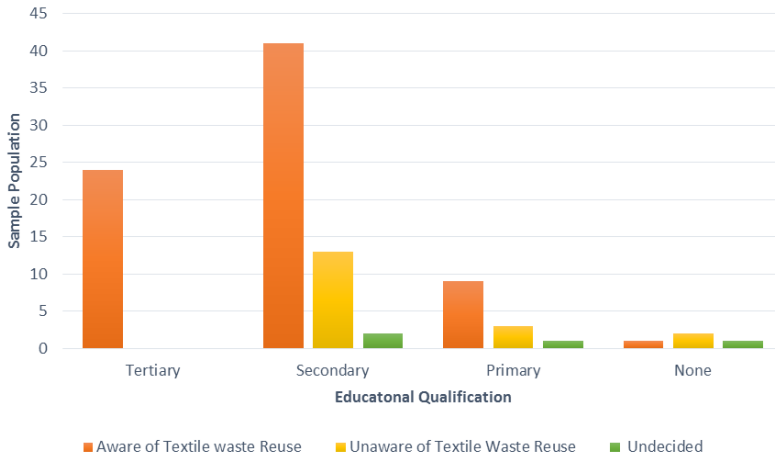

Figure 8 Bar chart showing the correlation between the educational qualification of sample population and their awareness of Textile Waste Reuse

CONCLUSION

Awareness of the impact current practices of textile waste disposal have on the environment is applicable to all spheres of life, industries, and countries, with emphasis placed on the wise and sparing use of resources. Design can incorporate the concept of environmentally responsible and ethical products, so that actual physical changes can impact on the local, national and international industry. This concept is hinged on reinvention, that is, reinvention of materials and the way they use them, reinvention of the value of waste and reinvention of both the role of the designer and of the consumer. This is very significant for future change as well as having an impact on the environment in terms of proper waste disposal (Smal, 2011). During times such as this where waste is regarded as an economical and environmental issue, a lot of consumers do not see the value in spending money on "recycled' products. Which is perceived as 'second hand' in comparison to brand new products. Although these processes are time and labour intensive and production is commercially viable on a small scale, the textile industry must address manufacturing in a sustainable and environmentally friendly manner if it is to remain relevant on the long term on its immediate environment.

Merging, Art, Design and Technology: A Virtual Tour Design of the Department of Industrial Design, Federal University of Technology, Akure, Nigeria

Ibiwoye, Tope Israel[1*]; Ogunlade, Benjamin[2] & Ugah, Henry Ojonimi[1]

[1]Department of Industrial Design, Federal University Of Technology, Akure, Ondo State
[2]Department of Fine & Applied Art, Ladoke Akintola University of Technology, Ogbomosho, Nigeria
[*] topibiwoye@yahoo.com

ABSTRACT

The fusion of Art, Design, and Technology is exemplified in many products and services in the contemporary society. These products and services range from computer games to interactive and non-interactive multimedia tutorial, animated cartoons and virtual reality tours, to mention but a few. The merging of the trio of Art, Design and Technology has influenced many of the activities of man in recent time, especially as man's romance with the ICT is becoming more intimate by the day. One of such domain of activities influenced by the computer technology is the Virtual Reality Tour, a feat made possible by an integration of art, design and technology. The paper therefore examines the relationship that exist between art, design, and computer technology and then narrow down to "the Virtual Reality Tour", one out of the numerous offspring of the union between art, design and technology. The case study of the virtual tour of the Department of Industrial Design of the Federal University of Technology Akure, Nigeria is considered. The paper therefore presents a technical report on how the virtual tour of the said department was conceptualized, designed and then produced.

Keywords: Art, Design, Technology, Virtual Reality Tour

INTRODUCTION

It has become a truism that the romance of art, design and technology, in the information age cannot be divorced; in fact, the relationship keeps getting stronger by the day. With the growth in the rate of software development in the areas of computer games, graphics and multimedia software and other forms of interactive graphic and multimedia packages, one would not but expect dynamism in the fusion the trio of art, design and technology.

Defining art has not been easy due to difference in individual view of the word "art". However, Art, as opines by Barnes (2009), is the product of creative human activity in which materials are shaped or selected to convey an idea, emotion, or visually interesting form. The word *art* can refer to the visual arts, including painting, sculpture, architecture, photography, decorative arts, crafts, and other visual works that combine materials or forms. Barnes (2009) also adds that art in a more general sense can include other forms of creative activity, such as dance, drama, and music, or could be used to describe skill in almost any activity, such as "the art of bread making" or "the art of travel."

Design as viewed by the Design Council, is an activity that translates an idea into a blueprint for something useful, whether it's a car, a building, a graphic, a service or a process. According to Brady (1998) the difference between art and design is in the way one look at them. Design is meant to be looked away from and art to be looked at and into. Brady (1998) notes that Design graces our lives with the aesthetic presentation of useful and beneficial things, and art graces us with representations of things to ponder and perceive. It further posits that Art and Design are closely related but nevertheless distinct, therefore the need to keep them straight.

Merritt (2009) defines Technology as the processes by which human beings fashion tools and machines to increase their control and understanding of the material environment. The term 'technology', Merritt (2009) states was derived from the Greek words *tekhnē,* which refers to

Ibiwoye, T. I. ; Ogunlade, B. & Ugah, H. O. (2016). Merging, Art, Design and Technology: A Virtual Tour Design of the Department of Industrial Design, Federal University of Technology, Akure, Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1083-1091

an art or craft, and *logia,* meaning an area of study; thus its concludes that technology, literally means the study, or science, of crafting.

The virtual tour of a design departmental building is an offspring of the merging or coming together of art, design and technology. The article elucidates the beauty and aesthetic which art represents the organisation and idea represented by design, and the tools in form of computer and graphic/multimedia software used symbolises the technology. The article therefore presents a report of a virtual tour, which gives credence to the fusion of art, design, and technology.

Advances in science and technology seem to occur almost weekly in today's world, The dynamic nature of technology has informed the invention of new machines; new ways of problem solving and quest to keep abreast of the latest development in the Information, Communication and Technology (ITC) world. Tenner (2005) opines that since the beginning of the 20th century, technological choices of man had been slow over decades. It believes that in a short while it will be possible to accomplish even more radical changes, such as altering the appearance not only of poodles (dog) and peonies (horses), but of human through genetic engineering. Tenner (2005) further postulates that man will be able to select from a wealth of information on his computers, and decide which older data to convert to new electronic formats and which one to abandon to extinction.

LIST OF ABBREVIATIONS USED

Virtual Tour - Computerized walk-through of a site, building and the likes

3-D - Three Dimensional

Rendering - the computer calculations that, based on light placement, surface types, and other qualities, generates the image.

Wire-Frame Representation – a composition of different basic shapes into an object in line format

CAD/CAM - Computer-aided design and manufacturing

VR applications - virtual reality applications

Auto-cad - Automatic Computer Aided Design

Archi-cad - Architectural Computer Aided Design

Spline- a spline is a tin invisible line that can be drawn and used in cinema 4d to create and guide objects

Cinema 4d tags- a command and preset object generation location tool in cinema 4d

Wmf- windows media file

Avi- windows movie

3dx- Three directX

Texture- a texture is the appearance of the surface of an object; it could be a leather, rubber, water, sand or grass surfaces and etcetera.

Scripting and Linking - programming languages in swish-max and the process of merging a command from a button with an object in swish-max.

Png- portable network graphics

Flv - Flash video

Virtual Reality and Tour

Virtual reality (VR) according to Al–Saedi and Ibrahim (2014) is a term that applies to computer-simulated environments that can simulate physical presence in places in the real world, as well as in imaginary worlds. Most current virtual reality environments are primarily visual experiences, displayed either on a computer screen or through special stereoscopic displays, but some simulations include additional sensory information, such as sound through speakers or headphones. Some advanced, haptic systems now include tactile information, generally known as force feedback, in medical and gaming applications (Al–Saedi and Ibrahim, 2014).

Lanier (2012) records that; Jaron Zepel Lanier (born 3 May 1960) is the American computer scientist, best known for popularizing the term virtual reality, the popularity of VR had seen continued growth, though steadily. Virtual Reality (VR) covers remote communication environments which provide virtual presence of users with the concepts of telepresence and telexistence or a virtual artifact (VA) either through the use of standard input devices such as a keyboard and mouse, or through multimodal devices such as a wired glove, the Polhemus, and omnidirectional treadmills. The simulated environment can be similar to the real world in order to create a lifelike experience, for instance, in simulations for pilot or combat training, or it could be somewhat differ appreciably from reality, as in the case of Virtual Reality games. In practice, it is currently very difficult to create a high-fidelity virtual reality experience, which of course is largely due to technical limitations on processing power, image resolution, and communication bandwidth; however, the technology's proponents hope that such limitations will be overcome as processor, imaging, and data communication technologies become more powerful and cost-effective over time (Al–Saedi and Ibrahim, 2014)

The virtual reality is a very compelling technology which aim at mimicking real world via the use of technology by computer-generated environment and engage all the senses of man. As a result of advancement in human-computer interface and emulation system, a brand new virtual world is maturing day by day with various applications such as digital heritage, training simulation, digital carving and virtual concert and so on, compare with traditional graphic research, virtual reality technology emphases on the interaction between user and system that is, the user could enter and experience the digital environment in real-time, feeling like being actually there (Wu,Wang, and Wang, 2015).

Brooks (1999) remarks that Virtual Reality is often used to describe a wide variety of applications commonly associated with immersive, highly visual, 3D environments. The development of CAD software, graphics hardware acceleration, head mounted displays, database gloves, and miniaturization have helped popularize the notion. Brooks (1999) further notes that Michael R. Heim, in the book titled, "The Metaphysics of Virtual Reality" highlighted seven different concepts of virtual reality as; simulation, interaction, artificiality, immersion, telepresence, full-body immersion, and network communication. VR is often identified with head mounted displays and data suits (Brooks, 1999). The Medical Product Manufacturing News (2008) believes that Virtual Reality can serve new product design, helping as a supplementary tool for engineering in manufacturing processes of new product prototypes, and simulation. Electronic Design Automation, Computer Aided Design, Finite Element Analysis, and Computer Aided Manufacturing are some of the generally utilized programs in Virtual Reality. The use of Stereo lithography and 3D printing shows how computer graphic modelling can be applied to create physical parts of real objects used in naval, aerospace, and automotive industries, which can be seen. The News also cites for instance, the VR laboratory of Volkswagen in Mladá Boleslav. It is also observed that away from modelling assembly parts, 3D computer graphics techniques are currently used in the research and development of medical devices used therapeutic processes, treatments, patient monitoring and early diagnoses of complex ailments.

Virtual Tour

Boland (2004) remarks that Virtual Tour is a simulation of an existing location usually composed of a sequence of video images. It sometimes involves the use of other multimedia elements such as sound effects, music, narration, and text. The phrase "virtual tour" is often used to describe a variety of video and photographic-based media. The phrases "panoramic tour" and "virtual tour" have mostly been associated with virtual tours created using still cameras. Panorama indicates an unbroken view, since a panorama can be either a series of photographs or panning video footage. However, such virtual tours are made up of a number of shots taken from a single vantage point. The camera and lens are rotated around what is referred to as a no parallax point, that is, the exact point at the back of the lens where the light converges.

In the case of a video tour, it is a full motion video of a location which differs from the virtual tour's static wrap-around feel; a video tour gives an impression or illusion of the viewer walking through a location. Using a video camera, the location is captured while moving from place to place. Video tours are continuous movement taken at a walking pace. The first use of a Virtual Tour and the derivation of the name, according to Realtor (2015) were in 1994 as a museum visitor interpretation, providing a 'walk-through' of a 3D reconstruction of Dudley Castle in England as it was in 1550. This consisted of a computer controlled laserdisc based system designed by British based engineer Colin Johnson. History has it that one of the first users of a Virtual Tour was Her Majesty Queen Elizabeth II, when she officially opened the visitor centre in June 1994. Because the Queen's officials had requested titles, descriptions and instructions of all activities, the system was named and describes as: "Virtual Tour, being a cross between Virtual Reality and Royal Tour" (Realtor, 2015).

King (2004) notes that 3D virtual reality is becoming widely used for urban regeneration and planning and transport projects. Virtual tours are very popular in the real estate industry. Several types of such tours exist, including simple options such as interactive floor plans, and more sophisticated options such as full-service virtual tours. An interactive floor plan shows photographs of a property with the aid of a floor plan and arrows to indicate where each photograph was taken. Clicking on arrows shows the user where the camera was and which

way the camera was pointing. Full service virtual tours are usually created by a professional photographer who will visit the property being sold, take several photos, and run them through stitching software. Full service virtual tours are usually more expensive than interactive floor plans because of the expense of the photographer, higher-end equipment used, such as a digital SLR camera, and specialized software. Real estate virtual tours are typically linked to the listing in the Multiple Listing Service (King, 2004).

Four technologies that is very crucial to VR as mentioned by Brooks (1999), Durlach and Mavor (1995), Burdea and Coiffet, (1994) are:

i. the visual (aural and haptic) displays that immerse the user in the virtual world and that block out contradictory sensory impressions from the real world;
ii. the graphic rendering system that generates, at 20 to 30 frames per second, the very changing images;
iii. the tracking system that continually reports the position and orientation of the user's head and limbs; and
iv. the database construction and maintenance system for building detailed and realistic models of the virtual world.

A completed campus virtual tour system is the composition of various technologies. The nub of it is the sub-system for environment models and user events processing, certainly, there are some other modules like user inter action and material management surrounding the kernel. To achieve the most lifelike feelings during user's virtual tour, Wu, Wang, and Wang, (2015) observe the need for integrated acoustic and haptic interfaces and their response effects into a system besides traditional real-time visual display. A typical virtual tour experience for instance could paint a picture of a user who starts off from somewhere in the campus, roams in some areas with the virtual locomotion device, (for instance, the user pedals to stimulate walking or running), and the surroundings are displayed on his head mount. The user may also hear same background sound along with the scene changing, liken to the sound of water when he is getting close to a fountain (Wu, et al. 2012).

METHODOLOGY

The techniques used for the study is the product design method, since the aim is to arrive at a multimedia product that can solve an information problem. The process includes:
Planning, selections of appropriate softwares to be used, production process, testing and finally packaging

Software Used

The software used includes:

i. Corel-Draw: - a vector based graphic design software used majorly for creating graphic designing.
ii. Adobe Photoshop: - an image editing software, it can also be used for graphic designing.
iii. Auto-card: - a 3d software but generally used for drawing of building plans and projection especially by trained architects and designers.
iv. Archi-card: - a 3d software mostly used by architects to raise plans of buildings with accurate block positions, aspect ratios and basic building components.
v. Cinema4D:- A 3 dimensional software used for 3d designing and modelling. It involves the use of basic shapes and other basic 3d elements such as lightening shadowing, textures, and etcetera.
vi. Adobe Premiere: - a video editing software.
vii. Adobe Media Encoder:- a video exporting software

viii. Swish-max: - a Flash enabled multimedia interactive video production software; it is also used for designing flash based websites

Equipment and Materials Used

The major equipment used is the computer system, digital camera, tripod stand, and printer. The materials include; compact disc, matte paper, Top Bond, Uhu gum and cutter.

PROCEDURES

Modelling with Cinema 4d Software

The buildings navigated in this multimedia project were modelled starting with the drawing of the plans with Auto-cad using the basic drawing tools, like pen tool. The plans were then saved in 3dx file format and exported to Archi-cad. In Archi-Cad the plans were raised to the appropriate sizes using the build or block tool that can be found in the tool box on the left side of the interface and the basic building components were then imputed and positioned properly starting from the first floor up to the last floor and the roof was finally built also in Archi-cad and raised properly with the proper roof type selected using 3D roof selection tool. The finished work was then scaled down to a reasonable size so as to reduce the size of the data it contains but yet maintaining the aspect ratios. It was then finally saved as a 3dx file and finally imported into cinema 4d for finally modelling and finishing.

In cinema 4d there are two types of interface options; the 2d, and the 3d interface options. Since the file to be processed was a 3d file, the 3d interface was activated by clicking on the left hand side of the menu bar where the edit option is located, this displayed a list of sub commands and the 3d editor view was clicked on and activated. After launching the 3d interface option the next step taken was to import the 3dx file into cinema 4d and this was done by clicking on the file option in the menu bar which is at the topmost part of the software interface, and clicking on the open option and selecting the file to be opened.

Fig. 2 Modelled Image of School of Environmental Technology

Fig. 3 Modelled Image Industrial Design Studios

Many textures were lost while importing the 3dx file into cinema 4d because cinema 4d could not recognize the texture format used by the other software used to create the document. The

next step was to correct all missing textures, and after correcting the missing textures, the windows, doors within the buildings were adjusted and properly positioned. The floors and ceilings within the buildings, and the various objects that featured in the buildings like chairs, tables, table tags, fans, lightings, computers, studio equipment, and the like were created from scratch using basic geometric shapes and cutting, trimming, welding, and merging the necessary areas. While choosing the appropriate texture types for the different surfaces, a number of tools were involved such as the polygon tool, the spline tool, the plane tool, the node or point tools.

After that, the surroundings and environment were created using planes. The trees and skies were modelled; the planes were filled with grass surface textures while the polygons and cubes were filled with flower textures. After this the proper lightening settings were done to give the environment and building a feel of realism and neutrality.

Virtual Camera Control

The next step taken was to apply the navigation effect and that was done using the camera and spline tools, A spline was drawn within the building starting from where the navigation should start and going along the necessary places the final viewers were expected to see to the desired end point. After that was done a camera was brought in using the camera tool and was merged or attached to the spline using cinema 4d tags under the command tool. The camera was then set to 0% at the starting point of the animation timeline which is located right under the visualization panes, and 100% at the end point. A total of 800 key frames where used because the doors were to be opened when approached by the cameras therefore each key frame on the animation timeline were edited to suit the camera and object's behaviour on that particular time line.

The finished work was then prepared for exporting by carrying out a preview test. And that was done by setting the exporting options to the desired modes, a resolution size of 1000(optimal), screen size of 1240 by 800, a pal DV widescreen and Avi video export settings and other output configurations were used for this test preview and it took almost two weeks to complete the preview test for each animated building. At the end of the preview test the previewing animation was slowed down and saved as an Avi video. And the video was taken and imported into Adobe Premiere where it was edited and slowed down to make navigation smoother and finally rendered, encoded with Adobe Media Encoder and exported as a Windows Media File (WMF) to step down the size and make it playable in all media formats. The video was then ready for use in swish-max.

In swish-max, there exists the layout interface face and the script or programming interface. This interactive project video was archived by first creating background templates for all the scenes to be viewed within the video, the backgrounds and images to be used were first designed in Corel-draw and then edited in Photoshop and saved as Portable Network Graphic (PNG) files after which they were finally imported into the swish-max library. And the various images and text documents were arraigned as desired within the various scenes where they were needed with the desired motion and behavioural effects attached to them.

Button Creation, Linking, Scripting

After the arraignment, the next step was to create buttons within the video, and that was done by converting an image, vector box and ellipse objects within swish-max into button objects that had over states, up states, down states and hit state.

All buttons created were then linked properly to perform the right actions or load the proper scenes they have been linked to when they are clicked upon. And to do this the interface was changed from the layout interface to the scripting interface, where the various buttons were

linked using programming languages also known as scripting in swish-max. The proper scripts were written and assigned to the respective buttons as commands for the buttons to obey with conditions and variable options.

The finished videos from Cinema 4d and Adobe Premiere were then embedded into their respective scenes within the swish movie, since the videos were in Wmf format or Avi and swish-max only recognizes Flv formats of videos, the swish-max application automatically converted the videos being imported into Flv formats and that action stepped down the quality a bit in order to make the video playable and user friendly in swish-max.

Fig 4 Modelling the School of Environmental Technology on Swish Mass Software

Saving, Exporting and Production

The movie was then saved as a swish-max movie and a preview test export was done with compression mode activated, and when the movie was believed to be okay, the whole document of video was finally exported with compression mode deactivated as a flash (swf) movie. The flash movie was finally burnt to /copied to Cds that had a design done in Corel-draw and Photoshop to represent the project printed on them and were finally slotted into Cd-jackets with a similar design printed on them.

CONCLUSION

The report gave an account of one the offspring of the fusion of art, design and technology. The offspring or product in this context being the virtual reality tour of the Industrial Design Department of the Federal University of Technology, Akure. This did not only give an insight into the world of virtual reality tour, but went further to describe the procedure involved in designing and producing a functional virtual reality tour. The quality of information packed in the produced Virtual Tour of the Industrial Design Department, presented a rich information about the department. The study noted that Industrial Design is associated with production of prototypes basically driven by human need, societal pressure and technological advancement, of which are encapsulated, in the produced Virtual Reality Tour.

The Production and Exploitation of Rattan Products for Interior Decoration

Komolafe Olubunmi

Department of Industrial Design, School of Environmental Technology, Federal University of Technology, Akure, Ondo State, Nigeria

* *okkomolafe@yahoo.com*

ABSTRACT

This study of the production and exploitation of rattan products for interior decoration explains the productions of rattan furniture for a sustainable development especially in the area of job creation. Rattan is the most common material used for the production of wicker furniture. Rattan furniture can be made from natural or man-made hard fibres such as rattan, cane, bamboo, willow, reed, rush, grasses, resins, and vinyl. Wickerwork is an old weaving process being used to make furniture sets such as chairs, sofas, dinning set, bedstead, barstools and so on with natural materials. The study explains the production of wicker products with different methods such as peeling, scraping, splitting / tearing, straightening and so on. Division of labour is very important because of series of measurement, nailing, brazing, patching, and treatment. These basic procedures are carefully explained for the best results.

Keywords: Rattan, Wicker, Production, Exploitation, Decoration

INTRODUCTION

In some developing nations rattan has served as a veritable tool to bridge the gap occasioned by raw wood material shortage (Renuka, 1999).Rattan is among the minor forest resources found in considerable quantity in Nigerian forests. Adewole and Onilude (2011) observe rattan grows naturally and abundantly available in Bayelsa, Akwa Ibom, Cross River and Rivers states. Rattan can grow up to hundreds of feet in length. It is one of nature's strongest vines. Rattan has a solid core, unlike bamboo pole, making it much more durable and harder to break. In the field of interior decoration, rattan is known to man as an ornamental plant. Lucas and Dahunsi (2004) further observe the diameter of rattans to range from 7.2 mm to 17.8 mm for small stemmed rattan species and from 12.5mm to 38.5mm for the larger diameter. It will not warp and is ideal for making furniture. Adewole and Onilude (2011) observe that, 70% of the rattan harvested and processed in four states goes for furniture making and 30% for weaving of local household items. Since creation of the world, man has been able to create out of God's creations.

Therefore, rattan has been adapted to making of things needed for a comfortable home especially the living room, bedroom, kitchen, toilet and bathroom. Also, provisions are made for offices, bars, restaurants, hotels and recreational centres and so on. For example, there are objects from rattan products such as chairs, tables, shelters, flower-vases, bedsteads, baby-cots, sieve, strainers, baskets, laundry-boxes, bedroom furniture, patio furniture, outdoor furniture, loveseats and rocking chairs and so on. Presently, rattan wicker workers all over the country have started to adopt and develop rattan into complex and technical productions. In order to make a good quality and a successful work, the rattan wicker workers make use of certain tools and materials such as nails, blue –blow lamp, wood-vanish, hack saw, pincher wood mallet and so on. It has been discovered that rattan wicker workers have greatly contributed to the development of interior decoration in homes, offices, hotels, restaurants and some recreational centres in Nigeria.

Komolafe, O. (2016). The Production and Exploitation of Rattan Products for Interior Decoration. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1092-1098

Source of Raw Materials

According to Ogunwusi (2012) rattan harvesting is very difficult but done by the commercial harvester. Rattans are selected, cutting from the base, drawing of rattan after cutting and trimming to commercial lengths of 12ft. After this, the rattans are bundled into packs, stacked, air dried for few days and sold (RMRDC, 2006). Processing of low quality rattan can result into low quality and poorly finished household furniture items. One of the notable concentration points for rattan wicker furniture processing is situated at Kosofe Local Government, Mende, Maryland in Lagos which is popularly known as Cane-Village. Rattan and willow come in bundles from suppliers from Edo, Delta, Rivers and Epe in Lagos and their prices range from N900:00 to N1, 400:00 per bundle according to their sizes (Okafor 2015). Rattans and willows are purchased from the dealers. On arrival at the workshops, the outer leaf sheaths are removed with knife and the old sheaths are thoroughly scraped off to leave the fresh, clean, workable rattan beneath. Furthermore, Rattan and willow are also found in Bayelsa, Akwa Ibom, Cross River and Rivers States. Warri, Port Harcourt and Benin. Willow is cut into 12 feet while rattan is cut into 12 feet for easy transportation. Harvested rattans and willows are transported to rattan processor in the city where they are usually sold.

Curing

The next step is to cure the rattan, turning its colour from a pale green into the yellow by smoking it in sulphur fumes. The raw, washed rattan is loaded into what looks like a wood-framed tent that has its floor about a foot off the ground. Raw rattan are piled on top of one another until the wooden frame is full. The frame is then covered with tarpaulin, which is secured to the ground using stone weights. The sulphur is ignited and placed under the tent, and the smoking process begins. It usually takes about a day or so to complete this curing and smoking process. The stems are left to dry .in the sun for a few days after which they are cut into workable diameter. Sometimes, most processors do not follow the optimal procedure which includes drying for about 2-3 weeks, curing in oil, bleaching, deglazing to remove silicified epidermis and fumigation (Liese, 2002). The moisture content of fresh stems varies between 130 and 160 percent, requiring about two to three weeks air drying to be reduced to about 20%. Similar with this, is curing which is done by immersion of canes in a hot oil bath to prevent deterioration by stabilizing the moisture content (Liese,2002) rattans are dried in the sun and often smoked using Sulphur. Large rattans are boiled in oil to make them dry and to protect them from insects.

MATERIALS, TOOLS AND EQUIPMENT FOR RATTAN -WICKER FURNITURE MAKING CURING

Cane

Cane is gotten when rattan's outer skin or peel is removed and cut into thin strips material. Cane when wet, are pliable to be woven and create unique wicker-weaved designs seen in wicker furniture. The designs on most rattan furniture are created with wicker weaved on top of the rattan core frame. Rattan cane is used for weaving chair seats or wrapping joints on wicker furniture and is produced in many different gauges, ranging from carriage fine to the largest slab rattan. Cane is considered beautiful in its natural state because it has a natural glossy finish and does not accept stain or paint very well.

Willow

Willow is used for framework of any cane products. It is rigid jointed stem-like rattan. Willow is between 25 millimetre and 50 millimetre in diameter. It is only used for frame work in rattan furniture production. Willow can be soaked for flexibility and woven or bent to form graceful, rounded shapes. Willow can be heated, processed and used to frame chairs, baby cots, flower vases and so on.

Tools and Equipment

Oxford Advanced Dictionary, define tools as an instruments held in the hands by workmen; similarly, rattan and willow require certain tools to make out a product. These tools include hacksaw, hammer, pocket knife, file, spanner, sharpen stone, pincers, blow-lamp and sewing machine. Tools alone cannot do the work, so some of these following equipment are necessary:- nails of various sizes, sand paper, plywood, measuring tape, wood vanish, enamel paint, painting brushes, glue, containers, wood foam and pesticide. Rattan and willow are the only raw materials used in the production of rattan products, without these materials and equipment, it would be impossible to produce any tangible and acceptable utilitarian objects.

Apprenticeship system

Rattan wickerwork is a craft which can be learnt. Before someone can become an expert he/she might have been a learner under somebody that is, he has to be an apprentice to a master who in turn teaches intricacies of the craft.

Qualifications:

Qualification depends on intelligence and an ability to work. Nowadays a minimum of Primary School Leaving Certificate is necessary not compulsory but the apprentice should be able to read and write. Education is necessary because of the intricacies of the work which must be studied, such things as measurement, calculation, proportion and ability to imagine very well are very crucial to the success of cane production. Both male and female who is eighteen years and above can apply as an apprentice.

Agreement

Interested candidate purchase a form from the boss, fill and submit. The apprentice pays some amount of money for his training. The amount varies and this depends on the duration. Usually, a fast learner can spend up to six months but the duration is between six months and two years. The apprentice then buys basic tools such as pocket file, measuring tape, hammer and some other necessary materials.

Division of Labour

In any set-up where there is a mass production of a particular production, there must be a division of labour. In the production of rattan work, there are different people who are been assigned to a work under a master. In order to make the work easier, it is shared among the apprentices into five stages which are scraping, splitting or tearing, framing, tying of joints and weaving. This division of labour is crucial as it enables the learners to be deep in the knowledge of the stages of all cane work.

Material Processing

Rattan

Rattan is slender and has a rough outer surface with jointed stems like that of sugar cane. It grows between ten millimetres and twenty millimetre in diameter. It creeps or trails over other vegetation and may reach the length of five hundred feet. Rattan leaves its raw stage to more refined stage by peeling, scraping, splitting or tearing.

Peeling

Rattan can be bent with hands to remove the bark. This is because the inner layer is flexible while the bark is stiff. So, when bent, the bark breaks and falls to the ground.

Scraping

Scraping is the second stage of production. It deals with the outer layer of the stem. A sharpened knife is required. The cane surface tends to be hairy after scraping, if the knife in use is not sharp enough. Scraping is either to scrape the outer layer of the cane with a sharp knife until becomes creaming white or peel the bark with hands. Then it is slated into the

required sizes. Scraping is better in sitting position, that is, either on a bench or any comfortable stool. Rattan is held in the left hand (for right handed person) with the index finger supporting it at the back. Hand is allowed to rest on the left thigh for comfort ability. Then a sharp knife is held on the right hand and placed against the rattan. The knife is allowed to rest at angle 60^{o} with the edge facing out. The edge of the knife is pushed hard along the surface of the rattan. Scraping continues until the surface becomes creaming white (depending on the type of cane). Then the rattan is allowed to dry in the sun for about five hours (weather determines this). Therefore, the rattan is now ready for splitting.

Splitting and Tearing

Splitting involves the breaking of rattan into smaller sizes. The sizes of the rattan and the type of work determine the number into which to split the rattan. Rattan for weaving is split horizontally into small sizes, this is called **flat**. The inner layer is then removed in order to make the flat flexible for a more complicated wickerwork. On the other hand, the flat used in basket weaving is heavier because the inner layer is not removed. The rattan is split into the size of between four piece and six pieces. After splitting, the flats are allowed to dry in sun for two hours, and then they are ready for weaving.

Willows

Willow is the wooden aspect of any cane product. It is used for framing only. It also consists of three layers like that of rattan. But the only difference is that the bark is already scrapped right from the forest. It is rough on the surface and also consists of jointed stem. The stem is not straight but wavy or curve. So willow cannot be used for any decent production without straightening, cutting and bending.

Scrapping

Scrapping of willow is done like that of sugarcane. Willow after scrapping, is allowed to dry in the sun for three days. If it is not allowed to dry very well the framework will sag and the frame will lose it rigidity. Therefore, the chair with which willow is used may collapse at any time. As earlier mentioned willow is not straight but wavy or curve. It becomes straight when heated with blow-lamp.

Straightening

Willow is held with the left hand (right handed person) and the blow lamp on the right hand. Intensive hot flame is directed on the surface of the willow. It is pulled straight when hot because, willow becomes soft when hot. Therefore, it can be bent or straightened as desired.

Cutting and Bending

Cutting goes along with measurement. Cutting depends on the size and the shape of work. The skill intelligence is highly displayed here. According to Alade (2014) cutting and bending is the most tedious of all stages of production. Because the outcome of a rattan product is determined by accurate measurement of the willow with measuring tape and cutting into the required sizes with a hacksaw. Measurement is done according to the planned sketches of the producer. When bending, the portion that is needed to be bent is heated then bent to the required shape with hands and hold into shapes until it cools, then cut into the desired sizes according to the design. After this, framing can be done.

Production Processes of a Chair

There are basic rules and guidelines towards production of rattan product. A rough sketch of a proposed chair is made; this will serve as a guide while the work is in progress. There is a standard measurement for a particular type of chair to be made. Then, the willow was cut with a hacksaw according to the size and proportion of the work. The type of work determined whether to cut and bend, or bend and cut. Accurate measurement during framing

enhances the finished products especially where there is a need to produce more than one of the same products (Ojo, 2014). Two lengths of willow which measured 50 inches each was cut and bent to an arc shape. These serve for arms' length and part of the chair's front legs. Other lengths of the willow were cut for the chairs back and for brazing.

Nailing

The already cut willow are arranged and placed side by side each other. Later they were nailed together to form a skeletal chair. It is advisable to make use of the right nail for the right place. Nails which are between the ranges of half and inch and four inches ($^1/_2$ "-4") were used prominently for the product. For example, if a big size nail is used for a small size willow, it will tear the willow apart and makes it useless. At the same time, if the nail is too small, it will not hold the willow tightly to each other. Therefore, the product will become weak and collapse in a very short time. Moreover, the proper application of willow (fat and thin) during framing is necessary for durability.

Brazing

Ten pieces length of willow which measured 24 inches were cut, heated and then bent to the desired shape. These were place in between the legs of the chair and at the corners. Each were placed in their appropriate place then nailed. This is known as brazing -the importance of brazing are:

i. to serve as a supporter and a shock-absorber in a chair or settee
ii. to serve as a form of decoration.
iii. to serve as a support in other products especially when brazing is placed at the arm-length of a chair.
iv. it is used to support the legs of a table.

Treatments

Willow is an organic plant. It has an inner layer where insects and pests such as gammaline 20, comprehnol and solignum. The chemical can be used separately or mixed with some quantity of water as directed by the manufacturer. The chemical was first applied with a brush ($1\ ^1/_2$ or 2 inches in size) to all the joints, then to all over the surface of the frame work. The chemical was also injected into the stem with a syringe. These chemical kills every available insect or pest in the willow and prevent other pest to enter or destroy it. Solignum, among all the three chemicals, changed the natural colour of the willow to a dark one. Finally, the chemical was allowed to dry before moving the product (chair) so as to avoid staining human skin. After this stage, patching was done.

Patching

There are various ways of decorating rattan product especially chairs or settees. The choice of design depends on individual taste and choice. These methods include, tying of joints, spooking, wrapping, netting, coiling and weaving. Two or more methods of decoration can be used for the chair's decoration.

Tying of joints/Landing

This involves the joining of two or more willow placed side by side together with a flat. The frame was tied to make a unified work. Landing is a process whereby the brazing is fastened to the main body. Flat is used in tying brazing together with the patched areas. Then landing are tied neatly with belts for a good finishing.

Spooking

Spooking is a process where bars of rattan are laid across the frame to form a seat. Cushion can be placed on it for comfort. The rattan used for spooking is only scrapped out but not

split so that it can be strong and rigid. Rattans are placed very close to one another. At times, spooking is done in spiral shape on a seat to create an additional aesthetics to the products.

Wrapping

This involves the covering of the wooden part of the work with a well scrapped flat. Wrapping is mostly done in bedstead and settee. Wrapping is done to cover the rough surface of the wooden part of the bedstead, to beautify the general outlook of the frame work and for good finishing of the product.

Netting

This is the nailing of rattans across each other to form a design. It is used to cover the back of a chair (this depends on the design). In shelf or room-divider, netting is used to block the back so that when things are kept inside, it will not fall to the other side. Netting is done according to the pre-planned of the designer.

Coiling

This is a process in which a length of a cane is wound into a continuous circular shape. It can occur at any part of the work but it is mostly used at the feet of a seat for the following purposes.

i. to serve as a support to the seat on which cushion is placed.
ii. to serve as legs to the settee.
iii. to serve as another type of design.
iv. to serve as an additional beauty to the cane products.
v. to make the settee unique.
vi. to serve as decoration on the rattan products.

Weaving

Weaving can be combined with coiling, netting and wrapping and spooking. Weaving is an interlacing of warp and weft at right angle. Plain weave is commonly used in basket weaving. Done completely by hand, weaving takes from one to four days, depending on the type and complexity of the piece. The tighter the weave, the more time is needed and the more costly the process. Rattan strips are attached and woven over the frame in either an open (spaced) or closed (tight) weave. Wicker called ‘kanash’. This weaving is highly decorative. The other type of kanash is called ‘double kanash’ (this type of weaving is more complicated and tedious to weave). It is used for sophisticated works especially the interiors (Folorunsho, 2014)

Finishing

The surface of the willow is sandpapered to make it smooth. A blowlamp (at a low range) is used to remove every rough fibre. The frame is used to burn some portions to create a decorative effect on the willow and rattan. Later, wood vanish is applied with either a spraying machine or a brush. It is allowed to dry and then re-coated for a finer effect. The wood vanish makes the cane products stronger, shine and water-proof. After this, the work is allowed to dry very well. At times, the work can be painted in oil (enamel) to suit the taste of the customer. Upholstery is done by another person who has specializes in the making of a seat-cover. The cushion is tied to the seat with a length of tiny strand of cloth. This makes it possible to remove and wash whenever it is necessary. Seat cover fabrics of beautiful colours are used. At times, batik-designed fabrics are used. Now, the product is ready for sale.

CONCLUSION

Rattan products, especially those that are used for interior purpose, such as settee, dinning set, room divider, bar and stool, trolley and so on have contributed greatly to the natural beauty which nature offer in homes. There is an urgent need to develop rattan industrial

sector in Nigeria Rattan products are cheaper to purchase than wood furnishings. Rattan products, if well treated during the production can last as much as wood products. If government can develop rattan sector, it can contribute to poverty alleviation, generate employment among the youths and boost foreign exchange earnings in Nigeria.It is advisable that master should be kind and genuinely reveal the secrets of the craft to their apprentices whenever it is necessary to do so. Also, the master should be considerate in terms of apprentice should be patient and obey the rules and regulations of the job because, one day, he will. As unemployment rate still high in Nigeria, rattan weaving business has been proffered as a way out, especially if government encourages teaching of the craft in schools. Learning is a continuous process. Therefore, people should be encouraged to learn such work instead of staying idle. It is a lucrative job which can serve as a good start in life. With N50, 000:00 the business can fully take off.

The production of rattan products has tremendously generated tax and income into Kosofe Local Government, Lagos. The government should encourage them by improving soft loans, through their cooperative societies.

RECOMMENDATIONS

It is recommended that, rattan products producers should build up more skills by consulting book and magazines (foreign) for more inspirations in their productions. Also, government should organize workshops so as to allow free interactions of ideas among the rattan workers.

ABSTRACT

The 21st Century Human Habitat is a function of what nature offers and what humans make of it. "What humans make of it", alludes to what we produce and utilize. This is to say that making things has been part of human existence over the centuries, and has turned out to be the basis for sustainable economic growth. Industrial design product innovation and development has been identified as key to sustainable economic growth. The programme is pivotal for Nigeria to industrialize but concerted efforts to train the manpower to handle it as a sustainable programme is even more pivotal. The study identifies a missing link along this line of thought. The paper looks into the problem using the questionnaire instrument to survey the opinion of respondents. A pilot study was conducted with the aim of testing the reliability and validity of the instrument. Data collected through purposive sampling technique was then analyzed using averages and mean values. Results were presented in paired sample table format while findings revealed that training product designer in the real sense of Industrial Design and getting them involved in the strategic plan for industrialization will not significantly facilitate the realisation of the industrialization dream.

Keywords: Economy, Corruption, Industrial Design, Industrialization, Sustainable Development

INTRODUCTION

Habitation of the earth since time immemorial by humans, other gifts of nature and recent exploration of space beyond the earth have profound impact on the ecosystem. With simple agrarian beginning, the world is gradually transforming into industrial nations and recently, cosmological expeditions have become the interest of fore front nations. The 21st Century habitat is pervaded with industrial products from various revolutionary human technological strides that have turned out to be the wealth of nations. Initialized in the late 18th Century, industrialization has far reaching social, economic and political consequences, however, centuries after, some parts of the world have remained under-industrialized and dependent, with globalization, trade liberalization and deregulation models making their economies weaker. Academic institutions over the centuries are known to offer innovations, research and development initiatives to industries. The Bauhaus, established in 1913, was significant in the propagation of the collaborative association and the establishment of the International Style, a modern design movement that left legacies in architecture, design and arts. Today, countries around the world are establishing technology-based institutions to further the ideals of technical education for economic development. Industrial Design and related academic disciplines are concerned with the creation and execution of design with recourse to appropriate use of form, function, ergonomics, usability, marketing and sales of products.

The economic strength of a nation is directly linked to her material and product resourcefulness and good governance. Raw mineral materials are abundant in many countries of the world, but what makes an economic difference among nations is the ability to extract and process these raw materials for *properly managed* internal consumption and export. Indeed, management of the economy is germane to the whole gamut of national development. That the economy has vascular sickness is neither an understatement nor unpatriotic remark.

Kayode, F. & Kanu, E. U. (2016). Training for industrial design product development and manufacturing in nigeria: implications for sustainable economic development. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1099-1107

There are challenges in the Nigerian education industry and the polity itself. That sector of education and training which are expected to play remarkable roles in human development has been discovered in Kruegar and Lindhal (2001), Dike (2002) to be neglected for decades. As it were, respect, integrity and responsibility are supposed to be fundamental moral values essential for any economy (Lickona, 1992). All these values are products of good quality education. Corrupt leadership and bad governance are closely knitted like seamen twins. Yet leadership problem that has confronted Nigeria since independence appears to be worsening because the state of the polity is rapidly deteriorating. Leaders in government appear to be good at identifying economic problems but lack the political will and integrity investment to get problem solved or provide the institutional framework for way out (Acemaglu, 2003, Dike, 2003, Edison, 2003, Dike, 2007). However, countries with capacity to convert processed raw materials into consumer products make more economic progress than those who export raw materials and import finished products and in turn provide better living condition for their citizens. Adeoye (2005) posits that governments in developing countries lay emphasis on extensive technology-based development of productive (manufacturing) system as a means to transform their economies. Good governance, in addition, guarantees judicious use of economic proceeds for infrastructural development and overall wellbeing of a nation. It is therefore factual to assert that industrialization is central to economic development. This paper, through historical and empirical analysis will attempt to highlight the implications of training for industrial design (products) innovation and development for sustainable economic development in Nigeria.

Problem Statement

The essence of the paper is to highlight the importance of training industrial designers in the quest for industrialization of Nigeria. Government formulates industrialization plans with neglect of the aspect of training Nigerians to design products for mass production. When all other factors such as power, transport system, primary health care, HIV/AIDS and the primary and intermediate raw materials processing for manufacturing are being addressed. There will be urgent need for designers to be empowered to provide indigenous prototypes for mass production else we continue to rely on direct foreign investment that ends with capital flight and non-transfer of technology.

Purpose of the study

Training product designers in the real sense of Industrial Design and getting them involved in the strategic plan for industrialization will facilitate the realisation of the industrialization dream of the Nigerian nation.

Hypotheses

H_o Training of manpower to handle industrial design products helps the economic stability of the public sector.

H_1 Training of manpower to handle industrial design products helps the economic stability of the private sector.

RELATED LITERATURE

Industrialization and Economic Development: An Overview

Three revolutions have taken place already in the industrial sectors of western civilization. They have been largely described as radical and disruptive spring in industrial processes characterized by greater productivity. According to Woodham (1997), there was wider availability of mass-produced goods, facilitated by electroplating, stamping, moulding and the exploration materials that had the capacity to imitate hand crafted luxury goods with high decorative finish, consequently, calling for the reconciliation of design thinking with the realities of mass-production techniques. Industrialization is simply growing manufacturing

activities of a nation alongside electricity generation, transportation facilities and communication networks. Kirk-Greene in Iwuagwu (2011) defines industrialization as "an increase in the share of manufacturing in the Gross Domestic Product (GDP) and in the occupations of the economically active population." Therefore to industrialize is to replace hand tools with machines and power tools, expected to yield huge socio-economic gains and increased advanced education. It is generally acknowledged that three phases of Industrial Revolution have been experienced and the fourth revolution imminent, with its precursors in digital technology as evident in the transformational changes and innovations taking place in digital domains. The first industrial revolution was centered on hydropower technology and evolution of machine tools. The second came in the widespread use of electricity and assembly line for mass production. While the third, in the form of green revolution, is focused on cleaner energy technology, electronics and information technology.

Industrial Revolution in Nigeria

Nigeria, since independence in 1960, has battled with the increasing challenges of economic development through rapid industrialization. Several economic development policies with focus on the industrial sector had been adopted and abandoned by successive governments, while diversification from the monolithic national economic earning from crude oil export remains a mirage. Electricity inadequacy increases the cost of production, reduces competitive advantage and threatens the survival of industries. The economy cannot absorb the labour supply, mainly unskilled; hence unemployment is on the rise. Advanced education has become a status symbol instead of a force for economic growth. Indeed, an industrial revolution is most needed in Nigeria. In February, 2014 the Federal Government of Nigeria renewed government commitment to industrialization, by launching the Nigeria Industrial Revolution Plan (NIRP), out-judged to be the "most ambitious industrialization programme" ever pursued in the country. (Economic Commission on Africa, 2014). The Plan, according to Nwoye (2014), is expected to add about N5 trillion to Nigeria's annual manufacturing revenue in the next 3-5 years. However, it is feared that the 2015 change of hands in governance may discontinue the implementation of the NIRP, as it had been with older plans and policies. Iwuagwu (2011) argues that Nigeria has never been lacking in policies, but the political will to implement policies that are capable of transforming the nation's processes from primary production.

According to Onwuma (2015), poor planning and monitoring of programmes, inadequate funding, corruption, and poor accountability were some of hindrances to the full implementation of the development plans namely:

i. First National Development Plan (1962-1968)
ii. Second National Development Plan (1970-1974)
iii. Third National Development Plan (1975–1980)
iv. Fourth National Development Plan (1981–1985)
v. Structural Adjustment Programme (1986-1989)
vi. National Rolling Plans (1989)
vii. Vision 2010 (1996)
viii. National Economic Empowerment Development Strategies (2003)
ix. Industrial Development Strategy (Cluster Concept) (2007)
x. Vision 20:2020 (2009)
xi. Nigeria Industrial Revolution Plan (NIRP) (2014)

The failure to totally implement the above plans has negatively impacted on the development of Nigeria's industrial sector. Adeoye (2005) asserts that the Nigerian economy has high import dependency on intermediate, finished and capital goods, which increases yearly with

higher domestic demands. He further explains that trade liberalization and globalization hinders an economy without strong basic and supporting industries from enjoying international market opportunities because of disadvantaged competitive position.

Assuming the government sustains the implementation of the NIRP, which is designed to accelerate growth in food and agricultural products processing, metals and solid minerals processing, oil and gas related industries, construction, light manufacturing and services; when electricity is in abundance and can support industrial activities; when the transport system and other infrastructural facilities have grown to facilitate positive socio-economic development, it is expected that the manpower needed to raise and sustain the industrialization process will have to come from the products of academic institutions. The question about the nature of the training and the quality of graduates come to the fore. Raji (2015) states that acquisition of technical and vocational education and training are instrumental to achieving the National Industrial Revolution Plan (NIRP) in Nigeria. Industrial Design, in its real sense, would play a key role in achieving the desired progress in the manufacturing sector.

Industrial Design and Industrialization

Industrial design, also known as product design and commercial design, has a key role to play in a big industrialization dream, particularly in manufacturing for the economy to grow. Developed after Industrial Revolution, which is characterized by mechanization of industry; Industrial Design concerns mainly with manufactured products by industrial mass production processes, ranging from kids toys to automobiles. Manufactured consumer goods usually undergo the process of design before mass production. Designing a product entails so much - specifying its overall shape, colour, and texture with consideration for ergonomics, user profile; choice of materials and production process. Point-of-sales related matters may be part of the design specification. According to Learn.org (2015) "Industrial designers carry a product from initial idea on paper and computer-assisted design to a physical prototype and final product. Multi-function cellular phones, 4x4 trucks, household appliances, retail displays and fixtures, running shoes, and product packaging are all results of industrial designers doing their jobs". Industrial design therefore, seeks to add aesthetic and usability values to manufactured products. A study, Tezel (2011) describes Industrial Design as a strategic tool for the developing economies to compete in the globalised international market in addition to its role as a vehicle to satisfying user physical functionality. The study particularly applauds Turkey's realization of the contribution of Industrial Design to government policies for sustainable development, as it is newly recognized as one of the developing economies of the world.

The NIRP described the manufacturing sector in Nigeria as structurally weak and lacking in basic industries such as steel and iron, and over many years has failed to transform and play a leading role in economic growth and development. It also stipulated that the technological base for manufacturing is lacking; skilled manpower needed to ensure competitiveness is grossly inadequate; deficient power and transport infrastructure have led to high production costs and non-competitive operations Federal Ministry of Industry, Trade and Investment (2014).

The growing global consumer class raises demand for manufactured goods thereby making manufacturing contribute 18 percent of the US$70 trillion global economy and accounts for 70 percent of global trade. Nigeria obviously has very insignificant share in this global wealth, however, the underlying philosophy of the NIRP is to build Nigeria's competitive advantage, broaden the scope of industry and accelerate expansion of the manufacturing

sector to become one of the global top 10 players in at least 10 key manufacturing categories within 5 to 10 years (Federal Ministry of Industry, Trade and Investment, 2014).

METHODOLOGY

The study is a survey that administered questionnaire as inventory to collect data from respondents about the importance of training Nigerians to be proactive in product design and manufacturing processes and whether such concept will help boost the economy of the public and private sectors. Stemming from the scope, the population is defined to be civil servants and entrepreneurs who are into private practice. Statistical method was used to analyse the collected data. Data were also analysed using average and mean values to determine the importance of some factors as indicated by the respondent. The percentages and the cumulative percentages of variables of interest were also determined. Percentages help in rating a number of factors according to the degree of importance attached to them. In order to reflect the relative importance, reliability or agreement of some of the relevant criteria over others and the indices were calculated as follow. Mean is expressed as:

$$X = \frac{fx}{N}$$

Where X =Mean
x= number of score
$\sum$ = summation
N= Number of Effective Questionnaire Collected

RESULTS

Hypothesis 1a

$H_{0:}$ Training of manpower to handle industrial design products development and manufacture significantly helps to stabilize the economy of the public sector.

$H_{1:}$ Training of manpower to handle industrial design products development and manufacture does not significantly help to stabilize the economy of the public sector.

Decision Rule: If the P-value is > α=0.05, do not rejectH_0. Otherwise, rejectH_0.

Paired Samples Statistics

		Mean	N	Std. Deviation	Std. Error Mean
Pair 1	Agree	120.55	20	32.662	7.303
	Disagree	24.75	20	22.133	4.949

Paired Samples Correlations

		N	Correlation	Sig.
Pair 1	Agree & Disagree	20	-.636	.003

Paired Samples Test

		Paired Differences				
		Mean	Std. Deviation	Std. Error Mean	95% Confidence Interval of the Difference	
					Lower	Upper
Pair 1	Agree - Disagree	95.800	49.759	11.126	72.512	119.088

Paired Samples Test

		t	Df	Sig. (2-tailed)
Pair 1	Agree - Disagree	8.610	19	.000

Since P-value=0.000< α=0.05, it is statistically right to reject H_0 for H_1.

Discussion: It can be inferred from the above test that, training of indigenous manpower to handle industrial design product development and manufacturing processes does not imply

significant stability for the public sector economy. This result seems not surprising because the inculcation of training though, will breed more efficient hands in the design and production sector, corruption in high places will make the whole efforts remiss.

Hypothesis 1b

$H_{0:}$ Training of manpower to handle industrial design products development and manufacture significantly helps to stabilize the economy of the public sector.

$H_{1:}$ Training of manpower to handle industrial design products development and manufacture does not significantly help to stabilize the economy of the public sector.

Decision Rule: If the P-value is > α=0.05, do not reject H_0. Otherwise, rejectH_0.

Paired Samples Statistics

		Mean	N	Std. Deviation	Std. Error Mean
Pair 1	Strongly Agree	110.35	20	44.157	9.874
	Strongly Disagree	50.70	20	37.838	8.461

Paired Samples Correlations

		N	Correlation	Sig.
Pair 1	Strongly Agree & Strongly Disagree	20	-.705	.001

Paired Samples Test

		Paired Differences		
		Mean	Std. Deviation	Std. Error Mean
Pair 1	Strongly Agree - Strongly Disagree	59.650	75.751	16.938

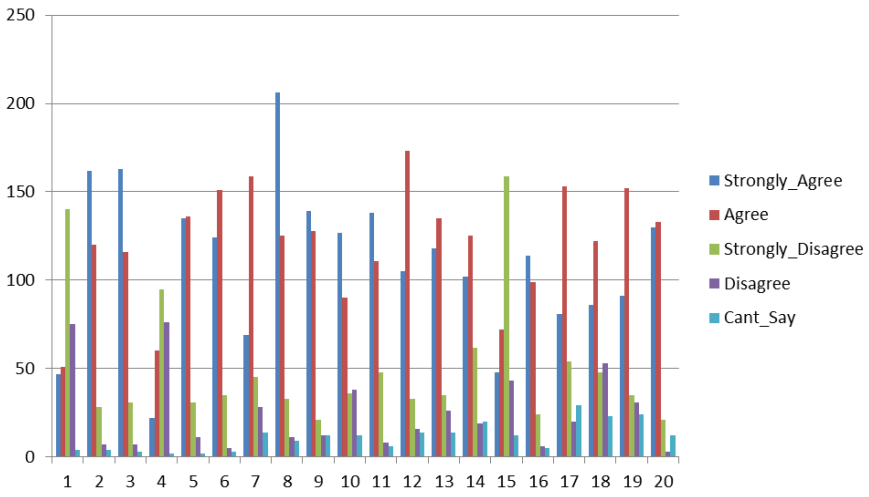
Paired Samples Test

		Paired Differences		
		95% Confidence Interval of the Difference		
		Lower	Upper	t
Pair 1	Strongly Agree - Strongly Disagree	24.197	95.103	3.522

Paired Samples Test

		Df	Sig. (2-tailed)
Pair 1	Strongly Agree - Strongly Disagree	19	.002

Since P-value=0.002< α=0.05, it is statistically right to reject H_0 for H_1.



Discussion: It can be inferred from the above test that, training of indigenous manpower to handle industrial design product development and manufacturing process in the public sector

does not significantly help to stabilize the economy of the public sector. This result seems not surprising because it is a commonplace to say that, no matter the depth and frequency of training, Nigerians need a change in the areas of corrupt leadership attitude, and economic mismanagement.

Hypothesis 2a

$H_{0:}$ Training of manpower to handle industrial design products development and manufacture helps to stabilize the economy of the private sector.

$H_{1:}$ Training of manpower to handle industrial design products development and manufacture does not help to stabilize the economy of the private sector.

Decision Rule: If the P-value is > α=0.05, do not rejectH_0. Otherwise, reject H_0.

Paired Samples Statistics

		Mean	N	Std. Deviation	Std. Error Mean
Pair 1	Agree	106.40	20	27.563	6.163
	Disagree	28.70	20	17.547	3.924

Paired Samples Correlations

		N	Correlation	Sig.
Pair 1	Agree & Disagree	20	-.529	.016

Paired Samples Test

		Paired Differences				
					95% Confidence Interval of the Difference	
		Mean	Std. Deviation	Std. Error Mean	Lower	Upper
Pair 1	Agree - Disagree	77.700	39.743	8.887	59.100	96.300

Paired Samples Test

		t	Df	Sig. (2-tailed)
Pair 1	Agree - Disagree	8.743	19	.000

Since P-value=0.000< α=0.05, it is statistically right to reject H_0 for H_1.

Discussion: It can be inferred from the above result that, training of indigenous manpower to handle industrial design product development and manufacturing process in the private sector does not significantly help to stabilize the economy in the private sector either.

Hypothesis 2b

$H_{0:}$ Training of manpower to handle industrial design products helps to stabilize the economy of the private sector.

$H_{1:}$ Training of manpower to handle industrial design products does not help to stabilize the economy of the private sector.

Decision Rule: If the P-value is > α=0.05, do not reject H_1. Otherwise, reject H_0.

Paired Samples Statistics

		Mean	N	Std. Deviation	Std. Error Mean
Pair 1	Strongly Agree	93.35	20	33.248	7.434
	Strongly Disagree	49.95	20	35.399	7.915

Paired Samples Correlations

		N	Correlation	Sig.
Pair 1	Strongly agree - Strongly Disagree	20	-.674	.001

Paired Samples Test

		Paired Differences		
		Mean	Std. Deviation	Std. Error Mean
Pair 1	Strongly Agree - Strongly Disagree	43.400	62.807	14.044

Paired Samples Test

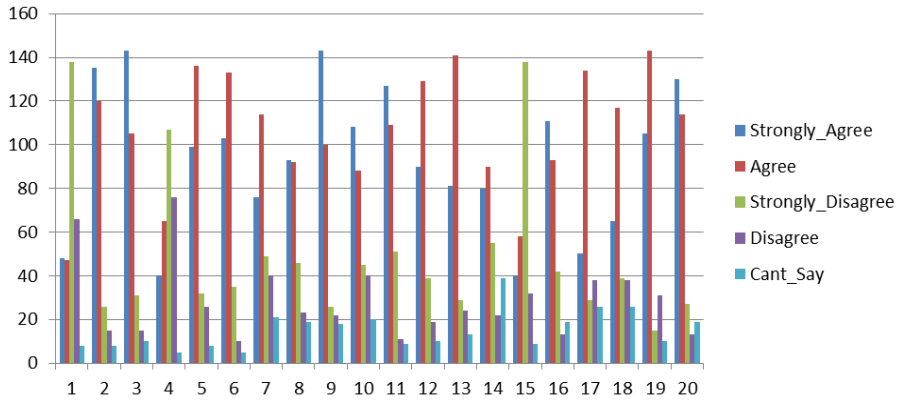
		Paired Differences		
		95% Confidence Interval of the Difference		
		Lower	Upper	t
Pair 1	Strongly Agree - Strongly Disagree	14.006	72.794	3.090

Paired Samples Test

		Df	Sig. (2-tailed)
Pair 1	Strongly Agree - Strongly Disagree	19	.006

Since P-value=0.006< α=0.05, it is statistically right to reject H_0 for H_1.

Discussion: It can be inferred from the above result that, training of indigenous industrial designers to handle industrial design product development and manufacturing process in the private sector does not significantly help to stabilize the economy in the private sector.



Empirical findings

Findings from the study actually show that there is a missing gap which is the training of young graduates to be able to participate in the industrialization process of the nation but the same findings also show that this does not make significant difference in the economy of both the private and public sectors. Nigerians' unsavoury integrity towards work and money seems to be a reason for this. The study also aggregately reveals that the Nigeria nation has been driven by different sectors of the economy such as oil and gas, power, transport, industry and leadership as well as education, but all have put both the public and private sector economies in messy, austere conditions. Over-dependence on crude oil explains the reason why the nation is unable to diversify her economy. What has not failed us and which has not been accorded the pride of place is training and re-training of industrial design manpower. Training product designers in the real sense of Industrial Design and getting them involved in the strategic plan for industrialization will facilitate the realisation of the industrialization dream. It is high time the emphasis is shifted to training of indigenous hands to take charge of product design economy and entrepreneurial development of the nation. This will help grow the economy of both the public and private sectors.

CONCLUSION

The hindrance to industrial revolution in Nigeria is the manifestation of the plethora of problems the nation has battled with over the decades, they include: bad governance,

indiscipline and corruption; poor policy implementation; deficient education sector. These altogether have hindered Nigeria from harnessing the full benefits of the first, second and third Industrial Revolutions; iron and steel processing, textile manufacturing, rail transport, electricity generation, new materials and cleaner technology, ICT, microelectronics, renewable energies and energy efficiency, 3D printing and digital manufacturing. It is, therefore, important to sustain the 2014 Nigeria Industrial Revolution Plan with intensified efforts in addressing the huge infrastructure deficit. Concerted efforts toward reducing importation and increasing local manufacturing must be made with purposeful training of Nigerians in designing for mass production. Hence, design courses should be given special attention in tertiary institutions, particularly, Industrial Design that is attuned to prototype generation for mass production. Transfer and acquisition of technology must be encouraged. Nwoye (2015) asserts that foreign assistance without adequate development of available local resources have stalled industrial sector growth, and that Nigeria does not have the capacity to channel her natural resources to industrial use; export of raw materials and import of manufactured products have become the practice over the years. This ugly situation can be reversed; only when proper measures are taken by all stakeholders.

ABSTRACT

Philosophical foundation is central to the successful practice of any discipline. Such should be focused, non-sectarian and result-oriented. Unfortunately, the practice of landscape architecture is guided by non-coherent and sometimes opposing philosophical thoughts. The purpose of this paper is to critically review the dominant philosophical paradigms of landscape architecture and their core tenets. These include naturalism, environmentalism and urbanism. The study attempts to compare their tenets to identify what are common and what are not. It brings together those commonalities to develop a holistic philosophical approach. The study singles out nature, environment and city from the three paradigms respectively and proposed Eco-natural Humanism as a holistic philosophy of landscape architecture. After addressing how to resolve the identified competing ideas among the existing three paradigms, the study reflects on the proposed paradigm and recommends its further intellectual criticism along geographical divides and human groupings.

Keywords: Ecology, Environmentalism, Humanism, Naturalism, Organic Architecture, Science, Urbanism

INTRODUCTION

The practice of every discipline is based on relevant theoretical backgrounds or philosophical foundations (Hunt, 2000; Certeau, 1984; Thomas, Sim and Poulton, 2001). These determine the roles and responsibilities of the practitioners and the procedures of their operations in the discipline. Such interaction between theory and practice is also true of landscape architecture as a discipline. Unfortunately, unlike many other disciplines, it has its origin from many theoretical backgrounds which are associated with the disciplines from which it has "borrowed" different parts at varying degrees. This results in disparity in the products of the discipline of landscape architecture. The situation is worsened by the changing roles of its practitioners over periods of time consequent upon changing environmental, social, political, economic, and cultural challenges (Davis and Oles, 2014).

Though landscape architecture has its primary origin in agriculture, it also leans on theories and practices from horticulture, gardening, forestry, engineering, architecture, fine arts and ecology. In view of these multiple source of theoretical background and philosophical thoughts, it belongs to the group of disciplines based on eclecticism, that is, "a conceptual approach that does not hold rigidly to a single paradigm or set of assumptions, but instead draws upon multiple theories, styles, or ideas to gain complementary insights into a subject, or applies different theories" (Leonard, 1975). According to Kelley (2005), eclecticism appears at the confluence of several intellectual movements and their paradigms.

The purpose of this study is to critically review each philosophical paradigm of landscape architecture and their core tenets; attempt to compare those tenets to identify what are common to all paradigms and what are not; discuss how to bring together those commonalities to develop a holistic philosophical approach by connecting the similar principles in all paradigms and by addressing how to resolve competing ideas among these paradigms; and reflect on the limitations of such a unified philosophy. This becomes necessary in view of the current negative impact of urbanization, like deforestation, on the built environment where nature has also been "designed out". Accordingly, landscape

Adedeji, J. A. & Arayela, O. (2016). Review of Philosophical Paradigms of Landscape Architecture. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1108-1123

architecture is expected to play significant roles in solving these environmental problems. While the study acknowledges the multiplicity of the theories applicable to landscape architecture, it is concerned with the key philosophical thoughts of naturalism, environmentalism, and urbanism and their respective disciplines of architecture, ecology and urban design in view of their core relevance to the current environmental sustainability debate. The study explored archival resources on writings and built works of practitioners and theorists in landscape architecture with respect to architecture, ecology and urban design. It compares their tenets to identify what are common to all paradigms and what are not, then proposes and discusses a unified philosophy towards application to solving the current problems in the built environment occasioned by urbanization. This position is also judged suitable in this discourse since a host of others are either derivates or can be subsumed in these majors.

NATURALISM AND ARCHITECTURE

Naturalism is a philosophical standpoint in architecture that has produced the theory of organic architecture. An examination of the duo as matrixes suggests the non-existence of one without the other. What then is philosophical naturalism in organic architecture?

Naturalism

Naturalism commonly refers to the viewpoint that "laws of nature operate in the universe" (Oxford English Dictionary). Followers of naturalism (naturalists) assert that "natural laws are the rules that govern the structure and behaviour of the natural universe, that the universe is a product of these laws" (Catholic Encyclopedia). Philosopher Kurtz (1990) argues that "nature is best accounted for by reference to material principles" including "mass, energy, and other physical and chemical properties accepted by the scientific community". It is a process of long evolutionary path including the interaction of humans with land to form landscape. The "understanding" of science and philosophy is one facet of this, even when it reflects upon its own emergence and science and other intellectual enterprises can be seen as building upon human capacities for dealing with their environment, improved piecemeal over many generations. Accordingly, science (ecology) is seen as a social phenomenon that is "cognitively reliable, and increasingly so" (Dress, 2003). Therefore, according to Kitcher (1993) "the human, historical, and social character of science need not undermine scientific credibility."

Naturalism therefore engages conceptually with landscape architecture without its other philosophical complexities in relation to religion as ecological design/design with nature paradigm. According to Dagenais (2008), "the nature with which landscape designers are working is manifold in its expression." He observed that "researchers as well as philosophers who have studied ecological concepts, theories and conservation practices contrast ideas of nature as a collection of objects, to ideas of nature as process." In fact, in the same way that conservation of biodiversity implies interventions akin to gardening, designing with biodiversity is very much compatible with garden and landscape design. In the second conceptualization of nature, it can be understood as a "force, a process, sometimes irrespective of the species or number of species involved in an ecological", perspective and is didactic to poetic descriptions of processes occurring in the landscape or garden as the only way to acknowledge and represent the passage of time (Dagenais, 2008).

Naturalism in environmental movements is a part of conservation ethic in relation to preserving natural ecosystems. It is a state of nature and conformity to nature as realism (http://www.mondofacto.com/facts/dictiona). Clark (1963) observed that

> *"we are surrounded with things· which we have not made and which a lift and structure different from our own: trees, flowers, grasses, rivers, hills, clouds. For centuries they have inspired us with curiosity and awe; They have been objects of delight; we have recreated them in our imaginations to reflect our moods. And we have come to think of them as contributing to an idea which we have called nature."*

Naturalism embraces "nature" in a more intentional and expressive way. First, any designer that calls his or her work "naturalistic," "sustainable", or "ecological" cites nature as an authority to justify their designs (http://landscapeofmeaning.blogspot.com/2010/05/modern-naturalism-artifice-in-natural.html). Secondly, ideas about nature ultimately reveal more about us than it does about the landscapes they describe (Alessandro, 2007). Spirn (1997) argues that "nature is an abstraction," and "a set of ideas for which many cultures have no one name, a singular name for the real multiplicity of things and living processes." Consequently, in landscape design today, "naturalism is a science (ecology), a moral calling, and an aesthetic. All true naturalism must first be humanism. According to her, the landscapes that captivate both intellectually and spiritually are those that blur the lines between natural and cultivated", since "nature is both given and constructed" (Spirn, 1997). These realities are true since nature outside of mankind as given landscape and nature that is inside of mankind as constructed landscape is one. The critical role of ecology therefore manifests being the body of knowledge concerning the economy of nature, the investigation of the total complex interrelations of all human and non-human nature.

Organic Architecture

The rule of nature in naturalism of landscape architecture has its expression in organic architecture as evident in the works and writings of Frank Lloyd Wright called "architect of the landscape". To Wright, nature was the manifestation of God: "Nature should be spelled with a capital 'N' not because Nature is God but because all that we can learn of God we will learn from the body of God, which we call Nature. Therefore "the noblest ministry of nature is to stand as the apparition of God" (Emerson, 1836) and designers who refer to their work as "natural" cites nature as authority to justify decisions to select some materials or plants and exclude others, to arrange them in particular patterns, and tend the result in certain ways (Spirn, 1997). The authority of science is cited to augment the authority of nature and God and most landscape architects regard ecological science as an important source of principles for landscape design (Emerson, 1836).

Indeed, the adoption of ideas from ecology contributed to a renewal of the discipline in the 1960s. Some, however, have embraced ecology as the primary authority for determining the "natural" (and therefore correct) way to design landscapes. To its most extreme practitioners, ecological design is deterministic, its "laws" couched in terms that recall religious dogma. Debates over what constitutes a "truly ecological landscape architecture" have escalated in recent years, with various groups accusing each other of "non-ecological" behaviour (George and Frederick, 1997). Accordingly, there have been bitter quarrels over the proper materials, styles, and methods of "ecological" landscape design. Some "advocate the exclusive use of native, as opposed to naturalized, plants. Some urge the eradication of "exotic invaders" and condemn others for planting naturalized, non-native, plants. Some conceal the artifice of their works; others celebrate the human ability to transform the landscape" (Spirn, 1991). "Some privilege the role of reason in design and promote science as the sole source of truth about nature, while others prefer personal revelation and reject science as a way of knowing" (Spirn, 1991).

Organic architecture is a philosophy of architecture which promotes harmony between human habitation and the natural world through design approaches so sympathetic and well integrated with its site that buildings, furnishings, and surroundings become part of a unified, interrelated composition (Wright, 1958) (Plate 1). The term organic architecture was coined by the famous architect, Frank Lloyd Wright. Architect and planner Pearson (2001) proposed a list of rules towards the design of organic architecture.

Plate 1: Edgar J. Kaufmann House, designed by Frank Lloyd Wright over a waterfall on Bear Run in the western Pennsylvania highlands (Source: Robin, 1995)

These rules are known as the *Gaia Charter* for organic architecture and design. It reads (Pearson, 2001):

> *Let the design: be inspired by nature and be sustainable, healthy, conserving, and diverse; unfold, like an organism, from the seed within; exist in the "continuous present" and "begin again and again"; follow the flows and be flexible and adaptable; satisfy social, physical, and spiritual needs; "grow out of the site" and be unique celebrate the spirit of youth, play and surprise; express the rhythm of music and the power of dance*

Freed (2007) takes a more seminal approach in making his description:

> *Using Nature as our basis for design, a building or design must grow, as Nature grows, from the inside out. Nature grows from the idea of a seed and reaches out to its surroundings. A building thus, is akin to an organism and mirrors the beauty and complexity of Nature."*

ENVIRONMENTALISM AND LANDSCAPE DESIGN

Environmentalism

There have been debates over what environmentalism should really mean for more than four decades after its emergence. This has been "characterized more by passion than by clarity, with definitive and persuasive answers hard to come by" (Conan, 2001). The goals of environmentalism thus include "creating, harmony between humans and nature, providing unity in nature, healing the environment, and restoring nature to the city" (http://www.doaks.org/resources/publications/doaks-online publications/environmentalism/env6.pdf).

Environmentalism is a broad philosophy, ideology and social movement regarding concerns for environmental conservation and improvement of the health of the environment, particularly as the measure for this health seeks to incorporate the concerns of non-human elements(Donald, 2003). It "advocates the preservation, restoration and/or improvement of

the natural environment, and may be referred to as a movement to control pollution. For this reason, concepts such as a Land Ethic, Environmental Ethics, Biodiversity, Ecology and the Biophilia hypothesis figure predominantly. At its crux, environmentalism is an attempt to balance relations between humanity and their broader organismic and biogeochemical milieu in such a way that all the components are accorded a proper degree of respect. The exact nature of this balance is controversial and there are many different ways for environmental concerns to be expressed in practice. Environmentalism and environmental concerns are often represented by the colour green, (Cat, 2009) but this association has been appropriated by the marketing industries and is a key tactic in the art of Greenwashing.

Environmentalism can also be seen as "a social movement that seeks to influence the political process by lobbying, activism, and education in order to protect natural resources and ecosystems" (http://modernsociety.wikia.com/wiki/Environmentalism). An environmentalist is thus "a person who may speak out about our natural environment and the sustainable management of its resources through changes in public policy or individual behaviour by supporting practices such as not being wasteful" (http://modernsociety.wikia.com/wiki/Environmentalism). In various ways (for example, grassroots activism and protests), environmentalists and environmental organizations seek to give the natural world a stronger voice in human affairs (Robert, 2005).

Evangelical environmentalism is an environmental movement in the United States in which some Evangelicals have emphasized biblical mandates concerning humanity's role as steward and subsequent responsibility for the caretaking of Creation (Gottlieb, 2005). While the movement has focused on different environmental issues, it is best known for its focus of addressing climate action from a biblically grounded theological perspective. The Evangelical Climate Initiative argues that human-induced climate change will have severe consequences and impact the poor the hardest, and that God's mandate to Adam to care for the Garden of Eden also applies to evangelicals today, and that it is therefore a moral obligation to work to mitigate climate impacts and support communities in adapting to change (http://christiansandclimate.org/learn/call-to-action).

Various rhetorical positions on environmentalism exist within the landscape architecture profession, categorized, for the purpose of this discourse, by deep environmentalism, preservation environmentalism, integrative environmentalism, and ecological environmentalism (http://www.doaks.org/resources/publications/doaks-online-publications/environmentalism/env6.pdf). Such categorisation is not intended to suggest absolute philosophical boundaries or established group Positions. This rhetorical analysis began with a metaphysical query into the differing possible relationships between humankind and the natural world. This led to the construction of categories that fell along a continuum from the most ecocentric position, in which humans see themselves as mere animals among all the other species of creation, to the most anthropocentric position, in which humans see themselves as owners of all of creation, which exists to please, satisfy, or profit them. The purely ecocentric position is that in which "humans are posited to be part of a larger ecosystem and, as such, have no privileged position within that system. The human animal is decentred, having as many rights to the riches of nature as any other animal, plant, or mineral."(http://www.doaks.org/resources/publications/doaks-online-publications/environm entalism/env6.pdf). This extreme position is best represented historically by Muir (1988). Ironically, although Muir is often cited as a "patron saint" of modern environmentalism, his metaphoric style did not become common parlance in landscape architecture (Hastings, 1996). Therefore, ecocentric environmentalism functions here as an ideal state of ontological parity-an unattainable limit that may only be approached by humankind.

The deep environmentalist (sometimes referred to as radical environmentalist or ecofundamentalist) position holds that the human actor is somewhat privileged, especially in acting on behalf of nature, which the moral stance of this position mandates. Deep environmentalism holds that "nature has intrinsic rights that stem from a spiritual base, although the origin of this spirituality is not uniform among deep environmentalists" (http://www.doaks.org/resources/publications/doaks-online-publications/environmentalism/env6.pdf). The spiritual experience of nature may be drawn from pagan Gaia worship, Eastern religions such as Taoism or Buddhism, or any of the many New Age understandings of the human-nature relationship (McHarg, 1969; Denig, 1985). Deep environmentalism functions as a transcendent value that infuses the other three categories to varying degrees. What deep environmentalists have in common are not their spiritual bases but their belief that nature has some intrinsic rights that humans are responsible for protecting (http://www.doaks.org/resources/publications/doaks-online-publications/environmentalism/env6.pdf). Deep environmentalism's proponents include Dave Foreman, Arne Naess, and Aldo Leopold (Nadenicek and Hastings, 2000).

Preservationist environmentalists seek to preserve "an unsullied nature and restore degraded lands. They are anthropocentric to the degree that they view humankind as being responsible for protecting and maintaining wild areas" (McHarg, 1969). Often, this is due to a deep environmental spiritual connection to nature, but not all preservationists are deep environmentalists; motivations can range from a romantic desire to return to a pre-Fall Eden to a selfish need to be "purer than Thou." (Nadenicek and Hastings, 2000).

Integrative Environmentalists understand their relationship to the natural world as Adam's post-Fall relationship to the Garden - as stewards of a world we did not create. From this vantage point, humans have a special responsibility to protect all creation, and this responsibility also endows us with the right to use all creation to meet our needs. Nature existed for us as a font of not only physical nourishment, but also spiritual nourishment; nature was essential to human spiritual development (Nadenicek, 1997). He advocated a harmonious integration of nature and human culture for the optimal mental, physical, and spiritual development of humankind. Soper's metaphysical view of nature aligns with this integrative category of environmentalism. According to Soper (undated) "One is invoking the metaphysical concept in the very posing of the question of humanity's relation to nature." Nature as a human construct, the idea of integration, and suppositions about human naturalness falls into Soper's category of the metaphysical perspective (Cronon, 1995). Ecological Environmentalism (Nadenicek and Hastings, 2000) distanced itself from the moralistic or sentimental understandings of nature as those offered by science. Ecological environmentalism brings an understanding of the world as process. Humans have the dual role of being both part of the process and observers of it. In view of the conceptual overlapping, ecological environmentalism also parallels with landscape ecology and shall be more discussed under it.

Criticisms of environmentalism tend to fall into two major categories: environmental skepticism and anti-environmentalism. Environmental skeptics dispute the claims of environmentalists, claiming they are either inaccurate or exaggerated (Huesemann and Huesemann, 2011). Anti-environmentalists, on the other hand, accept many of the claims made by environmentalists while simultaneously accepting that change is inevitable, regardless of cause and speed. They do not deny the impact of humanity, but they dispute the argument that humanity can kill the planet, citing life's several billion year history as evidence that it is more resilient than many environmentalists realize. Humans are now recognized as being a part of the natural world, and the ecological study of human interventions, even on the scale of landscape architecture, has become acceptable for

sympathetic ecologists. A deeper scientific understanding of the environment can also be a source of inspiration to landscape architects, both as motivation and as artistic idea (Nadenicek and Hastings, 2000).

Landscape Ecology

In the canon of the disciplines that made up Landscape Architecture practice in theory and practice, ecology provides the single indispensable basis for landscape architecture and landscape planning, landscape planning being the development and application of large scale strategies, policies and plans to create successful environments, in both urban and rural settings, for the benefit of current and future generations (Landscape Institute, 2011). Because landscape architecture has critical roles to play in the domestication and designing of nature in cities, there is the supremacy of the natural, and therefore of ecology, in the landscape discipline as an ideological imperative. When McHarg (Spirn, 1998) calls ecology "not only an explanation but a command" he conflates ecology as a science (a way of describing the world), ecology as a cause (a mandate for moral action), and ecology as an aesthetic (a norm for beauty). While landscape architecture practice therefore involves ecology, the location of the discipline in McHarg's science-design nexus rather suggests a type of practice that is ecological (Raxworthy, undated). Thus, ecology should be seen as a major consideration in the matrix of site information in landscape architecture practice. McHarg (1967) pointed out that where the landscape architect commands ecology he is only "the bridge between the natural sciences and the planning and design professions, the proprietor of the most perceptive view of the natural world which science or art has provided". Similarly, Williams and Patterson (1999) argue that:

> *viewing ecosystems as repositories of socially constructed meanings have implications for what counts as ecosystem knowledge, how we conceptualize and value ecosystems, and how we integrate this knowledge into theory and practice.*

The realist or scientific perspective in Soper's triad of perspectives on nature is similarly about the "structures, processes and causal powers" at work in the physical environment (Soper, undated). This is the nature to whose laws the world is subject.

McHarg (1969) promoted an ecological view in landscape architecture, in which the designer becomes very familiar with the area through analysis of soil, climate and hydrology. He argued for the need to define the problems of modern development and present a methodology or process prescribing compatible solutions. His work had an impact on a variety of fields and ideas. "Environmental impact assessment, new community development, coastal zone management, brownfields restoration, zoo design, river corridor planning, and ideas about sustainability and regenerative design all display the influence of" his works (Steiner, 2004). His *Design with Nature* (McHarg, 1969) had its roots in much earlier landscape architecture philosophies. The Woodlands (Plate 2) is one of the best examples of his ideals. Most of the actual work was done by a large team while McHarg was still there and by many others in the years since he left. The Woodlands continues to be a successful ecological community even today (Forsyth, 2003). He saw the earlier tradition as a precursor of his philosophy, which was rooted less in aristocratic estate design or even garden design and more broadly in an ecological sensibility that accepted the interwoven worlds of the human and the natural, and sought to more fully and intelligently design human environments in concert with the conditions of setting, climate and environment. Always a polemicist, McHarg (1969) set his thinking in radical opposition to what he argued was the arrogant and destructive heritage of urban-industrial modernity, a style he described as "Dominate and Destroy."

Plate 2: The Woodlands CDP, Texas co- designed by McHarg and established in 1974. (Source: U.S. Census Bureau, 2006)

Urbanism and Urban Design

Urbanism

The philosophy of urbanism posits that cities are vitally important to society. According to urbanists, the difference in population entails a difference in the social and political order as well (Eduardo and Rasna, 2007). Amin and Graham (1997) argue that the urbanscape can best be understood as a site of co-presence of multiple spaces, multiple times and multiple webs of relations, tying local sites, subjects and fragments into globalizing networks of economic, social and cultural change. Olmsted (1990), widely recognised as the pioneer and visionary of modern landscape architecture (Fadamiro, 2010), was among the foundational proponents of urbanism. He had high expectations for his design's psychology and visual effects on people. He believed that the perfect antidote to the stress and artificialness of urban life was a nice stroll through a pastoral park (Plate 3). He foresaw places with graceful undulating greensward and scattered growths of trees. He believed and promoted the idea that such an environment would promote a sense of tranquillity. Olmsted's vision was that the sense of calmness that would come from the park by his separation of the different landscape themes and conflicting uses. For Olmsted, the importance of contact with wilderness for human well-being, the effect of beautiful scenery on human perception, and the moral responsibility of democratic governments to preserve regions of extraordinary natural beauty for the benefit of the whole people (Roper, 1973) are non-negotiable. Olmsted favoured a more sanitized urbanism of parks and parkways and argues that aesthetic of urban design must therefore be rooted in the normal processes of nature and of living. It should link function, feeling, and meaning and should engage the senses and the mind. Similarly, Spirn (1988) concludes that the city is both natural and contrived a transformation of "wild" nature to serve human needs, an evolving entity shaped by both natural and cultural processes.

Plate 3: Panoramic view of Central Park, New York from the Rockefeller Centre,co-designed with Calvert Vaux by Olmsted, Frederick Law in 1857. (Source: Miller, 2003).

Urbanism in its wider sense also includes the study of the interaction between the city and the rural hinterland (http://www.cityvision.edu/wiki/node/15709). The word urbanism is also

used as a qualitative complement to the description of various urban and rural forms i.e.: informal urbanism, new urbanism, self-sufficient urbanism, sustainable urbanism, centralized or decentralized urbanism, neo-traditional urbanism, transitional urbanism, green urbanism and landscape urbanism. Green and landscape urbanisms in particular are the closest to landscape architecture practice.

Landscape Urbanism is a theory of planning and design for urbanism arguing that *landscape*, rather than *architecture*, is more capable of organizing the city and enhancing the urban experience (http://en.wikipedia.org/wiki/Landscape_urbanism). It describes "the ability to produce urban effects traditionally achieved through the construction of buildings simply through the organization of horizontal surfaces" (Waldheim, 2006). Landscape urbanism sees landscape as a medium of urban order for the contemporary city. According to Reed (2006)

> *Contemporary landscape practices are witnessing a revival of sorts, a recovery of the broader social, cultural, and ecological agendas. No longer a product of pure art history and horticulture, landscape is re-engaging issues of site and ecological succession and is playing a part in the formative roles of projects, rather than simply giving form to already defined projects."(http://wsd-landscape.blogspot.com/2012/03/landscape-optimism-interview-with-chris.html).*

Green urbanism is the practice of creating communities beneficial to human and the environment. According to Beatley (2000) it is an attempt to shape more sustainable places, communities and lifestyles (Bicknell et al, 2009) and consume 75percent of the world's resources (Karlenzig et al, 2007; Lehmann, 2010). Green urbanism is interdisciplinary, combining the collaboration of landscape architects, engineers, urban planners, ecologists, transport planners, physicists, psychologists, sociologists, economists and other specialists in addition to architects and urban designers.

Urban Ecology

The philosophy of urbanism has its role as Urban Ecology in landscape architecture practice. In contemporary urbanism, also known as urban design in many parts of the world, there are as many different ways of framing the practice as there are cities in the world. Barnett (2011) acknowledges a list of sixty contemporary urbanisms. Knox (2010) refers to one of many trends in contemporary urbanism as the "aestheticization of everyday life". Krieger (2009) studies urbanism theory in order to provide insight into how urban practitioners work. He identifies ten spheres in which urbanism takes place in practice. The ten are: the bridge connecting planning and architecture, a form-based category of public policy, the architecture of the city, urban design as restorative urbanism, urban design as an art of place- making, urban design as smart growth, the infrastructure of the city, urban design as landscape urbanism, urban design as visionary urbanism, and urban design as community advocacy or doing no harm. Krieger (2009) concludes by stating that "urban design is less a technical discipline than a mind-set based on a commitment to cities." Kelbaugh (2009) writes about three urbanisms on the cutting edge of theoretical and professional activity in Western cities. These three paradigms include New Urbanism, Everyday Urbanism, and Post-Urbanism (Kelbaugh, 2009).

Another important thinker in the history of ecological urbanism is Jane Jacobs who argues that, "human beings are part of nature" as are cities and that "nature, sentimentalized and considered as the antithesis of cities, is apparently assumed to consist of grass, fresh air and little else" (Spirn, 2011). She focused on the city as a human habitat and regarded urban design as a way to support and fulfil human needs. Jacobs advocated an ecological approach to designing and managing cities, arguing that cities are problems of organized complexity,

akin to living organisms, and that there are lessons for urban design from the study of systems where half-dozen or even several dozen quantities are all varying simultaneously and in subtly interconnected ways. Jacobs's, McHarg's, Lynch's, and Mumford's ideas about an ecological approach to the design of cities were supported by scientific knowledge about the place of cities in the natural world and the role of humans in shaping the environment (Spirn, 2011).

The growing literature on the environmental history of particular cities provides a temporal context for understanding the ways that human activities and settlements respond to and shape their natural environments. Ecological urbanism grew out of ideas and action in landscape architecture, architecture, and urban design and cities are part of the natural world. Accordingly,

> *Nature in the city is far more than trees and gardens, and weeds in sidewalk cracks and vacant lots. It is the air we breathe, the earth we stand on, the water we drink and excrete, and the organisms with which we share our habitat. Nature in the city must be cultivated, like a garden, rather than ignored or subdued. The idea of nature as consisting of the biological, physical, and chemical processes that create and sustain life, the earth, and the universe is fundamental to ecological urbanism. If one embraces this idea, then the false oppositions between city and nature, the given and the built, fall away (Spirn, 2011).*

Wilson's (1988) biophilia hypothesis argues that "humans have an innate attraction to life and life's processes". Urban design that fosters and intensifies the experience of the natural processes that sustain life fulfils this need. Aesthetic experience of such places has the potential for recentering human consciousness from an egocentric to a more bio-centric perspective. This is the whole essence of landscape architecture.

FINDINGS AND DISCUSSIONS

The goal of this section is to examine each of the paradigms in order to isolate their core tenets towards understanding their commonalities and disparities as shown in Table 1. To avoid rhetoric, each paradigm is summarized to definitional status of key words. In this sense, naturalism sees landscape as *nature* in time, established through "divine" ecological processes, governed by "supernatural" laws whose products are established in space. Landscape thus has history and geography as temporal and spatial entity. Therefore, naturalism exclude the thought of landscape as abstraction, an idea or mere concept that cannot be experienced, explained as science, lived-in and enjoyed by humans. While it accepts the centrality of humans at the receiving end through interaction with land to form landscape in a cultural process, it emphasizes the supremacy of divine rule as the verdict of what becomes of the landscape. Accordingly naturalism is partly humanism and majorly natural-determinism. It sees humans as part of the ecological system and at the same time stewards of its conservation. The tenet of naturalism that "nature is both given and constructed" collapses the partition between the inner-nature of man and the outside-nature of the landscape. Practitioners of naturalism make *nature* the authority for their landscape designs. With the interchangeableness of ecology and science and upholding the idea that nature should be respected as much as its Creator, being the manifestation of God, the key debates in naturalism are anchored on the words: natural, supernatural, ecology, reality, complexity, flexibility, free-flowing formation, fractal composition, dogmatism and divinity against personal revelation, intuition, ingenuity, simplicity, regularity, rigidity and artificiality.

Table 1: Core tenets of the philosophical paradigms of landscape architecture

Paradigm	Key word and Definition	Core tenet	Inclusions	Exclusions	Deductions
Naturalism	Landscape as *nature* in time, Established through "divine" ecological processes, Governed by "supernatural" laws whose products are established in space	Nature is both given and constructed" Anchored on the words: natural, supernatural, ecology, reality, complexity, flexibility, free-flowing formation, fractal composition, dogmatism and divinity against personal revelation, intuition, ingenuity, simplicity, regularity, rigidity and artificiality.	Centrality of humans Supremacy of divine rule	Landscape as abstraction, An idea or mere concept that cannot be experienced, explained as science, lived-in and enjoyed by humans	Naturalism is partly humanism and majorly natural-determinism. It sees humans as part of the ecological system and at the same time stewards of its conservation
Environmentalism	Landscape as total *environment* of humans and nature	Unity in biodiversity Nature in cities Healthy environment Biophilia hypothesis Ecological conservation Environmental restoration Proportional balance between humanity and its broader concerns, Eco-system and natural resources protection, Biblical stewardship of nature and activism.	Nature as a human construct The world as a process Humans as privileged, Do not believe in change Humanity can kill the planet.	Urban-industrial modernity, arguing that it is arrogant, destructive and domineering. Nature as a human construct The world as a process, Humans as privileged	Distances itself from the scientific explanations of ecology despite the systematic procedures in science
Urbanism	*City:* ideology on population, social and political order, economic and cultural change in globalizing networks	Cultivated nature in cities Ecological cities Designs that envision tranquillity, serenity, sense of calmness, contact with wilderness, beautiful scenery, normal processes of nature, multiplicity of spaces and times	The dictum and maxim of ecology City where landscape is the medium of urban order Human beings are part of nature	Oppositions between city and nature, the given and the built, as false	The city is shaped by both natural and cultural processes and therefore believe in change

Environmentalism sees landscape as total *environment* of humans and nature without complete clarity in spite of great passion. It pursues the following in its tenets: unity in biodiversity, nature in cities, healthy environment, biophilia hypothesis, ecological conservation, environmental restoration, proportional balance between humanity and its broader concerns, eco-system and natural resources protection, biblical stewardship of nature and activism. Conversely, in its approach of two diametrically –opposed extremes of ecocentric and anthropocentric positions in humans relation with nature, it betrays its self-confidence and exhibits lack of clarity. Environmentalism is also opposed to urban-industrial modernity, arguing that it is arrogant, destructive and domineering. Unfortunately too, it sees nature as a human construct, the world as a process, humans as privileged, do not believe in change and that humanity can kill the planet. While it agrees that human environments should be intelligently designed, it does not believe in change. Although it embraces ecology in its thoughts and actions, it distances itself from the scientific explanations of ecology despite the systematic procedures in science and still argues that a deeper scientific understanding of the environment can also be a source of inspiration to landscape architects. Without offering its contextual explanation of culture and probably having an oversight of landscape as product of modification of land by humans through cultural processes, environmentalism argues in favour of an "untouched" nature in consonance with human culture. The whole gamut of ideology in environmentalism is therefore not only inconclusive but self-betraying, confusing and unnecessarily complex.

The keyword in the philosophy of urbanism is *city*. It concerns itself with ideology on population, social and political order, economic and cultural change in globalizing networks. Because it is people-oriented it is humanistic and for its designs that envision tranquility, serenity, sense of calmness, contact with wilderness, beautiful scenery, normal processes of nature, multiplicity of spaces and times, it is naturalistic. In this wise urbanists argue that the city is shaped by both natural and cultural processes and therefore believe in change. By pursuing aesthetic of urban design through the normal processes of nature and of living and linking function, feeling, and meaning that engages the senses and the mind, urbanism truly conforms to the dictum and maxim of ecology. However, without hypocritical pretension of environmentalism, urbanism believes in designing cities in natural contexts by transforming wilderness to serve human needs incorporating parks and conservation areas in built environments. It envisions city where landscape is the medium of urban order and human beings are part of nature. It promotes human activities and settlements that respond to and shape the natural environments of plants, air, the earth and the organisms with which humans share their habitat. In consonance with naturalism, urbanism argues that nature in the city must be cultivated and therefore upholds the doctrines of "cultivated nature" and "ecological cities". To urbanism, oppositions between city and nature, the given and the built, is false, calling for bio-centric cities.

Table 2: Commonalities and disparities among naturalism, environmentalism and urbanism in landscape architecture

Commonalities	Disparities
Nature is superior, powerful, permanent, indispensable, desirable	Human ingenuity is inferior to nature
Nature can be given or constructed	Eco-balance implies untouched nature
Ecology is the scientific means of understanding nature	Change is not ecological
Humans are the theological, temporal and accountable stewards of earth	Cities and nature are in opposition
	Humans are destroyers of the earth.

In explicating the content of the above discourse on naturalism, environmentalism and urbanism as philosophical standings in landscape architecture theory and practice, the following key commonalities are extractable as shown in Table 2: nature is superior,

powerful, permanent, indispensable, most desirable and can be given or constructed; ecology is the scientific means of understanding and exploring nature for the best use of humans; humans are the theological, temporal and accountable stewards of God's planet earth and its built environment. Conversely, the areas of disparities among the trios are: human ingenuity is inferior to nature; eco-balance implies untouched nature and change is not ecological; cities and nature are in opposition and humans are destroyers of the divine heritage, called earth. A conscious effort is demanded to bring these commonalities together to a common ground by formulating a holistic philosophy for landscape architecture theory and practice and addressing how to resolve competing ideas among these paradigms.

A Unifying Philosophy for Landscape Architecture

Three common keywords have been singled-out so far as derivatives of the three identified philosophical paradigms. These are *nature*, *environment* and *city* from naturalism, environmentalism and urbanism respectively. Though inter-related in meaning at varying contextual scales, the trio inevitably suggests that any unifying philosophy of landscape architecture that may enjoy broad-based acceptability and wider application should be pluralistic. Since *nature* is indispensable, ecology is the science of understanding the natural *environment* and humans are central to the idea of *city*, it may be proposed that such pluralistic philosophy be called Eco-natural Humanism (Figure 1).

Eco-natural Humanism will then mean a holistic philosophy in Landscape Architecture that emphasizes the rule of nature in the design, construction and management of built environment generally, and the city in particular, and conservation areas in the best ecological milieu, in the optimal interest of humans who will be accountable to the Creator. Its tenets will encompass all those that are agreeable among founding naturalism, environmentalism and urbanism. The conflicting principles of this trio might be resolved by a tangential approach to the pluralized focus, *Eco-natural Humanism.* In this wise, human ingenuity will not be comparable with the *supreme* nature but rather enhances the adaptation of nature to the best use of humans in the most ecological stewardship. Furthermore, eco-balance will not imply "untouched nature" but change that is ecologically-compatible and sustainable in the environmental, social, economic, political and cultural agenda of the city. Also, in this approach, cities and nature will not be opposition but co-inhabit the environment of non-humans and humans in the most sustainable mix and then humans will not be labeled as destroyers of the divine heritage, called earth. Accordingly, landscape architecture will be playing significant roles in the environmental sustainability debate in the face of the onslaught of urbanization forces.

REFLECTION, RECOMMENDATION AND CONCLUSION

The confluence of nature and humans is significant to determining the merit or otherwise of any intellectual discourse on landscape architecture. According to Treib (2010) "meaningful landscape design should express a distillation of the essential qualities of human experience paired with a consideration of nature". Such design should be based on and guided by firm and factual theoretical underpinnings built on the nature-human nexus with "nature and ecology at sacrosanct values" (Hohmann and Langhorst, 2011). The proposed pluralistic and holistic *Eco-natural Humanism* philosophy of landscape architecture will belong to this larger school of thought. It will not be an empty idea, a manifesto for landscape political survival but a "food for thought", a flair for beauty, a scavenger of dumb landscape ideas and a catalyst for unimaginable result in the landscape experiment.

Despite its possible humble conception, inability for fuller expression and infancy of possible acceptability, *Eco-natural Humanism* signals the rejuvenation of a discipline in theoretical

disarray and practical confusion. In its broad application, in view of the universality of humanity, it will cross racial, geographic, intellectual and disciplinary boundaries. Whether landscape is conceptualized as rural or urban, heritage or modern, wild or constructed, *Eco-natural Humanism* promises to be a haven for all and more.

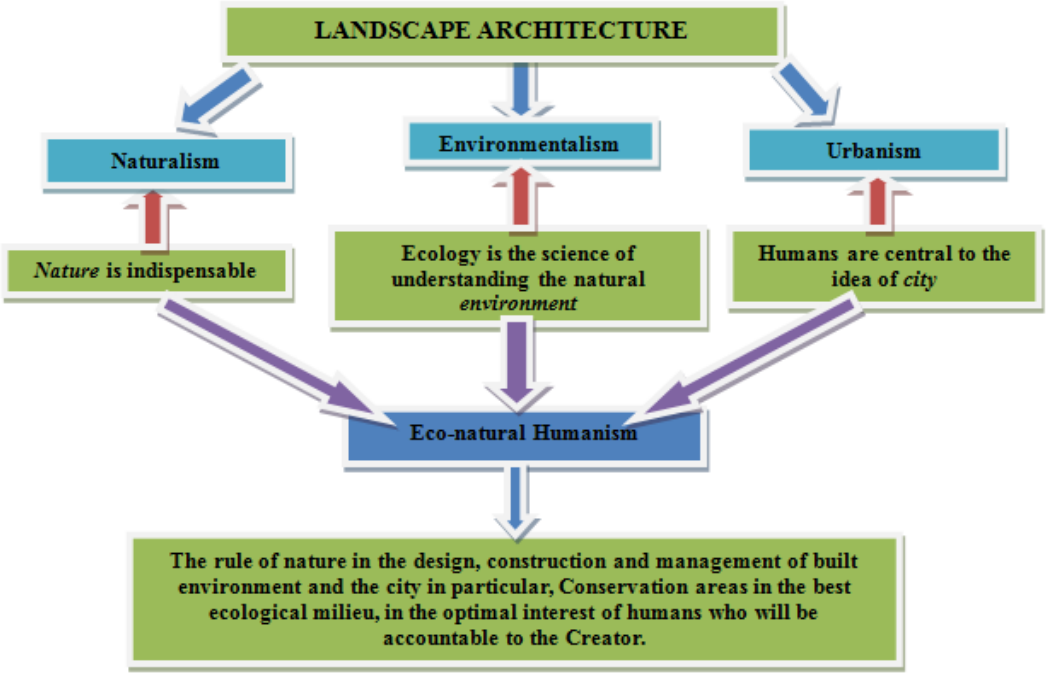

Figure 1: Schematic framework of a unifying philosophy of landscape architecture (Source: Authors, 2016)

However, in view of the peculiarities among genders, age groups and social classes, cultural distinctiveness and economic and quality of life indices, there is need for further analysis on and experimentation of this philosophy among differing human groups. Similarly, detail ecological considerations of this philosophy are necessary on geographical basis because of differences in climatic, geological, and vegetation parameters across regions. Since the profession of landscape architecture demands the rigor of theoretical criticism, *Eco-natural Humanism* could be a cutting-edge grounded theory of landscape architecture. It essentially belongs to the *realism* perspective in which the position that the picture that science (ecology) paints of the world is a true and accurate one (Chia, 2002). Therefore, because of this scientific source, *Eco-natural Humanism* promises to be precise in the key landscape architecture debates.

Adoption of Sustainable Risk Management: A Study of Chemical Exposure in Textile Industry in Nigeria

Akintayo, Wole Lateef

Vocational and Technical Education Department, Tai Solarin University of Education, Ijebu-Ode, Ogun State, Nigeria
* *akintayo2002@gmail.com*

ABSTRACT

The Nigeria textile industry consists of a number of units engaged in spinning, weaving, dyeing, printing, finishing and a number of other processes that are required to convert fibre into a finished fabric or garment. It is however regretted that, this industry exposes workers to many hazards and risks, ranging from exposure to noise and dangerous substances and chemicals, to manual handling and working with dangerous machinery. Each processing stage from the production of materials to the manufacturing, finishing, colouring and packaging posed risks for workers, and some of these are particularly dangerous to human's health. No industrial sector in the world including that of Nigeria today is free of risk belonging to its internal and external environment. This article identified each of these risks in relation to the Nigerian textile industries, along with the possible solutions for their assessment. This study recommends among others that an inventory and risk assessment of all chemicals and dyes that are present at the Nigeria Textile factory be undertaken by the management and the information in the inventory and risk assessment must be made available to all workers; Dyes, chemicals and other auxiliaries should be stored in a separate work area and access to this area should be limited to trained personnel. The storage area should be kept relatively cool and dry (within the range specified in MSDS), and all items must be recorded in log books and clearly labelled in a language understood by the chemical handlers.

Keywords: Chemical exposure; Sustainable Risk Management; Textile Industry; Nigeria

INTRODUCTION

The textile industry has been criticized as being one of the world's worst offenders in terms of pollution because it requires a great amount of three components: Chemicals, dyes and water. Many different chemicals are added to textiles in their different life cycle stages. Many of these can be found in the finished articles and part of them end up in waste water or liquid after washing or chemical cleaning of textiles. As many as 2,000 different chemicals are used in the textile industry, from dyes to transfer agents. According to Ojo, (2003) approximately 42% of chemicals manufactured globally are applied in textile industry and Nigeria's textile industry uses about 25% of the world's textile chemicals. Dyeing agents and different auxiliary substances are also used in textile dyeing processes, to improve the attachment of colour into the fibre (KemI, 2009).

Almost all dyes used in textile industry are synthetic organic compounds. According to Talvenmaa (2002), there are more than 8,000 different synthetic dyes and almost 40,000 commercial dye products. The selection of dyes depends on the quality of the fibre and the fabric as well on the desired colour and its properties (Priha and Riipinen, 2005). There are two types of dyes: textile dyes that attach into the fibres, and pigments that are attached into the fabric using a binding agent. Hazardous substances used in dyes include e.g. the heavy metals copper (Cu), nickel (Ni), lead (Pb), mercury (Hg), cadmium (Cd), chromium (Cr), zinc (Zn) and arsenic (As) (Parvath, Makin & Sutherland, 2009). Many of these substances are carcinogenic.

Water is a finite resource that is quickly becoming scarce, and is used at every step of the process both to convey the chemicals used during every step and to wash them out before beginning the next step. The water becomes full of chemical additives and is then expelled as wastewater; which in turn pollutes the environment: by the effluent's heat; by its increased

Akintayo, W. L. (2016). Adoption of Sustainable Risk Management: A Study of Chemical Exposure in Textile Industry in Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. Procs. of the Joint International Conference (JIC) on 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1124-1136

pH; and because it's saturated with dyes, de-foamers, bleaches, detergents, optical brighteners, equalizers and many other chemicals used during the process.

Traditionally produced fabrics also contain residuals of chemicals used during their manufacture—chemicals that evaporate into the air we breathe or are absorbed through our skin. Some of the chemicals are used by traditional dyers in the production of fabrics are equally carcinogenic and may cause harm to children even before birth, while others may trigger allergic reactions in some people. According to James, James & Ashe (1990), the population that is allergic to chemicals will grow to 60 percent by the year 2020. These chemicals can be hazardous to the health of humans and animals, especially when a factory's chimney breathes them out or when people drop the chemicals into lakes, streams, oceans or rivers. Also most of the washing procedures for textiles are harmful to our environment and possess challenges to industries in developing countries like Nigeria.

Exposures in the Nigerian Textile Manufacturing Industry

Textile is a general term which refers to any material made of interlacing of fibers such as fabric, cloth, carpet, and belt among others (Osobu, 2014). Generally, it is a flexible woven material consisting of a network of natural or artificial fibers which are often referred to as thread or yarn. The importance of textiles to human sustenance, and the socio-cultural and economic development of a nation cannot be over emphasized. Apart from food and shelter, textile (clothing) has been identified as the most important in the hierarchy of man's need. In Nigeria, the production of textiles had flourished at both cottage and industrial levels (Akintayo, 2010).

Nigerian Textile manufacturing Industry can be categorized either as traditional or modern/ industrial. According to Okeke (2002) Nigerian traditional textiles can be classified as woven, non-woven, dyed or patterned which are decorated and designed structurally at the surface. These include; "Aso Oke" (Yoruba)' Akwete, (Igbo) "Okene, (Ebira) Ashiasha (Tiv) and Adire (Yoruba) among others. Basically, these textiles are structurally decorated and produced on both vertical and horizontal looms that are exclusively handled by women and men weavers in the society. These fabrics have age long qualities such as high durability, unique textures and traditional designs. The surface decorated ones like Adire are produced by the process of dyeing, printing and direct application of other elements of finishing unto the surface of the locally woven fabric. Industrial textiles refer to textiles produced through the use of automated electronic machines which usually come in a variety of colours, designs, and quality. This became possible due to a number of factors. Traditionally, Nigeria is noted for the production of cotton, silk and other fibers, which are primary materials for the textile industries. Nigeria now relies on imported raw materials and foreign technology to make the industry function.

A typical flow for the transformation of raw cotton into finished fabric in the Nigerian textile manufacturing industry like any other industry according to Faleye (2013) is as follows. Raw cotton bales are opened, and the cotton may be blended with synthetic or other natural fibres at the opening line. The cotton is then delivered to the picking machines, which transfer the fibres to the cards. During these first stages, fibres may be transported by air currents (blowing). Cotton fibres are then processed at the card. From the card, the fibre strands are run on the drawing frame. From the drawing frame, strands of parallel fibres are moved to the roving frame. The product, called 'roving', goes to the spinning frame, and part is spun into warp yarn and part into filling yarn.

Fabrics can be produced in two ways-by weaving and by knitting. Of these two processes, weaving is the older, being thousands of years old (Asaju, 2004). The process of weaving involves the interlacing of two or more sets of yarn at right angles, the warp yarn running the

length of the fabric and the filing yarn being inserted across the fabric. Each cross-wise insertion is called a pick. Knitting is the process of making a usable fabric from threads or yarns by arranging them into interlocking loops (Ogundele,2000, Oloyede,2014). The processing of textile fabrics involves is a combination of three separate operations: (i) preparing, (ii) dyeing and (ii) finishing. The combination is also sometimes referred to as finishing. Most fabrics, except those prepared from wool, are dyed and finished after weaving. The end use of the textile determines whether it is dyed and/or finished.

i. Preparation involves the removal of undesirable materials from fabrics so that they can be dyed or finished in later processes. These processes involves (a) singing, (b) de-sizing, (c) bleaching, (d) scouring and (e) mercerization. In singeing, unwanted surface hairs or filaments are removed with a flame. The aim of de-sizing is the elimination of sizing agents applied earlier to warp yarns. Sizing agents are normally starch. In scouring, the fabric is boiled to remove the remaining sizing agents and impurities accompanying cellulose and other fibres. Mercerization is the short-term treatment of cotton fabrics with a sodium hydroxide solution, which changes the physical and chemical properties of fibres and increases their strength and capacity to absorb dye. Fabric bleaching is intended to eliminate natural substances that impart a grey shade to the fabric. Chlorine-releasing compounds (such as hypochlorites) and hydrogen peroxide are the most commonly used bleaching agents (Adisa, 2013).

ii. Dyeing: The aim of the dyeing process is to impart a certain colour to the fabric through application and fixing of dyes. ln dyeing, the dye molecules penetrate the pores of the swollen fibres and are retained there by chemical or physical forces. Cotton is generally dyed after the yarn has been woven or knitted into fabric, while wool yarn is usually dyed before. In printing, colour is applied to the fabric surface and is bound there by physical and chemical forces. The process is similar to that of dyeing. Sometimes, organic solvents (alcohols, ketones, esters, aliphatic and aromatic hydrocarbons) are used in printing dyes and for the cleaning of printing frames. Several printing techniques, i.e., direct, discharge and resist printing, are used. Printing is done by roller, flat and rotary machines.

Textile manufactures inc1udes spinning, weaving, knitting, dyeing and finishing of all types of natural and synthetic fibres. Machines vary from primitive looms used in cottage industries to sophisticated machines in modern factories (Faleye,2013). Textile workers are exposed to textile dusts (both natural and synthetic) throughout the textile manufacturing process. During spinning, weaving and knitting operations, the use of chemicals is limited. The most important chemicals used in these processes are sizing agents (e.g., starch) and yarn lubricants (spinning oil and polymers). Workers in the cotton industry have been exposed to mineral lubricants used in the spindles during the operation called 'mule spinning' (twitting of yarn). A wide variety of occupational health hazards are present in the textile manufacturing industry. The most ubiquitous exposure in textile mills is to organic dust, in particular to cotton dust. Chemical exposure in spinning and weaving is limited mainly to sizing agents and spinning oils. Raw cotton may be contaminated with bacteria, desiccants and defoliants; raw wool may be contaminated by pesticides from sheep dips. There are no data, however, to indicate the levels of desiccants, defoliants or pesticides in textile mills Makinde (2005). During fabric preparation, workers can be exposed to a variety of bleaching, scouring, singeing and mercerizing agents. In dyeing, printing and finishing, chemicals are widely used and exposures may be highly complex.

In weaving, dyeing and printing, workers are frequently exposed to dusts, dyes, a variety of acids such as formic, sulfuric and acetic acids, fluorescent brighteners, organic solvents and

fixatives. Workers in the finishing operations are frequently exposed to crease-resistant agents, many of which release formaldehyde, and to flame retardants, such as organic phosphorus compounds, chlorinated hydrocarbons and carbonates. These exposures may occur simultaneously with physical hazards, inc1uding noise, vibration and heat. These developments, as noted by Okeke (2002) might not be unconnected with the synthetic dyes and chemicals materials which the workers' were exposures separated from Nigeria's getting in contact with during the production processes.

Hazards and Health risks in the textiles Industry

The textiles industry has many hazards that can cause injury to workers, from transport in the workplace (lift truck), dangerous large work equipment and plant, to the risk of slips from a wet working environment. Workers being struck by objects, such as moving machinery parts and vehicles are a significant cause of injury in the sector. There also exists other health related risks as highlighted below by Heinrich, Petersen & Roos, (2000).

Musculoskeletal disorders

Musculoskeletal disorders (MSDs) are the most common work-related health problem in textile industry, with almost one in four workers reporting backache and one in five complaining of muscular pains. In the textiles industry, risk factors for Musculoskeletal disorders include: Working in awkward postures, such as during spinning, cutting, product control, and packaging; Repetitive movements, such as during spinning, cutting, product control, and packaging; Fatigue from manual handling, during the storage, inspection, treatment, shipping, finishing, and cutting of textiles.

Exposure to chemical agents

Many different groups of chemical substances are used in the textiles industry, including dyes, solvents, optical brighteners, crease-resistance agents, flame retardants, heavy metals, pesticides, and antimicrobic agents. They are used in dyeing, printing, finishing, bleaching, washing, spinning, dry cleaning, and weaving. The textile industry has been evaluated as a sector with an increased carcinogenic risk. Several studies have showed an increased risk of nasal, laryngeal and bladder cancer.

Exposure to dusts and fibres

The exposure of workers to dusts from material such as silk, cotton, wool, flax, hemp, sisal, and jute can occur during weaving, spinning, cutting, ginning, and packaging. Division of tasks along gender lines may mean that women are exposed to organic dusts more than men, with respiratory diseases being diagnosed more often in women than men. Exposure to fibres and yarns may cause nasal or bladder cancer.

Exposure to biological agents

In some activities, such as carding and willowing, workers may be exposed to biological agents such as *anthrax*, *clostridium tetani* (the causative agent for tetanus), and *coxiella burnetti* (which causes Q fever). Exposure to biological agents can result in allergies and respiratory disorders.

Exposure to physical agents

Workers may also be exposed to noise and vibrations, for example during weaving, spinning, sewing, twisting, and cutting. Exposure to loud noise can result in permanent hearing damage such as noise-induced hearing loss and tinnitus. Exposure to vibration, particularly together with risk factors for MSDs, can lead to long-term harm. Electromagnetic fields may also be found in some workplaces in the textiles industry.

In all, Chemical exposure is the most problematic risk challenges to textile workers and the environment. The National Programme on Dangerous Chemicals from 2006 identified

chemicals in textile articles as an issue where improved risk management is needed (Ministry of the Environment, 2006, p. 74-79). Also preliminary report on a study on "Control of chemicals in textile articles by (Häkkinen, 2010) identify the deficiencies of management measures on textile articles.

In most textile production processes variety of chemicals including hazardous ones are used liberally, due to both lacking regulation and management and to particular needs such as preservation during transport and for other such as market economic reasons thus, chemicals in textiles present a special challenge for risk management. The identification, assessment, management and surveillance of chemicals imported into textile articles pose therefore a major issue to be addressed.

LITERATURE REVIEW

The safety management principles of the ISO standards and of the standard textbooks on safety management seem to suggest that science and industry have reasonable models of how safe and reliable organizations should work. However, this is not the case. As Reber, Willin & Duhon (2003) point out, the organizational literature fails to deal specifically with either hazardous organizations or high levels of performance reliability. The standard texts on safety management, for example Heinrich, Petersen and Roos (2010), and Bird and Germain (2007) present neither specific models of the safety management system nor do they provide empirical evidence of how particular aspects of the suggested frameworks contribute to the overall level of HSE.

Hale and Baram (2009) conducted a thorough literature review on health, safety and environment (HSE) management and revealed a number of lines of research and isolated studies which seem to have few links with each other. They concluded that literature on SMS can be characterized, at least until the 1980s, as accumulated experience of common sense and as general management principles applied to the specific field of safety risk management. One of the earliest studies was that of Cohen (1997). He reviewed seven studies that dealt with critical determinants in different industrial settings. Some of the factors associated with high safety performance were: strong management commitment to safety; close contact and interaction between workers, supervisors, and management enabling open communications on safety as on other job matters; workforce subject to less turnover, including a large core of married, older workers with significant length of service in their jobs; high level of housekeeping, orderly workplace conditions, and effective environmental quality control; well developed selection, job placement, and advancement procedures and other employee support services; training practices emphasizing early indoctrination and follow-up instruction in job safety procedures; evidence of added features or variations in conventional safety practices serving to enhance their effectiveness.

Shafai-Sahrai (2001) examined 11 matched pairs of companies conducting on-site interviews and site inspections at each. Factors prevalent in low injury rate companies were senior management involvement in safety; prioritization of safety in meetings, and in decisions concerning work practice; better injury record keeping systems; use of accident cost analysis; reduced span of supervisor responsibility; spacious and clean workplace environment; and improved safety devices on machinery. Additionally, Cohen and Cleveland (2003) reported findings from a linked series of studies examining health and safety management in organizations with good safety performance across different industries. Methods included a questionnaire survey of 42 matched pairs of plants with low and high accident rates, with seven pairs of these subject to detailed site surveys. Those 7 with lower accident rates were characterized by a strong management commitment to safety; a humanistic approach to dealing with employees, with frequent positive contact and interaction; encouragement of

hazard identification by workers; better housekeeping and general plant cleanliness; presence of both informal and formal workplace inspections; greater availability and use of personal protection equipment; improved employee selection procedures; low turnover and absenteeism; and better plant environment.

Referring to these studies, Chew (2005) compared safety activities in 18 pairs of low and high injury rate companies, drawn from three Asian countries. Prevalent factors were supervisory involvement in safety activities; safety inspection; safety training; use of accident record analysis for prevention purposes; carefully applied safety rules; machine guarding; supply of personal protection equipment; and standard of housekeeping. Shannon, Walters, Lewchuk, et al. (2006) conducted a postal survey of over 400 manufacturing companies, each having at least 50 employees. The defining features of organizations with lower rates of lost time injuries included managers who perceived more participation in decision-making by the workforce and more harmonious management-worker relations; encouragement of long-term career commitment; provision of shortand long-term disability plans; definition of health and safety responsibilities in every manager's job description; performance appraisals with topics related to health and safety; and more frequent attendance of senior managers at health and safety meetings.

A Study conducted by (Priha & Riipinen, 2005) also showed that workers in the textile industry are also exposed to a number of chemicals, especially those engaged in the activities of dyeing, printing and finishing. Chemicals based on benzidine, optical brighteners, solvents and fixatives, crease-resistance agents releasing formaldehyde, flame retardants that include organophosphorus and organobromine compounds and antimicrobial agents are used in textile operations.

Mangal, (2010) examined the links between exposure to formaldehyde and nasal and lung cancer as well as to brain cancer and leukemia, which can be fatal. This study revealed that in the long run, exposure to formaldehyde could lead to respiratory difficulty and eczema. Contact of the chemicals with skin as well as inhalation of the chemicals can lead to several serious health effects.

Study conducted in by Hale & Hovden, (2008) revealed a correlation between the presence of cancer of the buccal cavity and pharynx and occupation in the textile industry. Another study revealed that textile workers were at high risk for developing cancer of the stomach while another study indicated a low degree of correlation between oesophageal cancer and working in the textile industry. Moreover, a high degree of colorectal cancer, thyroid cancer, testicular cancer and nasal cancer was observed among textile workers. Also, a relationship between the presence of non-Hodgkin's lymphoma and working in the textile industry was observed.

A study conducted on 1300 people working in 'tie and dye' units in Jodhpur and neighboring areas by Kant, 2012), 100 workers were observed to have occupation-related dermatitis. This constituted 7.69% of the total sample. Red RC base and naphthol were observed to be the most common culprits in this regard.

Shannon, Mayr and Haines (2007) reviewed 10 studies each including at least 20 separate workplaces or organizational units and using injury rates as an outcome variable. Forty-eight variables representing areas of management practices were examined. The study only listed the practices consistently associated with performance, i.e. the association was significant on one direction in at least two thirds of studies in which it appeared, and the direction of relationship was consistent for all studies.

Finally, an extensive review on the literature dealing with internal management system of

organizations was provided by Hale and Hovden (2008). Literature on risk management at the national or industry level dealing with regulation, standard setting, risk policies, enforcement, and the management of individual workplaces and work groups was excluded. These concern notably participative management studies and studies of high reliability organizations, which concern themselves with on-line management of risk, as opposed to the off-line concern with management structure found in much of the literature.

Risk and Risk Management

Every organization and association has its own risk management tools and techniques and it depending on the nature and size of business, and the level of risk is also depends on the size and operation of business. For example, textile companies with a complex chain of processes and whose business operation is across the world has more probabilities of risk occurrence and hence requires proper risk management policies and techniques for minimizing the risk.

Risk

Risk can be defined as the probability of harmful consequences (ISDR, 2002), or expected losses (lives lost, persons injured, damage to property and/or the environment, livelihoods lost, disruption of economic activity or social systems) due to the interaction between humans, hazards and vulnerable conditions. According to Hakkinen, (2010) the term risk can be defined as," the chance of something happening that will have an impact on objectives. A risk is often specified in terms of an event or circumstances and the consequences that may flow from it. Risk is measured in term of combination of the consequences of an event and their likelihood." Risk is usually associated with the inability of men to manage hazard events that may eventually lead to negative consequences like destruction of the environment, socio-economic activities, properties and losses of lives (Sadgrove, (2005).

In other words, Risk can be seen as the possibility that a particular hazard might exploit a particular vulnerability (Nierkerk, 2002). It is the production of the possible damage caused by a hazard due to the vulnerability within a community. In other words, risk is usually due to hazard events exploiting the vulnerable situation of an environment or community. A risk is a random event that may possibly occur and if it did occur, would have a negative impact on the organization goals (David, 2008). Risk is based on three factors: hazards, exposure and vulnerability.

Hazard

Hazard can be defined as a potentially damaging physical event, phenomenon or human activity which may cause the loss or life or injury, property damage, social and economic disruption or environmental degradation. Hazards can include hidden conditions that may represent future threats and can have different origins. These include natural (geological, hydro-meteorological and biological) and/or induced by human processes (environmental degradation and technological hazards) (ISDR 2004). According to Niekerk (2002), hazards can be single, sequential or combined in their origin and effects. Each hazard is characterized by its location, intensity and probability. Typical examples of hazards can be the absence of rain (leading to drought) or the abundance thereof (leading to flooding). Chemical manufacturing plants near settlements can also be seen as hazards. Similarly, chemicals, dyes and textile waters from factory chimney or when people drop the chemicals into lakes, streams, oceans or rivers. Hazards can either be a creation of humans or the environment. Although the former can be planned for than the latter, in both cases, the management of hazard will remain the same.

Exposures and vulnerabilities

Exposure

Exposure refers to the elements that are subject to the impact of a specific hazard (Aven, 2008). Tangible, intangible and institutional are the basic elements of exposure. Tangible elements include people, building and infrastructure related to power and water supply. Intangible elements include heritage and community relationship. Capacity to share information and the effectiveness of emergency management plans and coordination arrangements are the institutional elements. (Keml, 2009). Exposure shapes the risks from chemicals in textiles: the dose makes the poison. Exposure scenarios generally depend on the chemical and its occurrence in textiles or other materials after release, its bioavailability in the environmental matrices as well as on the vulnerability (proximity and behaviour) of the organisms exposed.

These scenarios need to be specified to assess risks more realistically. However, for many chemicals in textiles, assessment is based crudely on limited concentration. Exposure of workers and consumers to chemicals in textiles naturally takes place through skin and nose. These routes can be important for contact allergens and skin-permeable substances.

Vulnerability

According to Shafai (2001) the term vulnerability has been defined in the following words. "Vulnerability is the human dimension of disasters. To understand what makes people vulnerable, we have to move away from the hazard itself to look at a much wider, and a much more diverse, set of influences: the whole range of economic social, cultural, institutional, political and even psychological factors that shape people's lives and create the environment that they live in." All these variables, that is risk, hazard, exposure and vulnerability resulted in what is called disaster.

Disasters

Disaster is a serious disruption of the functioning of a society, causing or threatens to cause, widespread human, material, or environmental losses which exceed the ability of affected community to cope using only its own resources (Parvath, et. al, 2009). Disasters can be sudden (flash floods) or progressive (drought). Disasters are caused due to the interaction of humans with their environment. A disaster is a function of the risk process. It results from the combination of hazards, conditions of vulnerability and insufficient capacity or measures to reduce the potential negative consequences of risk (ISDR, 2002). Extreme natural phenomena do not in themselves constitute hazards. It is only when such phenomena occur in an environment where they pose a threat to human life, property, infrastructure or the environment that they can be classified as hazards. Similarly in the case of technological developments, it is only when such developments pose a danger e.g. industrial accidents, infrastructure failures. In essence, a disaster is the result of a hazard's impact on society. So the effects of a disaster are determined by the extent of a community's vulnerability to the hazard.

Hazards in themselves do not constitute disasters. The magnitude of disaster, according to Niekerk (ibid) is usually described in terms of the adverse effects which a disaster has had on lives, property and infrastructure; environmental damage; and the costs attached to post disaster recovery and rehabilitation. Simply out, therefore, disaster risk is the product of the combination of three elements – vulnerability, coping capacity and hazard (ISDR, 2004).

Risk Management

Risk management is any set of actions taken by individual corporations in an effort to alter the risk arising from their business Massey, Hutchins, Becker and Tickner (2008). Also Risk management is the identification, assessment, and prioritization of risks (defined in ISO

31000 (2009) as the effect of uncertainty on objectives, whether positive or negative) followed by coordinated and economical application of resources to minimize, monitor, and control the probability and/or impact of unfortunate events or to maximize the realization of opportunities; while risk assessment is the qualitative and quantitative evaluation of the risk posed to human health or the environment by the actual or potential presence or use of specific materials, conditions, or procedures. The end result of risk assessment is therefore termed risk management (David & Webster, 2007). Management as a function comprises all processes and functions resulting from the division of labor in an organization such as planning, organizing, leading and controlling (Crockford, 1996). In most organizations more or less formalized management systems serve to structure, develop, and direct business processes. Risk management within the organizations and government bodies is becoming very important in these days. All level of organization is involved in the management of risk. (Dorfman, 2007). No business is risk free as at any time, something wrong happen that leads to a heavy lose. While doing business, there is no point for avoiding risks completely.

The essence of risk management is to prepare, protect, and preserve the resources of the enterprise. This approach demands analyzing the current and past operating hazard, risk, and loss producing patterns and forecasting expected hazard, risk, and loss-operating patterns. According to Bamber (2003), risk control strategies may be classified into four main areas: risk avoidance, risk retention, risk transfer and risk reduction. Risk avoidance means the deliberate decision on the part of the organization to avoid a particular risk. Risk retention relates to the decision of the organization to meet any resulting loss from within the organization's financial resources. Risk transfer refers to the legal assignment of the costs of potential losses from one party to another. The most common approach is by insurance. The principles of risk reduction or risk control rely on the implementation of a Health, Safety and Environment (HSE) program, whose basic aim is to protect the company's assets from wastage caused by accidental loss.

The system elements to be managed in risk management include amongst others:

i. health and safety of employees, suppliers, contractors, customers, and residents of the community (e.g. improvement of public health and safety)
ii. reliability and safety of products and services, of materials, equipment, work systems and plants, of transport of hazardous goods
iii. integrated pollution control, radiation protection, waste minimization, recycling, and waste disposal
iv. sustainable management of natural resources (soil, water, natural areas and coastal zones), reduction in the consumption of non-renewable energy.

Sustainable development means the improvement in the quality of life which does not impair the ability of the ecosystem to maintain life. Managing for sustainability is predominantly based on the principles of inter-generational and intra-general equity as well as social and ecological balance (Covello & Allen, 1988).

Adoption of Sustainable Risk Assessment and Management in Textile industry

Risk management process helps in risk management plan, and steps involved in this process that has been set out by health, safety and environment risk management standard (1997) & Kant, (2012) **can** be highlight generally.

Step 1: Identifying hazard risks and those at risk

The first step is identifying risks and description by determining the possible causes. Many techniques can use for identification. Examples are records, experience, brainstorming, system analysis and scenario analysis. Risk identification is a step where organization

exposure to uncertainty can be identified. For this purpose, in -depth knowledge of organization is essential. Marker in which it is operating, legal, political, social and cultural environment in which it exits needs interrelated knowledge. Risk identification is an approach that ensures all significant activities within organizations and all possible risk flown from these activities defined. Looking for those things at work that have the potential to cause harm, and identifying workers who may be exposed to the hazards. Using workers' knowledge helps to ensure hazards are spotted and workable solutions implemented. Consultation encourages workers to commit themselves to health and safety procedures and improvements.

A risk assessment should cover all workers regardless of whether they are employed on long- or short-term contracts. Where there are persons employed by another organisation on site, there is a duty on the two employers to cooperate and safeguard the health and safety of workers. Risk assessment should take account of differences in workers, such as by gender, age, or disability. For example, older employees may learn differently than a younger worker, and also have different concepts of risk due to a lack of experience. Different prevention measures may be required for these worker groups. Work, its organisation and the equipment used should be adapted to the worker.

Step 2: Evaluating and prioritising risks

Having spotted the hazards, you then have to decide what to do about them. The law requires you to do everything 'reasonably practicable' to protect people from harm. You can work this out for yourself, but the easiest way is to compare what you are doing with good practice.

Evaluate how likely it is that the hazard will lead to harm or injury, and how severe that injury is likely to be. Consider what control measures are in place and whether they are sufficient. It is essential that the work to be done to eliminate or prevent risks is prioritised. The focus for cost-effective and sustainable risk management should be on collective protection and preventative measures.

Step 3: Deciding on preventive action

Strategies are made directing towards risks that are evaluated in the previous step and actions for, avoiding the risk by stopping the activity that generate risks, Reducing the consequences of the occurrence and transferring the risk. Selected treatment strategy are used for specify risk. Identifying the appropriate measures to eliminate or control the risks. List the preventive measures needed in order of priority, then take action, involving the workers and their representatives in the process. Targeting the underlying problems is the most cost-effective method of risk management.

In other words, it is the process in which selected and implemented measures modify the risk. Every organization and association has its own risk treatment system. International Risk Standard (IRS) 2002 explains that any risk treatment system should provide as minimum effective and efficient operation, effective internal control and compliance with legal rules and regulations of organization.

Step 4: Taking action

Risk assessment is the first step to successful risk management. Put in place the preventive and protective measures through a prioritisation plan (most probably all the problems cannot be resolved immediately) and specify who does what and when, when a task is to be completed, and the means allocated to implement the measures. Interventions should be agreed with the workforce, either directly or through worker safety representatives. The agreed solutions should be carefully implemented, monitored and evaluated. The information arising from the risk assessment must be shared with the appropriate persons. Action should be supported by appropriate training.

Step 5: Monitoring and reviewing

Monitoring is an important step in the risk management process. It contains about monitoring all steps involved in the process and any new risk and changing the current assessment strategies. For monitoring risk, a registered database is main tools for this purpose. Ranking of risks, persons responsible for specific risk are recorded in this database. Time to time updating of register data base would be an integral part of the ongoing project management process. It has to be revised whenever significant changes occur in the organisation or as a result of the findings of an accident or "near miss" investigation.

CONCLUSION

Assessing and managing the risks of hazardous chemicals should play an important role in any textile industry. It is essential that the workers be aware of the various occupational hazards in the industry. At the same time, it is necessary that the management take the necessary steps to protect workers from potential hazardous situations. Safety management in the textile workplace should be more than just a "paper system" of policies and procedures. A Safety Management System (SMS) should start and end with an analysis of what is contained in the paperwork and emphasize how the system should be transferred into practice. Such an analysis should identifies what an organization should be doing to protect its workers, the public and the environment from harm and also reveal what is actually happening at the worksite and whether or not people and the environment are being protected and adverse events are not occurring.

The following suggestions can be made to improve and manage the risks of hazardous chemicals to workers' health conditions the in textile industry:

i. The management should regularly check and document the national laws and regulations concerning workplace safety and develop a protocol through which to implement these laws.
ii. An inventory and risk assessment of all chemicals and dyes that are present at the factory must be undertaken by the management and the information in the inventory and risk assessment must be made available to all workers.
iii. Dyes, chemicals and other auxiliaries should be stored in a separate work area and access to this area should be limited to trained personnel. The storage area should be kept relatively cool and dry (within the range specified in MSDS), and all items must be recorded in log books and clearly labelled in a language understood by the chemical handlers
iv. To minimize exposure to hazardous chemicals appropriate personal protective gear should be used. This may include gloves, safety glasses and masks depending on the chemicals being handled
v. Employees that work in the laboratory must be made aware of the risks of the chemicals and equipment they are using. They should be properly trained in the use of machinery, laboratory equipment, and the use of dyes and chemicals, as well as the importance of keeping logs of chemicals used
vi. Sufficient fire extinguishers should be made available and signs should be placed in prominent places so that people are aware of their presence; and there should also be signs saying "No Food and Drink" in areas such as the laboratory, store room and factory floor, and any other areas where it is not safe to consume food, for example because of the risk of contamination by chemicals.
vii. The working environment should be kept as dry as possible to prevent accidents. Signs informing people of damp and wet floors must be displayed when required. Dust should also be minimized or extracted to reduce inhalation of particles

viii. Proper training on the use and maintenance of machinery and other equipment; Health and Safety; and Fire Hazards and Emergency, needs to be provided. Training should be repeated regularly - at least once a year.

ix. Medical examinations should be conducted by the employers for the workers from time to time. If significant occupational health problems are observed, appropriate measures should be taken by the management.

Education and Professional Ethics

Facilities Maintenance-Towards Enhancing Learning and Teaching Environments: Case Studies of Higher Education Institutions (HEIs) in Nigeria

Mohammed Olowoake

Moshood Abiola Polytechnic, Abeokuta, Nigeria
olowoake.mohamed.mapoly.edu.ng@gmail.com

ABSTRACT

The purpose of this paper is to identify factors preventing effective maintenance of the Higher Education Institutions built environments in Nigeria. The study focuses on sustaining HEIs built environments in Nigeria, as this will enhance the performance levels of students and the faculty staff, thereby encouraging increased productivity. The study is based on the collection and application of both soft and hard data, (that is, semi-structured interviews, and questionnaire survey), and were analysed by using thematic contents analysis and correlation analysis respectively. The objectives of the study include: identification of factors militating against effective facilities maintenance management of HEIs buildings in Nigeria; to provide effective budgeting system and strategies; and develop an effective framework. The findings revealed that, the following sustainable variables, such as: adequate and regular supply of electricity; water, waste collection and disposal; drainage system; use of appropriate procurement strategies; maintenance method; maintenance budget; and post occupancy evaluations are not adequately provided due to poor or lack of budget. It is therefore recommended that, HEIs in Nigeria could provide those variables mentioned above via appropriate budgeting; use of effective strategies; and the developed framework.

Keywords: budget, environment, maintenance, strategy, sustainable

INTRODUCTION

The British Standard (BSI, 1993) defines building maintenance "as a combination of any actions required to retain an item or restore to, an acceptable condition". David (1999) explains that frequencies of maintenance works on a building or asset depends on many factors, such as quality of materials used, quality of workmanship, frequency of use, nature of use, the age of the asset, ecological factors, nature of activities within and around the asset. Alan (1998) defines defects as ugly spots on both old and new buildings, and such spots reduce the commercial values of the assets as well as their service years. Chika (2008) asserts that, no single maintenance method and strategy can effectively provide needed remedies to both natural and artificial defects on buildings.

Figure 1

In Nigeria, ownership of Higher Education Institutions (HEIs) can be categorised as being Federal government owned, state owned, and those in private ownership. However, meaningful skills and knowledge need to be imparted to learners in a very conducive environment .In addition the workplace for academic and other faculty staff must also be

Olowoake, M. (2016). Facilities Maintenance-Towards Enhancing Learning and Teaching Environments: Case Studies of Higher Education Institutions (HEIs) in Nigeria. In Ebohon, O. J., Ayeni, D. A, Egbu, C. O, and Omole, F. K. *Procs. of the Joint International Conference (JIC) on* 21st Century Human Habitat: Issues, Sustainability and Development, 21-24 March 2016, Akure, Nigeria, page number 1138-1144

conducive. The restoration of a building into an appropriate and acceptable standard in an appropriate timescale, taking into account an approved budget are necessary steps in maintaining a sustainable built environment.

Background of the Research

The restoration of a building into an appropriate and acceptable standard in an appropriate timescale, taking into account approved budgets is necessary steps in maintaining a sustainable built environment. A well maintained Higher Education Institutions (HEIs) building connotes a better and effective teaching and learning environment for students and other faculty staff. A healthy building will impact on staff and learners' performance, and improve their productivity levels. If the asset is not maintained on time, dilapidation will follow which in turn could lead to collapse. A cursory look at some of the HEIs buildings being studied suggests that, they are not well maintained in the last five years as revealed by the current interviews conducted for the Directors of the twelve HEIs being considered in this study.

Justification of the Study

A healthy building will impact on staff and learner performance, and improve their productivity levels. A cursory look at some Higher Education Institutions buildings in Nigeria, especially those built more than five years ago, suggests that they are not well maintained. It is suspected that some Higher Education Institutions (HEIs) have not considered budgeting for maintenance at all. The study sampled government owned HEIs (Federal and states).

Scope of the Research

The scope of the study will cover the general maintenance management of all elements of a building (from foundation to roof, including finishes) and services (mechanical, electrical and plumbing systems) that provide comfort to the users. Also, consideration will be given to project production information documents (drawings, bills of quantities, specifications, schedules and contract agreement), and project production management documents (construction programme, construction methodology, early warning system chart, information requirement schedule and others).The study used all the twelve Higher Education Institutions in south western Nigeria as case studies which three each of the Federal and State Universities and three each of the Federal and State Polytechnics.

FACILITIES MAINTENANCE MANAGEMENT

Xianhai (2014) defines facilities management as the integration and alignment of the non-core services required to operate and maintain a business to fully support the core objectives of an organisation. Joe, et al., (2010) assert that asset maintenance management focuses on life cycle management of the physical assets of an organisation for the purpose of making products or for providing services in a manner that satisfies various business performance rationale. Nichola (2010) asserts that, physical asset maintenance management is the management of fixed or non-current assets, such as equipment and plant.ISO 55-2 (2004) asserts that the following tools are associated with successful asset management, such as: value engineering, life cycle costing, reliability centred maintenance, and risk based inspection. These guidelines classify assets management into five types as explained in page one above. In addition, these guidelines are comprehensive and generic for the use of all organisations, and allow each organisation to adopt and use any procurement strategy, and maintenance method that suit its policy and objectives. However, these guidelines could not specify the appropriate technique that could be used in gathering data for preparing maintenance budget. In contrary, each HEI could use outsourcing for large and complex projects and in-house technical staff for simple and small projects. David (1998) defines

facilities management as the practice of co-ordinating the physical workplace with the people and works of the organisation, integrates the principles of business administration, architecture, and the behavioural and engineering sciences. This author explains further that, facilities management integrates the people of an organisation with its purpose (work) and place (facilities).

RESEARCH METHODOLOGY

For the purpose of the study, the researcher used mixed methodology for data collections, and used the multiple regressions for data analysis. For the first phase of data collection, the researcher conducted semi-structured interviews for the twelve directors of the selected HEIs in Nigeria. The researcher used questionnaire survey for the second phase of data collection in order to collect information from 144 facilities users of the selected HEIs in Nigeria to describe, compare or explain their knowledge, feelings, values and behaviours.

FACTORS MILITATING AGAINST EFFECTIVE FACILITIES MAINTENANCE MANAGEMENT OF HEIS BUILDINGS

Procurement Strategies

Majority of the HEIs in Nigeria do not have full complements of technical staffs, almost all of their facilities maintenance projects (small and simple, and large and complex) are outsourced. Those HEIs with a few numbers of technical staffs still combine the use of in-house technical staff with outsourcing. Some of the HEIs in Nigeria with a few numbers of technical staffs on their pay roll; still prefer outsourcing of their projects (both small and simple, and large and complex) for lack of skilful manpower.

Maintenance Methods

On maintenance method, majority of the HEIs in Nigeria adopt and use curative maintenance method (run to a halt) for shortage of maintenance funds or suffer long delays before maintenance cash is released. Some combine the use of curative and routine maintenance methods together. Some of the Directors of the HEIs work and services departments interviewed agreed that, Planned Preventive Maintenance Method is the appropriate method, but complained of poor funding and low technical skills on the part of the technical staff. However, the use of Planned Preventive Maintenance Method backed up with the use of Maintenance Control Toolkit could be the best alternative.

Maintenance Budget

Some of the HEIs do not run maintenance budget, they prefer the use of central budgeting system. Maintenance projects are carried out whenever there is the need to rescue situations that are going out of control (curative method). Furthermore, those HEIs that are running maintenance budgets, majority of them prefer to add certain percentages to the previous year maintenance budgets for the coming year.

Post Occupancy Evaluations

Majority of the HEIs sampled do not carry out Post Occupancy Evaluations of their built environments. They over rely on letters of complaints from the facilities users.

Projects Quality Control

Majority of the HEIs are aware of the existence of some regulatory requirements on environmental protection and maintenance management of their built environments, but do not comply. However, works and services departments of HEIs in Nigeria only control project qualities by enforcing contractors to comply with all projects specifications and schedules. For personal gains, contractors influence project quality by using inferior project materials, components, and labour.

Sustainable Programmes

Majority of the HEIs in Nigeria do not prepare and use sustainable programme for their built environments at the face of incessant power outages, lack of or poor supply of drinkable and sanitary water. Other factors include: poor or lack of adequate drainage systems, recreational facilities for staffs and students. In addition, majority of the HEIs students' lecture rooms and staff offices need repairs or replacements of some building elements now in dilapidated conditions.

Cultural Influences

Majority of the technical staffs cannot interpret projects drawings, specifications, and schedules. Others include: the attitudes of some them to work connote dereliction to duties. Technical staffs' absenteeism and lateness to work are common, while official corruption among technical staffs is on the high side.

Use of Maintenance control toolkits

Maintenance Schedule

Olowoake (2006) asserts that maintenance schedule is a comprehensive list of works to be done to each item and at what intervals it must be done. Bamisile (2004) explains that, it is detailed information about works to be done at specific periods.

Maintenance Planning

Maintenance planning helps in establishing in advance the works to be done, the methods, tools, calibre of labour required and the timing necessary (Chika, 2008; and Olowoake, 2006).

Maintenance Programme

Maintenance programme is a design to establish when each element shall receive the specified attention throughout the planning period, preferably by the planning department in collaboration with the maintenance department (Bamisile, 2004; and Olowoake, 2006).

Maintenance Records

Maintenance records are records of all maintenance works carried out. It is explained further that, these records are needed when budgeting in maintenance, preparation of maintenance schedules, design, costs of labour and materials (Chika, 2008; David, 1999; and Olowoake, 2006).

Maintenance Profile

Maintenance profile is a short description or biography of the types of maintenance works carried out on a particular plant or building elements in the past, and the periods of such maintenance (Taiwo, 2010; Olowoake, 2006; and Oyewande, 1992).

The Facility Register

The facility register is used to establish what needs to be maintained, and also determines the type and the amount of the equipment to which it relates It is explained further that, a card is created for each element making up a building in order to identifying which of the elements it refers, given such constructional and technical details and other information, such as drawings and manufacturer's handbooks (Iwarere and Lawal, 2011; and Olowoake, 2006).

The History Records

The history records are provided on the history of each building for the purpose of recording and analysing results achieved on facility register, maintenance schedule, job specification and the programme in order to improve on these procedures. It is explained further that, there should be summarised details of adjustments made, failures and the action taken to rectify them, it is the memory of any planned maintenance scheme (Akinpelu, 2002; David, 1999; and Olowoake, 2006).

Job Specification

According to (Bamisile, 2004; and Olowoake, 2006) master job specifications are used in detailing the various periodical operations required by individual element each operation on each element is detailed.

Codes of Practice

Codes of practice are issued by the British Standard Institution, and they cover workmanship requirements and methods of carrying out various classes of works It is explained further that, they are valuable when used in drafting specifications for building maintenance and alteration works Each professional body has codes for their members (Bamisile, 2004; and Olowoake, 2006)

Preparation and use of Facilities Maintenance Budgets

i. *Previous year budget plus a percentage*: Many HEIs works and services departments use the previous year maintenance budgets to prepare the current year budget with only a percentage increase, and the current prices of building components and materials.
ii. *Some based the budget preparations on "Forecasts".* However, the best approach is to conduct reconnaissance surveys of the built environment (to identifying the existing defects, and possible future defects), and use letters of complaints from the users

Analysis on Budget Preparations

However, the preparation, and the use of maintenance budget helps in saving project costs by avoiding project over-run. The defects identified are measured and priced in order to give accurate budget figure. In addition, for prompt approval and release of maintenance cash, the following maintenance control toolkit could be attached, such as, maintenance programme, maintenance schedule, jobs satisfaction, and facility register. The use of Bills of Quantities are also very essential—to allow for competitive tendering.

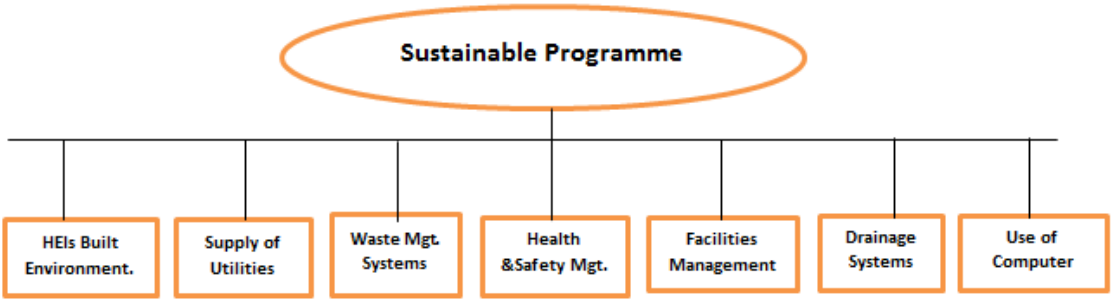

Figure 2 Sustainability Diagram for the Built Environment

Analysis of Built Environments Sustainability

Sustainability of HEIs built environment could be treated in three integrated principal ways, such as: environmental; economic; and social. Most HEIs in Nigeria are characterised with irregularities, such as: epileptic supply of electricity; poor drinkable water supply; poor waste collection, treatment, and disposal system; poor drainage system; poor maintenance budgeting system, and poor maintenance method. In spite of the erratic supply of electricity, majority of them use direct current (use of generating plants), only that poor budgeting system and the delay in releasing maintenance cash hinder the efforts. In addition, only a few of the HEIs in Nigeria are residential, and those that do, can only accommodate a few students due to limited numbers of bed spaces. Due to increasing numbers of candidates seeking admissions, and students' population explosion, more academic programmes were introduced. As a result, a few students admitted to existing programmes increased astronomically, with little or no improvement on the existing teaching and learning facilities.

CONCLUSIONS AND RECOMMENDATIONS

Conclusions

The study objectives, especially the identification of factors militating against effective maintenance of HEIs built environments, budgets, and effective strategies were achieved by reviewing relevant literature, and by conducting semi-structured interviews for 12 Directors of the selected HEIs in Nigeria. In addition, the framework was developed from the strategies derived as mentioned above.

Maintenance Budget
