# Assessing the Impact of University Library Services on Academic Performance of Students: Exploratory Factor Analysis of a Survey Instrument

Yisa Yakubu<sup>1</sup> and Usman Abubakar<sup>2</sup>

Department of Statistics, Federal University of Technology, Minna, Niger State, Nigeria.

## Abstract

University library provides the needed required materials, data, information, and literature for research, which is crucial to human knowledge and scientific advancement. These libraries are set up to enhance academic output of students. Several factors contribute to determine Students Academic Achievement in the university, however, the extent to which students use library facilities has not been fully considered to be one of such factors. Thus, this study performed an exploratory factor analysis of a survey instrument assessing the impact of library services on academic performance of students in Federal University of Technology, Minna, Nigeria, as part of a project to address this concern. The survey instrument was developed on the basis of a qualitative study and distributed to 450 randomly selected students, using simple random sampling technique. The instrument included a five-category Likert-type scale with 44 items. Responses to 28 of the survey's Likert scale items were examined, including inter-item correlations and internal consistency (Cronbach's alpha). Exploratory factor analysis was performed to identify domains of students' satisfaction with the services available in the library. It was observed that none of the items were redundant and the scale had appropriate levels of internal consistency (Cronbach's alpha = 0.81). The exploratory factor analysis identified six factors. Factor one, labelled 'environmental conduciveness', explained 10.0% of the variance. Factor two accounted for 8.83% of the variance and was labelled 'staff courtesy'. Factor three, labelled 'visiting purpose', explained 8.56% of the variance. Factor four accounted for 7.93% of the variance and was labelled 'availability of library facilities' while factor five, labelled 'accessibility of library facilities' explained 7.25% and factor six accounted for 4.94% and was labelled 'service-improvement program'. The instrument demonstrated acceptable library qualities and appears effective in obtaining valid data, which should assist in assessing the library's performance.

**Keywords:** Library services, Academic performance, Survey instrument, Exploratory Factor Analysis

## 1.0 Introduction

Libraries are collections of books, manuscripts, journals and other sources of recorded information [1]. A library is a place where any member of the community can come to gather information, look for a book to read so as to advance their knowledge. Successful libraries come in all shapes and sizes but they share certain characteristics that help them operate efficiently, meet the needs of their communities and provide an environment where users of all ages and interests can discover, explore and develop a love for learning and reading. Thus an academic library can be described as the "heart" of the learning community, providing a place for students and faculty to do their research and advance their knowledge. The librarians and library staff provide numerous services to these users, addressing their diverse needs, characteristics, and interests.

The library collections include reference works that provide factual information and indexes that help users find information in Library and information centers; creative works such as poetry, novels, short stories, music scores, and photographs; non-fiction, for example biographies, histories and other factual reports and periodical publications, including magazines, scholarly journals, and books published as part of a series, use of CD-ROMs and audiotapes as well as video tapes and other forms of media resources [2]. However, with the advent of online catalogs, CD-ROMs, online data-bases, other electronic

resources, new methods of document delivery, and access to information, the role of the academic library has begun to change. Students do not have to be physically present in the library in order to access the library's resources. With the Internet and the availability of new technologies and numerous indexes, abstracts, and databases, the range of services that academic libraries can provide has increased dramatically. Users can access the libraries' resources without stepping into the library building. They can also very easily access other libraries' resources, such as online catalogs and unrestricted databases. The Internet has opened the resources of libraries to students and faculty worldwide. Thus, users do not sometimes need a physical library since almost everything can be accessed electronically.

The main aim of every student at a tertiary institution like University is in terms of academic success, hence libraries are set up in these institutions to enhance academic output of students. Several factors contribute to determine Students Academic Achievement in the university. However, the extent to which students use library facilities has not been fully considered to be one of such factors. Thus, this study performed an exploratory factor analysis of a survey instrument assessing the impact of library services on academic performance of students in Federal University of Technology, Minna, Nigeria.

Questionnaires are the most frequently used data collection method in educational and evaluation research. They help gather information on knowledge, attitudes, opinions, behaviors, facts, and other information. Development of a valid and reliable questionnaire is a must to reduce measurement error, where reliability, indicates the accuracy or precision of the measuring instrument [3].

Exploratory factor analysis (EFA) is a multivariate interdependence technique that is widely used in research in the field of administration, especially research of the survey type [4]. It helps to obtain a minimum number of factors that contain the maximum possible amount of information contained in the original variables used in the model, and with the greatest possible reliability. This reduction in the number of variables is desirable when it is intended to submit the data to other multivariate analysis techniques, in which there can be no strong correlations between the independent variables, as is the case with regression techniques, thus generating a more parsimonious model. Although there may be a correlation between these factors, factor analysis guarantees a concentration of the information from the original variables.

### **1.1 Literature Review**

Factors that influence students to actually use the libraries have not been much discussed in literature. Some of the library and information science literature examines library usage and academic success. Other researchers examine library use and instruction, while still others discuss library skills, usage, and grade point average. There has been only few studies focusing specifically on usage of libraries by students. The effectiveness of libraries has often been measured by the volume of library materials available to clients, the amount of use of services and resources, and the apparent or quantified satisfaction of clients; very little research has taken into account the objectives of the clients [5]. The author's article deals mostly with library usage of undergraduate students and their academic achievements. She examines the number of times each student visited the library and whether there was any correlation between the library visit, the grades achieved, and the diversity of resources the student used in the library. Her study does not ask the students why they use the library, but what resources and services they used in the library, and the impact these had on their academic success.

Other sources discuss library use by different categories of students. Libraries represent one area in which international students have to adjust. The previous library experiences of these students is a critical determinant of how much adjustment to the United States library system is needed [6]. Some of the reasons why international students used the library include: studying for tests, reading books on reserve, checking out books, using computerized indexes and online facilities, and meeting friends. These library usage characteristics of international students are also pertinent to other students. Providing quality services in academic libraries is now a major issue among academic librarians; they see the library more in terms of the provision of and access to service quality than as just a physical place. Access to information provided by libraries is seen as more important than the materials physically available in a library. The electronic library operates within an electronic collaborative environment with an emphasis on access to information regardless of its location [7]. Several factors that influenced user satisfaction have been identified to include responsiveness, competence and assurance (which translated to demeanor), tangibles, and resources [8]. However, these authors did not investigate whether quality services leads to increased usage of the library itself.

### **2.0 Methodology**

The main instrument used for data collection is the developed structured questionnaire. A total of 500 undergraduate students were sampled out of those who regularly use the university library by the simple random sampling technique. This sample consists of 300 and 200, respectively, from the permanent and the temporary sites of the university. Thus, 500 copies of structured questionnaires were administered to the respondents, out of which only a total of 459 questionnaires, representing 91.8 percent, were completed and returned from the two campuses. The instrument included 44 categorical, 5-point Likert-type scale attitude items as given in TABLE 1.

**Table 1:** 5-point Likert-type scale

Strongly Disagree(SD)	Disagree(DA)	Undecided(UD)	Agree(A)	Strongly Agree(SA)
	(2)	(3)	(4)	(5)

These items were designed to explore students' satisfaction with the services being offered by the university library.

## 1 Statistical Analyses

Data were checked for missing values or data entry errors. Respondents with missing data were excluded from the study to minimize problems with the identification of factors. Reliability test of the selected items in the questionnaire were then examined. This involved calculating the inter-item correlations, item total correlations and internal consistency (Cronbach's  $\alpha$ ) [9]. Any items that had low item total correlations, inter-item correlations, and/or substantially lowered the internal consistency were inspected further and if appropriate were excluded. The basic statistic often used in factor analysis is the Pearson product moment correlation coefficient, which determines the strength of the relationship between two variables,  $X$  and  $Y$ . It is given as

$$r = \frac{N \sum XY - (\sum X)(\sum Y)}{\sqrt{(N \sum X^2 - (\sum X)^2)(N \sum Y^2 - (\sum Y)^2)}} \quad (1)$$

where  $N$  is the sample size.

This statistic was used to study the degree of relationship between the variables in the data. Eigen value test was used to determine the optimal number of factors to extract. We further computed some statistics that enabled us to examine the data set to see if it was suitable for EFA. We looked at the *Bartlett's Test of Sphericity* [10]. This technique tests the hypothesis that our correlation matrix is an identity matrix, which would indicate that our variables are unrelated and therefore unsuitable for factor detection. Small values (less than 0.05) of the significance level indicate that a factor analysis may be useful with the data to confirm that our data has patterned relationships. Then we looked at the *Kaiser-Meyer-Olkin Measure (KMO) of Sampling Adequacy* [11]. KMO is a statistic that indicates the proportion of variance in the variables that might be caused by underlying factors. High values (close to 1.0) generally indicate that a factor analysis may be useful with the data. If the value is less than 0.50, the results of the factor analysis probably won't be very useful. These results are given in TABLE 2. Data were then subjected to factor analysis using Principal Axis Factoring and orthogonal Varimax rotation.

### 1.1 Mathematical Models

The classical factor analysis mathematical model is given by

$$x_i = a_{i1}f_1 + a_{i2}f_2 + \dots + a_{im}f_m + e_i \quad (2)$$

where  $x_i$  is the  $i^{\text{th}}$  variable [ $i = 1, 2, \dots, p$ ] in vector  $x$ . There will be  $p$  such equations, one for each variable.  $f_i$  is the  $i^{\text{th}}$  factor, and  $m$  denotes the number of underlying factors. Hence, this model assumes that there are  $m$  underlying factors whereby each observed variable is a linear function of these factors together with a residual variate  $e_i$ . A factor loading is the correlation between a variable and a factor that has been extracted from the data; it gives an idea about how much the variable has contributed to the factor. For the model 2, the factor loadings are  $a_{i1}, a_{i2}, \dots, a_{im}$  which denotes that  $a_{i1}$  is the factor loading of  $i^{\text{th}}$  variable on the first factor.

The computed factor loadings are given by the component matrix in TABLE 4. The communalities were then computed, which are the variances in the observed variables that are accounted for by the common factors; these are summations of the squared correlations of the variables with the factors (i.e factor loadings). Communalities are computed by

$$c_i = a_{i1}^2 + a_{i2}^2 + \dots + a_{im}^2 \quad (3)$$

where  $a$  equals the loadings for  $i$  variables.

The best linear estimate of a variable  $x_i$  is given as

$$c_i = a_{i1}f_1 + a_{i2}f_2 + \dots + a_{im}f_m \quad (4)$$

Equation (3) is called the *common part* of  $x_i$  because this part of the variable has something in common with the other variables as an outcome of their links to the factors [12].

The residual term  $e_i$  in model (2) is the sum of two uncorrelated parts,  $s_i$  and  $\epsilon_i$ . That is,

$$e_i = s_i + \epsilon_i \quad (5)$$

where  $\epsilon_i$  is *measurement error* and  $s_i$  is specific part of  $x_i$ . It contains that part of  $x_i$  unaccounted for by the factors and not due to measurement error. Now, by substituting equations (4) and (5) into model (2), we have

$$x_i = c_i + e_i = c_i + s_i + \epsilon_i \quad (6)$$

One of the assumptions of the factor analysis model given by equation (2) is that all the terms on the right side of equation (6) are uncorrelated, and thus the total variance of a variable  $x_i$  can be decomposed into

$$\sigma_{x_i}^2 = \sigma_{c_i}^2 + \sigma_{e_i}^2 = \sigma_{c_i}^2 + \sigma_{s_i}^2 + \sigma_{\epsilon_i}^2 \quad (7)$$

where  $\sigma_{c_i}^2$  denotes the common variance, or *communality*. This represents that part of the variance of  $x_i$  that is in common with the other variables and is involved in the covariances between them.  $\sigma_{\epsilon_i}^2$  is the *residual variance* often referred to as the *uniqueness*. It is the variance of  $x_i$  unaccounted for by the factors.  $\sigma_{s_i}^2$  is the specific variance, or *specificity*, of  $x_i$ . It denotes the variance specific to a variable.  $\sigma_{\epsilon_i}^2$  is the error variance of  $x_i$  due solely to measurement error. This total variance is computed for each variable and presented in the second column of TABLE 3.

### 3.0 Results and Discussions

Out of 500 questionnaires distributed, a total of completed 459 questionnaires were received. The average age of the sample was 22.5 years (range 19-28 years); about 310 (67.5%) of the sample were female. Most inter-item correlation coefficients were between 0.20 and 0.50, with none exceeding 0.85; this suggests that none of the items overlapped considerably. Most of the item total correlations were also moderate and ranged from 0.45 to 0.70. The Cronbach's alpha for the scale was 0.81, which reflects an adequate level of internal consistency [13,14]. The results of the *Bartlett's Test of Sphericity* and the *Kaiser-Meyer-Olkin Measure (KMO) of Sampling Adequacy* were presented in Table 2. From this Table, the p-value for the *Bartlett's Test of Sphericity* is less than 0.05 while the KMO value is 0.841, which is above the cut-off value of 0.50. Indeed these testsshow that we do have patterned relationships amongst the variables. Then we looked at the diagonal elements of the *Anti-image Correlation* matrix that has the 'a' superscript. By the results of all these tests, our data set is suitable for EFA as the KMO is .84 and the individual diagonal elements of the *Anti-image Correlation* matrix were each > 0.60.

**Table 2: KMO and Bartlett's Test**

Kaiser-Meyer-Olkin Measure of Sampling Adequacy.	.841
Bartlett's Test of Sphericity Approx. Chi-Square	6730.363
df	946
Sig.	.000

On the basis of these results, all of the 44 items were included in the subsequent factoranalysis.Principal axis factoring identified a six-factormodel as the optimal factor structure as shown in Table 3.

### 3.1 Factor Extraction and Rotation

The total variance explained by the initial solution, extracted components, and rotated components are computed and given in Table 3:

**Table 3: Total Variance Explained**

Component	Initial Eigenvalues			Extraction Sums of Squared Loadings			Rotation Sums of Squared Loadings		
	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %	Total	% of Variance	Cumulative %

44	.208	.473	100.000

Extraction Method: Principal Component Analysis.

The first section of this table shows the Initial Eigenvalues. The Total column gives the eigenvalue, or amount of variance in the original variables accounted for by each component. The % of Variance column gives the ratio, expressed as a percentage, of the variance accounted for by each component to the total variance in all of the variables. That is

$$\% \text{tage variance} = \frac{\text{latent root}}{\text{total variance}} \times 100 \quad (8)$$

The Cumulative % column gives the percentage of variance accounted for by the first  $n$  components. For the initial solution, here are as many components as variables. However, in this work, we requested that only eigenvalues greater than 1.5 be extracted and so the first six principal components form the extracted solution.

The second section of the table shows the extracted components. They explain nearly 48% of the variability in the original forty-four variables. The factors are arranged in descending order based on the most explained variance. The *Extraction Sums of Squared Loadings* is identical to the *Initial Eigenvalues* except that factors that have eigenvalues less than 1.5 are not shown. These columns give the eigenvalues and variance prior to rotation.

The *Rotation Sums of Squared Loadings* show the eigenvalues and variance after rotation. The rotation maintains the cumulative percentage of variation explained by the extracted components, but that variation is now spread more evenly over the components.

### 3.1.1 The Scree Plot

The scree plot is given in figure 1. This plot helps us to determine the optimal number of components; the eigenvalue of each component in the initial solution is plotted. The components on the shallow slope of the plot contribute little to the solution compared to the components on the steep slope. The last big drop occurs between the sixth and seventh components, so the first six components are optimal.

The factor loadings are given by the component matrix in TABLE4.

% of variance	10.00	8.83	8.56	7.93	7.25

The factor loadings show that our factors are fairly desirable with at least 3 variables per factor that are above .32. Data were subjected to factor analysis using Principal Axis Factoring and orthogonal Varimax rotation.

TABLE 6 shows our final factor loadings after rotation using a significant factor criterion of 0.3. Items that aren't related and those that measure more than one factor were discarded. Factor 1 accounted for 10.00% of the variance. It comprised the following items (in order of decreasing factor loading): 10, 3, 39, 4, and 12. These items related to: the respondent's concerns about the library environment (sufficient work areas to meet the needs of various users; The library environment is a meditative environment; The library environment has space that facilitates quiet study; The library environment is a contemplative environment; and special display areas that invites exploration, discovery and love for learning). As a result this factor was labelled 'environmental conduciveness'. The factors loadings for all items were acceptable (0.698- 0.561).

The second factor accounted for 8.83% of the variance and consisted of items 22, 23 and 24. These items assessed the respondents' concern about the library personnel (library personnel are trained and always willing to provide orientation to visitors; library personnel are Employees who deal with users in a caring fashion; and the library personnel are employees who are consistently courteous). As a result this factor was labelled 'staff courtesy'. The factors loadings for all items were acceptable (0.844-0.713).

The third factor accounted for 8.56% of the variance and consisted of items 29, 25, 9, and 30. These items assessed the respondents' concern about their aim of visiting the library (I go to library to read lecture notes; I go to library to read newspapers and magazines; I go to library to access online resources; I go to library to consult textbooks and journals). As a result this factor was labelled 'visiting purpose'. The factors loadings for all items were acceptable (0.722-0.529).

The fourth factor accounted for 7.93% of the variance and consisted of items 16, 8, 7, 6, and 41. These items assessed the respondents' concern about availability of relevant materials (textbooks are available and adequate in the library; there is complete runs of journal articles; the library has sufficient number of theses and projects; steady and constant internet facility; and online resources are available and adequate). As a result this factor was labelled 'availability of relevant facilities'. The factors loadings for all items were acceptable (0.672-0.464).

The fifth factor accounted for 7.25% of the variance and consisted of items 37, 34, 35, 32, 1, 28, 33, and 31. These items assessed the respondents' concern about accessibility of available library materials (available library materials are accessible; available materials are accessible and relevant to my field; library internet facilities are accessible; available online reference materials are accessible; the reserve unit in the library is standard; the circulation unit is standard; there is a functioning binding unit; and library has book lending programs). As a result this factor was labelled 'accessibility of library materials'. The factors loadings for all items were acceptable (0.640-0.448).

The sixth factor accounted for 4.94% of the variance and consisted of items 42, 15, and 26. These items assessed the respondents' concern about the available programs for the library to improve on its services to the university community (Interdisciplinary library needs are always being addressed; librarians do regular planning, evaluation and monitoring so as to improve services; and the library develops and manages an inventory of books). As a result this factor was labelled 'service-improvement programs'. The factors loadings for all items were acceptable (0.562-0.466). Thus the extracted factor names are (1) environmental conduciveness (2) staff courtesy (3) visiting purpose (4) Availability of relevant facilities (5) accessibility of library materials (6) service-improvement programs, as given in Table 5.

The structure of these factors together with their loadings are given in TABLE 6.

The extracted factor items are given in TABLE 7:

**Table 7: Extracted Factor items**

<b>Factor</b>	<b>Item No.</b>	<b>Item</b>
1	10	sufficient work areas to meet the needs of various users
	3	The library environment is a meditative environment
	39	The library environment has space that facilitates quiet study
	4	The library environment is a contemplative environment
	12	special display areas that invites exploration, discovery and love for learning
2	22	library personnel are trained and always willing to provide orientation to visitors
	23	library personnel are Employees who deal with users in a caring fashion
	24	the library personnel are employees who are consistently courteous
3	29	I go to library to read lecture notes
	25	I go to library to read newspapers and magazines
	9	I go to library to access online resources
	30	I go to library to consult textbooks and journals
4	16	textbooks are available and adequate in the library
	8	there is complete runs of journal articles
	7	the library has sufficient number of theses and projects
	6	steady and constant internet facility
	41	online resources are available and adequate
5	37	available library materials are accessible
	34	available materials are accessible and relevant to my field
	35	library internet facilities are accessible
	32	available online reference materials are accessible
	1	the reserve unit in the library is standard
	28	the circulation unit is standard
6	33	there is a functioning binding unit
	31	library has book lending programs
	42	Interdisciplinary library needs are always being addressed
	15	librarians do regular planning, evaluation and monitoring so as to improve services
	26	the library develops and manages an inventory of books

## 4.0 Conclusion

This study involved an exploratory factor analysis of a new survey instrument to assess the impact of university library services on academic performance of students. This provided a number of useful outcomes in the context of the study sample. First, the instrument had acceptable properties with adequate levels of internal reliability and no indication of redundant items. Second, six distinct factors were identified which were labelled (1) environmental conduciveness (2) staff courtesy (3) visiting purpose (4) availability of relevant facilities (5) accessibility of library materials, and (6) service-improvement programs. The development of such a valid tool to assess students' level of satisfaction with the university library services is timely as it explores students' level of anticipation of improved services.

The factor analysis suggests that the information generated by the forty-four items used for the study can be better generated by six underlying constructs: (1) environmental conduciveness (2) staff courtesy (3) visiting purpose (4) Availability of relevant facilities (5) accessibility of library materials (6) service-improvement programs. The instrument shows strong promise in being effective in providing valid data to assist in assessing the performance of the university library.
