Editor's Note

CONCLUSION OF VOLUME 38, ISSUES 1 TO 4, 2019

Dear Readers,

Today marks the 59th anniversary of Nigerian independence from Britain.

As far as our publications are concerned, we are still on top of all Engineering and Technology-related journals in the Sub-Saharan Africa. We continue to be in the lead because of our ever-improving quality of peer-review.

Our statistics shows an improvement in the number of authors and dispersion of institutions from where papers are submitted. Polytechnics and industry are joining and finding NIJOTECH a good venue to report their research.

A unique peculiarity of this particular issue, (Vol. 38, Number 4 of October 2019) is that articles in section B dominated all other sections, an index of enhanced materials science research.

Peer review is becoming faster, we engaged 72 new reviewers and this has injected more new blood into the peer review mechanism.

Table 1 below shows our article statistics for the year ending 2019 publications.

I thank the Associate Editors, the peer reviewers and the entire editorial team for the wonderful cooperation give me. I also thank the esteemed authors for their work and for finding NIJOTECH worthy of being their journal. To the readers also, I thank you for being a part of our success story.

Nsukka, October 01, 2019

Engr. Prof. Emeka S. Obe,
Editor and Journal Manager

ABSTRACT

High quality reduced graphene oxide (RGO) nanosheets were prepared from natural graphite using an improved modified Hummers method. The morphological, structural and electrochemical properties of the RGO were characterised by scanning electron microscope (SEM), Raman spectroscopy, X-ray diffraction (XRD) analysis, Cyclic Voltammetry (CV) analysis and Electrochemical Impedance Spectroscopy (EIS) analysis. The SEM image of the RGO showed that, there was a small increase in the number of grain boundaries, indicating a collapse of the surface coalescence of the graphene oxide. The XRD peak at 24.56° corresponds to the (002) diffraction plane with the interlayer spacing along the c-axis of 2.0989 Å. The Raman shift for the reduced graphene oxide gives the I_D/I_G intensity ratio of 1.04. The RGO exhibited good electrochemical characteristics with energy density and power density of 19.2 Whkg⁻¹ and 149.3 Wkg⁻¹ respectively.

Keywords: Reduce Graphene Oxide, Structural Properties, Morphological Properties, electrochemical properties

1. INTRODUCTION

Graphene oxide is an exclusive material that can be regarded as a single molecular layer of graphite with several oxygen-containing functionalities such as hydroxyl groups, carbonyl, carboxyl. The exceptional structure of monolayer graphite provides it with many outstanding properties such as, high quantum hall effect, amazing electronic transport properties and good chemical stability [1]. When the GO is reduced with an appropriate process, the reduced graphene oxide (RGO) formed looks like graphene but comprising residual oxygen and other heteroatoms, as well as structural defects. GO and RGO have been used in nanocomposite materials, polymer composite materials, energy storage, catalysis and as a surfactant with some overlaps between these fields. Reduce graphene oxide is one of the exciting topics in many research fields particularly in the field of nanotechnology. RGO has excellent thermal mechanical and electrical properties [2]. The general consensus is that it is very difficult to remove all the

oxygen containing groups from graphene oxide. It is worth noting that the electrical performance of RGO depend on the strenght of the reducing agent. Detailed study of the structure of RGO is considered as an important step to understand the properties of this material. Graphene, a two-dimensional (2D) nanostructure of carbon, has attracted a great deal of attention, though it was experimentally discovered in 2004 [3].

2. EXPERIMENTAL

The Reduced Graphene Oxide was synthesis using modified Hummer's method. In the synthesis of the reduced graphene oxide, 5 g of graphite, 2.5 g of NaNO₃ and 115 mL H₂SO₄, were put together and stirred for 30 min using a magnetic stirrer, the temperature of the mixture was controlled at approximately 5°C. The mixture was then moved into an ice bath, then 15 g KMnO₄, was added slowly to mixture and maintained reaction temperature at below 20 °C, after the KMnO₄ was added, the temperature

* Corresponding author, tel: +234 – 806 – 245 – 9364

then rises to 35 °C. The mixture was stirred again for another 30 min, it became thickened and the volume increases, 230 mL of distilled water and ascorbic acid (5 mg dispersed in 10 mL of water to produce a 0.5 mg mL⁻¹) to aid reduction was then added slowly to the mixture and reaction temperature rises to 98 °C and stirred for another 15 min. The mixture gradually became brown. At the end of the 15 min, 400 mL distilled water and 50 mL H₂O₂ at 30% was added to the mixture to reduce residual permanganate and manganese dioxide to colourless soluble manganese sulphate. The colour of the mixture gradually changed from dark brown to bright yellow, it was then filtered and then washed with 1 M HCl repeatedly until the pH value of the filtrate was close to 7 and no deposit of MnSO₄ appeared in the filtrate with BaCl₂ test. The sample was finally washed with 100 mL DI water and a cake of the reduced graphene oxide was obtained and dried in an electric oven for 60 min.

3. RESULTS AND DISCUSSION

The structural properties of the RGO were analysed using the following characterisation; Phenoworld Pro

X Model Scanning Electron Microscope (SEM) operated at 2 kV in secondary electron detection mode, high resolution Jobin-Yvon Horiba T64000-Raman Spectrometer and an XPERT-PRO X-ray Diffractometer (PANalytical, Netherlands).

3.1 SEM Analysis

Figure 1 shows a typical crumpled, pitted and fragmented flakes of graphene oxide stacked together forming a typical multi-layer structure of the reduced graphene oxide. The SEM image of the RGO showed that, there was a small increase in the number of grain boundaries, indicating a collapse of the surface coalescence of the graphene oxide. Individual nanosheets were visible and agglomerated layers were also noticeable, this is due to crumples in the RGO sheets and their interaction with other sheets. The heterogeneous surfaces of RGO comprising edge plane nano-bands which are exclusively the sites of electro-catalysis and therefore has a dramatic effect on the materials properties and electrochemical reactivity.

Figure 1 SEM images for RGO

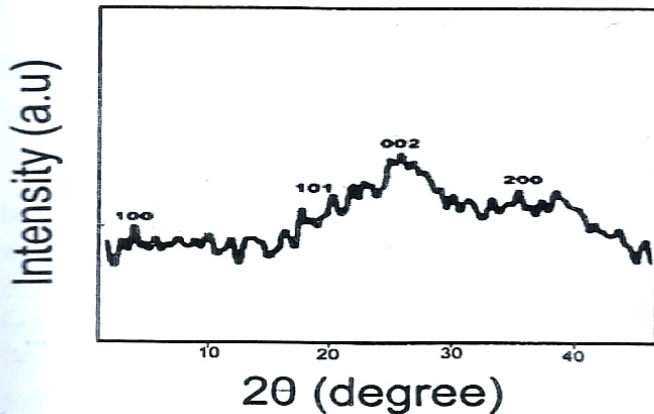

Figure 2: XRD Diffractograms for RGO

3.2 XRD Analysis

The crystal structure of the reduced graphene oxide nanocomposites was characterized by X-ray diffraction (XRD) with CuK α 1 radiation source of wavelength 1.5406Å. Figure 2 shows the XRD diffractograms of the RGO, with Bragg diffraction peaks at 2θ values of 4.84° , 20.01° , 24.56° and 33.86° , corresponding to (100), (101), (002) and (200) reflection planes respectively which is well indexed to the pure tetragonal rutile phase (JCPDS card no. 71-5324). The RGO peak at 24.56° corresponds to the (002) diffraction plane with the interlayer spacing along the c-axis of 2.0989 Å. This spacing is slightly larger than that of the d spacing of bulk graphite. The interlayer spacing was determined from the (002) peak by applying Bragg's law. Particle-size distribution at a size of agglomeration may also be responsible for the unexpected reduction in the peak intensities. In general, the reflection planes in the reduced graphene oxide sample are in very poorly order along the stacking direction revealing that the reduced graphene oxide comprises of largely free graphene sheet but with little of insertion of interplanar oxygen group, this is in agreement with [4].

The crystallite size was calculated using Debye Scherer's equation [5].

$$D = 0.9\lambda/\beta\cos\theta \quad (1)$$

Where λ is the wavelength of CuK α 1 radiation source and β is the FWHM for the peaks. The d-spacing was calculated using Bragg's equation

$$2d\sin\theta = n\lambda \quad (2)$$

Where θ is the Bragg's diffraction angle, d is the d-spacing and $n = 1$

The microstrain was calculated using the Williamson-Hall equation [6]

$$\beta\cos\theta = 2\epsilon\sin\theta + \frac{K\lambda}{D} \quad (3)$$

Where β is the FWHM, θ is the Bragg's diffraction angle, $k = 0.9$, ϵ is the microstrain, D is the crystallite size and λ the wavelength of CuK α 1 radiation source.

The dislocation density was calculated using the equation [7, 8]

$$\rho = \frac{1}{D^2} \quad (4)$$

Where ρ is the dislocation density and D is the crystallite size.

The crystallite size is one of the most important parameter of the micro-structure of crystalline materials. It has a fundamental importance because of its macroscopic properties and technological application. Smaller crystallite size as obtained from the RGO material increases the inter-grain conduction leading to an increase in electronic conduction. Microstrain of any sample is a root mean square value and hence its value is always positive [9], the values showed that the distance of the relevant crystal planes are not indistinguishable, possibly due to the presence of defect and stress. The values of the microstrain are also ascribed to crystal imperfection, such as excess volume of grain boundaries, vacancies and vacancy clusters. The nanostructures of the RGO have small crystallite size and microstrain as a result, contributed to broadening of the XRD peaks and this is due the non-uniform displacement of atoms with respect to their reference-lattice position.

Table 1 FWHM, Crystallites size, microstrain and dislocation density for RGO

2θ (degree)	hkl	FWHM (β)	Crystallite size D (Å)	d-spacing (Å)	Microstrain ϵ	Dislocation density $\rho \times 10^{18}/m^2$
10.84	100	0.2952	5.2187	3.4451	0.0492	3.6717
22.01	101	0.7344	2.1802	2.9752	0.1414	2.1038
24.06	002	0.5904	3.2143	2.0989	0.1605	9.6789

35.58 200 0.3936 3.7629 1.7392 0.0175 7.0624

It is worth stating that microstrain is not electronic in origin (distortion of electron shell) but it reflects an effective displacement of the atomic nuclei because lattice microstrain takes place even when static magnetic order is suppressed. The dislocation density defines the length of dislocation lines per unit volume of the crystalline material of the RGO since the formed phase is crystalline, so line defects can easily occur.

3.3 Raman Analysis

Figure 3 shows the Raman spectra of the reduced graphene oxide. The D band is the defects and disorder mode in the reduced graphene oxide, while the G band is the sp²-bonded vibration from carbon atoms (hexagonal lattice of graphite). The G and the D band are due to the bond stretching of all pairs of sp² atoms and the vibrating modes of the sp² bond [11]. The Raman shift for the reduced graphene oxide gives the I_D/I_G intensity ratio of 1.04. From the relative high intensities of the D and G band, it can be resolved that the magnitude of the sp² domains increases during the reduction of the graphene oxide. This decrease in the G band intensities relative to D band in the RGO discloses the disorder present in the sample.

3.4 Electrochemical Analysis

The electrochemical properties of the reduced graphene oxide (RGO) was analysed using Cyclic Voltammetry (CV) and the Electrochemical Impedance Spectroscopy (EIS) analysis. The cyclic voltammograms from the Cyclic Voltammetry analysis for the RGO is given in figure 4 and the Electrochemical Impedance Spectroscopy (EIS) in Figure 5.

The specific capacitance (C_{sp}) was calculated using the equation [12]

$$C_{sp} = \frac{S}{2mk(E)} \tag{5}$$

Where C_{sp} is the specific capacitance, S is the integral charge surface area of the CV curve in (mA.V), m is the mass of the electrode material in (g), k is the scan rate in (mV/s) and E is the value of the electrode potential in (V).

The energy density (E_D) and power density (P_D) were calculated using equations [13]

$$E_D = \frac{1}{8} C_{sp} V^2 \tag{6}$$

$$P_D = \frac{1}{4 \times (ESR) M} V^2 \tag{7}$$

The electrochemical properties of the RGO were studied using three electrode system by cyclic voltammetry (CV) and electrochemical impedance spectroscopy (EIS). The CV curve in Figures 4 gives a quasi-rectangular shape similar to report by [13].

Figure 3: Raman spectra for RGO

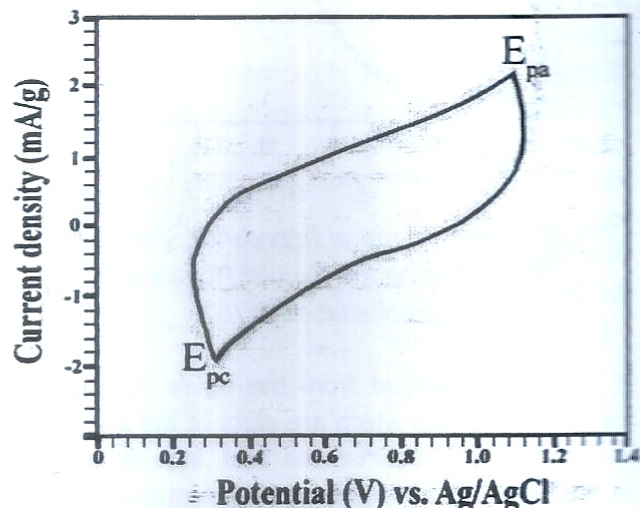

Figure 4 Electrochemical Analyses Showing Cyclic Voltammogram for the reduced graphene oxide (RGO)

Table 2 Summary of results from electrochemical analysis

Sample	Mass (g)	C _{sp} (F/g)	ERS (Ω)	E ₂ - E ₁ (V)	E _D (Wh/kg)	P _D (W/kg)
--------	----------	-----------------------	---------	-------------------------------------	------------------------	-----------------------

RGO	0.234	60.1	5.2	1.01	19.2	149.3
-----	-------	------	-----	------	------	-------

This is due to the kinetics of electron transportation in the electrode material and the ion adsorption-desorption at the electrode-electrolyte interface and also due to the substantial contribution of electrons in the conduction band, this is also in agreement with report by [13].

The EIS analysis is a powerful and informative technique which determines the rate that the electrode material can be charge/discharge [13], therefore an important factor in determining the power density and to evaluate the properties of conductivity and charge transport. In order to gain insight on the intrinsic electrochemical properties of the composite electrode, EIS measurement was carried within the probed frequency range of 100,000 to 0.1 Hz.

Figure 5 Electrochemical Impedance Spectroscopy Analyses Showing the Nyquist Plot for reduced graphene oxide (G)

It is clearly observed from the figure 5, that the impedance curves, which are plots of the imaginary impedance (Z'') against the real impedance (Z') consist of an arc and followed by a slanted line in the low frequency region. While in the high frequency region, the intercept of the semi-circle on the real impedance axis of the Nyquist plot represent the solution equivalent series resistance (5.2 Ω) which can be correlated to the Ohmic resistance of the electrolyte in the system and the charge transfer resistance between interface of the electrode materials and the electrolyte as shown in Table 2. The

Warburg impedance is related to the diffusional impedance of the electrochemical system which is employed to fit the straight line at the intermediate frequency, followed by a near vertical line at the lower frequency region as seen in Figure 5.

4. CONCLUSION

In summary the reduce graphene oxide (G) was synthesized using the improved modified Hummer's method. The morphological and structural properties of the RGO were studied. The SEM image of the RGO shows that, there was a small increase in the number of grain boundaries, indicating a collapse of the surface coalescence of the graphene oxide. The XRD peak at 24.56° corresponds to the (002) diffraction plane with the interlayer spacing along the c-axis of 2.0989 \AA . The Raman shift for the reduced graphene oxide gives the I_D/I_G intensity ratio of 1.04. The RGO gave good electrochemical properties with energy density and power density of 19.2 Whkg^{-1} and 149.3 Wkg^{-1} respectively.
