ABSTRACT

This study reports the preparation of nano-adsorbent from Multi-Walled Carbon nanotubes (MWCNTs) for the This study are the thing and Cu (II) ions from pharmaceutical wastewater. Fe-Ni/Kaolin catalyst was prepared by wet removal of the carbon nanotubes (CNTs) was synthesized in horizontal chemical vapour deposition impregnate (CVD) reactor using acetylene at 200 mL/min and nitrogen at 100 mL/min. The CVD reactor was operated at a (VD) reactor was operated at a temperature of 750 °C for a period of 45 minutes. After which the as-synthesized CNTs was purified With 100 mL temperature of the purified CNTs (P-CNTs) and functionalized with 100 mL of 20 % poly ethylene glycol of 30 % rate of 20 % poly ethylene glycol (PEG) to give functionalized CNTs (F-CNTs). The catalyst and CNTs synthesized were characterized to determine its properties to determine its surface area, morphology/elemental composition and the internal morphology via Brunner Emmett Teller (BET), Scanning Electron Microscopy/ Energy Dispersion Spectroscopy (SEM/EDS) and High Resolution Transmission Electron Microscope (HRTEM) respectively. The SEM depicts the formation of long-continuous strand of CNTs formation while the HRTEM shows the hollow nature of the CNTs with multiwalls formation. The results obtained showed that F-CNTs produced has a larger surface area of 970.81 m²/g than P-CNTs .The P-CNTs and F-CNTs were then applied for the removal of Fe (II) and Cu (II) from pharmaceutical wastewater. The effect of contact time, dosage of CNTs, and temperature for P-CNTs and F-CNTs were investigated. The optimum conditions for the adsorption of Fe and Cu ions from pharmaceutical wastewater were 60 minutes, 0.4 g and 60 °C respectively with % removal of 74.37 for Fe and 79.65 for Cu ions. Freundlich models as well as pseudo-second order kinetic best fitted the adsorption of Fe and Cu from the pharmaceutical wastewater. The result revealed P-CNTs and F-CNTs were effective adsorbents for the removal of selected heavy metals from pharmaceutical wastewater.

INTRODUCTION

Water is known to be the most important part of lives and the basic component on earth and it is considered as the most significance resource for development. The consistent access towards pure and reasonably price water is the most reliable goal for civilization, but it remains as the greatest task for 21st century worldwide, (Alizae et al., 2016). The pollution of water by noxious heavy metals is a universal challenge. Contemporary measures, for instance, purifying, metal plating, mining colors, cadmium-nickel-batteries, metal make and release fluid effluents comprising irregular dosage of overwhelming metal particles.

The interest in nanotechnology as a mitigation tool of environmental problems, specifically the nanofiltration, is noticeable for the treatment of drinking water and wastewater (Ali et al., 2014). Based on modern technology, current research focuses objectively on nanoadsorbent, nanoadsorbent base metal, zeolite, polymeric

nanoadsorbent and nanoadsorbent mainly based on the Carbon nanotubes (CNTs) (Somborn-Schulz, 2015). Carbon nanostructures such as fullerenes, carbon nanotubes (1-D) and graphene sheets have been extensively studied. studied due to their unique properties such as good electrical/thermal conductivity, excellent corrosion resistance. resistance, and enhanced chemical compatibility. Hence, they have found a wide range of applications which include address: include adsorption, polymer composites, electrochemical energy storage and conversion, catalysis, filtration and biotechnology. biotechnology. Adsorption is of great relevance to wastewater treatment and is also very efficient. Of all the adsorbents by adsorbents known in use for adsorption, CNTs have so far, proven to be the widely researched material for adsorption pures.

In this study, the sourced catalyst was employed for the synthesis of Carbon nanotubes in a CCVD reactor. The Purification and polyethylene glycol (PEG) Purification and functionalization of CNTs were carried out by acid treatment and polyethylene glycol (PEG) addition respectively. addition respectively. Adsorption Studies 2.4

The effects of contact time, adsorbent dosage and temperature on the percentage removal of Fe and Cu ions were investigated in a batch adsorption process. The concentrations of both ions were determined using AAS technique. The kinetics, isotherm and the thermodynamic of the adsorption process were then studied.

3.0 Result and discussion

The scanning electron micrograph of the produced carbon nanotubes for both the as-synthesized and purified

MWCNTs are depicted in Figure 1(a-b).

nanotubes was partitional composition of the purified CNTs and the functionalized CNTs were determined and the results depicted in Fig. 3 (a-b). The EDS spectrum revealed that the composition of the purified CNTs are determined and the results The elemental analysis revealed that the CNTs are relatively purified CNT was composed basically of are as depicted. The elemental analysis revealed that the CNTs are relatively pure containing about 80.92% carbon and carbon. The containing about 80.92% carbon and low amount of other impurities like Si (2.367%), K (0.07%), Fe (0.82%), Ni (0.76%) and Al (1.91%).. Low amounts low amounts of Fe and Ni shows that the CNT walls are almost free from the catalyst and the support. (the Fe and the Ni of Fe and The CNTs are direct indication of the nature of the catalyst used during the CNTs synthesis).

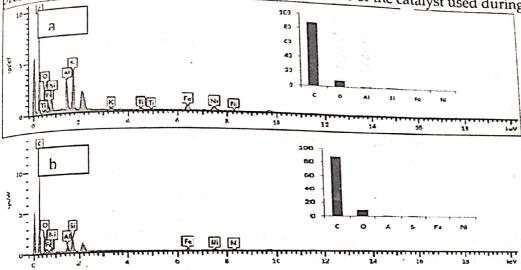

Fig. 3. EDS Spectral of (a) purified and (b) functionalized CNTs

After functionalization; Fig. 3b, the elemental composition of carbon present increased to 88.56%. All other constituents were significantly reduced due to the treatment with PEG.

Adsorption Results 3.1

The effect of varying contact time was investigated between 10 to 120 min for the adsorption of Fe and Cu. The effects of contact time on the percentage adsorption of Fe and Cu are depicted in Fig. 4 (a-b).

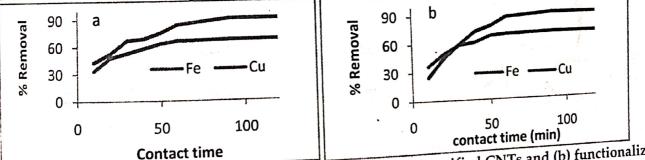

Fig. 4. Effect contact time on the Fe and Cu removal using (a) purified CNTs and (b) functionalized CNTs.

The offer is a functionalized CNT are shown in the functional contact time on the Fe and Cu removal using (a) purified CNTs and (b) functionalized CNTs. The effect of contact time on the removal of Fe and Cu for purified CNT and the functionalized CNT are shown in Figure 4.4 in Figure 4 (a-b). For purified CNT adsorbent, as the contact time is increased, the amount of Fe and Cu This correlates with the from wastewater is increased from the various percentage removals of both Fe and Cu. This correlates with the report of the concentration gradient between the report of Mishra et al, (2016). The higher adsorption rate is a function of concentration gradient between the liquid layer. liquid layer of the adsorbate and the surrounding active sites of adsorbents available for adsorption of metal ions. The effect of the adsorbate and the surrounding active sites investigated and the result is shown in Figure 5. The effect of adsorbent dosage on the percentage removal was investigated and the result is shown in Figure 5.

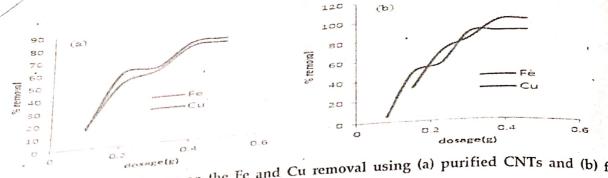

Fig. 5. Effect adsorbent dosage on the Fe and Cu removal using (a) purified CNTs and (b) functionalized CNTs.

From Figure 5 (a-b), there is increase in adsorption capacity of the adsorbents, as more adsorbent provides wide surface area of active sites for adsorption to take place. The cessation in the percentage removal of metals beyond equilibrium is associated with the overlapping of sorption sites due to excess of adsorbent particles (Mishra et al. 2016). It implies that till a certain range of initial metal concentrations, the metal removal is associated with the soil sorption capacity. This is in correlation with the report of (Qiang et al, 2017).

The effect of temperature on the percentage removal of Fe and Cu is depicted in Figure 6.

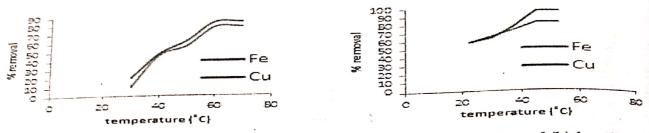

Fig. 6. Effect of temperature on the Fe and Cu removal using (a) purified CNTs and (b) functionalized CNTs. From Fig 6, it was observed that increase in temperature from 30°C to 70°C resulted in an increase in the percentage removal of both Fe and Cu from the pharmaceutical wastewater, that is, temperature varies directly with % removal of the metals. However, 60°C is the optimum temperature because the most % removal of 74.57 for Fe and 79.65 for Cu are achieved at this temperature. First, increasing the temperature increases the rate of diffusion of the metal ions from the bulk of the solution to the bulk of the adsorbent. Second, the increase of temperature increases the ionization of the function groups (adsorption active sites) which increases their activity towards the adsorption of from the solution (Badawi *et al*, 2017).

3.2 Adsorption isotherm

Table 1: Isotherm parameters for adsorption of heavy metals onto P-CNTs and F-CNTs

Isotherm	parameters for adsorption P-CNTs	~	<u>F-CNTS</u>	13 A 14 A 15 A 16
	Fe	Cu	Fe	Cu
Langmuir				
K ₁ (min ⁻¹)	0.040906	0.80625	0.37043	0.8591
$Q_m(mg/g)$	66.67	1.1325	5.05817	7.2294
R ²	0.730	0.828	0.902	0.5635

The R² values of Langmuir isotherms are gotten to be 0.730 and 0.828 for Fe and Cu purified CNTs, and 0.902 at 0.5635 for Fe and Cu functionalized CNT. These values are lower than 0.999 as given in literatures to test the fit of the isotherm parameter. As such Langmuir is not a best fit for isothermal adsorption. Table 2 depicts isotherm parameters for the adsorption of Fe and Cu onto P-CNTs and F-CNTs.

rable 2: Isothe	rm parameters	for the adsorpti P-CNTs	on of Fe and Cu on	to P-CNTs and F-CN	VTs.
		Fe		F-CNTS	4
(min-1)		and the second s	Cu	Fe	Cu
(min-1)		1.2750	0.6052		
(mg/g)		2.7246		1.6405	2.8563
		2.10	1.1612	0.0017	0.6205
		0.8295	0.8615	0.000	
				0.9935	0.9167

Langmuir and Freundlich models were also studied for use in adsorption to determine which model has the best adsorption capacity. The correlation coefficients were calculated by fitting the experimental equilibrium data for the various metal ions system using both Langmuir and Freundlich isotherms, and are presented in Table 1 and Table 2 respectively. These results clearly show that the adsorption of Fe and Cu ions from purified CNTs fits well with the Freundlich model as seen from the high values of R2 from Freundlich table compared to Langmuir which is much lower.

The other Freundlich constant, n, is a measure of the deviation of the adsorption from linearity. If the value of n is equal to unity, the adsorption is linear. If the value of n is below unity, it implies that the adsorption process is unfavourable, and if the value of n is above unity, adsorption is favorable. The n value of the Freundlich model is 1.275, 1.6405 and 2.8563 which are all in the range of 1 to 10. This is a criteria required for the freundlich model to fit the adsorption process. The fact that the Freundlich model is a good fit to the experimental adsorption data suggests good and high physical adsorption.

Adsorption kinetics

Table 3: Table 4.6: Kinetic Parameters for adsorption of selected heavy metal ion on P-CNTs and F-CNTs.

100,00				
Kinetic Parameters	P-CNTs			
	Fe	Cu	Fe	Cu
Pseudo first order				
$K_1(min^{-1})$	0.0279	0.0149	0.0023	0.0111
q _e (mg/g)	14.5814	0.1508	0.3399	0.2726
R ²	0.7885	0.2452	0.0029	0.3608
Pseudo second order				
K ₂	0.0003	0.0037	0.0003	0.0112
	147.059	11.3766	3.9793	93.09
q _e (mg/g) R ²	0.9316	0.9316	0.9536	0.9997

From the Table 3, it could be observed that the results obtained from the analysis did not fit the pseudo-first order rate law, because the coefficient correlation (R2) values for all the parameters is lower than 0.999. In this pseudofirst order, the rate of adsorption was assumed to be proportional to the difference between the maximum adsorption capacity at equilibrium (qe) and adsorption at any time (qt) of the adsorption in a first order at the

When the results were subjected to the pseudo-second order rate kinetics it was observed that the correlation coefficient value (R2) for most of the parameters studied was higher than 0.9, this is an indication that the treatment fit the pseudo-second order rate kinetics. This suggest that the adsorption system is not a first order reaction and that the pseudo-second order model, is based on the assumption that the rate limiting step may be chemical adsorption or chemisorptions involving covalence forces through the sharing of electrons between the

From Table 4, the values of ΔG are all negative. This implies that the adsorption process occurred spontaneously. The process was endothermic in nature values of ΔG are all negative. From Table 4, the values of ΔΘ are an negative. This implies that the sorption process was endothermic in nature which means values of ΔH, however, were positive. This signifies that the sorption process was endothermic in nature which means a locally increase in the degree of discrete. that heat was absorbed into the system during adsorption. There is also an increase in the degree of disorderliness of the system as observed from the positive values of ΔS .

Conclusion

The adsorption capacity of purified and functionalized CNTs for the removal of Fe and Cu from pharmaceutic wastewater was investigated in this study. The synthesized CNTs obtained were purified by acid treatment and functionalized with PEG. TEM revealed the crystalline nature of F-CNTs was more thermally stable than P-CNTs. BE results revealed that F-CNTs had an improved surface area of 970.81 m²/g than P-CNTs. The CNTs adsorbents were employed in the adsorption of selected heavy metals and other contaminants from pharmaceutical wastewater Optimum adsorption was obtained at adsorbent dose of 0.4 g, 60 °C and equilibrium time for adsorption was achieved within 60 min of contact time. The increase in surface area of the nanoadsorbent contributed to its effectiveness in adsorption process. The kinetic data of Fe and Cu removal were fitted to the pseudo-second order kinetics and Freundlich model described the adsorption isotherm. The thermodynamics studies revealed that ΔG was negative which implies spontaneity of adsorption process. The results of this study also showed that the values of AS were positive which implies an increase in the disorderliness of the system. Finally, a decrease in physicochemical properties of pharmaceutical wastewater was observed due to effectiveness of nanoadsorbents.
