#### Abstract

This study involved the use of full factorial method to evaluate the effect of cutting variables on surface roughness and types of chip formation in turning of AISI 304L alloy steel with coated carbide insert under dry condition. The input variables used were cutting speed, feed rate and depth of cut. Minitab 17 software was used to analyse the data. The analysis of variance shows that feed rate has the most significant effect on surface roughness with 79.86% and the relationship between feed rate and cutting speed at constant depth of cut shows that as feed rate increase for every cutting speed, the surface roughness increases. It was observed that the chips formed at different cutting conditions were continuous, helical, straight, and serrated types.

Keywords: Cutting speed, feed rate, depth of cut, surface finish and turning process

#### INTRODUCTION 1.0

Engineering products are produced from different materials and these products are manufactured into its usual form from processes such as turning and milling Whereas others do not, but operations. working to further require component of the desired shape and size (Rajender, 2006). In metal turning process, cutting tools remove a certain layer of material and impart the required shape, size and surface quality to the workpiece. Varieties of cutting tools have been developed to satisfy the requirements of production for its smooth running. In turning and facing operations an improper selection of cutting parameters will cause undesired surface roughness and high tooling cost. All dimensions and shapes are determined either analytically or graphically during design of cutting tools. For effective production, researches were carried out in the past and many are in progress for the purpose of reducing manufacturing and production cost compromise without parameters product quality (Kapil et al., 2013).

In any metal cutting operation the features of tools, input work materials and machine parameter settings will influence the process efficiency and output quality characteristics. A significant improvement in process efficiency may be obtained by optimization process parameter identifies and determines the regions of critical process control factors leading to responses outputs ОГ acceptable variations ensuring a lower cost

of manufacturing. For turning process, the cutting conditions that is, speed, feed and depth of cut plays an important role in the efficient use of a machine tool. In order to determine the optimum cutting conditions, there is the need to estimate the tool life and cutting forces with a reasonable degree of accuracy since many of the constraints on the process are influenced by these parameter (Raoa et al., 2014). In metal cutting processes, the desired cutting parameters are determined either experience or by using a handbook which does not ensure the selected parameters to be optimal. To determine the optimal cutting conditions, reliable mathematical models have to be formulated to associate with cutting parameters the cutting of statistical performance in terms approach. In literature, Response Surface Methodology (RSM) has been used by some researchers for the analysis and prediction of surface roughness (Lalwani et al., 2008). Many works on machining of carbon or alloy steel have applied a full or partial factorial design (Abouelatta and Mádl, 2001, Lawal et al, 2014, Lawal et al, 2015).

Ilhan and Harun, (2011) optimized turning parameters based on the Taguchi method to minimize the surface roughness. They carried out dry turning tests on hardened AISI 4140 (51 HRC) with coated carbide cutting tools. To ensure accurate readings of the surface roughness each experiment were repeated three times. Analysis of (ANOVA) variance was used investigate the effects of cutting speed, feed rate and depth of cut on surface roughness. It was concluded that the feed rate has the most significant effect on surface roughness. Ali, (2010) investigated the surface roughness in the turning of AISI 8660 hardened alloy steels using ceramic based cutting tools studied in terms of cutting parameters such as cutting speed, feed rate, depth of cut as well as

tool nose radius, by means of a statistical approach. Machining tests were carried out with physical vapour deposition (PVD) coated ceramic cutting tools different conditions. An orthogonal design, signal-to-noise ratio and ANAOVA were employed to find out the effective cutting parameters and nose radius on the surface roughness. The results obtained showed that the feed rate was the most dominant factor among controllable factors on the surface roughness, followed by depth of cut and tool's nose radius. The interaction of feed rate and depth of cut was found to be significant on the surface finish due to surface hardening of steel. Lanjewar et al., (2008) conducted experiments to evaluate the performance of AISI304 steel on auto sharpening machine by using Taguchi method. The results revealed that tools shape and feed are significant factors.

Ahmed, (2013) studied the effects of cutting speed, feed rate, tool path and depth of cut process parameters on the surface roughness in the pocket machining of AA5083 aluminium alloy materials using Taguchi method. It was found that surface roughness correlates positively with feed rate and depth of cut, but negatively with cutting speed while the tool path pattern factor is of less significance. In this study, the effect of cutting variables on surface roughness and chip formation during turning of the AISI 304L austenitic stainless steel using coated design adopting carbide inserts experiment via full factorial design method would be investigated.

# 2.0 MATERIALS AND METHODS 2.1 Materials

The workpiece material employed in this investigation was AISI 304L alloy steel with the following chemical composition as shown in Table 1. The cutting tool used in the turning process was coated carbide inserts (CNMG 120408-DM).

Table 1: Chemical composition of AISI 304L (AK Steel, 2007)

| % C % Si |       |       | ( THE OLOCI, 2007) |        |        |       |       |       |

#### 2.2 Method

This design technique involves the combination of three factors at three levels necessary to study the combined effect of the experimental factors on a response. A complete trial or replications of all the possible combinations of the levels of the factors were investigated in this study.

The factors and their levels are shown in Table 2. Three factors at three levels experimental design layout as specified by full factorial design  $[L_{27}(3^3)]$  is shown in Table 3 using Minitab 17 software. The confidence level specified for this analysis is 95%.

Table 2: Factors and their levels

| Parameter             | LI  | L2  | L3  |  |

The turning process was conducted on a computer numerical control (CNC) lathe (model SPT-32) as shown in Figure 1 with the following configuration: - slant bed turning centre and maximum spindle speed of 4000 rpm, rapid traverse of 15,000 mm/min, spindle motor power of 28 KW motor drive, maximum work weight of

300 Kg and maximum swing diameter over bed of 490 mm. The workpiece was prepared to a diameter of 50 mm and length of 200 mm. This was necessary to maintain a ratio of 1: 4 (diameter to length) of workpiece so as to ensure the required stiffness of chuck/workpiece/cutting force (Lawal et al., 2014).

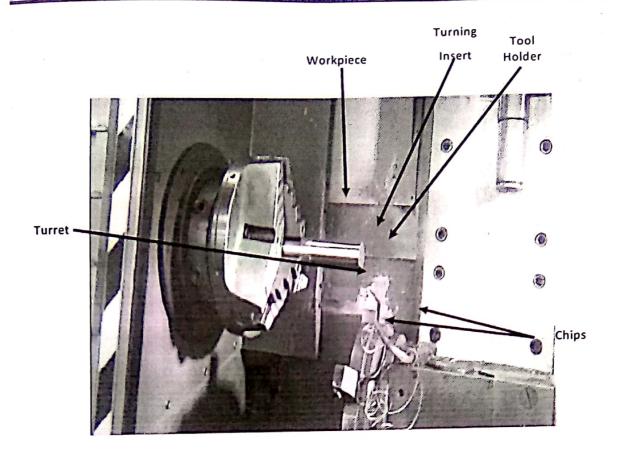

Figure 1: Experimental set up for turning operation

Each turning experiment was conducted for ten minutes and a new cutting tool was used for each run. After each turning operation, the surface roughness of the machined surface was measured using Surface Roughness Tester (SRT-6210S) having a diamond stylus tip of radius 5 μm. The experimental set up for surface roughness measurement is shown in Figure 2. A cut-off length (or sampling length) of 0.8 mm was used for surface roughness

measurements between 0.36 and 2.5  $\mu m$ , while 2.5 mm cut-off length was used for surface roughness measurements above 2.5  $\mu m$ . The roughness surface (R<sub>a</sub>) was measured at three positions along the machined surface, that is, at the middle and 10 mm from the two ends of the machined surface. The average of the three R<sub>a</sub> values measured was calculated and recorded for each experimental run.

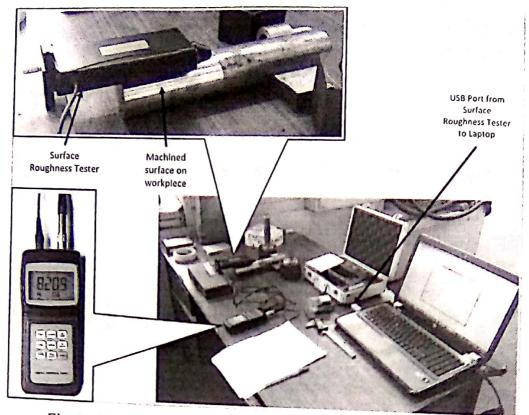

Fig. 2: Experimental set up for surface roughness measurement

After the completion of each experimental run, sample of the chips formed were collected and labelled. The surface morphology of the samples of chips formed during each of the experimental runs was investigated at 100 x magnification under the Nikon Eclipse — ME600 optical metallurgical microscope.

# 3.0 RESULTS AND DISCUSSION

# 3.1 Surface Roughness

The results of the effect of machining parameters (cutting speed, feed rate and

depth of cut) on the response (surface roughness) during the machining of AISI 304L steel when using coated carbide tools are presented in Table 4. Signal-to-noise ratio analysis of the surface roughness values were determined using the smaller the better characteristic quality as shown in equation I and presented in Table 4.

S/N = -10log
$$\frac{1}{n}(\sum_{i=1}^{n} y_i^2)$$
 (1)

where n = number of outputs in the combination of factor level, y = the outputs for the specified combination of factor level.

# 2.2 Analysis of Variance and Main Effect Plot of Surface Roughness

Analysis of variance (ANOVA) was conducted to identify the significance effect of machining parameters on the surface roughness of the workpiece. The relative importance for each parameter is given by the order of their percentage contribution (p-value) during the machining process. Table 5 shows the results of the analysis as well as the p-value of each parameter.

Table 5: ANOVA for Surface Roughness

|                     | DOF | SS      | MS     | F       | p-value (%) |
|---------------------|-----|---------|--------|---------|-------------|
| Variables           |     |         |        |         | -1 -        |
|                     | 2   | 5.935   | 2.967  | 441.59  | 18.14       |
| Cutting speed (rpm) |     |         |        |         |             |
|                     | 2   | 26.13   | 13.065 | 1944.19 | 79.86       |
| Feed rate (mm/rev)  |     |         |        |         |             |
|                     | 2   | 0.5179  | 0.259  | 38.53   | 1.58        |
| Depth of cut (mm)   |     |         |        |         |             |
|                     | 20  | 0.1344  | 0.007  |         | 0.41        |
| Error               |     |         |        |         |             |
|                     | 26  | 32.7173 | 1.258  |         | 100         |
| Total               |     |         |        |         |             |
|                     |     |         |        |         |             |

It can be observed that cutting speed, feed rate and depth of cut have percentage contribution of 18.14, 79.86 and 1.58 % respectively. This indicates that the feed rate (79.86%) has the most significant effect on the surface roughness during the turning process.

The main effect plot for the surface roughness is shown in Figure 3. It was observed from the main effect plot that the optimal values of the cutting speed, feed rate and depth of cut are at level 3 (250 rpm), level 1 (0.1 mm/rev) and level 3 (0.7 mm) respectively. A model equation 2 for the output parameter (surface roughness) was obtained using Minitab 17 software.

When the optimal values of the input variables were substituted in the model equation, the predicted optimum surface roughness value of  $0.515~\mu m$  was obtained. However when confirmation test was conducted, the value of surface roughness obtained was  $0.522~\mu m$ . The percentage error in this experiment is 1.44% which is acceptable.  $R_a = 2.08 - 0.01143s + 9.56 fr + 0.48 doc$  (2)

where cs is cutting speed, fr is feed rate and doc is depth of cut The values of  $R^2$  and adjusted  $R^2$  are 68.33 % and 64.20 % respectively. These values

are lower than accepted values which may be due to experimental uncertainty.

LAWAL S.A., SU Evaluation of Cutting variation

Figure 5 shows the interaction plot for surface roughness. When the effect of one variable depends on the level of the other variable interactions plot can be used to visualize the possible interactions of the variables. Parallel lines in an interaction plot indicate no interaction while two independent variables interact if the effect

of one of the variables differs depending of one of the other variable it was the on the level of the level observed that cutting speed has the level obse observed that significant influence at 150 rpm of chillips and 0.3 mm/rev of the feed like significant mas mm/rev of the feed speed and 0.3 mm/rev of the feed speed of feed rate was noticed. speed and of feed rate was noticed tale. The effect of feed rate was noticed at the modern the depth of cut was noticed at the contract of the cut was noticed at the cut was not cu The effect of the depth of cut was fig mm.

### 3.2 Chip Formation

The types of chip formed at different cutting conditions are shown in Figure 6 during turning of AISI 304L alloy steel with coated carbide insert. The chips are observed to be continuous, helical, straight, and serrated. Figure 6 (a, b) shows the chips generated at constant cutting speed of 150 rpm, feed rate 0.10 mm/rev and with different depths of cut of 0.5 and 0.6 mm, respectively. noticed that with the increase in the depth of cut, the chip transforms from wavy to the saw toothed type. With the decrease of chip curvature, the chip thickness, and the contact length are increased. Figure 6 (ce) shows the chips formed at constant cutting speed 200 rpm, depth of cut 0,5

mm, and with three different feed rates of 0.10, 0.20, and 0.30 mm/rev. respectively for c, d and e. With the increase of the feed rate, the chips are transformed gradually from wavy to serrated, the chip curvalur was changed, and at the highest feed rall (0.30 mm/rev), the chip breakage occurs Figures 6 (d) and 6 (f) show the chips formed at constant feed rate of 0.2 mm/rs and depth of cut of 0.5 mm with 100 different cutting speeds of 200 and 210 rpm respectively. The chips are continuous at all cutting speed; however, at cutting speed 200 rpm, the chips are segments and a reduction in chip curvature observed. As the speed increased from to 250 to 250 rpm, the chip thickness decrease while the while the radius of curvature increases.

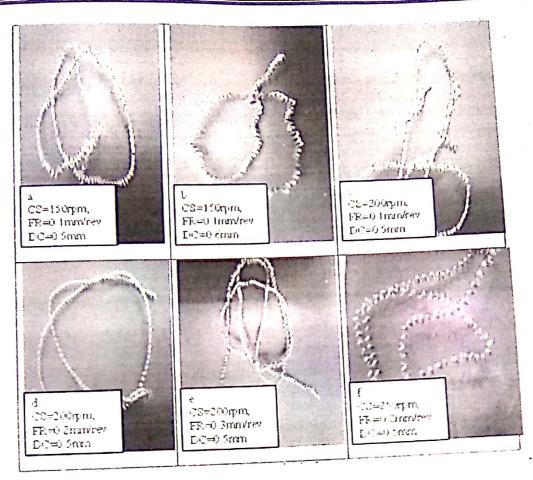

Figure 6: Types of Chip

### 4. CONCLUSION

The analysis of variance shows that feed rate has the most significant effect on surface roughness with 79.86%, while cutting speed has 18.14% significant and the least effect is depth of cut with 1.58% significant. The relationship between feed rate and cutting speed at constant depth of cut as depicted in the contour plots show that as feed rate increases for every cutting speed, the surface roughness increases. It was observed that the chips formed at conditions cutting different continuous, helical, straight, and serrated type. It was noticed that with the increase in the depth of cut, the chip transforms from wavy to the saw toothed type. With the decrease of chip curvature, the chip thickness, and the contact length are increased.
