Abstract

The effect of storage period on the nutritional qualities of smoked African Catfish (Clarias gariepinus) were evaluated. Fresh fish samples were obtained from a fish market in Minna, Nigeria. Fish samples were gutted, thoroughly washed with clean tap water, brined in 25% salt solution for one hour and smoked in a modified drum smoking kiln. Samples were kept at room temperature and analysed for nutritional quality indices over a period of six weeks. The result indicates no significant difference (p>0.05) in mean proximate composition of the smoked fish samples during storage periods. Composition of the smoked fish samples during storage periods showed no significant difference (p>0.05) in Crude Fibre, Fat, NFE and total volatile base nitrogen (TVB-N) contents. Significant differences (p<0.05) were recorded in moisture, ash and percentage crude protein contents of the smoked fish product during storage period. The result of this finding showed significant difference (p<0.05) in Potassium (K), Calcium (Ca) and Phosphorus (P), however there was no significant difference (p>0.05) in Sodium (Na), and Magnesium (Mg) content. The result also depicted that there was significant difference (p<0.05) in the mineral composition (potassium and phosphorus) during the storage periods of melon shell briquettes smoked fish samples.

Introduction

Fish smoking is the commonest preservation method in Nigeria because of the ease of processing which makes it acceptable in remote fishing villages where the technology for other preservation methods is not readily available (Overo, 1999).

Wood is the largest source of fuel in many developing countries like Nigeria, especially for fish smoking with about 200 million people in developing nations, depending on wood biomass for their daily domestic energy needs (FAO, 1990). There is huge pressure on the use of fuel wood. With increasing pressure on the earth's resources, turning different kinds of organic waste into clean-burning fuel such as briquettes helps save forests and cut greenhouse gas emissions by substituting wood, charcoal and fossil fuels for fish smoking and other industrial processes. Biomass briquettes are potential energy source for fish smoking, as they are currently generated as waste in many homes in developing countries. Aside from being cleaner and easier to handle him and the save to have the save the save to have the save the

easier to handle, biomass briquettes are also less polluting (David and Anne, 2014).

Catfish (Clarias gariepinus) is a commercially important freshwater fish species in Nigeria; it has enjoyed wide acceptability in most parts of the country because of its exceptional taste, flavor and good

The fish were turned regularly to prevent charring for 13 hours until dried to a constant The proximate analysis of the fish samples smoked with melon shell briquettes and firewood for weight.

The proximate analysis of the moisture, ash and carbohydrate contents were determined as described by AOAC (2005). Crude protein fibre and fat contents were determined using the methods described by Pearson (1976). The TVB-N was

determined as described by Malle and Poumeyro (1989).

Mineral contents of all the samples were also determined by atomic absorption spectrometry (AAS), flame photometry and spectrophotometer according to the methods of AOAC (2003).

The data collected was subjected to statistical analysis using one way Analysis of variance (ANOVA) and Duncan Multiple Range Test was used for mean separation. The statistical analysis was conducted by using IBM SPSS version 20 software.

Results

The result of proximate composition of the firewood-smoked fish samples during storage periods in Table 1 showed no significant difference (p>0.05) for all parameters. The table also depicts that the mean proximate compacition proximate compositions of the melon shell briquettes smoked fish samples during storage periods showed no significant different differen showed no significant difference (p>0.05). However, there were differences in mineral contents of firewood smoked figh and the mineral contents of firewood smoked fight and the mine firewood smoked fish product during storage periods as shown in Table 2. There was significant difference (p<0.05) in Potential Potentia difference (p<0.05) in Potassium (K), Calcium (Ca) and Phosphorus (P) values, but sodium (Na) and Magnesium (Mg) showed no significant. Magnesium (Mg) showed no significant difference.

The result in Table 2 also showed that there was a significant difference (p<0.05) in the K and P ing the storage periods in melon statute. during the storage periods in melon shell briquettes smoked fish samples. However, Na, Ca and Mg did not vary significantly.

Discussion

The mean proximate composition during storage period of firewood smoked fish samples and that of the melon shell briquettes, were not significantly different at first day to 42nd day of storage. This is inline with the report that protein forms the largest quantity of dry matter in fish (Pannevis, 1993). There was an increase in the percentage of crude protein of the smoked fish products during the storage periods. This could be due to gradual decrease in the moisture content of the smoked fish product (Eyo 2001). Changes observed in percentage ash and percentage lipid content during storage may have been due to leaching out of some extractable soluble minerals and hydrolysis of some of the lipid fractions (Daramola et al., 2013).

Decrease in the percentage moisture content during storage, could be attributed to the temperature of the storage medium (25°C-34°C) room temperature. Fish at 10-15% moisture content, reportedly had a shelf life of 3-9 months when stored properly (Jallow 1995). Reduction in lipid content could be attributed to oxidation of poly-unsaturated fatty acids (PUFA) contained in the fish tissue to products such as peroxides, aldehydes, ketones and the free fatty acids (Horner 1992). However, the rate of fat deterioretic deterioration was very gradual. Fish oil has been found to be more liable to spoilage than other oils due to their areas. to their greater number of unsaturated fatty acids as shown by the lower specification number and higher iodine value (E. iodine value (Eyo 1993). The greater the degree of unsaturation, the greater would be the tendency for fall oxidation (consisting prolonged storage conditions due fal oxidation (rancidity). There might be high risks of rancidity during prolonged storage conditions due to the fatty note.

The Total Volatile Base Nitrogen (TVB-N) increased during storage. This is widely used as an eater of the decision of the deci Indicator of the degree of lipid oxidation (Daramola; et. al., 2013). It helps to measure the level of fish appliage and to spoilage and to explore the shelf life of fish. TVB-N to the Total Nitrogen has been recommended as a useful index of an index useful index of quality in fish (Huss, 1988). Kirk and Sawyer (1991) suggested the value of 30-40mg N
