and small motor-driven pumps (Eicher and Baker, 1982). Considering the relatively low level of capital requirement and the simplicity of the technologies involved, small-scale irrigation might be more beneficial to a developing country like Nigeria, than the large-scale schemes.

The Research Problem and Objectives

To successfully develop small-scale irrigation in Nigeria, empirical information on the economics of crop production under the existing small-scale irrigation schemes is essential. Such information would highlight the potentials and constraints of the schemes. Policy makers, irrigation development planners, as well as research and extension workers would then recognise the specific aspects of small-scale irrigation systems on which to focus their attention.

Presently, there is a dearth of empirical information on the worth of investments in small-scale irrigation systems. The very few studies on the economics of small-scale irrigation in Nigeria determined costs and returns, as well as productivities of resources in the year of study (Orewa, 1978; Erhabor, 1982; Olukosi and Orojekwu, 1983). But, since investment in small-scale pump irrigation is a strategic investment, with costs and returns spread out over many years, it is necessary to study the schemes over their entire life span.

This study, therefore, aimed at evaluating the profitability of investment in small-scale irrigation based on small motor-driven pumps, with particular reference to Bauchi state of Nigeria. The specific objectives of the study were to:

 determine the costs and returns of crop production under the pump irrigation system;.

 estimate the net present value (NPV) and the internal rate of return (IRR) on investments in the systems;

(3) identify the constraints to increased returns under the systems; and

(4) derive from the result of the study, implications for policy and research and extension work on small-scale irrigation development in the country.

METHODS OF DATA COLLECTION AND ANALYSIS

The study area

The study area is the Western Zone of the Bauchl State Agricultural Development Programme (BSADP). This Zone, as at the time of this study consisted of four Local Government Areas (LGAs), namely, Bauchl, Dass, Tafawa-Balewa, and Toro LGAs, and had an estimated population of 483,878 people. Annual

pumps are used to lift water from the streams, ponds, streams, along the flood plains, which some smallseven months during which little or no rainfall is mm, with a duration of about five months (usually beginning in May and ending around October)(BSADP, wells, and more recently, from scale farmers use to irrigate their plots. Motorised received. The area is, however endowed with a few rainfall in the area ranges from 1,000 mm to 1,300 pepper, eggplant and onion. grown are This leaves a period of dry season of about mostly vegetables, including washbores. tomato,

Data collection

Data collected were of two types. The first set of data were the "fixed point" and/or "registened" information which were not expected to change during the research period. They included information on size of households, and type, number, age and value of tools and equipment used in irrigation farming:

at home or given out as gifts, quantity sold, prices received. and June 1988 by four enumerators stationed in the means of observations and interviews using a structured scale pump irrigation and accessibility. villages was based on their relative prominence in small-Balewa LGA and Dass in Dass LGA. The selection of the to use pump for irrigation. The villages selected were Juga Data were collected from forty-five farmers in four villages cost of repair, as well as expenditure on fuel and lubricant. cost of transportation, frequency of pump breakdown and application, quantity of crops harvested, quantity consumed fertilizers used on each plot; frequency and length of water category were type, quantity, source and cost of seeds and persons involved. Other types of data included in undertaken, wages paid and number, sex, and hours of family labour and non-family labour input, tasks registered" types which included input-output data such as selected villages throughout the survey period questionnaire, was undertaken between December 1987 and Tundunwada-ribina, in Toro LGA, Dajin in Tafawaselected purposively to include only those that were known The second set of data were the "continuous" and "non-Data collection, by age of this

The analytical model

The data collected were analysed using a net farm income (NF) model to determine the costs and returns of pump irrigation farming projected over a five year period, 1988-1992. These costs and returns formed the basis for estimating the NPV and IRR of investment in pump irrigation. The NPV was defined as:

$$NPV = \left(\sum_{t=1}^{5} A_{t} (1+i)^{-t}\right) \cdot C \dots (1.0)$$

while the IRR was obtained by solving the following equation for: γ :

where:

net returns for period "t",

- c = initial investment in pump irrigation (defined as cost of capital items such as pumps, water hoses, washbores, hoes, cutlasses, etc., which the farmers needed to begin irrigation in 1988).
- t = time periods in years (t = 1, 2.....5), and
- Internal rate of return.

Assumptions

To facilitate data analysis, the following assumptions were made:

- The cost of pump, washbore, water hose, cutlasses, and hoes, together, constituted the initial investment requirements for dry season farming using motorised pumps.
- While pumps and washbores have a life span of 5 years water hoses, hoes and cuttasses were assumed to last only 3 years.
- (3) The costs of production increased at an annual rate of 49.27%, while returns increased at an annual rate of 25.74% (FOS, 1990; Baba et al., 1990).
- (4) The discount factor was 19.50%, which was the ceiling lending rate in 1988 (CBN, 1988).
- The first year of investment is 1988, which was when the survey was conducted.

RESULTS AN DISCUSSION

Costs

The estimated costs for the 1987/88 season are presented in Tables 1 and 2. The total variable cost was 3,601.76/ha (Table 1). However, about 65% of this was accounted for by unpaid family labour. When hired labour was included, labour input accounted for about 71% of the variable cost. This result identifies labour as the single most costly input in operating an irrigated farm. This situation is not unexpected since all farm operations, including land clearing, ploughing.

Table 1: Variable costs under pump irrigation for the 1987/88 season.

Item of cost	Amount (N/ha)	% of total variable cost
Seeds	182.78	5.08
Fertilizer	207.33	5.76
Repairs and maintenance	122.70	3.41
Fuel	245.65	6.82
Hired labour	225,45	6.26
Family labour	2,358.85	65.49
Marketing and others	258.70	7.18
Total variable costs	2,601.76	100,00

marketing were relatively low. In .this study, initial fuel, repairs and maintenance, fertilizer, seeds, and accomplished through manual labour. The levelling, channel construction, planting, costs of the above-listed items were depreciated over their useful life using the straight line method, (89.96%) of the initial investment was accounted for by pump, while washbore, water hose, cutlass and dry season farming using small motorised pump. capitals items which a farmer may require to begin unit of pump, water hose, washbore, and hoe and investment was defined as the acquisition costs of a assuming zero salvage value (Table 2). To obtain the fixed costs attributable to 1988, the hoe constituted 6.82%, 2.09%, 0.84%, Data in Table 2 show that the major proportion in 1988. These constitute the digging of wells, and harvesting, were respectively weeding, durable cost of

and, indeed, the washbores, dried up midway into the season and irrigation was barely sustained through manual digging and re-digging of shallow wells in the river beds. Labour for digging of wells was mostly supplied by the farmer and family rembers. This tended to increase family labour input which explains the low NPV in this village, when family labour was costed. The severe water shortage also reduced yields, culminating in low returns in the area.

The situation was, however, remarkably different

returns in the study area wide margin, Thus, the IRR, when family labour was costed, did not exceed the cost of capital of 19.50% (in 1988) by a costed, and 159% for the average farmer, when family labour was The IRR on investments was found to be 24% and income group, when family labour was costed compared to only 13% of farmers falling into this farmers obtaining an NPV of N20,000.00 or more, as NPV was N15,582.64/ha with more than 33% of the when family labour was not costed. In this case only 11% of the farmers produced at a loss. The average when ₩hich it was not costed, respectively further underscores the WO

boreholes and tubewells would be more reliable than washbores which easily dry up. The erection of small-scale dams could also enhance water availability in subsidised rates, for some of the farmers, the effects of this effort was not felt because most of the it would be considered that as far as ground water washbores dried up in the dry season. In view of this, Development Project (BSADP) sank washbores, season irrigation, government would have to go beyond providing only pumps to farmers at subsidised rates, and provide also reliable sources of water for dry digging of wells would become unnecessary consumption and production costs reliable the area. It should also be noted that availability of development strategy is concerned, the water farming. sources Bauchi Mould State reduce since manual Agricultural go beyond sinking iabour 2 9
