General low fertility status of soils in the tropics is highly related to the low level of organic matter, rapid depletion of nutrients and poor physical condition of the soil as one of the major constraints to crop production (Agbede and Adekiya, 2009; Okonkwo *et al.*, 2011). Intensively cropped soils are prone to deterioration in soil physical properties with the following resultant effects: increased soil bulk density, reduced porosity, high root penetration resistance, low water holding capacity, low soil water content, reduced soil aggregation, increase in sand and silt fractions over clay fraction, leaching and erosion when compared to the uncultivated state of the soil (Mehdizale *et al.,* 2013). Application of organic fertilizer helps to improve soil structure, water holding capacity, porosity, bulk density, moisture retention and eventual growth and yield of crops (Atakora *et al.,* 2014). The decline of soil organic matter with cropping is a major factor affecting sustainability of many cropping systems in sub-Saharan Africa (Buyanovzky *et al.,* 1984). Studies also indicated that soil physical, biological and chemical properties can sustainably be improved through the improvement of soil organic matter (Usharani *et al*., 2019). This can be done through practices like mulching and addition of manures (Du *et al*., 2022).

Mulching is an effective method of manipulating crop growing environment to increase yield and improve product quality by controlling weed growth, ameliorating soil temperature, conserving soil moisture, reducing soil erosion, improving soil structure and enhancing organic matter content (Iqbal *et al*., 2020). Ginger (*Zingiber officinale* Roscoe) is of the family Zingiberaceae, it is indigenous to the warm tropical climates, particularly South eastern Asia. It is a monocotyledon with a slender perennial herb-like habit, but is usually grown as an annual. It is an erect plant propagated through its rhizomes which are underground. Ginger is an important spice used as a condiment in vegetable preparations. Ginger tea is also used as a carminative and in the symptomatic treatment of colds. The oil and oleoresins obtained from ginger are also used in many food items, soft drinks and beverages (Singh *et al*., 2008). Ginger is basically considered to thrive best on rich medium loams with good supply of humus. High humidity throughout the crop period is necessary. According to Ojeniyi (1995) and Agboola *et al*., (1992), soils in Nigeria suffer deficiencies common to tropical soils. These include low organic matter content, shallow depth and high acidity. About 63% of the agricultural soils in Nigeria are low in productivity and over 90% are Alfisols and Ultisols that are low in organic matter and have low activity clays. There is therefore the need to identify the best rate of organic fertilizer and the level of mulch suitable for ginger production with the ultimate aim of improving its productivity.

MATERIALS AND METHODS

The experiment was conducted at National Horticultural Research Institute, Ibadan (7° 30'N, and 3° 54'E; in an altitude of 234 m above sea level), Oyo State. Ibadan is located in the derived savannah agro-ecological zone. The soil is well drained with fine to coarse texture and brown in colour. It is a sandy loam of basement complex origin in the Ibadan series (Smyth sand Montgomery, 1962) and of the order Alfisol (Askira, 2000). The experimental design used was a split plot design consisting of three levels of mulch as main plots and organic fertilizer treatments as subplots replicated three times. The three different levels of mulch and organic fertilizer were randomized within each replicate main plot. The plot size was 2 m x 2 m. Ginger was planted at a spacing of 20 cm x 25 cm to a depth of 4 - 5 cm. Three levels of mulch employed were 0, 15 and 30 t ha^{-1} and five different rates of organic fertilizer were 0, 10, 15, 20 and 25 t ha^{-1}. The three levels of mulch and five rates of organic fertilizer resulted in 15 treatment combinations. Pre-soil and organic fertilizer analyses were presented in (Table 1 and 2). The annual rainfall was 1680.6 mm. The monthly maximum temperature ranged between 28 – 36 ^{O}C while minimum temperature ranged between 22 – 36 ^{o} ^{O}C

The gravimetric method as reported by Donahue *et al*., (1990) was used for soil moisture content determination. The soil was sampled (using screw auger) in each plot at 4, 8, 12, 16 and 20 weeks after planting at 0 - 15 cm depth of soil and put into container, oven dried at temperature of 105 ºC to a constant weight. Core sampler method as reported by Blake and Hartage (1986) was used for soil bulk density analysis. The soil was sampled using core sampler in each plot at 4, 12, and 20 weeks after planting at 0 - 15 cm depth. Soil samples were oven dried at temperature of 105 ºC to a constant weight. The core size was 7.0 cm in diameter and 6.5 cm in height.

Bulk density was determined using Equation 1

$$\text{Bulk density} = \frac{\text{Soil mass oven dried}}{\text{Soil volume}} \quad (1)$$

Volume of soil sample = Volume of the core (cylinder)

$$= \pi r^2 h$$

Where r = inner radius of the cylinder

h = height of the cylinder

Soil porosity was determined at 4, 12, and 20 weeks after planting using Equation 2

$$TP = \left[1 - \frac{BD}{PD}\right] \times 100 \quad (2)$$

Where TP = Soil total porosity, BD = Soil bulk density, PD = Particle density (2.65 g cm^{-3})

Soil water filled pore space was calculated at 4, 12 and 20 WAP using Equation 3

$$\text{Soil water filled pore space (\%)} = \frac{\text{Volumetric water content}}{\text{Soil porosity}} \times 100 \quad (3)$$

Data were analysed and subjected to analysis of variance using linear model procedure of statistical analysis system (SAS, 2003). Mean were compared using the Duncan's Multiple Range Test (DMRT) at 0.05 level of probability. Correlation analyses were run between the soil physical properties and ginger yield for the cropping period following the procedures of Steel and Torrie (1960).

RESULTS

Soil bulk density was significantly affected by levels of mulch at various weeks after planting. Four weeks after planting, control (0 t ha^{-1}) had the highest mean value of 1.62 g cm^{-3} and 30 t ha^{-1} of mulch gave the least mean value of 1.56 g cm$^{-3.}$ There was significant difference ($P < 0.05$) in levels of mulch at 20 WAP with control also having highest value of 1.79 g cm^{-3} and 30 t ha^{-1} of mulch gave the least value of 1.62 g cm^{-3}. Application of organic fertilizer at different levels had significant effect on soil bulk density at various weeks after planting. Significant difference was observed among organic fertilizer rates with 0 t ha^{-1} having highest mean value of 1.83 g cm^{-3} and 25 t ha^{-1} organic fertilizers had least mean value of 1.61 g cm^{-3} at 20 WAP. The interaction of mulch and organic fertilizer had no significant effect on soil bulk density at 4 WAP and 12 WAP while significant difference was observed in interaction of mulch and organic fertilizer at 20 WAP (Table 1). Table 2 showed the combined effects of levels of mulch and rates of organic fertilizer with plot without mulch and organic fertilizer application having the highest mean bulk density value of 1.78 g cm^{-3} while mulch at 30 t ha^{-1} and organic fertilizer at 25 t ha^{-1} had the least value of 1.58 g cm^{-3}.

Soil porosity was significantly affected by different levels of mulch and organic fertilizer rates. At 4 WAP there was no significant difference between the levels of mulch at 15 t ha^{-1} and at 0 t ha^{-1} on soil porosity. Also, at 12 WAP, there was no significant difference observed between the levels of mulch at 30 t ha^{-1} and at 15 t ha^{-1} on soil porosity. At 20 WAP significant differences were observed among the levels of mulch with 30 t ha^{-1} mulch treatment having the highest value of 38.90 % porosity. There was significant difference ($P < 0.05$) in organic fertilizer rates applied on soil porosity at various weeks after planting with 25 t ha^{-1} organic fertilizer having the highest value of 39.30 % porosity. Moreover, mulch and organic fertilizer interaction had no significant effect on the percentage soil porosity at 4 WAP and 12 WAP, but significant interaction was observed at 20 WAP (Table 3). Mulch applied at 30 t ha^{-1} and organic fertilizer at 25 t ha^{-1} had the highest porosity value of 40.11 % while plot without mulch and organic fertilizer application had the least mean value of 33.04 % (Table 4).

Soil moisture content was significantly affected by levels of mulch and organic fertilizer treatments with 30 t ha^{-1} of mulch treatment and 25 t ha^{-1} of organic fertilizer having the highest mean values of 13.49 % and 13.48 % respectively at 12 WAP while 0 t ha^{-1} mulch and organic fertilizer gave the least mean value of 12.19 % and 12.20 % respectively at 12 WAP. At 20 WAP 30 t ha^{-1} of mulch and 25 t ha^{-1} of organic fertilizer had the highest value of 2.26 % and of 2.46 % respectively. A gradual decrease in soil moisture was observed from 12 WAP to 20 WAP. Moreover, mulch and organic fertilizer interaction had no significant effect on the soil moisture content (Table 5). Ginger mean yields were significantly difference ($P < 0.05$) among the levels of mulch and rates of organic fertilizer applied. Mulch applied at 30 t ha^{-1} had the highest rhizome yield mean value of 7.16 t ha^{-1} and least value by the control. Organic fertilizer treatments had a significant effect on the rhizome yield. Significant mean yield differences were observed among ginger plants fertilized with 25 t ha^{-1} organic fertilizer and organic fertilizer applied at 25 t ha^{-1} that gave highest rhizome yield of 6.91 t ha^{-1} while 0 t ha^{-1} of organic fertilizer recorded the least value of 4.73 t $ha^{-1.}$ Mulch and organic fertilizer interaction had significant effect on the rhizome yield (Table 6). Table 7 shows the combined effect of levels of mulch and rates of organic fertilizer with mulch at 30 t ha^{-1} and 25 t ha^{-1} organic fertilizer treatments having the highest yield mean value of 8.30 t ha^{-1} and mulch at 0 t ha^{-1} and organic fertilizer at 0 t ha^{-1} gave the least yield mean value of 2.60 t ha^{-1}. Table 8 shows the correlation coefficients of the relationships between soil physical characteristics and yield. Yield had significantly negative correlation with soil bulk density and was significantly correlated with soil moisture content and soil porosity.

DISCUSSIONS

The significant differences observed in bulk density as a result of mulching treatments at 4 - 20 WAP could probably be associated with the achievement of crust elimination, improvement in surface aggregation and improved microbial activities thus improving the bulk density, total porosity and the infiltration capacity of the soils (Luna *et al*., 2017). The highest value of bulk density (1.79 g cm^{-3}) recorded at 0 t ha^{-1} of mulch could be attributed to the direct impact of raindrop on the soil which led to the reduction and eventually blockage of soil pores and crust formation. Organic fertilizer at 25 t ha^{-1} produced lowest bulk density (1.71 g cm^{-3}) as compared to the soil with 0 t ha^{-1} organic fertilizer (1.83 g cm^{-3}). These results obtained were similar to what was reported by Erdal (2012) who observed a relation between organic matter and bulk density and showed strong correlation between them. The significant differences observed in the case of soil moisture content could probably be attributed to the beneficial effects of mulch and organic fertilizer treatments which were due to several interacting factors, including improvements in soil quality and resilience. Mulching decreased the rate of decline of soil structure by improving soil moisture and temperature regimes (Lal, 1986), stimulating activity of soil fauna, and decreasing runoff and soil erosion. This is supported by the findings of Kumar (2020) who reported improved structural stability, lower bulk density and improved soil moisture properties with the addition of organic matter.

Furthermore, the significant differences shown in porosity at various weeks after planting could probably be attributed to the surface factors such as soil crust and mulch interact very highly with rainfall characteristics of an area to determine infiltration of water into the soil and this depends on the micro and macro porosity of the soil. The least value of percentage porosity recorded at 0 t ha^{-1} of mulch treatment was attributed to compaction resulting from crust formation that led to the blocking of micro and macro pores dues to direct impact of raindrop. The significant difference observed in ginger yield as a result of mulching and organic fertilizer treatment could probably be associated with the improved soil structure, soil organic matter and soil aggregation, lower bulk density and higher porosity, decreased soil pH and improved soil moisture properties and favourable nutrient status. Mulching improves plant growth, yield and yield quality (Singh *et al.,* 2007). This observation agrees with the findings of Cotching *et al.,* (2002) who stated that ginger is a heavy feeder of nutrient therefore needed proper application of mulch and organic fertilizer to ensure proper yield.

The relationship of some soil physical properties with yield showed that yield was strongly negative correlation with the bulk density, but with strong positive correlation with moisture content and total porosity. Hence, the factors which largely determined the performance of a crop are moisture content, bulk density and porosity of the soil. This association of yield with some soil physical properties was reported by Sainju *et al.,* 2022)

CONCLUSION

Mulching and organic fertilizer treatments influenced soil physical properties and ginger yield. Therefore, mulching and organic fertilizer are imperative in assessing or evaluating some soil physical properties. The combination of both mulch and organic fertilizer either at 30 t ha^{-1} of mulch and 25 t ha^{-1} of organic fertilizer followed by 30 t ha^{-1} of mulch and 20 t ha^{-1} of organic fertilizer and followed by 15 t ha^{-1} of mulch and 25 t ha^{-1} of organic fertilizer better-improved moisture content, lower bulk density and high total soil porosity and gave better yield when compared with either mulching and organic fertilizer used separately. However, the use of mulch at 30 t ha^{-1} and 25 t ha^{-1} of organic fertilizer was recommended.

ABSTRACT
The tomato industry is a significant player in the global as well as the Nigerian agricultural landscape. The adoption and utilization of technologies can be gender-biased, affecting women's access to resources, market opportunities, and decision-making power. This study examines the adoption and impact of various technologies on women's participation in various stages of the tomato value chain. This study analyzed the percentage losses, hotspots for losses and technologies adopted by stakeholders to reduce tomato post-harvest. losses in Nigeria. Through a comprehensive stakeholder interviews and mapping, this study explores the complex interplay between post-harvest technologies, gender roles, and women's socio-economic empowerment within the tomato value chain. By identifying barriers and enablers, the study further seeks to inform strategies and policies that foster inclusive and gender-responsive growth, empower women, and promote sustainable development in the tomato industry.
***Keywords**: technology, gender, tomato value chain, women empowerment, Nigeria.*

INTRODUCTION

In Nigeria, tomato is an economic and political crop and is consumed in every household in the country as an important part of the daily diet. Estimated potential production yield is relatively high, at about 20-25mt/ha. There exist a large domestic and regional market (unmet) demand for tomatoes in the country and Nigerians alone consume an estimated 2.3 million tonnes of tomatoes annually. High rate of post-harvest losses is however experienced throughout the tomato value chain of Nigeria. In its 2019 State of Food and Agriculture report, FAO emphasised the importance of gender-sensitive approaches to food loss reduction, stating, 'interventions to improve women's standing and decision-making power in the consumption and sale of household production may help reduce food losses' (FAO,2019, p. 79). In many agricultural contexts, gender disparities exist, with women facing unique constraints and limited access to resources and decision-making power. Such inequalities are also prevalent within the tomato value chain. Even as women play an outsized role in the post-harvest handling and processing stage of the value chain, where considerable food loss occurs, they may also be at higher risks of experiencing high post- harvest loss due to lower access to resources and information as well as lower ability to adopt loss-reduction technologies. These dynamics are also context specific.

Women face constraints when adopting post-harvest reduction technologies as they may have different preferences for Post Harvest loss (PHL)-reduction technologies than men (SDC,2015, Theis et-al, 2017), but the technology design process often does not include the voices of women or prioritizes those of men. These dynamics have potential implications for technology adoption. And because losses occur throughout the value chain, achieving a major reduction in loss levels would require such technologies to be adopted, where relevant, throughout the value chain—e.g., in the warehousing, cold storage, logistical, wholesale, processing, and retail services that link farms to consumers (AGRA, 2018). There are numerous techniques and technologies for reducing post-harvest loss levels. These ranges from simple solutions such as reusable plastic crates for storing and transporting fresh fruits and vegetables, which can significantly lower levels of loss—for example, from 40% to 5% in studies in Nigeria (Kok et-al 2019) and from 15-20% to 4-5% in research in India (WEFORUM, 2014). They also include those that are more technologically complex, such as, processing technologies, or refrigerated trucks and cold-storage rooms. However, gender norms and stereotypes often restrict women's participation in certain activities, such as transportation.

The decision to deploy these potentially impactful interventions, is generally made by individual farmers, entrepreneurs, or business owners within a supply chain. As such, it is important to consider these actors' needs, preferences, and constraints, as well as the relationships between them. These actors comprise both men and women, interacting with one another and embedded within larger social structures that are not necessarily gender neutral—making gender issues relevant to consider. Lack of access to financial services, technology, and training further exacerbates gender-based constraints. Addressing these challenges requires a gender-inclusive approach that empowers women, promotes their participation, and provides equal opportunities throughout the tomato value chain. By integrating gender perspectives and ensuring women's active involvement, the value chain can become more inclusive, equitable, and economically viable. This study is an attempt to contribute to existing studies on gender and post-harvest losses in the tomato value chain in Nigeria and how to mitigate the losses.

METHODOLOGY

Method of Data collection: The data for the study was collected from both primary and secondary sources. Secondary data and information were collected from desk reviews of published literatures and primary data collected with the aid of semi-structured questionnaires, Key-informant interview (KIV) and Focus Group Discussion (FGD)

Sampling procedure: One hundred and seventy-five (175) key actors in tomato value chain actors. a total of 93 value chain actors from the North (Kano and Kaduna states) and 82 from the Southern States of Oyo, Ogun and Lagos were purposively selected for the study. Data collection was done with the use of semi-structured questionnaires. Key informant interview was conducted on one-on-one on basis while Focus Group was used in eliciting information on gender roles within the chain. Tomato farmers, processors, marketers' as well as transporters were the major stakeholders identified and interviewed in this study.

Method of Data Analysis: The data was analyzed using descriptive statistics**.**

RESULTS AND DISCUSSION

Women are often less involved than men in cooperatives and other professional networks; this can further limit access to processing facilities, technologies, and markets, exacerbating PHL (FAO,2019). Women's limited access to assets and financing (Quisumbing et-al, 2014) may also make them less able to adopt PHL-reduction technologies (IFC,2016). It can also limit access to knowledge and social capital, which facilitate technology adoption. Women also generally have lower access to high-quality storage facilities and technologies, which can result in more damage and loss (IFC,2016).

Table 1: Socioeconomic characteristics of Respondents

Characteristic	F (%)				F (%)			
	North				South			
	Farmer	Marketers	Processors	Transporters	Farmer	Marketers	Processors	Transporters
Sex								
Male	45(91.8)	9(64.3)	9(69.2)	17(100)	66(83.5)	18(90.0)	20(66.7)	17(100)
Female	4(8.2)	5(35.7)	4(30.8)	0(0.0)	13(16.5)	2(10.0)	10(33.3)	0(0.0)

Primary	4(8.2)	4(28.6)	4(30.8)	2(11.8)	11(13.9)	0(0)	0(0)	2(11.8)
Secondary	28(57.1)	6(42.9)	6(46.2)	0(0)	12(15.2)	10(85.0)	15(50.0)	5(29.4)

Source: Field survey, 2023

Table 1 describes the sex and educational status of tomato value chain actors in the study area. The results show that there are more male tomato farmers in the north (91.8%) than females. These variables have implications on technology adoption as well as post-harvest practices. There are also more male marketers and processors in the north and the transporters are all males. This distribution shows the gender roles in the region as male involvement in the tomato value chain is more is higher than those of the females. In the south, there are also more male farmers than females, but female (90%) marketers are more. There are also more male processors than female ones and all the transporters are males. With respect to educational status, tomato farmers, marketers and processors in the north have primary and secondary school education in addition to Qur'anic education. In the south, all actors have secondary school education with marketers having the highest number (85%) of educated members followed by processors (50%).

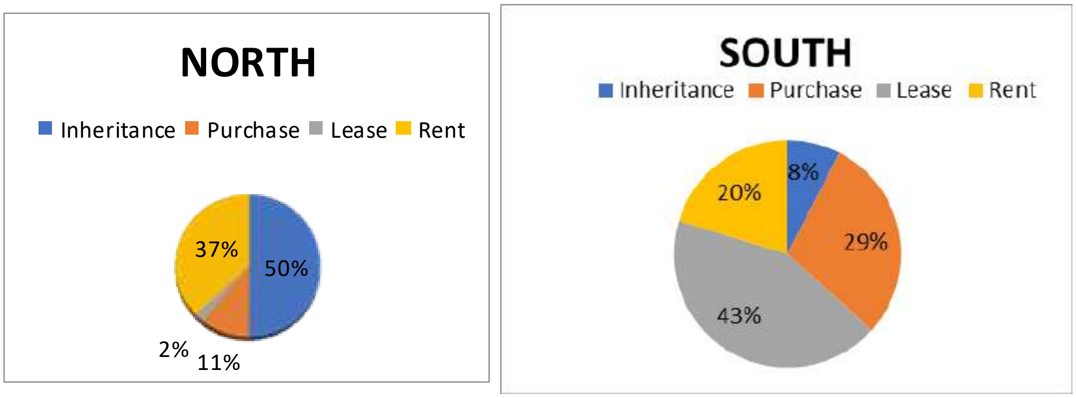

Figure 1: Land ownership structure among tomato farmers
Source: Field survey, 2023

Land is a very important input of factor of production in agriculture. The land ownership structure of tomato farmers is the study areas is as shown in Fig.1. In the northern states of kano and Kaduna, land purchase and leasing is not so common as most (50%) farmers acquired their farmland through inheritance and rentage (37%). This is perhaps one of the reasons, among other factors why the bulk of tomato comes from the north as land is readily available. This form of ownership structure also allows for some relative degree of freedom on production decisions as well as adoption of technologies. However, in the southern part of the country, ownership of land by inheritance is very small as only 8% of farmers cultivate on inherited land. Thus, land used for agricultural activities is acquired through leasing (43%), purchase (29%) and rentage (20%). Most of the land is being used for housing or companies as these states in the south are peri-urban or urban. So, the lands are only released and made available for agricultural activities in the short and medium term only. Thus, the production of tomatoes in the south is relatively small when compared with the quantity of tomatoes from the northern part of Nigeria. In addition, women's ownership of land also typically lags far behind that of men (Doss et-al ,2018), which may make them less willing or able to invest in PHL-prevention equipment or practices**.**

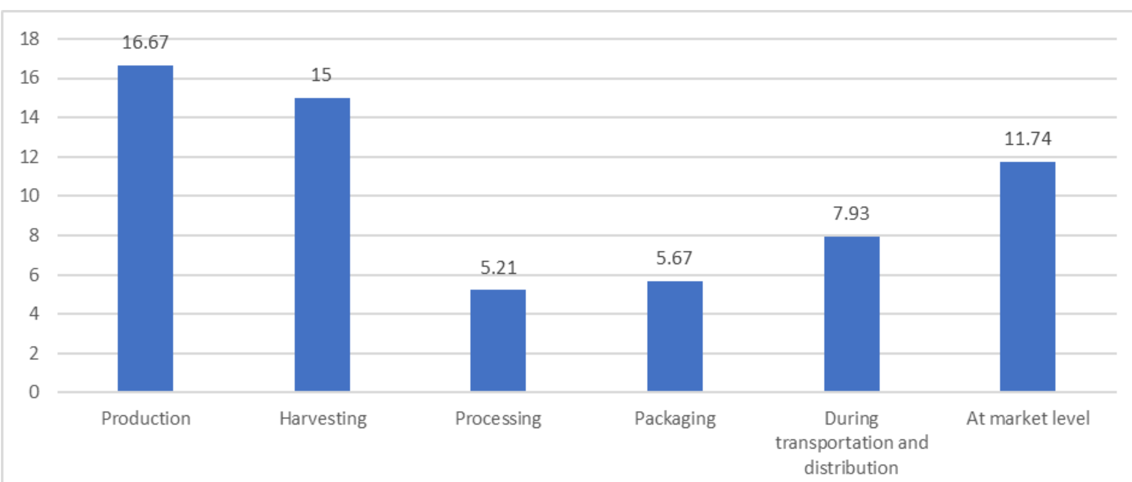

Figure 2: Post -harvest Loss Hotspots in Tomato Value Chain
Source: Field survey, 2023

Tomato post-harvest hot sports is captures in figure 2. Losses in tomato is highest at the farm/production and harvesting stages. This is probably due to poor production and management problems. The method of harvesting could also result in losses as tomatoes are vegetable fruits with delicate skin coat that gets easily damaged when not properly handled. The losses at the market level are also relatively high. Damages at this stage could be from mechanical injury during loading /offloading. Tomato losses at the market also emanates be from poor packaging materials, poor storage facilities at the market store for preserving unsold tomato fruits, amongst other constraints.

During transportation and distribution, losses are also experienced. Delays in delivery due to bad roads and long queues at destination markets all contribute to tomato fruit losses as highly perishable vegetables. Finally, some losses are experienced during value addition in the form of processing and packaging. The method of processing is still majorly rudimentary or traditional; sorting, grading, drying by sun drying. Only a few processors use solar for drying tomatoes. The few tomato processing companies are currently out of operation due to inadequate fruits to feed the plant as farmers prefer to take their produce to the local markets where they get premium prices. This analysis further reveals that there are more women than men in those value chains where post-harvest losses occur. These include harvesting, processing, packaging and at the marketing stage. With respect to production, there are more men, and there are no women involved in the transportation of tomatoes.

Figure 3: Awareness on different PHL technologies on mitigating tomato loss
Source: Field survey, 2023

The level of awareness, among value chain actors, on measues to mitigate tomato losses is captured in Fig. 3. In the north , there is general awareness amongst all actors. Awareness is relatively high among farmers(63,3%) , Marketers (50%)and 41% among transporters. The processors are least (38.5%) aware of tomato losses mitigation intervention. In the north, there are more males than females in all the value chains except in processing where women are more. And this value chain with more women is where awareness on loss mitigation techniques and technology is the lowest. The implication is that tomato women processors in the north may continue to experience more losses unless their capacity is built-up. However, in the south, awareness levels on tomato losses interventions programmes is highest amongst markerters, who are mostly women and this is followed by processors and farmers. Thus, women tomato marketers are more informed about mitigation measures that can be deployed to prevent losses.

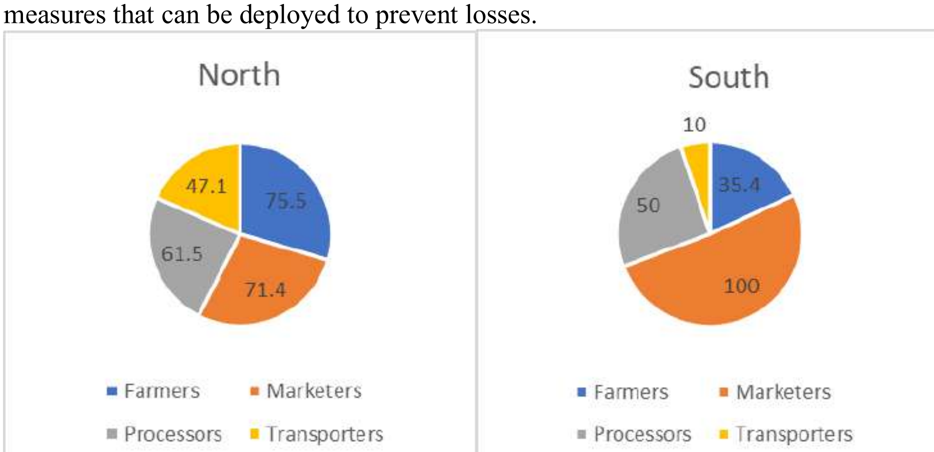

Figure 4: Participation in Tomato Post-harvest Programs/Intervention
Source: Field survey, 2023

In Fig 4, the rate of participation of value chain actors in tomato-post harvest programs is analyzed. Participation rates are generally high in the north among farmers, marketers, processors as well as transporters. This is probably because huge tomato production is done in the north. Similarly in the south, participation in post -harvest programs are highest among tomato marketers since they are the most informed about the various tomato mitigation measures. This is followed by processors and then farmers. Transporters of tomatoes in the south participate in the least at post-harvest programs.

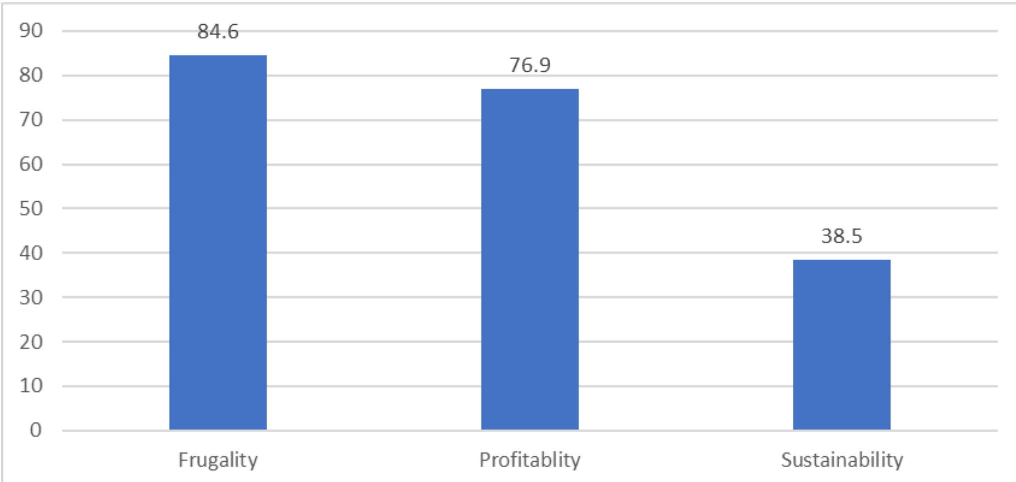

Figure 5: Electricity powered cold room.
Source: Field survey, 2023

Fig 5. represents the opinion or perception of processors on the use of electricity powered cold room as a post-harvest technology. The technology is affordable (provided there is power supply from the national grid), which would make it is both economical and affordable(frugality), and because it will be profitable, but the sustainability of the technology is not guaranteed because of the erratic power supply of electricity which is still a major problem in the country.

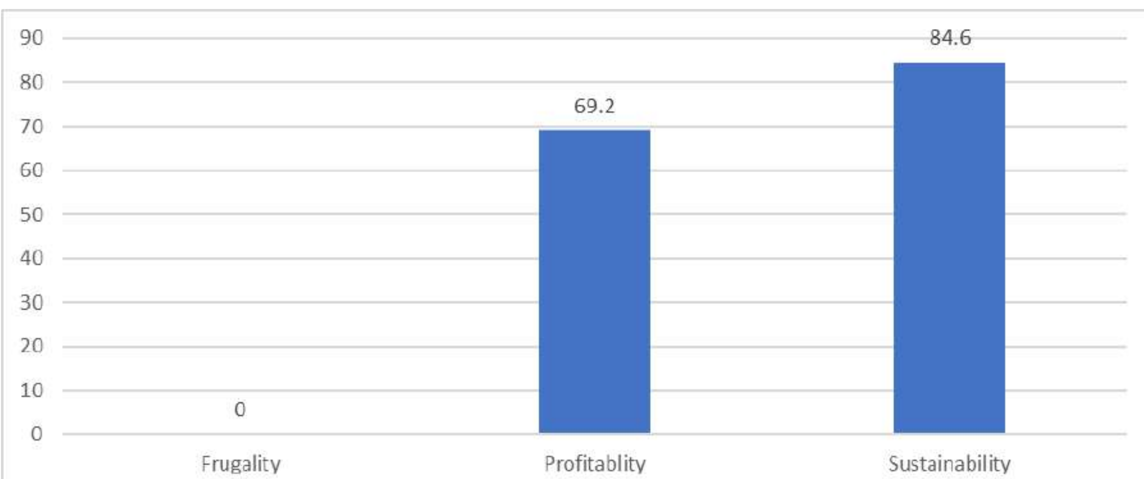

Figure 6: **Solar powered cold rooms**
Source: Field survey, 2023

The perception of processors on the use of solar -powered cold room is captured in fig 6. The processors opined that this technology may not be affordable even as they believe it is a profitable technology which can stand the test of time. That is, it is sustainable.

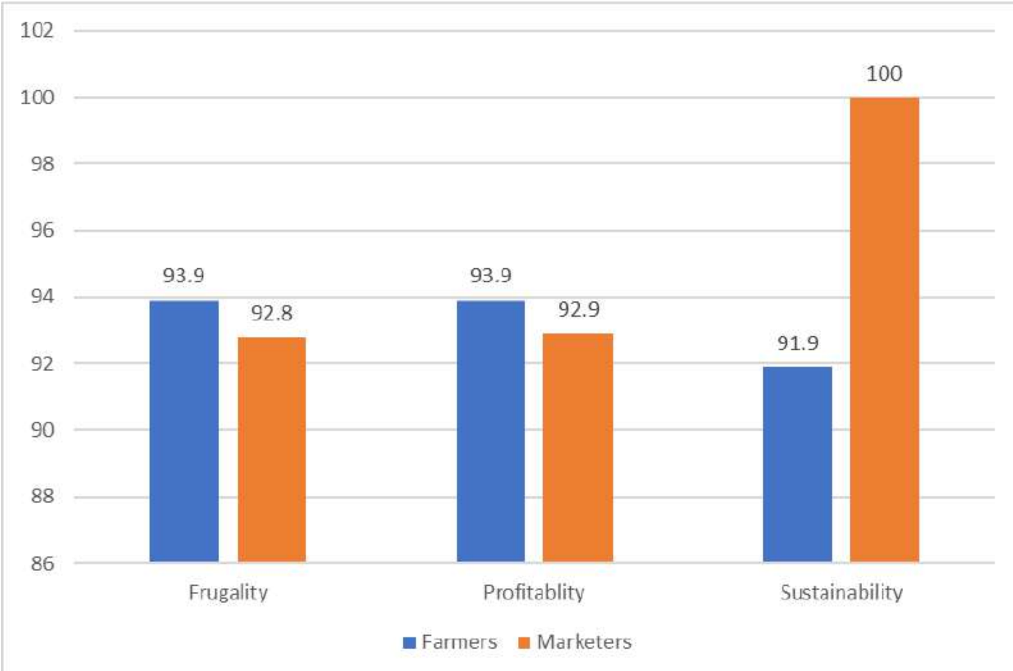

Figure 7: Plastic Crates
Source: Field survey, 2023

The use of plastic trays as an improvement over the raffia baskets used in packing and transportation of tomato was examined. The view of farmers and marketers who use these trays is shown in fig.7. Both actors find the use of plastic rates economical and affordable, improves profitability and the technology is also believed to be a sustainable one.

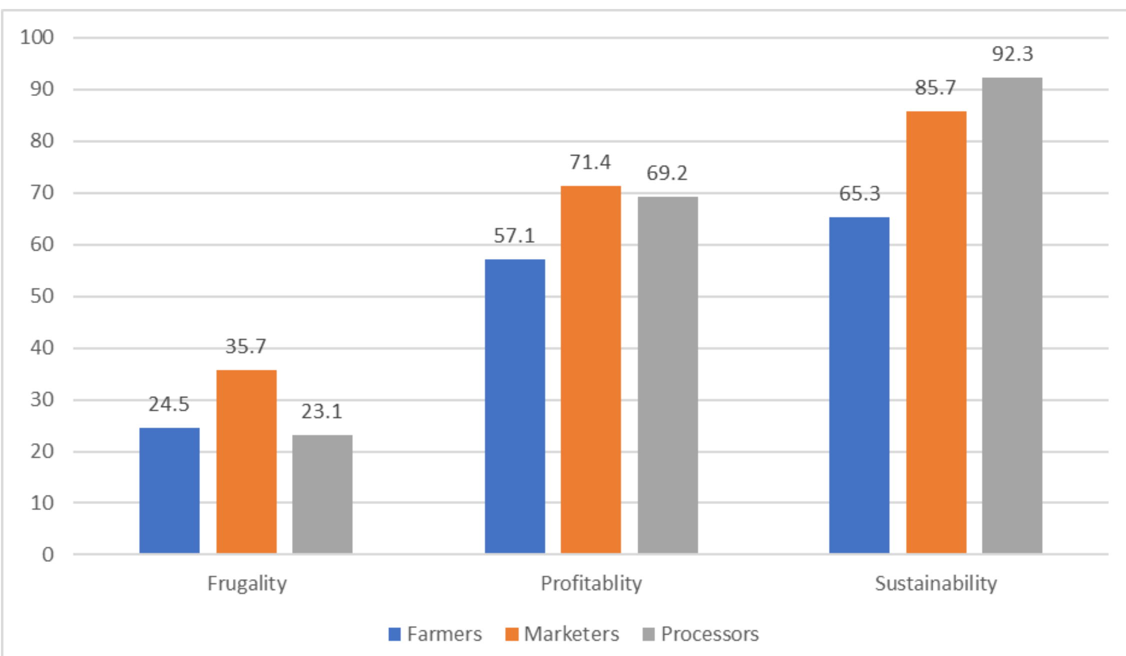

Figure 8: Solar dryer

Fig.8 captures the use of solar dryer as a post-harvest technology in tomato. Farmers, marketers, and processors all believe that the technology is relatively affordable, highly profitable, and sustainable. The technology is particularly good and accepted in the northern part of the country when there is a longer higher of sunlight for most part of the year.

CONCLUSION AND RECOMMENDATION

In addition, gender inclusive strategies such as giving financial support to assist in the acquisition of machinery used in improved production and value-added processing be put in place. Post-harvest loss interventions should be designed based on an understanding of the local gender context, in partnership with women, and with an eye to increasing their empowerment. It is pertinent to also promote capacity building/ training on handling post - harvest losses along the value chain particularly at farm level and processing sites as well as marketplaces.

ABSTRACT
A field experiment was conducted between May and August, 2022 to assess the economic production of tomato fruit in Dan-daura village, Kauru L.G.A in Kaduna state (Lat. 10.69^0, Long. 8.05^0). The objective of the study was to identify the economics of tomato production in the area with the view to ensure its profitability or otherwise. Land was prepared for nursery and seeds planted on 11th April. Seedlings were transplanted between 4th and 7th May, 2022. Harvestings carried out between 30th July and 25th August, 2022. The Input-Output Benefit analysis revealed that, the venture produced a favourable Benefit Cost Ratio (BCR 2.4:1) indicating that every naira invested in the production yielded # 2.40 within the production period. It is therefore recommended that farmers interested in tomato production the area should engage between April / May up to August, as its production cost is low and the selling price is higher as such attracts higher profits.
***Keyword**: BCR, Input-Output: Benefit Analysis*

INTRODUCTION

Tomato (*Lycopersicon lycopersicon L.*) belongs to the family solanaceae, genus Lycopersicon, subfamily Solanaideae and tribe solanaeae where pepper, potato, tobacco and eggplant belong (Habu, *et al*, 2016). It is the second most important remunerable solanaceous vegetable crop after potato. FAO (2009) reported that tomato is a native to South America and widely cultivated in 140 countries of the world with an annual production of 150 million tons. Shobo *et al* (2014) stated that, it is the most important and popular commercial vegetables grown in the tropics and could be grown in green houses as well as in open fields. In global perspective, the major producing countries of tomato are USA, China, Egypt, Turkey and India, with an average yield of 92.42t/ha, 56.86t/ha, 42.25t/ha, 41.89t/ha and 22.83t/ha respectively (FAOSTAT, 2013).

Twanya, et al (2017) was introduced to West Africa and Nigeria in particular at the end of the 19th century. In Nigeria however, the producing area of tomato lies between lat.7.5^0 11^1 and 13.0^0 N and within a range of temperature of 22-30^0C .The average yield there was estimated at 6.34t/ha which is very low compared to the global yield (FAOSTAT, 2013). Tomato crop is very important in terms of diet and economy in Nigeria both the rain fed and irrigated crops. It is currently considered to be one of the main vegetable crops in the world, and constitutes the income of main growers (Omar, 2005). The large scale tomato is grown in Northern Guinea Savannah of Nigeria, where relatively high yield could be realized by planting between June and December. However, planting between March and May results in low yield that cannot sustain demand. Olaniyi *et al* (2010) reported that the low tomato production in Nigeria is due to the differences in crop environmental conditions, lack of high yielding varieties and cultural practices applied to the crop. The bulk of its production is from dry season particularly in Northern states. However, NIHORT (undated) opined that, tomato requires a cool dry climate for optimum production, with temperature range of 21-25^0 C, while a temperature of between15-21^0 C during fruit formation increase yields. On the other hand, Okpara, et al (2017) mentioned that the performance of tomato under high rainfall and humid condition of southern Nigeria is poor compared with Northern dry savannah environment.

Tomato cultivation now move to places and seasons that were originally unsuitable for its productivity, thereby results in the economic importance of the crop (Ibrahim *et al*, 2017). Tomato production as any other crop enterprises, involves a variety of operations which start from land acquisition, land clearance and preparation, planting and /transplanting, weedings, chemical application and harvesting. These explained different cost components incurred by the farmer with the hope of getting some returns. Generally, the overall interest of researchers and policy makers is to reduce production costs and increase output which results to increase in return to farmers.

Objectives of the Study

The main objective of this study is to identify the economics of the tomato production in the area. Specifically,

a. to highlight the cost of producing one hectare of tomato in the area.

b. to explain the yield and benefit of tomato production in one hectare of land.
c. to proffer possible suggestions to the intending tomato farmers in the area.

MATERIALS AND METHODS

The trial was carried out at Dan-daura, village in Kauru L.G. A. Kaduna state (Lat.10.68^0, Long.8.05^0). Dan Syria tomato variety was planted on the nursery on 7th May, 2022. The seedlings were transplanted after three weeks. All agronomic activities were carried out. A total of 130 baskets were realized in nine (9) harvests towards the end of August 2022. The total cost of production stood at # 430,000. And the selling price of the total products was #1, 450,000. NPV, BCR were used. Thus,
BCR = Benefit/ (1+i)n /Cost/(1+i)n. where, cost = # 498,000 and benefit = # 1,648,000.
Where, I is the interest @ 12.5%.
Thus, 1,648,000/ (1+i)n / cost/ (1+i)n.
1,648,000/(1+i) x (1+i)/ 498,000.
1,648,000/498,000 = 3.31
So, the Benefit Cost Ratio (3.31) indicates that the venture is favourable, since in every Naira invested, # 3.31 will be realized within the period of production (Table 3).

RESULTS AND DISCUSSION

Table 1: Production Cost of Tomato per Hectare in Kaduna state.

Input / Material	Quantity	Cost (#)
Seeds	12 tins @ # 2000/ tin	24,000
Fertilizer	4 Bags NPK @25,000 and 4 Bags Urea @ 19,000	# 100,000 and # 76,000
Land fee/ Rent	1 season	60,000
Cost of Land preparation: Harrow and Ridging	1 hectare	28,000
Nursery Preparation	A portion of land	8,000
Transplanting	8 mandays @ # 1,500	12,000
Weeding	Three times @ # 16,000	48,000
Fertilizer application	Twice @ # 2,000	4,000
Harvesting	260 Basket @ # 300/ Basket	78,000
Transportation	Vehicle fuelling	60,000
TOTAL COST		**498,000.**

Table 1 indicates the quantity of items/ materials used and the amount spent for the operation. From the table, it revealed that a total of # 498,000 was spent in the purchase of inputs and the operation carried out in one hectare of land in the study area.

Table 2: Yield – Benefit per Hectare in Kaduna State.

Frequency of Harvest	Number of Basket	Price per Basket (#)	Total Price (#)
1	28	7,000	196,000
2	12	8,000	96,000
3	36	6,500	234,000
4	36	7,000	253,000
5	48	6,500	312,000
6	40	5,000	200,000
7	32	6,300	201,600
8	20	6,000	120,000
9	8	4,500	36,000
TOTAL	260	-------	1,648,000.

Table 2 indicates the yield and the cost of the yield at the time of the harvests. It can be seen from the table that, the tomato fruits do not ripe at the same time. So in this operation, the frequency of harvests were spread to nine time which gave the total output to 260 baskets in one hectare, and sold at the total cost of # 1,648,000.

Table 3: Input – Output Benefit

(Cn) Cost of Production (#)	Total Yield (Basket/ha)	Revenue (#)	Discount Factor (12.5%)	Benefit Cost Ratio (BCR).
498,000	260	1,648,000	206,000	3.31

Cn = Total cost of production
Discount factor (12.5%).
Benefit Cost Ratio = Benefit/(1+i)n / Cn/ (1+ I)n
Bn/ (1+i)n/ x (1+i)n/ Cn/(1+i)= 1,648,000/498,000 = 3.31

CONCLUSION

Tomato fruit as an essential ingredient in the diet of both rural and urban dwellers as well as an important raw material for food industries. It is known to grow mainly between June and December in Nigeria. But during that time, farmers rush in its cultivation, this leads to glut in the markets. The result of this finding revealed that, the low fruit yield during the end of dry season towards the onset of rainy season and the resultant increase in price at that period, compensate the loss encountered by farmers. Because, a basket at the time of glut can be sold at as low as # 500 - # 1000. While, in our finding, there was no harvest among the nine a basket sold at a price lower than # 6000, which price of a basket is equivalent to the price of six to twelve basket at a glut period. The finding therefore recommend that farmers interested in tomato production in the area should engage between April / May up to August, as its production cost is low and the selling price is higher as such attracts higher profits.

COST AND BENEFIT OF SMALL-SCALE SOAP PRODUCTION USING PLANTAIN/BANANA STALKS

Adeoye I.B and Akinrinola A.O
National Horticultural Research Institute, P.M.B 5432, Idi-Ishin, Ibadan.

Correspondence: iyaboadeoye4@gmail.com

ABSTRACT
Alkali produced from Plantain/Banana wastes can be utilized for production of household items such as soap thereby reducing environmental pollution. The study evaluated costs and returns in small scale processing of Plantain/Banana wastes into paste and liquid gel soap. Data on quantity of input requirements and price, output and price were compiled in a series of trainings on empowerment of youth and women on soap production organized by National Horticultural Research Institute. The data was analyzed using profitability indicators such as Benefit to Cost Ratio (BCR) and Rate of Return on Investment (ROI). The total cost and revenue incurred in processing 200 kg of Potash into paste was ₦1,196,600 and ₦2,100,000 while total cost and returns of ₦1,360,200 and ₦3,000,000 was incurred in processing 200 kg of Potash into liquid soap. Benefit to Cost Ratio (BCR) obtained in Liquid gel soap (2.2) and Rate of Return on Investment (1.2) was greater than BCR obtained in paste soap (1.8) and Return on Investment (0.8). The BCR and ROI indicated profitability of the enterprises (Paste and liquid gel production). The study recommends adequate training of the stakeholders on the processes to kindle interest in the natural soap processing using plantain wastes.
Keywords: *Plantain waste, Paste soap, Liquid gel, Profitability, Rate of returns on Investment,*

INTRODUCTION

Plantain/banana represent the world's second-largest fruit crop (Okoli, 2020). It is used in the food industries for the manufacture of chips, flakes, cakes, thereby creating important opportunities to the populace directly or indirectly and invariably income for small holder farmers (Kainga and Seiyabo, 2012). Plantain/Banana is an economic crop which has a relatively high value product in common with most horticultural crops. Almost all the parts of the Plantain/banana plant, for example, fruit, peel, leaf, stem, stalk, and inflorescence (flower), can be utilized in agriculture and cottage industries. They are used in numerous food and non-food-related applications such as thickeners, colorants and flavorings, macro and micro-nutrient sources, livestock feed, fibers, bioactive compound sources, and organic fertilizers (Okoli, 2020). The major wastes of plantain and banana processing in Nigeria are their peels and stalks and the peels account for 40% of the total weight of fresh bananas or plantains and these peels are currently either used as fertilizer or discarded in many countries (Eun-Hye *et al,* 2010). Plantain/Banana stalk waste, could be burnt to produce edible ash or alkali for local soap production in some cultures (Okoli, 2020); but in areas where these are not feasible, these wastes end up polluting the environment (Williams, 2001).

The Plantain/Banana stalks waste is normally disposed in municipal landfills, which contribute to the existing environmental problems (Prashanthi and Chaitanya, 2020). While Warra *et al* (2009) has observed that alkali content of potash obtained from ashes of plants origin were high and good for soap production. Production of soap using agricultural wastes is a veritable source of gainful employment for individuals. It is believed that if plantain/banana stalks could serve as a supplement in soap production, it will go a long way in converting the wastes into wealth. Past empirical studies focussed on use of Plantain peel ash as source of alkali and concluded that solid soap, could be made from ash-derived alkali (Onyegbade *et al*, 2002) while Nnyia *et al (*2023) examined the preparation and physicochemical analysis of local black soap from coconut oil and plantain peel biochar. Their overall results show good soap properties suitable for domestic purposes. None of the aforementioned studies estimate the cost and return involved in the natural soap production. The study therefore evaluate cost and return in soap production using plantain wastes in order to ascertain the viability for prospective investors.

MATERIALS AND METHODS

The study was carried out at National Horticultural Research Institute, Ibadan. Paste soap and liquid gel soap were produced from Plantain fruit stalks. Plantain fruit stalk was collected from Oje market, Ibadan. The fruit stalks were washed with distilled water, sun dried for 168 hours and then ashed in a furnace and stored. The ash was dissolved in water to form alkali and then processed into soap through saponification. For the economic analysis, information was collected on the variable input materials requirement and depreciation estimated for fixed inputs. Budgetary analysis and profitability indicators were employed to determine the viability of the products. The profit indicators: benefit to cost ratio and rate of return on investment were employed in the analysis.

RESULTS AND DISCUSSION

The cost, returns and profitability indicators of producing natural paste soap and liquid gel soap is presented in Table 1 and Table 2. Processing of 200 kg of potash obtained from plantain/banana stalks is capable of generating 280 kg of natural paste bar soap. The variable inputs in the production are plantain/banana stalk ash, cooking gas, packaging materials, Nose masks, and labels. Other include labour that will be utilized in the operation. Depreciation value was calculated for fixed items such as Plastic overhead water tank with metal stand, Industrial plastic drums for extraction, paint buckets (25 ml), hydrometers, scoop bowls (long handle), long cooking iron spoons, long cooking wooden stirrers, metal sieves, plastic sieves, normal weighing scale, safety goggles, industrial gloves, rain booth and mortar and pestle. The estimated cost and revenue in processing of 200 kg potash into paste soap were ₦1,196,6000 and ₦2,100,000 per 200 kg of potash respectively. The net profit was ₦903,400 per 200 kg of potash processed while rate of return to investment was 0.8 with Benefit to cost ratio of 1.8. The benefit to cost ratio of 1.8 implied that for every one naira spent on the enterprise, ₦1.8k will be realized while the rate of return on investment of 0.8 indicated that every naira invested in processing of potash to paste soap returned ₦0.80k as profit. The profit level obtained showed the profitability of processing potash into paste soap. Processing potash from plantain/banana wastes into the soap will go a long way in managing environmental pollution that would have resulted from the wastes.

The total cost incurred in processing 200 kg of Potash into liquid gel were ₦1,360,200 per 200 kg of Potash processed while total revenue of ₦3,000,000 per 200 kg potash processed was estimated. The net profit of ₦1,639,800 was obtained in the processing of potash into liquid gel soap. Rate of return on investment of 1.2 while the benefit to cost ratio was 2.2. The benefit to cost ratio of 2.2 indicated that for every ₦1 invested in the business, ₦2.2 will be realized. The return per naira invested was ₦1.2 k indicated that the enterprise is profitable (Table 2).

CONCLUSION AND RECOMMENDATION

Succinctly, processing of plantain/banana stalks into value added products are profitable and will go a long way in minimizing environmental pollution due to the large volume of the waste. However, Liquid gel soap had higher ROI compared to the paste soap. The study recommends adequate training of the stakeholders on the processes to kindle interest in the natural soap processing using plantain/banana fruit stalks.

ABSTRACT
Members of the genus Ocimum are difficult to characterise due to the presence of many species, subspecies and varieties which do not differ significantly in morphology. Using molecular markers to evaluate genetic diversity in basil population produces reliable results. This study evaluated genetic relationship in eight Ocimum species using ten Start-Codon targeted polymorphism (SCoT) primers. Polymorphic Information content (PIC) and gene diversity were used as discriminatory parameters to assess the level of informativeness of the primers used at differentiating the species studied. A total number of 117 amplified bands were produced, out of which 28 were polymorphic. SCoT 13 and SCoT 3 produced highest and lowest PIC and gene diversity values respectively. Unweighted Pair Group Mean with Arithmetic (UPGMA) grouped the species studied into two clusters, where members within each group are more closely related. The findings of this study ascertained the suitability of SCoT markers at evaluating genetic diversity in basil population.
Keywords: *Basil, Markers, SCoT, Polymorphism, Primer*

INTRODUCTION

The genus *Ocimum* (basil), considered the largest in the family *Lamiaceae*, contains over 150 species of annual and perennial herbs and shrubs, distributed across tropical and subtropical parts of Asia, Africa, Central and South America (Abuhashem *et al*., 2023). In addition to being rich source of high economic essential oils and aromatic compounds, *Ocimum* species are valued as culinary herbs, insect repellants, herbal drugs and attractive ornamentals (Baczek, 2019). However, high level of cytological, chemical and morphological variability exists in the genus, forming the basis of the various classifications (Alves *et al*., 2019). While chromosome number is a dependable trait for species identification, the genus *Ocimum* exhibits chromosome number variations, making cytological identification difficult (Edet and Aikpopodion, 2014). In addition, environment largely affects morphological and chemical traits, making the results obtained in such studies not exclusively usable, thereby propelling the need for a more stable, widely applicable system of classification made possible by molecular markers (Labra *et al*., 2004).

Molecular markers are useful in the study of genetic diversity existing between plant species in the best possible manner (Tiwari *et al*., 2016). Rios Rodriguez *et al*. (2021) reported that markers provide a more detailed and accurate method of tracking genetic variation within basil population. Recently, the use of markers in crop improvement has been upgraded with the development of more informative types such as Target Region Amplification Polymorphism (TRAP) (Hu and Vick, 2003), Start-Codon Targeted Polymorphism (SCoT) (Collard and Mackill, 2009), etc. In Nigeria, Odesola *et al* (2021) reported considerable genetic diversity from 25 *Ocimum* genotypes using ISSR primers. Gupta *et al* (2021) however reported that SCoT markers gave higher polymorphism and resolving power than ISSR markers in their study of genetic relationship between 36 *Ocimum* accessions. Igwe *et al*. (2017) also reported that SCoT markers are better at resolving genetic diversity and relatedness than ISSR due to their longer primer length, higher annealing temperature and polymorphism. This study was therefore conducted to further explore the efficiency of SCoT markers at studying genetic relationship among *Ocimum* species collected across three South-western states in Nigeria.

METHODOLOGY

Eight *Ocimum* species collected from different locations in Oyo, Ogun and Ekiti states, Nigeria were used for this study. The seeds were planted for maintenance and stability in a screen house at National Horticultural Research Institute (NIHORT), Ibadan. Genomic DNA was extracted from approximately 200 mg of young fresh leaves of the *Ocimum* species using modified cetyltrimethylammonium bromide (CTAB) procedure (Mignouna *et al*., 1998). DNA quality was done using agarose gel electrophoresis. Only samples of high quality were used for SCoT Polymerase chain reaction (PCR). A total of 10 polymorphic SCoT primers were used in this study. PCR amplification for SCoT reactions was carried out in a 25 µl volume in a 96-well microliter plate. The total reaction volume contained 25 ng of template DNA, 2.5 µl each of dNTPs, 10×PCR buffer and 25 mM $MgCl_2$, 2.0µl of 5µM of primer, 1 unit of Taq DNA polymerase (Bioline). The plate was subsequently placed in a Eppendorf Mastercycler Nexus Thermal Cycler (USA Scientific, Inc.) for amplification, where cycling conditions were initial duration at 94°C for 5 min, followed by 40 cycles consisting of denaturation for 30 secs, annealing at 50-60°C for 1 min, extension at 72°C for 45 secs and final extension at 72°C for 10 min. Ten microlitre (10 µl) of the PCR amplicons were resolved with 1.5% agarose gel containing 0.5 mg/mL ethidium bromide and viewed under Vilber Lourmat E-Box CX5.TS UV Trans-illuminator. The molecular weights of amplified bands were estimated using 100bp DNA ladder (bioline) as standard.

Estimation of diversity among the 8 studied *Ocimum* species was done by scoring for the presence or absence of amplified bands as '1' or '0' manually and respectively across the 10 SCoT primers, to generate a binary matrix from the gel pictures of the markers used. Scoring was done only for clear, unambiguous and reproducible bands. To distinguish between the *Ocimum* species studied, polymorphic information content (PIC) and gene diversity were determined. NTSYSpc (Rohlf, 2005) and Power marker statistical soft wares were used to construct UPGMA dendrogram using hierarchical clustering.

RESULTS

Table 1 showed the distribution of the *Ocimum* species used. The eight species comprised three *O. basilicum*, two *O. canum*, two *O. tenuiflorum* and a species of *O. gratissimum*. *Ocimum basilicum* (B_1) is distinct with its lack of purple colour while the other two had purple colouration but *O. basilicum* (B_2) has prominent hairy raceme in addition. *Ocimum canum* (C_2) is hairier with small leaves compared to *O. canum* (C_1). The two *O. tenuiflorum* species had varying colours. While *O. tenuiflorum* (Tp) is purple, *O. tenuiflorum* (TG) is green in colour. The SCoT markers used showed considerable level of polymorphism. A total of 117 amplified bands were observed, out of which 28 were polymorphic (23.93%; Table 2). SCoT 13 showed both the highest polymorphic information content {(PIC), (0.5815)} and gene diversity (0.6563) while SCoT 3 showed the least PIC (0.3047) and gene diversity (0.3750), with average PIC and gene diversity values of 0.4771 and 0.5500 respectively (Table 2). The number of alleles detected varied from 2 (SCoT 3, SCoT 28) to 3 (SCoT 1, SCoT 13, SCoT 16, SCoT 22, SCoT 33, SCoT 35 and SCoT 36; Table 2). Major allele frequency ranged from 0.3750 (SCoT 13) to 0.7500 (SCoT 2 and 3), with an average of 0.5625 (Table 2). The phylogenetic analysis separated the 8 *Ocimum* species into two groups, where *O. basilicum* (B_1), *O. basilicum* (B_2), *O. basilicum* (B_3) and *O. gratissimum* (GR) belonged to Group 1 while *O. canum* (C_1), *O. canum* (C_2), *O. tenuiflorum* (TG) and *O. tenuiflorum* (TP) belonged to Group 2 (Figure 2). Members within each group showed a higher level of relatedness than members in the other group.

DISCUSSION

Estimating genetic diversity and taxonomic relationship among *Ocimum* species is necessary for the conservation of its gene pool and design of appropriate crop improvement program per time (Makmur *et al*., 2020). Using molecular approach in the assessment of this diversity offers the advantages of providing data that is not environment-dependent, can be objectively analysed and obtained within a relatively short time (Jonah *et al*., 2011). Development of new alternative markers such as SCoT, in which polymorphism is generated from genic regions in the genome have resulted from recent advancement in genomics (Tiwari *et al*., 2016). Bhawna *et al*. (2017) stated that amplification products by these markers might be related to traits and their functional genes. Abuhashem *et al* (2023) stated that huge success has been recorded in the use of SCoT markers to distinguish between closely related basil plant species and cultivars, making them invaluable in the study of genetic relationships in the genus *Ocimum*.

The present study on the molecular characterisation of *Ocimum* species collected from different parts of Nigeria, revealed the level of inter-specific relatedness and diversity in the genus. Considerable amount of genetic differences, as deduced from the average gene diversity (0.5500) and PIC (0.4771) was observed among the eight *Ocimum* species studied. Gupta *et al* (2021) reported average PIC of 0.65, following the assessment of 36 accessions of *Ocimum*, using 18 SCoT markers. Their result, although slightly higher than the result obtained in this study, may be due to the utilization of large number of materials. Using SCoT for intensive diversity studies of *Ocimum* species in Nigeria will help in the reliable identification of several genotypes spread across the country and possibly, novel traits that can be used in future breeding programmes.

ABSTRACT
Pineapple is an important tropical fruit crop all over the world, however its field genetics and breeding has not been extensively explored. Pineapple stems where cut into 3 equal parts from the leaf producing regions-proximal, median and distal. These cuttings were further done horizontally and vertically for each region. The ratoons were planted in different growth Media – Topsoil, Sawdust and 50/50 Topsoil with Sawdust. Sole topsoil media recorded the highest number of suckers (5.8611) while the lowest sucker production was recorded in topsoil and sawdust mixture (3.8611). The highest number of overall suckers were recorded at the distal position which was split horizontally before sowing. From the study, it shows that the optimum sucker production was achieved when the distal region of the ratoon was cut horizontally and sown in sole topsoil.
Keywords: *Pineapple, Stem, Sucker, Sole Topsoil, Sawdust.*

INTRODUCTION

Pineapple (Ananas comosus var. comosus) is a monocotyledon perennial plant in the family Bromeliaceae (da Silva et al., 2013; Reinhardt *et al*., 2018). Pineapple is an important tropical fruit, which is rated third most produced fruit in the world (Chotangui *et al.,* 2019). This fruit crop lacks proper study in the field genetics and breeding; however, few improved varieties are available which in MD2 (Bartholomew *et al.,* 2010, Tang *et al*., 2014). Pineapple is mainly propagated asexually through crowns, slips and suckers (Hossain, 2016) in Nigeria, the use of crowns and slips in vivo are most common. The commonest varieties cultivated in Nigeria include, 'Sugarloaf', 'Queen' and 'Smooth Cayenne'; the latter is the commonest and most cultivated in the country (Chotangui *et al.,* 2019). Nigeria is ranked among the highest producer of this fruit in the world, with the production of more than 40% pineapple production in the continent (FAO, 2013) but the production has dropped over the years (FAOSTAT, 2017).

One of the major constraints in pineapple production is the lack of enough quality planting materials that are relatively uniform in age and/or sizes (Ranawana and Eeswara, 2008; Agogbua and Osuji, 2011; Dennis and Okpeke, 2018). Unavailability of planting materials has been attributed to one of the impediments of technical efficiency in pineapple farming business in Nigeria, crumbling the livelihood of many farmers that depends of pineapple production (Baruwa, 2013). Adegbite and Adeoye (2015) reported that pineapple farmers' productivity will increase with an increase in numbers of being suckers cultivated. In-vitro sucker production could have solved the problem but the cost implication remains the impeding factor.

Most farmers often resort to the use of planting materials obtained from cultivated fields which may be infected and are always not uniform. In vivo propagation of pineapple still remains the simplest and cheapest means sucker production in order to breakeven in pineapple production business. Harnessing the buds present on pineapple stem (ratoon) to increase production of suckers is imperative in solving technical efficiency of pineapple production in the country. Consequently, this study aims to study different media for production of pineapple suckers from ratoons while potency of the bud's position on the stem were also examined.

METHODOLOGY

The was carried out in National Horticultural Research Institute (NIHORT), Ibadan using a screenhouse. The stems were cut into three equally from the leaves producing region respectively and labelled proximal, median and distal (Plate 1). Some of the split ratoons were sown whole (W) while some were further divided into two (S) before sowing either vertically (V) or horizontally (H). The ratoons were buried into different growth media which are Topsoil, Sawdust and 50/50 Topsoil and Sawdust. Watering was done when necessary. Sprouted suckers were removed when they attained 15 cm height while the number of suckers produced per treatments were recorded. Data were analysed using descriptive data analysis.

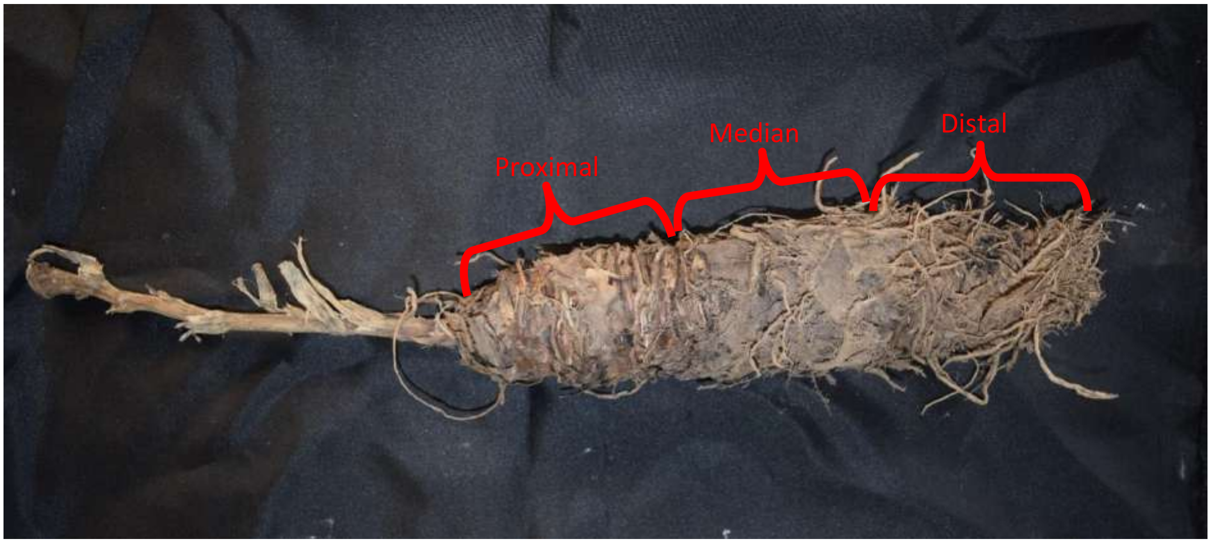

Plate 1: Pineapple stem (ratoon) and the label showing divisions of the stem

RESULTS AND DISCUSSIONS

The highest number of suckers were produced in sole topsoil media (5.8611 suckers) while the lowest sucker production was recorded in Topsoil and sawdust mixture (3.8611 suckers). The increase in highest number of suckers production from topsoil media could be as a result of higher temperatures which could aid sprouting of dormant axillary buds compare to other media. Hepton (2003) reported the importance of temperature in sucker production through pineapple ratoons. The ratoons planted sown whole produced less than less of the ratoons split into two before sowing (Table 1; Figure 1). The sectioning of the stems can further aid in suppression of lateral buds hormones for the initiation of axillary buds. Reinhardt et al. (2018) and Maerere (1995) reported that the techniques of pineapple macro propagation is dependent on inhibiting lateral buds for the development of axillary buds.

The overall position where suckers' production was recorded was at the proximal; however, the highest number of overall sucker and was recorded at the distal split horizontally sown ratoon (10.11 suckers; Table 1; Figure 1). This result corroborates the report of Reinhardt et al. (2018) and Hepton (2003) that presences of dry matter on pineapple stem is a good indication of starch reverses for initiation of axillary buds. Reduction in sucker production recorded in distal position in other treatments may be as a result of limited period allotted for this experiment.

ABSTRACT

This study was carried out to evaluate the attenuation effect of ethanol leaf-extract of Phyllantus reticulatus on dexamethasone induced oxidative stress in albino rats. Thirty (30) rats were used and was divided into six groups of five rats each (Aa, Ab, Ac, Ae, Af, and Ca). They were allowed to acclimatize for two weeks and were given feed and water, with their weight taken every morning. Different dose (30 ug/kg) of dexamethasone was injected into the rats for 4 days depending on their body weight through intra-peritoreally (IP) so as to induce oxidative stress. 10 g of the extract was dissolved against 100 mL of water. The extract was administered orally for 14 days to treat the rats. Blood sample of the rats was collected for laboratory analysis before and after the treatments inorder to check the oxidative stress indices. The results revealed that malondialdehyde (MDA) level (141.67 ± 6.81) before treatment increased unlike the normal control group (50.67 ± 1.53) while after the treatment, the MDA levels (41.31 ± .70) were significantly (p<0.05) lower compared to negative control group (140.44 ± 44). The result also revealed the effect of the extracts on reduced gluthathione in dexamethasone-induced rat, the treated rat increased significantly (p<0.05) after the treatment (117.21 ± 3.45) when compared to the negative control before treatment (33.68 ± 3.64). From our results, this study revealed that the ethanol leaf extract of Phyllantus reticulatus has a therapeutic effect on dexamethasone induced oxidative stress.

INTRODUCTION

Plants remains the valuable starting material in drug development which include allopathic medicine, herbal medicine, homoeopathy and aroma therapy (Ajibesin, 2011). The distribution of these important plants cut across all plant family, the knowledge which plants has been passed down through generations of traditional medicine practices. *Phyllanthus reticulatus* remains an important traditional medicinal plant whose different plant part has been used in treatment. *Phyllanthus reticulatus* is a multi-potential plant which has the capacity to heatstroke, helminthiasis, oral infections, oral lesions in the mouth, tooth and tongue (Ariful *et al*., 2010). *Phyllanthus reticulatus* has been proved to show antidiabetic, antiviral, anticancer, antiplasmodial, hepatoprotective, antibacterial and anti-inflammatory activities. The plant contains tannic acid, terpenoids, flavonoids, phenolic compounds and steroids as main chemical constituents (Sharma *et al.*, 2013). The issues of oxidative stress and its modulation by antioxidants currently have received more attention than ever before. Oxidative stress is the result of an imbalance in pro-oxidant/antioxidant homeostasis that leads to the generation of toxic reactive oxygen species (ROS), such as hydrogen peroxide, organic hydro peroxides, nitric oxide, superoxide and hydroxyl radicals etc.

Despite, the belief that oxidative stress is detrimental and should be treated or prevented, several recent studies, meta-analyses, and systematic reviews (Bjelakovic *et al*., 2007; Hereberg *et al.,* 2004; Bjelakovic *et al*., 2008) were unable to confirm the expected benefit of supplemental antioxidants. Some studies even found deleterious effects related in individuals randomized usage of supplemental antioxidants which is referred to has antioxidant paradox (Halliwell et al., 2000). The search for natural antioxidants from plants would continue to be a dominant research interest for many years. These antioxidant molecules often neutralize or quench the reactive oxygen species (ROS) by either hydrogen atom transfer or single electron transfer mechanisms. Several chemical and biochemical protocols have been used in the evaluation of plant extracts as antioxidants. Thus, the capacity to scavenge ROS and free radicals or inhibits lipid peroxidation can be measured quantitatively as the strength of antioxidant activity. This study aims to evaluate the attenuation effect of ethanol leaf-extract of *Phyllantus reticulatus* on the treatment of induced oxidative stress in albino rats. Thus, the objectives of this study is to access the effect of ethanol leaf-extract of *Phyllantus reticulatus* on the levels of malondialdehyde and reduced glutathione in the induced albino rats.

METHODOLOGY

The leaves of *Phyllantus reticulatus* was collected from hilltop waterworks road in Abakaliki Ebonyi State. The leaves were washed and air dried at room temperature for three (3) weeks. The dried leaves were then grinded into powdered, stored in airtight container which were kept in refrigerator ($4^{O}C$). 100 g of the sample was weighed and poured into a container, 1000 mL of ethanol was then added to it and stared in other to get a homogeneous mixture and this was allowed to stay for two (2) days. White muslin was used to sieve the sample to get the extract in liquid form. The ethanol was allowed to evaporate leaving extract in the container which was then stored in a refrigerator for usage. A total number of 30 albino rats were used for this study. They were allowed to acclimatize for two weeks and fed with commercially available rat feed and clean water. The albino rats (n=30) were divided into six (6) groups (Aa, Ab, Ac, Ae, Af and Ca); group Aa, Ab, Ac, Ae, and Af were administered dexamethasone depending on the weight of the rat for four (4) days in other to induce oxidative stress while group Ca was the normal control which was given only normal saline. Two (2) rats were taken from each treatment after 2 weeks to ascertain the effect of oxidative stress induced.

Group Aa, Ab and Ac were administered with the ethanol leaf extract of *Phyllantus reticulatus*, Ae was given only standard drug (Amlodipine) while Af and Ca remained Negative and Normal control groups respectively. Group Aa, Ab and Ac were treated with 200 mg/kg, 400 mg/kg, 600 mg/kg respectively. The treatments were administered for 2 weeks after which blood samples were collected for analysis of malondialdehyde (MDA) and reduced gluthathione.

Biochemical analysis

For determination of test for malondialdehyde, 5 mL of serum was mixed with 4.5 mL of normal saline and 1 mL of sample was mixed with 3 mL of TCA. The mixture was then centrifuged and 2 mL of the supernatant was taken and mixed with 1 mL of TBA. The mixture was then boiled for 20 minutes and its absorbance taken at 530 nm. Determination of the Activities of Reduced Gluthathione was carried out using 1 mL of the supernatant from MDA mixed with 2.5 mL of phosphate buffer and 0.5 mL of DTNB, its absorbance was taken at 412 nm.

RESULTS AND DISCUSSION

In malondialdehyde, the result of the effect of ethanol leaf-extract of *Phyllantus reticulatus* on the level of malondialdehyde (MDA) as shown in figure 1 revealed that before the treatment, there was a significant increase ($p > 0.05$) among negative control, standard drug, 200 mg/kg, 400 mg/kg and 600 mg/kg when compared with the normal control. Administration of ethanol leaf-extract of *Phyllantus reticulatus* after treatment reveals a significant decrease ($p <0.05$) in the level of MDA which was toward the normal control.

In reduced gluthathione, the result of the effect of ethanol leaf-extract of *Phyllantus reticulatus* on reduced gluthathione (GSH) concentration as shown in figure 2 revealed that before the treatment, the level of GSH significantly decreased ($p < 0.05$) in negative control, standard drug, 200 mg/kg, 400 mg/kg and 600 mg/kg when compared to the normal control. Administration of the extract brought about a significant increase ($p < 0.05$) in the level of GSH. The malondialdehyde (MDA) and reduced gluthathione results obtained from this study are in line with the report of Alizadeh and Kheirouri (2019) who studied the effect of administration of Curcumin on human beings, stating that MDA level significantly reduced while GSH level increased after treatment. Glutathione (GSH) is a thiol and tripeptide which is synthesized by glycine, cysteine, and glutamate in the liver and acts as a vital factor in metabolic protective functions, including the reduction of hydroperoxides, the quenching of free radicals, and the detoxification of xenobiotics (Wu *et al.,* 2004). The GSH-dependent antioxidant system consists of GSH and an array of functionally related enzymes, including glutathione S-transferase (GSH-ST), glutathione peroxidase (GSH-Px) and glutathione reductase (GSH-Rd). GSH-ST is not only capable of conjugating a number of potentially toxic electrophilic xenobiotics to the nucleophilic GSH, but can also catalyze reactions to reduce peroxides. Glutathione can reduce hydroperoxides as well as H_2O_2 but also oxidizes GSH. Glutathione then reduces oxidized glutathione (GSSG) to the GSH.

CONCLUSION

Ethanol leaf extract of *Phyllantus reticulatus* has the potential to attenuate dexamethasone induced oxidative stress in rats

INTRODUCTION

Fluted pumpkin (*Telfairia occidentalis*), commonly known as ugwu in Nigeria, is a nutritious leafy vegetable widely cultivated in the southern and eastern parts of the country [1]. This green leafy vegetable is highly consumed and used in preparing different types of meals, and even the squeezed green leaves (green drink) are normally taken as traditional medicine [2] due to their high nutrient content. The role of vegetables cannot be overestimated, as they play a significant role in humans nutrition. Vegetables are indispensable constituents of the human diet, supplying the body with minerals, vitamins, dietary fibre, certain hormones, and precursors in addition to protein [2]. *T. occidentalis* belongs to the family *Oliffieaceae* and the sub-family *Cucurbitaceae* [3]. The shrub is a dioecious plant whose sex is not known until after flowering. The female plant has very broad leaves with a big stem and is usually more succulent, producing fruits that contain seeds, while the male plant produces only flowers with smaller leaves and tiny stems [3]. Akwaowo *et al*. [4] reported that the older leaves of fluted pumpkin were higher in percentage crude protein, crude fat, ash, and crude fibre, while the younger leaves were higher in moisture content and carbohydrate.

The leaves are rich in proteins, oil, vitamins, and minerals that are advantageous to human health, though they have a low crude fibre content. They are also very rich in folic acid, calcium, zinc, potassium, cobalt, copper, iron, and vitamins A, C, and K [5]. The leaves have both medicinal and nutritional values [6], while the young leaves can be sliced and stored in a bottle to which salt and coconut water are added and subsequently used for the treatment of convulsions [7]. While previous research has investigated the phytochemical and nutritional profiles of *T. occidentalis* leaves, limited attention has been given to the potential sex-based differences in these properties. Investigating such differences is essential for a comprehensive understanding of the plant's chemical composition and its potential implications for dietary and therapeutic applications. This research aims to bridge the existing knowledge gap by comparing the phytochemical and nutritional properties of male and female *Telfairia occidentalis* leaves.

MATERIALS AND METHODS

Collection and identification of plant materials

Fresh leaves of 20 accessions of *Telfairia occidentalis* (male and female), were taken from an experimental plot at the National Horticultural Research Institute (NIHORT), in Ibadan, Oyo State, Nigeria. The plants were identified by a Plant Breeder from Genetic Resource Unit, National Horticultural Research Institute (NIHORT), Ibadan, Oyo State, Nigeria

Preparation and treatment of *Telfairia occidentalis* leaves

The leaves were separately and thoroughly washed with water and dried in a dehydrator at 40 ºC for 48 hours to avoid loss of active compounds. The dried leaves were ground to powder using an electric grinder. The powder samples were then stored in appropriately labelled, airtight bottles for further use [20].

Proximate Analysis of leaves of Male and Female *Telfairia occidentalis*

Determination of protein content

The crude proteins were determined by the macro Kjeldahl method as described in literature [21]. Briefly, 2g of the sample was introduced into a Kjeldahl digestion flask together with 10g of copper sulphate and sodium sulphate in the ratio of 5:1. 25 mL of concentrated sulphuric acid was added to the digestion flask and the digestion was carried at about 1500 °C in the fume cupboard until frothing ceased. A clear and light blue coloration was observed. The digest was cooled and diluted up to the mark with distilled water in 100 mL volumetric flask. 10 mL of the diluted mixture was poured into the distillation apparatus and 18 mL of 40% of sodium hydroxide was added. 25 mL of 2% boric acid was added into the receiving conical flask and two drops of bromocresol green and methyl red mixed indicator was added. The distillation was continued until boric acid solution turned from pink to yellowish green. After the distillation, the solution in the conical flask was titrated against 0.1N hydrochloric acid until the end point was reached. A blank was taken using the same procedure using only with distilled water. The protein was calculated as:

$$\text{Protein (\%)} = \frac{TV \times 0.014 \times 100(mL) \times 0.01 \times 100 \times 6.25}{\text{Weight of the sample (g) Aliquot used for distillation (ml)}}$$

where,
TV = Titre Value

Determination of crude fat content

The fat content was determined as described in literature [22]. Briefly, 5g of sample was mixed with 0.88mL of ammonia solution and 10 mL of 95% ethanol and mixed well. 25 mL of diethyl ether was added to the mixture and shaken vigorously for 1 minute. This was then followed by addition of 25 mL of petroleum ether and shaken vigorously to mix well. The mixture was then left to stand for an hour to allow aqueous and organic phase to separate. The fat extract (organic phase) was collected and the solvent was removed by distillation. The fat in the flask was dried in the oven at 100 ºC for 30 minutes and the solvent was removed completely. The flasks were then cooled in a desiccator and were weighed for their mass of fat. The percentage fat was calculated by the following formula.

$$\text{Crude fat (\%)} = \frac{W4 - W3}{W2 - W1} \times 100$$

where; W1 = Weight of empty thimble, (g) W2 = Weight of thimble + sample, (g); W3 = Weight of empty flask, (g) W4 = Weight of flask + fat, (g)

Determination of Crude Fibre

The crude fibre was determined according to the procedure reported in literature [23]. It was determined as the fraction remaining after digestion with standard sulphuric acid and sodium hydroxide. Briefly, 2g of the sample was hydrolysed in a beaker containing 299 mL of 1.25% of sulphuric acid and then boiled for 30 minutes. The mixture was filtered under vacuum and the residue was washed with hot distilled water for 3 times and then boiled again for 30 minutes with 200 mL of 1.25% of sodium hydroxide and filtered again. The digested sample was washed with hydrochloric acid to neutralize sodium hydroxide and then with hot distilled water for 3 times. The residue was taken into a crucible, dried at 100 ºC for 2 hours in an oven, the sample was cooled in a desiccator and then weighed. The sample in the crucible was incinerated at 500? for 5 hours until all carbonaceous matter were burnt. Finally, the crucible containing the ash was cooled in the desiccator and weighed.

The percentage crude fibre was calculated by the following formula;

$$\text{Crude fibre} = \frac{W1 - W2}{W} \times 100$$

where: W1 = Weight of the sample before ashing, g; W2 = Weight of the sample after ashing, g; W = Weight of the sample, g

Ash content determination

The ash content was determined by direct heating method as described in literature [24]. Briefly, 2g of each one of the yoghurt samples was weighed in dried glass crucibles separately. The samples were then incinerated to ash in a muffle furnace for 3 hours at 550 ºC. The crucibles were then removed, cooled in desiccator and the weight of the ash was determined. The percentage ash content was calculated by the following formula.

$$\% \text{ ash} = (Z-X/Y-X) \times 100$$

where; X=weight of empty crucible; Y=weight of crucible + sample; Z=weight of crucible + ash

Determination of moisture content

The percentage of moisture content was determined by oven method as described in literature [24]. Briefly, 2g of yoghurt samples was dried in the oven for 24 hours at 100 °C. The percentage moisture content was calculated by the following formula.

$$\text{Moisture content (m.c \%)} = \frac{Wm}{Wm + Wd} \times 100$$

where; *m.c.* = moisture content, percent wet basis; Wm = mass of water evaporated, g; Wd = mass of dry matter, g

Determination of carbohydrates content

Carbohydrates were determined using a mathematical function below as described in literature [24].

CHO=100 - % (ash + protein + fat + crude fibre + moisture)

Phytochemical analysis of leaves of the male and female *Telfairia occidentalis*

Determination of tannins

Tannin determination was done according to the method of AOAC with some modifications. 1mL of the extract was filtered into a 100 mL volumetric flask, followed by adding 20 mL of distilled water, 2.5 mL of Folin-Denis reagent and 10 mL of 17% aq. Na_2CO_3 was also added and thoroughly mixed together. The mixture was made up to 100 mL with distilled water, then mixed and allowed to stand for 20 min. The bluish-green color developed at the end of the reaction mixture of different concentrations ranging from 10-50 ppm. The absorbance of the tannic acid standard solutions as well as sample was measured after color development at 760 nm using the AJI-C03 UV-VIS spectrophotometer. Results were expressed as mg/100L of tannic acid equivalent using the calibration curve: Y = 0.003x - 0.0084, R2 = 0.9818, where x was the absorbance and Y was tannic acid equivalent.

DPPH scavenging assay

The method of Shen *et al* [29] was used for the determination of scavenging activity of DPPH radical in the extract solution. A portion of 0.135 mM DPPH prepared in methanol containing 0.5 mL of the extracts. The reaction mixture was vortexed thoroughly and left in dark at room temperature for 30 min. The absorbance was measured spectrophotometrically at 517 nm. The scavenging ability of the plant on DPPH was calculated using the equation:

DPPH scavenging activity (%) = [(Abs control – Abs sample)]/ (Abs control)] ×100, where Abs control is the absorbance of DPPH + methanol; Abs sample is the absorbance of DPPH radical + sample extract or standard. The results were expressed in % % inhibition = DPPH scavenging activity (%).

Determination of total carotenoid content

Total carotenoid content was quantified according to the method outlined by Campos *et al*. [25]. About 1 g sample was homogenized in 20 mL acetone and the solution was filtered. The process was repeated until attaining complete removal of colored pigments. Acetone was evaporated and dry sample extract dis-solved in 60 mL petroleum ether, filtered, transferred to 100 mL volumetric flask and volume completed with petroleum ether. Then, 2 mL of this solution was placed in a test tube with 8 mL petroleum ether. Absorbance was read at 475 nm using UV-Vis spectrophotometer and concentration was calculated with a standard β-carotene curve.

Ascorbic acid determination

Ascorbic acid content was determined applying AOAC official method 967.21 [26]. Sample (5 g) was homogenized in 100 mL metaphosphoric acid-acetic acid solution in ratio of 1.0: 0.5 and filtered. The resulting solution was titrated using phenol-2,6-dichloroindophenol dye (prepared using 50 mg 2,6-dichloroindophenol and 42 mg $NaHCO_3$ in approximately 50 mL water and dilute to 200 mL with water) until light pink color was obtained persisting for at least 5 seconds. Ascorbic acid solution was used to standardize the dye.

Total antioxidant assay

The antioxidant power of LTE and standards was evaluated by the phosphomolybdenum reduction assay according to the procedure described by Prieto *et al*. [27] A reagent solution prepared contained ammonium molybdate (4 mM), sodium phosphate (28 mM), and sulfuric acid (0.6 M), mixed in 1:1:1

ratio, respectively. Accurately, 0.3 mL of the concentrations of the extracts was mixed with 3 mL of the reagent solution. The mixtures were incubated for 1 h at 95°C after which the absorbance of the green phosphomolybdenum complex formed was measured at 695 nm against a blank. For standards ascorbic acid, concentrations of 20–100 µg/ml were used. Each concentration was prepared in triplicates. A mixture containing 0.3 mL methanol and 3 mL reagent solution was used as a blank.

Extraction and determination of phytate

The principle of this method relies on a conversion of free phytic acid and a colorimetric measurement of the liberated organic phosphorus. Sample (2.0 g) was extracted with 40 ml of 2.4% HCl (68.6 ml of 35% hydrochloric acid in total volume of 1 litre of D2O) under constant shaking at room temperature (25°C) for 3 h. All extracts were then filtered using Whatman No. 1 filter paper. The content of phytate was determined by using a spectrophotometric method, with an absorbance (A) wavelength at 640 nm, outlined in Nkama, and Gbenyi, [28]. The amount of phytic acid was calculated from the organic phosphorus by assuming that one molecule of phytic acid (containing six molecules of phosphorus (P)) was digested as per the equation below [28]:

Phytate mg/g sample

$$\text{Mean } \frac{K'' * A * 20m}{0{:}282 * 1000}$$

Where, A = absorbance; ''K'' = standard P (µg)/ [A/volume (ml)]; phytate = 28.2% P; 20 = extract volume (ml) of 1 g sample; 1000 = conversion from µg/g to mg/g. The results were reported in percentage of phytate in 100 grammes of sample.

Determination of mineral composition

The sample was investigated for elemental composition by using atomic absorption spectrophotometer (AAS- Bulk Scientific model AVG 211) after ashing (0.5g of the sample) and acid digestion. Appropriate working standard solution was prepared for each element. The calibration curves were obtained for concentration versus absorbance. The data were statistically analysed by using fitting of straight line by least square method. Laboratory procedures for the preparation and determination of micronutrients were used as outlined by Paul *et al*. [18] for samples

RESULT AND DISCUSSION

Compositional values of phytochemicals in male and female *T. occidentalis* leaves

The male and female *T. occidentalis* leaves contain varying levels of certain phytochemical components such as vitamin C, tannin, and total antioxidant (Table 1), while total carotenoid, phytate, DPPH, and Iron chelating were relatively equal quantities in both male and female, with a difference of less than 0.1. As shown in Table 1, vitamin C and total antioxidant content were higher in the male leaves (36.64 g and 561.61 g, respectively), while in the female leaves, tannin (60.87 g) was higher. Male and female *T. occidentalis* contain several vital phytochemicals, as seen in this study. The study agreed with the earlier findings by Temitope *et al*. [8] that the pumpkin contains tannin and other phytochemicals that may inhibit inflammation and tumour growth and boost the production of detoxifying enzymes in the body. Vitamins found in the *T. occidentalis* leaves of the male were in higher amounts than in the female plants [8]. Hussaine *et al*. [9] explained that most of the phytochemicals are secondary metabolites produced in plants and do not participate in metabolic processes within the plants but are the result of metabolic activities in the plant.

Compositional values of proximate in male and female *T. occidentalis* leaves

The proximate contents of the male and female leaves are represented in Table 2. With more than 40% of carbohydrates were the most prominent components present in both male and female leaves, followed by crude proteins (21.13% and 21.05%) and crude fibres (15.00% and 14.92%). The Ash content mean values in male and female leaves were 9.91 and 10.00%, respectively. Moisture content (6.29% and 6.27%) and lipid content (6.09% and 6.25%) of the male and female *T. occidentalis* leaves sampled were generally low when compared with the values obtained by Idris [10], who got 87%, although a slight increase in protein, ash, fiber, lipid and CHO content was observed in the leaves of female plant. This report contrasted the values presented by Usunobun and Egharebva [11], who obtained 7.45%, 6.60%, and 10.94%, respectively, which were closer to the values obtained in this study.

The values obtained for the various proximate contents between the male and female *T. occidentalis* were very close. The findings in the study agree with the report by Mohd *et al*. [12], Kajihausa *et al*. [13], Adeyeye and Omolayo [14], and Temitope *et al*. [8], who noted that the ash, protein, carbohydrate, lipid, and moisture content of the two sexes compared in the study were within the same range. Kajihausa *et al*. [13] reported an ash value of 8.19 to 10.75. Adeyeye and Omolayo [14] obtained a higher ash value (12.3%), which is not in agreement with the results of this study. The crude fibre content obtained in the study agree with the values reported in the study carried out by Temitope *et al*. [8]: 14.32–29.60% (female) and 14.42–27.01% (male). The results of this study agree with the lipid values reported by Usunobun and Egharebva [11], which are 6.46% and 4.22% by Adeniyi *et al*. [15]. The male and female pumpkin leaves contained a low amount of fat, making them suitable for weight reduction [8].

Rao and Netwmark [16] mentioned that crude fibre has the advantage of aiding digestion, reducing high cholesterol levels, reducing high blood pressure, combating diabetes, and preventing breast cancer. Similar to the ash content, crude fibre content between the male and female *T. occidentalis* was not significantly different. Protein is an important part of the diet responsible for the growth and replacement of worn-out tissues. The female plant obtained higher protein levels as reported by Ajibade *et al*. [5] for protein and fat, which agreed with the results of this study. Ajibade et al. [5] also observed that the male plants had higher fibre and ash contents, which disagreed with the ash value being higher in the female plant leaves in the present study. Ash content reported for female *T. occidentalis* had a higher value than that reported for male *T. occidentalis*, which showed that the female plant leaves contained a higher amount and content of minerals than their male counterparts [12].

Mineral Composition of Male and Female *T. occidentalis* leaves

Table 3 shows the mineral composition of male and female *T. occidentalis*. Zinc, sodium, iron, potassium, and calcium were the minerals extracted, and the amount of mineral content was higher in male leaves than in female leaves. The test obtained presented no trace of lead in the two sexes sampled. The findings agreed with those of Idris [10], who reported that the amount of sodium in the female *T. occidentalis* leaves is low when compared to the male leaves; Adeyeye and Omolayo [14] (Fe: 6.4 mg/100g); and Verla *et al*. [19] (Fe: 7.64 mg/100 g), but it is not in agreement with results of Temitope *et al*. [8] where the minerals obtained from the male and female *T. occidentalis* leaves were the same for calcium, sodium, manganese, and zinc.

Calcium is needed for strong skeletal buildup and formation. The amount of calcium in the body is determined by the ratio of Phosphorus to calcium, as a high amount of phosphorus leads to calcium loss through the urine. Verla *et al*. [19] mentioned that the elements sodium and potassium maintain osmotic balance in body fluids, regulate the uptake and adsorption of glucose, and also enhance the retention of protein. Iron is an important constituent of haemoglobin and is responsible for the transport of oxygen from one part of the body to another [8].

CONCLUSION

This finding highlights the differences in phytochemical and nutritional composition between male and female *T. occidentalis* leaves. Male leaves were found to possess higher levels of vitamin C, total antioxidants and minerals compared to female leaves. These compounds are important for their potential antioxidant, and immune-boosting properties. On the other hand, female leaves exhibited higher tannin content, which has been associated with anti-inflammatory and potential anti-tumor effects. The proximate analysis of the leaves revealed that both male and female *T. occidentalis* leaves had similar ranges of ash, protein, carbohydrate, lipid, and moisture content.

Results from this study show that male and female *T. occidentalis* leaves are rich sources of beneficial phytochemicals and essential nutrients. They could have implications for dietary and therapeutic applications, potentially contributing to antioxidant activity, anti-inflammatory effects, and overall health improvement. However, further research is needed to fully understand the bioavailability and potential health benefits of the identified compounds in *T. occidentalis* leaves.

TECHNICAL EFFICIENCY OF TOMATO PRODUCTION IN YAMALTU-DEBA LOCAL GOVERNMENT AREA OF GOMBE STATE

***Layade, A.A., Adeoye, P.O. and Idowu, O.O.**
National Horticultural Research Institute, P.M.B 5432, Idi-Ishin, Ibadan

*Corresponding author: jumlay408@gmail.com

ABSTRACT
The study investigated technical efficiency of tomato farmers in Yamaltu-Deba Local Government Area of Gombe State. A multistage sampling technique was used to select eighty tomato farmers from the study area. Information was obtained from the sampled farmers through the use of a structured questionnaire. Stochastic Production Frontier Analysis (SPFA) with Cobb-Douglas functional form was used to analyze the technical efficiency of the farmers. The result revealed the tomato farmers in the study area were technically efficient with mean technical efficiency level of 0.87. Fertilizer use, organic manure, pesticide and farm size enhanced tomato output and technical efficiency of the farmers at 1% and 10% alpha level. Return-to-scale of 0.32 was estimated, implying the farmers operate in the stage two of production where doubling the input lead to less than double in the output. Farmers should therefore pay attention to their input combination to avoid diminishing returns.
Keywords: *Production function, tomato, stochastic frontier, inefficiency*

INTRODUCTION

Tomato (*Lycopersion esculentum* mill) is one of the leading vegetable crops in Nigeria. The crop is high in nutritional values and it is rich in vitamins, mineral and fibre. It is widely used in varieties of dishes as raw, cooked or processed products in Nigeria. The production of tomato started experiencing increase from 1.79MT in 2010 until 2015 when it hit the production volume of 4.22 MT. However, the country could not sustain the increase as the production value declined to 3.57 in 2021 (FAOSTAT, 2021). The decline in production volume has raised an important policy question such as what factors are responsible for the dwindling production figure of tomato in the country. The answer perhaps could be in the technical efficiency of the farm or the farmers which is referred to as the ability of a farm to produce as much as output with the level of inputs, given the existing technology (Erena *et al*, 2021). The study therefore seeks to support literatures in production efficiency by analyzing the technical efficiency of tomato farmers in Yamaltu-Deba Local Government Area of Gombe State. Specifically, the study described the socio-economic characteristics of tomato farmers; estimated the determinants and levels of technical efficiency of tomato farmers in Yamaltu-Deba Local Government Area of Gombe State.

MATERIALS AND METHODS

Study Area

The study was carried out in Yamaltu-Deba Local Government Area (LGA), Gombe State. Yamaltu-Deba is one of the eleven Local Government Areas in the State with its headquarters in Deba. According to NBS (2009), the result of 2006 census indicated a population of 255,726 for Yamaltu-Deba LGA. The LGA covers an area of about 1,981 square kilometers and lies at latitude $11^0$31' N and longitude 11˚24' E with the temperature ranges from 20^0C to 31^0C and mean annual rainfall of 750mm. The soil is rich clay-loam, making it ideal for agricultural activities (Saleh *et al*., 2021). The LGA is known for cultivation of a wide range of vegetables, fruits and cereals. It hosts parts of the lake Dadinkowa and shares boundaries with parts of Borno State to the North, Balanga LGA to the South, Gombe and Akko LGAs to the East (Erie *et al*, 2019). The target population was tomato producers.

Sampling technique

A multistage sampling technique was used in the choice of individual respondent. The first stage was purposive selection of Yamaltu-Deba LGA from eleven LGA in Gombe state. Yamaltu/Deba was selected because it is known for production of tomato. The second stage was random selection of two belts within the LGA based on size of tomato production- Dadinkowa and Kwandon. The third stage involved random selection of forty tomato producers from each belt, making a total of eighty. However, data from seventy-seven respondents were found useful for analysis.

Data source and analysis

Primary data were used for this study. Data were collected by the use of well-structured questionnare. Respondents were asked to indicate socio-economic characteristics and production variables (quantities of inputs used and output).

Data analysis involved the use of descriptive and Stochastic Production Frontier Analysis (SPFA). The descriptive analysis was used to analyze socio-economic characteristics of farmers while SPFA with Cobb-Douglas functional form was used for estimating the determinants and levels of technical efficiency.

$$Y_i = f(X_i, \beta)e^{v_i - u_i} \ldots\ldots(1)$$

$$\ln Y_i = \beta_0 + \beta_1 \ln X_1 + \beta_2 \ln X_2 + \beta_3 \ln X_3 + \beta_4 \ln X_4 + \beta_5 \ln X_5 + \beta_6 \ln X_6 + \beta_7 \ln X_7 + v_i - u_i \ldots\ldots(2)$$

where,

Y_i = Observed individual *ith* farm output of tomato (Kg)

X_1 = Farm size (ha)

X_2 = Quantity of seeds (Kg)

X_3 = Fertilizer (Kg)

X_4 = Organic manure (Kg)

X_5 = Herbicides (litres)

X_6 = Pesticides (litres)

X_7 = Labour (man days)

$\beta_{i's}$ =Technology parameters to be estimated

ln = Natural log

The v_{is} are random error variable that are assumed to have normal distribution $iid\,N(0, \delta_{vi}{}^2)$. The u_{is} are non-negative random variable having half of normal distribution $iid\,N^+(0, \delta_{ui}{}^2)$ which measures technical inefficiency effects.

Accordingly, Technical efficiency (TE) of individual tomato farmer is defined as the ratio of observed output (Y_i) to the corresponding frontier output (Y_i^*), conditioned on the level of input used by farm. Technical inefficiency is therefore defined as the amount by which the level of production is less than the frontier output. The model for TE will be expressed as:

$$TE = \frac{Y_i}{Y_i^*} = \frac{f(x_i;\beta).\exp(-u_i)}{f(x_i;\beta)} = \exp(-u_i) \ldots\ldots(3)$$

where, Y_i is the observed and Y_i^* is the frontier output. Technical efficiency takes value between 0 and 1 i.e $0 \leq TE \leq 1$.

In addition, the study measured technical inefficiency, u_i , of the tomato farmers. The technical inefficiency effects are as follows:

$$\ln Y_i = f(\alpha + \beta) + e_i \ldots\ldots(4)$$

$$u_i = \alpha_0 + \alpha_1 Z_1 + \alpha_1 Z_1 + \alpha_1 Z_1 + \alpha_1 Z_1 + \alpha_1 Z_1 + \alpha_1 Z_1 + \alpha_1 Z_1 + \alpha_1 Z_1 + v_i + u_i \ldots\ldots(5)$$

Where,

Ui = technical inefficiency of equations 4 and 5 respectively

α_i = Vector of parameters
Z_1 = Age of tomato farmers (years)
Z_2 = Marital status (Married 1, otherwise 0)
Z_3 = Education (years)
Z_4 = Household size of the farmer
Z_5 = Membership of association (1 if farmer belongs to association, 0 otherwise)
Z_6 = Extension visit
Z_7 = Training
Z_8 = Record keeping (1 if farmer keeps record of farming activity, 0 otherwise)
e = Random error

The u_i is non-negative random variable having half of normal distribution $iid\, N^+(0, \delta_{ui}^{\ 2})$.

RESULTS AND DISCUSSION

Socio-economic characteristics distribution of respondents

The distribution of socio-economic in table 1 revealed that most of the producers were within the age range of 20-39years with mean age of 37years. This is an indication that the farmers in the study area enjoys involvement of young persons in farming activities. About eighty-one percent of the respondents were male, indicating that men engage more in the tomato production in the study area. This is in conformity with finding of Saleh *et al,* (2021) and Usman and Bakari (2013) who reported the mean age of approximately 40years in their study areas. Over 68% of those engaged in tomato production were married with the mean household size of 11 persons, implying that most of the respondents have advantage of supply of family labour. The result is in line with Pius *et al*, 2006 who opined that farmers with sizeable family could engage them to their farm business. Eighty-three percent of the respondents had formal education, indicating that majority of respondents were literate and this could assist them in effective communication in doing their business (Asogwa and Okwoche, 2012). In term of experience, 54.6% had spent between 6 and 15 years the tomato farming, indicating a relatively high knowledge in tomato production. The greater the year of farming experience, the more knowledgeable the farmer is in minimizing costs and maximizing the profits.

Summary of quantity of input used by tomato farmers

A tomato farmer in the study area harvested an average output of 5,758.78kg from 1.08ha of land and about 5.63kg tomato seeds. The farmer applied an average of 130.24kg of fertilizer, 21.94 litres of herbicides, 43. 37litres of insecticides and utilized average of 481.94 mandays per hectare (Table2).

Table 2: Summary of quantity of input used by tomato farmers

Variables	Mean
Average farm size for tomato (ha)	1.08
Seed (kg)	5.363
Fertilizer (kg)	130.24
Herbicides (litres)	21.94
Insecticides (litres)	43.37
Labour (manday)	481.94
Output (kg)	5,758.78

Maximum Likelihood Estimate for the Stochastic frontier

The result of stochastic frontier analysis and the inefficiency model are presented in table 3. The variance parameters for sigma squared (σ^2) and gamma (ϒ) are 0.0304 and 0.978 respectively for tomato farmers and are significant. The sigma squared is an indication of goodness of fit and correctness of the distributional form assumed for composite error term while the gamma shows that about 97.8% of total variation is due to technical inefficiency and 2.2% accounts for random shocks. The result further shows that the coefficient of the parameter estimates of farm size was positive and significant to output at 10%, use of organic and inorganic fertilizer was positive and significant at 1% and insecticide have positive significant influence on tomato output at 1%. While the coefficient of the parameter estimates of herbicide had negative and significantly effect on output at 10%. This implies that a unit increase in farm size, organic and inorganic fertilizer, and insecticide will increase tomato output by 0.016, 0.058, 0.072 and 0.162 respectively. However, a unit increase in quantity of herbicide will reduce the output by 0.119. The estimated elasticity of all the inputs are less than one, indicating decreasing returns to scale. This implies that the farmers operate in the stage two of production, and should be careful to know when to stop increasing input because increase in input combination by 1% will result to less than 1% increase in total output.

The lower panel of Table 3, presents the estimated parameters of the inefficiency model in the stochastic frontier production function of tomato farmers. The signs of inefficiency model of the stochastic frontier production function had important implications on technical efficiency. The result revealed that only the coefficient of the parameter estimate of membership of association was positive and statistically significant to technical inefficiency which implies that membership of professional association reduces efficiency of the farmer. This is against the *apriori* expectation and may be due to the fact that some decisions being taken by the executives are having negative influence on the activities of the members. Although record keeping, training, household size and marital status were not statistically significant but had negative signs. The negative signs indicate parameters that reduce technical inefficiency of the farmer, and thus increase their efficiency.

Distribution of technical efficiency estimates for tomato farmers in the study area

Frequency distribution of technical efficiency of the farmers shows the efficiency of the farmers ranges from minimum value of 0.58 and maximum value of 1 with the mean technical efficiency value of 0.87 (Table 4). This shows that if the farmers with minimum efficiency are able to achieve the maximum level of efficiency, they would be able to save 42% of production resources. Likewise, the efficient farmers will be able to save 13% of their usual production input. The mean technical efficiency value also indicates that tomato farmers in the study area were technically efficient (Coelli *et al*., 2015).

Table 4: Frequency distribution of technical efficiency estimates for tomato farmers in the study area

Efficiency range	Frequency	Percentage
Less than 0.50	-	-
0.51-0.60	1	1.30
0.61-0.70	5	6.49
0.71-0.80	10	12.99
0.81-0.90	25	32.47
0.91-100	36	46.75

CONCLUSION

Based on the findings, the study concludes that farmers were technically efficient and could improve their output and efficiency through proper input combination. Fertilizer and pesticide contributed largely to output in the study area, the study therefore recommends policy that will encourage input distribution to farmers in order to boost tomato production. Training of farmers should be encouraged as this could improve their efficiency.

ABSTRACT
Loss of crop production due to microbial plant pathogens poses serious threat to food security. Implementing appropriate management strategies against pathogens only produces positive results, following reliable detection and adequate understanding of their dynamics. Global yield losses in pepper production have been attributed to viral pathogen infection. About 68 viruses are associated with yield loss on Capsicum spp. A diagnostic survey was conducted on protected Capsicum spp. at Wells Hosa Farm, Benin city, Edo state, Nigeria to determine the prevalent viruses at the surveyed location. Enzyme-linked immunosorbent assay (DAS and TAS-ELISA) detected tomato spotted wilt virus (TSWV) in the samples tested at incidence rate of 71.4%. Molecular analysis for detection of Begomoviruses, based on amplification of a 500 bp fragment did not discover the virus in all the samples tested.
Keywords: *Pepper, DAS and TAS-ELISA, TSWV, Begomovirus, PCR*

INTRODUCTION

Pepper (*Capsicum* spp.), belonging to the family *Solanaceae*, is among the economically valuable vegetable crops, ranked second after tomato globally (Akpan *et al*., 2023). In human diet, it is an excellent source of minerals, micronutrients (Ca and Fe), vitamins (A, C and E) and natural antioxidants. *Capsicum* spp can be eaten raw in salad, cooked or processed. Nigeria is the largest producer of pepper in Sub-Saharan Africa, where it is regarded as the third most important vegetable after onion and tomato (Adetula and Olakojo, 2006). Cultivated peppers are relatively susceptible to about 68 viruses, which cause important production losses globally (Ojinaga *et al*., 2022). Members of the genera *Cucumovirus*, *Potyvirus*, *Orthotospovirus* and *Begomovirus* cause significant damages to *Capsicum* spp. (Jo *et al*., 2017). Ayo-John and Odedara (2017) reported incidence of Cucumber mosaic virus (CMV, *Cucumovirus*) and Pepper veinal mottle virus (PVMV, *Potyvirus*) across three south-western states in Nigeria. Tomato spotted wilt virus (TSWV), a member of *Orthotospovirus*, has a large host range, including tomato, amaranth and pepper (Wang *et al*., 2022). Incidences of TSWV are well documented in North and South-west Nigeria (Alegbejo, 2015). *Begomoviruses* constitute the largest group of plant-infecting single-stranded DNA viruses, transmitted by whiteflies of *Bemisia tabaci* complex and affecting diverse plants in tropical and sub-tropical regions, including vegetable crops such as *Capsicum* spp. (Zerbini *et al*., 2017; Leke *et al*., 2015). This study was conducted to determine the incidence and distribution of selected common plant viruses, namely CMV, *Potyviruses*, *Begomovirus* and TSWV in a protected commercial farm in Benin city, Edo state, Nigeria.

MATERIALS AND METHODS

Survey and collection of virus-infested samples

Survey was randomly conducted in five pepper-growing green houses at Wells Hosa Farm, Benin city, Edo state, in December, 2020. Leaf samples from as many parts showing virus-like symptoms were collected alongside the asymptomatic samples. Each sample was placed inside sample bottle containing silica gel and cotton wool for proper storage prior to the commencement of laboratory works.

Enzyme-linked Immunosorbent Assay (ELISA)

Serological testing was performed using Double (CMV, *Potyviruses*) and Triple-Antibody Sandwich (TSWV) ELISA. Microtitre wells of ELISA were coated with 100µl of appropriately diluted immunoglobin G (IgG: 1:1000) for the three viruses under test in carbonate coating buffer (0.015 M Na_2CO_3 and 0.034 M $NaHCO_{3,\ pH\ 9.6}$). Plates were incubated at 37^0C for 2h and afterwards washed three times with PBS-T (Phosphate saline buffer containing 0.05v/v Tween-20). ELISA plates were tapped and allowed to dry. Afterwards, 100µl aliquot of extracted sap of infected pepper, alongside negative and positive controls, obtained following thorough grinding of the concerned samples with conjugate buffer (0.1g egg albumin, 1g polyvinylpyrollidone) was dispensed into the wells and incubated overnight at 4^0C. Contents of well were decanted and plates washed and allowed to dry as described previously. For the detection of TSWV, 100 µl of appropriately diluted monoclonal antibody (Mab: 1: 1000) in conjugate buffer was added and incubation observed for 1 h. Afterwards, 100 µl of enzyme-labelled antibody (IgG-alkaline phosphatase) cross-adsorbed using healthy pepper leaf sap extract was dispensed in each well and incubated for 1 h. Wells were washed as aforetime and 100 µl of 1 mg/ml para-nitrophenyl phosphate (PNP) dissolved in substrate buffer (97 ml/L, pH 9.8) was added to each well and the content incubated for 4 hours after which spectrophotometric readings were taken at 405nm using ELISA plate reader (EL×1000, Global Diagnostics, Belgium).

DNA Extraction and Polymerase Chain Reaction (PCR) Assay

Total genomic DNA was extracted from the collected leaf samples, following modified CTAB protocol (Mignouna *et al*., 1998). DNA pellets were re-suspended with 50µl sterile distilled water and stored at 4^0C. Extracts were evaluated for the presence of *Begomoviruses* by PCR using degenerate primers AVcore-FP (5'-GCCHATRTAYAGRAAGCCNAGRAT-3') and ACcore-RP (5'-GGRTTDGARGCATGHGTACANGCC3'). PCR cycling condition included initial denaturation at 94°C for 2 mins, followed by 35 cycles consisting of denaturation at 94°C for 1 min, annealing at 60°C for 2 mins, extension step at 72°C for 2 mins and final extension at 72°C for 10 mins. Extracted and amplified DNA fragments were electrophoresed on 1.2% agarose gel in 0.5×TBE buffer, stained with ethidium bromide at 80 V for 30 min and visualized under a UV transilluminator.

RESULTS

Table 1: Reactions of tested samples to DAS- and TAS-ELISA

S/N	Sample Identity (GH)	Reactions to DAS (CMV,Potyviruses) TAS (TSWV)		
		CMV	Potyviruses	TSWV
1	6	-	-	-
2	6	-	-	-
3	8	-	-	+
4	8	-	-	+
5	10	-	-	+
6	13	-	-	+
7	13	-	-	+

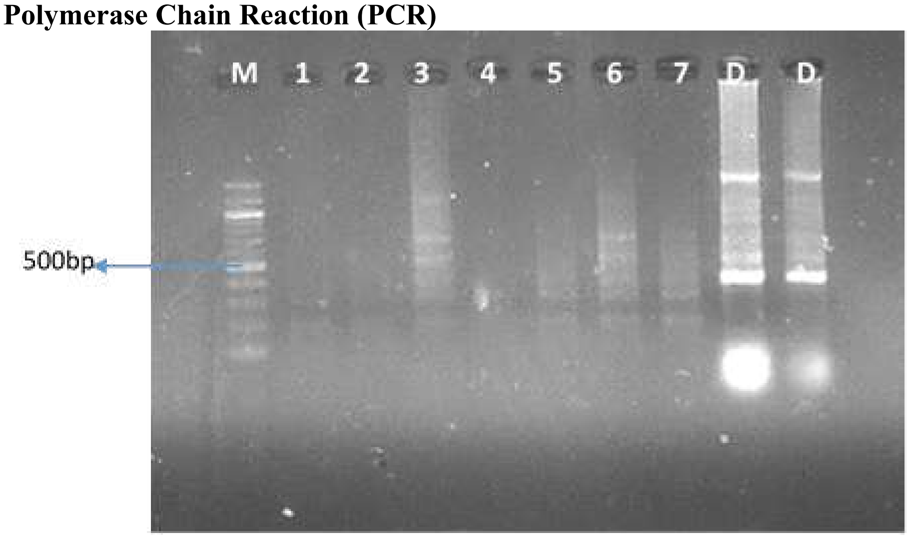
	PC*	2.509[a]	2.494[a]	2.987[a]

[a]Sample was considered CMV, Potyvirus and TSWV positive when mean absorbance (A405 nm) was two times greater than the absorbance from uninfected plant controls.
[z]CMV= cucumber mosaic virus, TSWV=tomato spotted wild virus
*GH= Green house, NC= Negative control, DC=Disease control

Serological Analyses

The sampled pepper plants exhibited a wide range of symptoms, including mosaic pattern of light and dark green, leaf deformation, veinal chlorosis, leaf curl and wrinkling under the protected environment. Serological analyses of all samples tested using specific antibodies for CMV and Potyviruses were negative to the viruses in the two genera. However, out of the 7 samples tested, 5 were found positive for TSWV, with incidence of 71.42% while the virus was not discovered in 28.57% of the samples. Disease incidence was estimated as the percentage of the number of symptomatic over the total number of leaves analysed. Samples were considered positive when the ELISA reading obtained was at least twice that of the healthy control used in the study.

Polymerase Chain Reaction (PCR)



Lane M=100 bp DNA ladder, 1&2=GH6-7, 3&4=GH8, 5=GH10
6&7=GH13, D=Disease control

Figure 1: Detection of begomovirus at expected band size of 500 bp

PCR Analysis

Begomovirus detection by PCR was confirmed only in the positive (diseased control) samples used in the study, yielding 500 bp amplicon size. Obtaining the expected band size in the diseased samples stands to confirm the validity of the PCR result.

DISCUSSION

Viral diseases constitute a major biotic constraint to pepper production, affecting both yield and quality of fruits produced (Nono-Womdim, 2001). Transmission and spread of viruses in pepper poses great danger to its sustainable cultivation and vegetable farming at large (Arogundade *et al*., 2012). Out of about 68 viruses associated with *Capsicum* spp., about 15 have been identified in Africa (Kenyon *et al*., 2014). Cucumber mosaic virus and *Potyviruses* have been reported among the most prevalent in SSA (Dafalla, 2001). Our result however did not detect either CMV or *Potyviruses* in the sampled location. This could be attributed to the absence of aphid vectors (the transmission agents of these viruses) in the protected green houses. TSWV has been listed as one of the viruses affecting *Capsicum* spp. even under protection (Simon *et al*., 2016). TSWV is transmitted exclusively by a number of thrips, especially *Frankliniella occidentalis* (Whitfield *et al*., 2005). The presence of thrips in GH 8,10 and 13 explains why our results tested positive to TSWV in the concerned green houses. Jones (2005) also reported transmission of TSWV through mechanical inoculation and grafting.

The use of chemical control measure for TSWV has not been highly recommended, as thrips have been reported to develop resistance to synthetic insecticides over time (Chattopadhyay *et al*., 2017). Breeding of resistant cultivar to TSWV, harbouring the pepper resistant gene Tsw has been considered more efficient (Gunes and Gumus, 2019). Screening of planting propagules for TSWV and thrip infestation, regular monitoring of thrip infestation, removal of reservoir weed host around pepper cultivation and roguing of infected pepper stands, are some of the control measures that have been recommended for the management of TSWV (Zitter and Daughtney, 1989).

ABSTRACT
Cool storage can prolong the shelf life of produce hence, this study deals with the construction of ZECC with modifications in its design and construction in order to achieve this purpose. Temperature measuring tests were conducted on it to determine the capacity of the structure to lower temperature. Zero Energy Cooling Chamber was designed, constructed, and evaluated. The chamber is a double-walled structure made of bricks having a cavity filled with mixtures of river sand, charcoal and sawdust. The evaluation showed that temperatures inside the chambers ranged from 10^0 ^{O}C to 15^0 ^{O}C lower than the outside ambient temperature and the relative humidity was 80%. The rise in humidity and fall in temperature was achieved by watering the cavity to ensure appropriate cooling of the chamber. The ZECC was evaluated over a period of 21 days with Roma tomatoes. For these periods of 21 days, loss in weight was calculated to be 29 % in the cooling chamber and 67.5 % under ambient conditions. Moreover, firmness, total soluble solids and colour were maintained over these 21 days.
Keywords: *Loss in weight, relative humidity, temperature control. Tomato storage and zero energy cooling chamber (ZECC),*

INTRODUCTION

Evaporative cooling is generally known to be an efficient and economical system and means for reducing temperature and increasing relative humidity in an enclosure. This effect was extensively tried to increase the shelf life of horticultural produce in some tropical and subtropical countries. (Lal Basediya *et al.,* 2013). Methods of evaporative cooling and their application for the preservation of fruits and vegetables are among other methods of evaporative cooling. A zero-energy cooling system could be used effectively for short-duration storage of fruits and vegetables. This reduces the storage temperature but also increases the relative humidity of the storage device which is essential for maintaining the freshness of the commodities. Fruits and vegetables are stored at a lower temperature because of their highly perishable nature. (Lal Basediya *et al.,* 2013)

Zero Energy Cooling Chamber (ZECC) is a cooling chamber which works through the principle of an evaporative cooling chamber. Cooling is required to maintain the freshness of fruits and vegetables during storage. Spoilage of fresh fruits and vegetables has been a long-term problem in tropical countries. Cool storage however prolongs the shelf life of fresh produce, whereas refrigeration equipment which serves alternative purposes is expensive to buy, expensive to run, and expensive to maintain. A practical, low-cost alternative for on-farm fruit and vegetable storage which employs the cooling power of evaporation is affordable and generally acceptable by farmers. (Lal Basediya *et al.,* 2013). Vegetables are the fresh and edible portions of herbaceous plants. They are important food and highly beneficial for the maintenance of health and the prevention of diseases. They contain valued food ingredients which can be successfully utilized to build up and repair the body. Vegetables are valuable in maintaining an alkaline reserve in the body. They are valued mainly for their high carbohydrate, vitamin and mineral contents from different kinds of vegetables (Hanif *et al.,* 2006)

The main importance of fruits and vegetables is that they provide vitamins and other nutrients that help for the proper functioning of the body. Hence, fruits and vegetables are essential building blocks of any diet, it is not only that they are loaded with vitamins and minerals which are essential for healthy living, but they also give satisfaction as part of the balanced diet (Peter E. M. G. *et a.,* 1997). Evaporative cooling was found to be an efficient and economical means of reducing temperatures and increasing humidity in a man-made enclosure where the humidity is comparatively low (Dadhich *et al.,* 2008) Evaporative cooling is a well-known system to cool a specified environment with the aid of an adiabatic process, in which ambient air is cooled as a result of transferring its sensible heat to the evaporated water carried with the air. In the evaporative-cooled structure, the maximum advantage of the natural environment was employed to lower the temperature of the outside ambient air to a considerably low level. The evaporative cooling storage system is easy to operate, efficient and affordable most especially for peasant farmers in developing countries like Nigeria where other methods of preservation are quite expensive and unaffordable (Ihekoronye *et al*., 1985). This study was carried out by designing and constructing an adaptable ZEEC for farmers, to determine the water-holding capacity of the ZECC cavity material and to examine the post-harvest qualities of fruits and vegetables stored in the chamber.

MATERIAL AND METHOD

Zero Energy Cooling Chamber:

A Zero Energy energy-cooling chamber was constructed from clay soil made of bricks. The clay soil was sieved, pounded and moulded with the aid of a mould constructed to specification at the back of the processing unit of the National Horticultural Research Institute, Jericho, Ibadan. The bricks were set and arranged to form a double wall brick that had a cavity in between. The cavity was filled with layers and mixture of river sand, coco-peat and charcoal with sawdust. The inside was further divided into four chambers that could accommodate four different horticultural crops. This structure was raised over a single row of brick floors and a double layer of brick wall on the sides having an interspace of 8 cm filled with sawdust. The top of the storage space was covered with coconut leaves in bamboo roofing covered with tarpaulin. The cool chamber will be saturated with water for the first time thereafter sprinkling of water carried out once in the morning and once in the evening and was enough to maintain the required temperature and humidity. These chambers will help to maintain a very high humidity of 95 % throughout the year and reduce the temperature of the chamber during summer months. These chambers are ideal for storage for a short period and helpful for small and marginal farmers to store their produce. (Ashitha *et al*., 2010)

Cooling chambers work on the principle of evaporative cooling. Evaporative cooling is the reduction in temperature resulting from the evaporation of a liquid, which removes latent heat from the surface from which evaporation takes place. (Ashitha *et al*., 2010) Evaporation of water produces a considerable and appreciable cooling effect emphatically establishing that the faster the evaporation the greater the cooling. This indicates that when the temperatures are the same, no net evaporation of water in the air occurs, which means that there is no cooling effect. The principle of working of this system is 'when a particular space is conditioned and maintained at a temperature lower than the ambient temperature surrounding the space, there should be the release of some moisture from outside the body'. This maintains low temperature and elevated humidity in the space compared to the surroundings. The evaporative cooling chamber fulfils all these requirements and is of great importance to small farmers in rural areas (Dadhich *et al*., 2008)

MATERIALS

The following materials are used to construct a specialized model of ZECC.

- Bricks,
- Composite mixture of river sand, sawdust and coco peat,
- Charcoal,
- PVC pipes,
- Bamboo shoot, net taped a wood species and coconut leaf
- Clay mortar and
- Tarpaulin

Construction Procedure

The following procedure is adopted to construct a specified model of ZECC.
- An existing water tank was connected to enable a constant supply of water.
- Floor of size 348cm × 348cm was made.
- The double wall was erected at a height of 90 cm having a cavity of 17cm.
- PVC pipes (2 inches diameter) are installed horizontally along the square shape of the cavity in order that it will enable water to run through the cavity.
- the square-constructed double wall which accommodates 280cm x 280cm was further divided into four and
- the four chambers were averagely 130 cm x 130 cm each,
- before the installation of PVC pipes, perforations were made on its surface and the perforations were such that it was channelled through the upper layer of the cavity to percolate the materials fixed in the cavity in the process to ensure cooling.

Design and Consideration of the Cooling Chamber

The cooling chamber is square in shape and designed to specifications.

In geometry, a Square is a flat figure or shape which has four equal sides and every angle is a right angle, i.e. 90°. From this, it follows that the opposite sides are also parallel. It is also described as a rectangle which has two adjacent sides having equal lengths. The area of a square can therefore be found by measuring the amount of space occupied within the square.

$$A=L^2$$

where L is the length of sides in cm

since L = 280cm

$$A = 280^2 = 280cm \times 280cm$$

$$A = cm^2$$

The volume of a Square formula is the volume of a column with a squared face, a polygon with 4 equal sides of length (L) and height (H).

$$V = L^2 H$$

Where L=280cm and H= 90cm

$$V = 280^2 \times 90$$

$$V = 7,056,000cm^3$$

For the volume of the cavity, $V = L \times B \times H$

Right and Front = Left and Rear

So we calculate right as

$$V_r = L_r \times B_r \times H_r$$

$$V_r = 348cm \times 17cm \times 90cm$$

$$V_r = 532,440cm^3$$

For the front, $V_f = L_f \times B_f \times H_f$

$$V_f = 314cm \times 17cm \times 90cm$$

$$V_f = 480,420cm^3$$

Total volume, V_t the cavity contains = Right +Front + Left + Rear

$$V_t = V_r + V_f + V_l + V_{re}$$

$$V_t = 532,440 + 480,420 + 532,440 + 480,420$$

$$V_t = 2,025,720\ cm^3$$

Examination of Lateral pressure and Bending

Equations (1) and (2) are the lateral pressure calculation formula for the material poured by general internal vibro-compaction for which its mixture is ≤75 mm and the depth is ≤0.5 m. The equation can be used for walls when the pouring speed is <0.8 m/h and the pouring height is <1.5 m. In the equation, "p" is the horizontal pressure (Kn/m^2), "R" is the pouring speed (m/h), and "T" is the material temperature in the formwork (°C). "C_w" is the unit weight factor with a value of 1 corresponding to the unit weight ranging from 22.5 to 24 N/m^3, which was used based on the Building Code. "C_c" is the chemical additive factor with a value of 1. (Singh *et al.,* 2006)

$$P = Cw\ Cc\ [(7.2 + 790R)/T+18\} \quad (1)$$

$$Cw = Cc = 1 \quad (2)$$

$$P = 7.2 + (790 \times 1.2) / (31+18) = 19.5kN/m2$$

The flexural strength was calculated using a thickness of 200 mm and a lattice bar spacing of 2800 mm. The following equations show the results of the working load moment (M), bending stress (σ), allowable tensile stress under crack width limitation (ft), and flexural reinforcement (Mu). (Vala and Joshi, 2010)

$$M = pL2/8 = [19.5(2.8)2\ ]/8 = 19.11\ km$$

$$\sigma=M/Z=M/(bh2/6) = 6(19.11)\ /0.93(0.2)2 = 3082.3\ kN/m2 = 3.1\ MPa$$

$$=3.1\ MPa > 1.4\ MPa - o.k. \quad (3)$$

Equations (13)–(16) show the shear performance based on the PCDW lateral pressure examination results. "Vu" is the ultimate shear force in the cross-section, and "∅" is the strength reduction factor.

$$V=pL2=19.5(2.8)2=109.2\ kN \quad (4)$$

$$Vu=1.2\times109.2=131.04\ kN \quad 5)$$

$$\emptyset Vn=\emptyset(16)fck{-}{-}{-}\sqrt{}bwd=0.75(16)35{-}{-}\sqrt{}(1000)(30)(10-3) \quad (6)$$

$$=22.19\ kN>11.13\ kN-o.k.$$

Experimental Procedure

Maximum and Minimum temperature and relative humidity were recorded inside and outside the chamber for three weeks. The inside temperature and its humidity and the outside temperature and its humidity were determined with the aid of a hygrometer and thermometer.

A comparative study was made for the storage of tomatoes inside the cooling chamber and in the ambient condition and their weight loss; colour changes and freshness were observed to know how long it will take to reach perishable state.

RESULT AND DISCUSSION

Temperature and Humidity

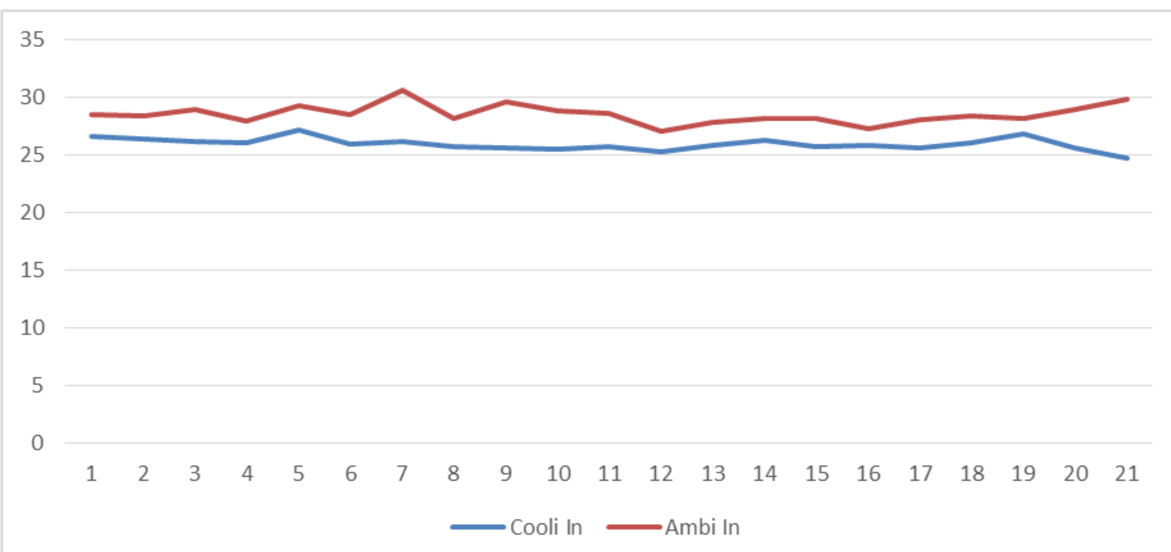

Figure 1: Temperature profile in the colling room and ambient per time

As presented in Figure 1, the temperature was measured inside, outside and inside the room during different time intervals over the period of 21 days. The temperature readings were taken after the watering of the Zero-energy cooling chamber. The outside temperature varies with time and intensity of sunlight but the inside temperature remains nearly the same at all the time of temperature measurement in a day. The day-to-day variation in temperature inside the chamber is considerably low. From the experimental study conducted on an energy-cooling chamber, it was clear that Zero energy energy-cooling chamber can reduce the inside temperature from 10^0 °C to 15^0 °C lower than the outside temperature. And also it can maintain a constant temperature inside the chamber.

Comparative Study

Weight Loss

The record of weight loss of tomatoes kept inside the chamber was determined. Percentage loss in weight (PLW) was determined by weighing the tomatoes over an interval of time during storage with the equation used by [6, 7] as stated below and was compared with the ambient.

$PLW = (W1 - W2)/ W1 \times 100$

where W1=Weight of the sample before storage, Kg and W2=Weight of the sample after storage, Kg.

% Loss in Weight for cooling chamber after 21 days = (1 – 0.71)/1 x 100= 29%

% Loss in Weight for ambient after 21 days = (1 – 0.33)/1 x 100= 67.5%

Colour Variation

Colour chat was used to identify the observed colour changes as it applied from the chat over the period of 21 days.

Total Soluble Solids

The total soluble solids also known as brix were maintained at 4 over the period of 21 days for the cooling chamber whereas it was stylishly decreasing from 4 to 2.5 over the period of 21 days.

Firmness

Firmness was measured with the aid of a penetrometer and was retained at 7 for the cooling chamber while it deteriorated to 4 over the period of 21 days.

CONCLUSION

The rise in humidity and fall in temperature was achieved by watering the cavity to ensure appropriate cooling of the chamber. The ZECC was evaluated over a period of 21 days with Roma tomatoes. For these periods of 21 days, loss in weight was calculated to be 29 % in the cooling chamber and 67.5 % under ambient conditions. Moreover, firmness, total soluble solids and colour were maintained over these 21 days.

ABSTRACT
Clonal propagation is a vegetative technique used in the propagation of plants without seed. This study was designed to compare the response of two cultivars of Fluted pumpkin (Telfaria Occidentalis) cultivation using three different substrates which includes: Semi Autotrophic Hydroponic, Composted sawdust and sawdust only. There were two treatment hormones which consisted of synthetic hormone Indole Butyric Acid (IBA) and natural hormone (coconut water). The experiment was a closed randomised design (CRD). The percentage increase in growth parameters revealed that Calabar cultivar pre-treated with synthetic hormone (IBA) and planted in SAH had the highest increased vine length of 51.5 %, and Calabar cultivar pre-treated with coconut water planted in SAH with 50.8 % while the highest vine length increased for Yoruba cultivar pre-treated with coconut water with 47.6 %. Highest percentage increase in number of leaves was observed in pre-treated Calabar cultivar in SAH and there were significant man treatment differences due to the substrate, treatments, and interaction between the cultivars. This study revealed that high nutrient concentrated media and growth hormones greatly supported Telfaria plants growth and leaves production.
Keywords: *Clonal propagation, Coconut water, Composted sawdust, Semi Autotrophic Hydroponics and Tefaira occidentalis.*

INTRODUCTION

Fluted pumpkin (*Telfairia occidentalis*) belongs to the family of Cucurbitaceae, a dioecious climbing perennial vine which is partially drought tolerant (Imosemi, *et. al* 2010). *Telfiaria occidentalis* is cultivated for its edible leaves, stems, and seeds as a backyard plant particularly by the Igbo tribe. And spread to other parts of the country as the Igbos migrates from one part to another. (Akoroda, 1990). Ghana and Cameroon was the major producer in Africa (Kayode, *et. al.* 2011) but the cultivation skewed towards the southern part of Nigeria. Both the leaf and seeds are rich in both macro and micronutrients such as carbohydrates, protein, essential oils, vitamins, minerals, and fibre (Ellah, *et al.,* 2016).

Seed propagation is the major means of propagating *T. occidentalis*; however, the seeds are recalcitrant in nature, which causes shortage of seeds and in turn make the seeds expensive. Although, tissue culture technique has been used for rapid clonal propagation of *T. occidentalis* (Akinyemi and Esuola, 2012, Esuola and Akinyemi, 2011, Esuola and Akinyemi, 2010) but this technique and the output seedlings were expensive for most farmers. Rapid clonal propagation of *T. occidentalis* can be harnessed for rapid multiplication of this crop which allows true to type, faster growth and plant uniformity propagations when compared to seeds propagated techniques. Roots initiation through vine cuttings of fluted pumpkin with the use of indole butyric acid (IBA) was reported by Acha, *et. al*. (2004) but the cost implication and availability of the hormones to farmers has been a major impediment. This makes the need to develop a multiplication technique for fluted pumpkins which are less expensive and readily available for farmers use is imperative. Consequently, this study focused on the rate of fluted pumpkin multiplication improvement through stem cuttings with the use of different substrates as influenced by natural hormones.

METHODOLOGY

The experiment was carried out at the National Horticultural Research Institutes (NIHORT), Ibadan vertical farmhouse, using two cultivars of *Telfairia occidentalis* ("Calabar" and "Yoruba" cultivars). Seeds of the cultivars were collected from vegetable programme/project 5 experimental field and were sown in sawdust substrate for sprouting. Vines from pre-germinated seeds were excised using sterilized surgical blades and pre-treated separately in synthetic hormone (Indole Butyric Acid (IBA)) and natural hormone (coconut water). These pre-treated vines were planted in three different media which includes sawdust only, commercial SAH compost and composted sawdust. The experiment was laid out in a complete randomised design (CRD). The germinated vines were monitored for growth attributes for 6 weeks. Data were collected at 2, 4, and 6 weeks after planting (WAP) on vine length (cm), number of nodes, number of leaves, and leaf length (cm).

RESULT

The data obtained (Table 1) showed the percentage increase in the agronomic parameters of the fluted pumpkins cultivars vines that were pre-treated with different hormones the in different media. The highest percentage increase in vine length (51.5 %) was recorded in Calabar cultivar pre-treated with synthetic hormone and planted in SAH commercial compost, while the same cultivar pre-treated with natural hormone (Coconut water) and planted in the same media had 50.8 % (Table 1). This could be because of the higher nutrient concentrations in SAH which would have supported better elongation of the vine. On the other hand, the highest percentage increase in vine length recorded for the Yoruba cultivar pre-treated with coconut water and planted in composted sawdust was 47.6 % (Table 1). This could be attributed to low essential elements present in the composted sawdust, this agrees with the findings of Agbede (2008) who found out that the number of crops significantly increased with increase in the concentration of nutrients in the substrate. Moreover, the highest percentage increase in number of leaves was observed for the Calabar cultivar pre-treated with coconut water and sown in SAH compost (Table 1), while there was no increment in the number of leaves for the Yoruba cultivar with same treatment (Table 1). SAH media for the Calabar cultivar produced 50 % and 51.6 % increment in the number of nodes using IBA and coconut water pre-treatments respectively (Table 1). The data also showed that there was no increment observed in the number of nodes for the Yoruba treated cultivar. Hence, IBA, coconut water and SAH compost could be noted to contain ingredients for plant growth that helps to support better leaf production. This trend was reported by Esuola and Akinyemi, (2010) in which they stated that plant growth hormones increases leaf and multiple shoot production in *Telferia occidentalis*.
Data on Table 2 showed that there were significant differences in the substrates and treatments used for this study. Also, there were interactions between both the substrates and the treatments, which mean differences were significantly different for both cultivars (Table 2). This submission was supported by the findings of Esuola and Akinyemi (2011) that there was significant increase in growth parameters of Ugu grown in-vitro under the influence of various regimes of growth hormones.

CONCLUSION

In this study, the use of commercial SAH compost (Dizengoff) with or without coconut bio-fortification was highly useful for rapid clonal propagation of *T. occidentalis* vine cuttings after six weeks of planting compared to using sawdust only or its compost.

EVALUATION OF GROWTH MEDIA ON MORPHOLOGICAL CHARACTERISTICS OF *Aschersonia aleyroides*: AN ENTOMOPATHOGENIC FUNGUS

Adesegun, E. A*., Umeh, V. C., Elum, C. G and Fajinmi, O. B
National Horticultural Research Institute (NIHORT), P.M.B. 5432, Idi-Ishin, Ibadan, OyoState, Nigeria

ABSTRACT
The fungus, Aschersonia aleyroides (Deuteromycotina: Hyphomycetes) is an entomopathogenic fungus reportedly to be host specific to white fly and probably the earliest known entomopathogenic fungus reported on scale insects. In a bid to search for appropriate medium of growth for cultivation and mass production of A. aleyroides as biocontrol agent to curtail the menace of white fly in citrus orchards, leaf samples with Aschersonia growth were obtained from NIHORT, Ibadan farming system orchard and isolation was carried out on Malt extract Agar, Potato dextrose agar and Saboraud dextrose agar. Identification was done based on cultural and morphological observations. PDA gave the best (45.33mm) mycelial growth 21 days post inoculation. Conidia of the fungus were spindle shaped, and hyaline. Based on the ability of A. aleyroides to produce large quantities of conidia on PDA, it was considered as the most suitable medium for the growth of the isolated A. aleyroides.
Keywords: *Aschersonia, agar, citrus, conidia control, entomopathogen*

INTRODUCTION

The utilization of the insect pathogenic fungal genus *Aschersonia* for control of pest has been studied extensively in different countries (Fransen *et al*., 1987, Chanley and Collins, 2007). *Aschersonia aleyrodes* (Webber) was the first fungal species applied to control insect in North America with the potential control of citrus whiteflies in Florida (USA) being attained in the early 1900s (Liu *et al*., 2006). *Aschersonia* spp. are not hazardous to mammals and some species have been reported to be effective bio-control agents against insects (Qiu *et at*., 2013). Consequences of the hazardous effect of the indiscriminate use of pesticides to manage insect pest (white fly) on citrus has necessitated the search for alternatives such as biocontrol agents as part of integrated pest management options to control insect population on the field. Entomopathogenic fungi are able to infect phloem-feeding insects naturally by penetration of the insect cuticle, which make them suitable pathogens of whitefly (Fransen 1990). *Aschersonia aleyrodids* causes epizootics in whitefly populations in the tropics and subtropics (Stefan, 2023). Fransen et al. (1987) found that conidia of *A. aleyrodis* could survive on leaf surfaces of cucumber for at least 3 weeks and will still be able to infect nymphs of greenhouse whitefly. Mass production of entomopathogenous fungi is an important step in successful utilization of entomopathogenic fungi as biocontrol agents. According to Dokgluaymai, *et al*., (2016), the production of conidia is dependent upon the culture medium and its nutritional source plays important role in determining the quantity of conidia in terms of spore germination. Few attempts have been made to multiply mycopathogen using synthetic media. The objective of this study is to investigate the most suitable synthetic medium that will accelerate the growth and sporulation of the *A. aleyroides* for laboratory cultivation.

MATERIALS AND METHODS

Isolation of Entomopathogen; *Aschersonia aleyroides*

Three different synthetic culture media; Malt Extract agar (MEA), Sabouraud Dextrose Agar (SDA) and Potato Dextrose Agar (PDA),) were used to assay the mycelial growth of the pathogen based on the method of Fovo *et al*. (2017). Citrus leaf samples with growth of *Aschersonia* specie were obtained from National Horticultural Research Institute (NIHORT), (Farming system programme orchard) and brought to the pathology laboratory of the institute for isolation. The samples were cut into small pieces and sterilization was done using (5%) NaOCl solution for 1 minute and rinsed in 3 changes of sterilized distilled water. These samples were placed on autoclaved sterilized agar; Potato dextrose agar (PDA), Malt extract agar (MEA) and Sabouraud dextrose agar (SDA), incubation was done at 26 ± 2°C for 21 days. Mycelial growth of the fungus single colony was transferred to fresh media plates to obtain pure culture. Cultural and morphological identification was done as described by Liu *et al.,* (2006) and Wang *et al*., (2013).

Cultural and morphological identification

Fig 1c: Photomicrograph of *Aschersonia aleyroides.*
Fig 1d: Mycelial growth of *Aschersonia aleyoides* at 21 days after inoculation (front view)
Fig 1e: Mycelial growth of *Aschersonia aleyoides* at 21 days after inoculation (reverse)

Table 1: Effect of three growth media on mycelial growth of *Aschersonia aleyroides*

Medium of growth	**Mycelial diameter (mm)**	**mycelial raised edge (cm)**
Malt extract agar	38.33	0.57
Sabouraud dextrose agar	32.67	0.23
Potato dextrose agar	43.33	0.13
LSD ($P \leq 0.05$)	4.00	0.16

The colony of *A. aleyroides* obtained in this study had a characteristically slow growth on the three media used until after 21 days of incubation. The growth culture on MEA was observed to be raised and woolly with uneven edges while that of PDA was slightly flat with even edges, however, SDA culture had slightly raised growth with rough edges. The mycelial growth was also observed to be significantly ($P \leq 0.05$) influenced by culture media. The colony on the culture media was whitish light pink in colour with pink white spore mass and light pink to brown on the reverse of the culture plates. Mycelial growth ranges from 32.67, 38.33, and 45.33mm on SDA, MEA, and PDA while the measurement of the raised culture edge was however found to be 5.70, 2.33 and 1.33cm on MEA, SDA and PDA respectively. The conidial shape was fusoid, spindle shaped pointed towards both ends, hyaline and germinate by producing one or two germ tube

DISCUSSION

The entomopathogenic fungus *A. aleyroides* in this study was identified based on colony morphology and morphological characteristic of conidia and this corroborate the identification reported by Wang *et al*., (2005), Liu (2006), and Wang et al (2013). The production of conidia had been reported to be dependent upon the culture medium and its nutritional source plays important role in determining the quantity of conidia in terms of spore germination (Sikder, 2019). Also, Zhu *et al*., (2008) and Qiu *et al*. (2013) concluded that basic nutritional requirements have significant effect on culture growth, sporulation and morphology in entomopathogenic fungi. Since mass production of entomopathogenic fungi is important step to successful utilization of entomopathogenic fungi as biocontrol agents. In search of suitable synthetic media for the cultivation of *A. aleyroides* among the three media were compared, based on the radial growth of the fungal colony, PDA extract agar gave the best result in term of mycelial growth followed by SDA. However, based on the ability of the fungus to produce conidia, PDA was considered the most suitable medium for *A. aleyroides* mass cultivation, this is in line with the report of Rabbani et al. (2011) and Westphal et al. (2021) that among different culture medium, Potato dextrose agar produced good growth (9.0 cm) and abundant sporulation (2.31 x 10^6) of *A. aleyrodis* and that the main constituent of Potato dextrose agar medium is dextrose and potato which might have been utilized as source of carbon which resulted in profuse growth.

CONCLUSION

Potato dextrose agar is recommended for mycelial growth cultivation and mass production of *Aschersonia* conidia. However, there is need to further investigate the pathogenic ability of the isolated *A. aleyroides in vitro* with citrus white fly.

ACKNOWLEDGEMENT

The authors wish to acknowledge the support of NIHORT, Project 6 on Integrated Pest Management (IPM) and the efforts of all the staff of pathology laboratory, especially Miss Joy Obire (Laboratory Technologist) for her untiring support.

ABSTRACT
Given the contemporary promotion of organic fertilizers over their inorganic counterparts, it is essential to assess organic nutrient sources for their suitability in supplying plant nutrients for crop use. The 3 month experiment was established within a nursery environment. The organic materials used in this study are Brewery Spent Grain (B), Palm Kernel Cake (P), and the combination of both (BP) applied at 4t/ha (1) and 2t/ha (2). The treatments include NF as no fertilizer treatment, B1 (BSG at 4t/ha), B2 (BSG at 2t/ha), P1 (PKC at 4t/ha), P2 (PKC at 2t/ha), BP1 (BSG+PKC at 4t/ha) and BP2 (BSG+PKC at 2t/ha). The nutrient composition of the organic materials was determined in the lab. Percentage emergence was recorded at 2, 3 and 4 weeks after sowing and morphological data were collected at 1, 2 and 3 months after sowing. 100% emergence was observed among the treatments except PB2 at 2 weeks after sowing. The result showed a significant difference in plant height, number of leaves and leaf area. NF had the highest seedling height (53.30 cm), stem diameter (7.59 mm) and leaf area (90.71 cm^2). BSG, PKC and the combination of both at the rates applied did not influence cashew seedling emergence and growth.
Keywords: *Cashew, Seedling, Waste, Organic Fertilizer and Nursery*

INTRODUCTION
The cashew tree, scientifically known as *Anacardium Occidentale* L., is a prominent species of the *Anacardiaceae* family (Subbarao *et al*., 2011). It is an economic important crop in the global market due to its high demand, with Nigeria being one of the top producers. Cashew is primarily cultivated for its valuable wood, cashew apple, and, most importantly, its nut (Adeigbe *et al*., 2015). This tree plays a crucial role in generating substantial income for both farmers and local buyers (Taiwo, 2015) or individuals or bodies engaging in any of its value chains such as seedling production. Cashew is mostly propagated by seed and usually by raising them in the nursery before transplanting to the field. The general vigour of cashew seedlings raised in the nursery plays a significant role in their establishment on the field after transplanting (Brown, 1984). Cashew seedlings are usually transplanted 2 to 3 months after raising in the nursery (Adenikinju *et al*. 1989). Fertilizer application is common in the nursery and it has been observed that cashew responds well to fertilizer application (Gawankar *et al*., 2020).
Plant source wastes from industries and agro-allied factories are known to be a major source of environmental pollution however, there are recent studies on some of these wastes as fertilizers for use in raising both arable and cash crops. Brewery Spent Grain (BSG) is a type of waste produced in large volumes in brewery factories (Aliyu and Bala 2011). It is rich in nutrients (Mussatto *et al*., 2014) which makes it a prospective organic fertilizer source. Palm Kernel Cake (PKC) is another common waste generated in oil processing factories that can be used as livestock feed. Recent research on it has also revealed its potential as an organic fertilizer in raising crops (Olowoake, A. A. 2017; Chidi *et al*., 2022).
With the current advocacy for the use of organic fertilizers as against the use of inorganic fertilizers, it is important to evaluate organic sources for the supply of plant nutrients for crop use. It is important to study the response of cashew seedlings to these two organic fertilizer sources. Therefore, the objective of this study is to evaluate the growth response of cashew seedlings to BSG, PKC and the combination of both before transplanting to the field.

MATERIALS AND METHOD

The 3-month experiment was carried out in the nursery at Cocoa Research Institute of Nigeria (CRIN) Headquarters, Ibadan. The experiment was a Complete Randomized Design (CRD) which consisted of 2 factors which are fertilizer types and application rates. The fertilizers used are Palm Kernel Cake (PKC), Brewery Spent Grain (BSG) and the combination of PKC and BSG while the application rates are 4t/ha and 2t/ha. The total number of fertilizer treatments is 6 which are B1 (BSG at 4t/ha), B2 (BSG at 2t/ha), P1 (PKC at 4t/ha), P2 (PKC at 2t/ha), BP1 (BSG+PKC at 4t/ha) and BP2 (BSG+PKC at 2t/ha). A control treatment with no fertilizer applied (NF) was included as a check making a total number of 7 treatments. The treatments were replicated three times. The cashew nuts used were medium nut size. Topsoil was sourced within the institute and sieved with a 2mm sieve to remove debris. The fertilizers were thoroughly mixed with the soil before potting in 2.5kg capacity polythene bags which were used in raising the seedlings. Watering was done twice a week. Data on % emergence of seedlings were recorded at 2, 3 and 4 weeks after sowing (WAS) while morphological data such as plant height (cm), number of leaves, stem diameter (mm) and leaf area (cm^2) were recorded at a monthly interval from 4 WAS to 12 WAS. Data collected were subjected to Analysis of Variance (ANOVA) using GenStat statistical software and treatment means were separated using Tukey at 0.05% probability level.

RESULT AND DISCUSSION

Analysis of soil amendment materials is important (Mora *et al*., 2019) as it reveals the nutrient composition of the material before use as a fertilizer source. The BSG used in this experiment was air dried before use as fertilizer as it has a slurry form in its natural state. The air dried BSG was analyzed in the lab and it was observed to contain 0.31% N, 0.10% P and 0.40%K as revealed in Table 1. The analysis result of PKC as also shown in Table 1 include 1.63% N, 0.70% P and 0.06% K. This result indicates that basic macronutrient needed by plants are present in both fertilizer source but are low in quantity when compared with other commonly used organic fertilizers such as groundnut cake, neem cake, castor cake, coconut cake, cotton seed cake, poultry manure and farm yard manure (Ganeshamurthy *et al*., 2015). However, PKC is richer in N and P than BSG.

Table 1: Nutrient composition of BSG and PKC waste.

Parameters (%)	Plant Source Wastes	
	BSG	PKC
Nitrogen (N)	0.31	1.63
Phosphorous (P)	0.1	0.7
Potassium (K)	0.4	0.06

BSG = Brewery Spent Grain, PKC = Palm Kernel Cake

Figure 1 shows the % seedling emergence of cashew seedlings as influenced by the fertilizer treatments applied. At 2 weeks after sowing (WAS), NF, B1 and P1 attained maximum seedling emergence (100%), followed by B2 (66.67%), P2 and BP both having (33.33%) while emergence was not observed to have occurred in BP1. From this result, the fertilizer treatments might not play a major role in cashew seedling emergence as the control treatment NF had 100% emergence at 2 WAS. At 4 WAS, 100% seedling emergence was observed across all the treatments. It has been observed that the emergence of cashew seedlings depends greatly on the genetic makeup or cashew nut type sown (Hammed *et al*., 2014).

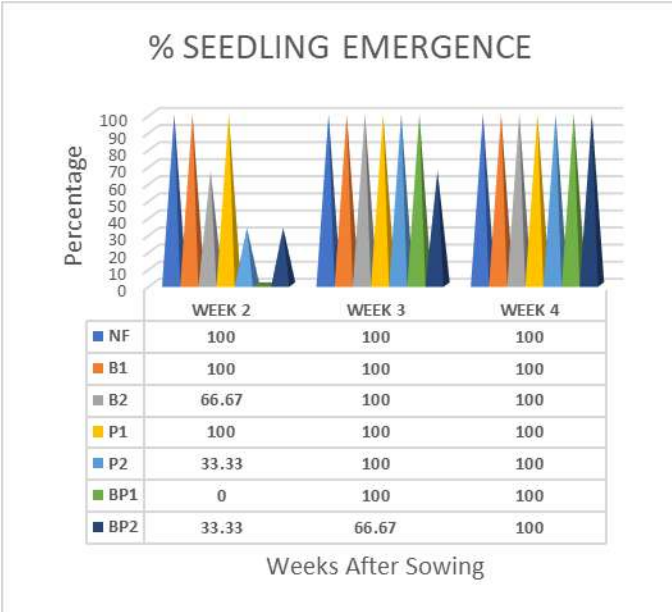

Fig. 1: Cashew seedling emergence as influenced by organic fertilizer treatments.

Table 2 shows the growth response of cashew seedlings to the organic fertilizers used at 3 WAS which was the terminating period of this study. Cashew seedlings responded significantly to the fertilizer treatments in plant height, number of leaves and leaf area while no notable response was observed in stem diameter. The control treatment NF (53.30cm) had a significantly taller plant height than the fertilizer treatments except for BP1 (44.60cm) which had a statistically similar height. B1 (26.60cm) performed least in seedling height and was not comparable with BP2 (30.40cm), B2 (33.33cm), P1 (35.00cm) and P2 (37.20cm). This result implies that the application of the fertilizers did not improve cashew seedling height. Organic manure such as cow dung was observed not to improve cashew seedling height (Opoku-Ameyaw & Appiah, 2000), likewise cocoa pod husk (Agele & Agbona, 2008). PKC1 (29) had the highest number of leaves but was not comparable with PKC2 (20). B1 (11) had the least number of leaves but was not significantly different from BP2 (12), B2 (14), NF (16) and BP1 (18). Only PKC1 (29) gave a statistically higher number of leaves than NF (16). A similar result was also observed by Olowoake, (2017). NF (7.59mm) had the thickest stem diameter however, no comparable difference was observed when compared with other treatments. No improvement in leaf area was also observed among the fertilizer treatments as NF had the largest leaf area (90.1cm^2) followed by BP1 (77.88cm^2), P2 (75.47cm^2), BP2 (73.20cm^2), P1 (72.93cm^2), B2 (62.13cm^2) and B1 (46.80cm^2).

Generally, both fertilizer sources and combinations at both levels did not give an impressive result as expected as NF performed best in plant height, stem diameter and leaf area. This result could be a result of the rates of application used which might not be sufficient enough to make any significant improvement in cashew seedling growth. Organic fertilizers have been observed to be needed in high quantities (Roba, 2018) to make significant improvements in the growth of crops.

Table 2: Growth response of cashew seedlings to plant source wastes.

Treat	*Plant Height (cm)*	*Number of Leaves*	*Stem Diameter (mm)*	*Leaf Area (cm^2)*
NF	53.30[a]	16bc	7.59a	90.71a
B1	26.60c	11c	6.62a	46.80c

B2	33.33bc	14bc	6.96a	62.13bc
P1	35.00bc	29a	6.65a	72.93ab
P2	37.20bc	20ab	6.52a	75.47ab
BP1	44.60ab	18bc	5.87a	77.88ab
BP2	30.40c	12bc	6.46a	73.20ab

CONCLUSION

BSG, PKC and the combination of both as used in this experiment had no influence on cashew seedling emergence as the non-fertilizer treatment attained 100% emergence at 2 weeks after sowing. Cashew seedling growth was not improved by the application of BSG and PKC in this study. However, a higher rate of application is recommended as a trial to further check for the effectiveness of both fertilizer sources in raising cashew seedlings.

ABSTRACT
A field experiment was carried out on the farm centre of the Kwara State College of Education, Ilorin Agricultural Science Department in 2022 planting season to determine the effect of different types of organic manure on vegetative, leaf yield and cost benefit of using the two types of fertilizer on jute mallow. The experimental design was randomized complete block design (RCBD) with three replicates. The treatments were control, manufactured organic manure and produced organic manure. The experimental land was prepared by manual cultivation. The sizes of the experimental plots were 2m by 2m consisting of nine beds with 1m gap. Plant was done by using broadcasting method and the beds were watered thoroughly after planting. Performance indices were plant height, number of leaves /plant, shoot yield, leaf yield, total cost, total return and profit. Data collected from different treatments were subjected to analysis of variance (ANOVA) and the mean separated using DMRT (Duncan Multiple Range Test). The result shows that different types of organic manure had the higher vegetative yield while the non fertilized jute mallow. However the formulated organic manure had the more vegetative growth than the manufacture organic manure. The result also shows that produced organic manure had the highest yield, return and profit. It was concluded that different types of organic manure had significant effect on the vegetative and leaf yield in jute mallow. However, the produced organic manure had more vegetative and leaf yield than manufactured organic manure. It can also be concluded that different types of organic manure had effect on the total cost, total return and profit in jute mallow production. However the produced organic manure had more yield, total return and more profit than the manufactured organic manure.
Keywords: *Jute mallow, manufactured organic manure, produced organic manure, vegetative, leaf yield, profit.*

INTRODUCTIONS

Jute Mallow (*Corchorus olitorius)* is a popular and leafy vegetable of great importance in Nigeria (Dansi *et al*., 2008, 2009). It is an erect annual herb that varies from 60 cm to approximately 150 cm in height depending on the cultivar. It grows in fields next to the houses, on the market garden sites and home gardens around the world. Jute mallow plays an important role in nutrition and household food security. The leaves contain an average of 15% dry matter, 4.8 g of protein, 259 mg of calcium, 4.5 mg of iron, 4.7 mg of vitamin A, 92 µg of folates, 1.5 mg of nicotinamide and 105 mg of ascorbic acid per 100 g of leaves (Grubben and Denton, 2014; Harborne *et al.*, 2019). Despite its nutritional and economic importance, it has been neglected by scientific research and development in Nigeria.

However, there is also a growing international recognition that Neglected and Underutilized Species (NUS) play a role in providing food and nutrition security and income opportunities among smallholder farmers. These NUS crops, trees and animals can help in adapting agriculture and food systems to climate change. Many farmers, especially in marginal areas, rely on NUS for their livelihoods. Consequently, cultivated varieties run the risk of genetic erosion and their cultivation is in serious decline due to low fertility soil, poor yield, pest and diseases. In traditional farming systems, low quantity of fertilizer is applied (Ayodele *et al.*, 2016). In addition, these systems benefit from only the natural soil fertility and possibly small amounts of fertilizer applied to increase the production of other associated crops. This residual fertility is insufficient to meet the crop nutrient supply. Therefore, adequate fertilization is essential to maximize their yields. Indeed, jute mallow requires nutrients such as N, P, K, Mg, Ca, Na and S for a good yielding. These nutrients are specific in function and must be supplied to the plant at the right time and in the right quantity.

Jute mallow responds well to fertilization, particularly nitrogen (Ogunrindé and Fasinmirin, 2011). Moreover, this crop is mostly carried out by marginalized producers of whom access to mineral fertilizers is prohibitive because of their low income (Gensch et al., 2011). Besides, excessive and indiscriminate use of chemical fertilizers leads to soil degradation and imposes a serious threat to human health (Fujimoto, 2018). Also, jute mallow is cultivated on a small scale by women only, so that the production cannot pay back the cost of purchase and transportation of mineral fertilizers. All the above reasons underscore the acute need of alternative sources of fertilizer for sustainable crop production. Organic waste could be a viable alternative to chemical fertilizers. The use of organic manure, e.g. poultry manure and cow dung has improved agricultural productivity in West African countries. Organic farming has enough positive impacts: the long-term productivity in soil conservation and improvement of soil fertility involves the sustainability of production for future generations, stability and food security in diversity cultures and environmental impact using manure. Indeed, organic manures enhance soil moisture, increased soil organic matter, nitrogen, pH, phosphorus, and cation exchange capacity (CEC), and reduced soil exchangeable acidity (Adeniyan and Ojeniyi, 2013; Mbah, 2016)

In Nigeria, various types of organic manure exist for plant nutrition. This can be divided into two that is farmer manufacture type and readymade manufactured type from Fertilizer Company. Hence there is a need to carry out a comparative study to determine the effect of the two types of organic fertilizer on vegetative, leaf yield and cost benefit of using the two types of fertilizer on jute mallow production.

MATERIALS AND METHODS

A field experiment was carried out on the farm centre of the Kwara State College of Education, Ilorin Agricultural Science Department in 2022 planting season between February to May 2022 to determine the effect of different types of organic manure on vegetative, leaf yield and cost benefit of using the two types of fertilizer on jute mallow. The experimental design was randomized complete block design (RCBD) with three replicates. Jute mallow seed used for the experiment was obtained from an Grtet seed in Ilorin, Kwara State Nigeria. So also is the organic manure. The other materials used were weighing scale and poultry manure produced in the department of agricultural science Kwara State College of Education, Ilorin. The treatments were control, manufactured organic manure and produced organic manure. The experimental land was prepared by manual cultivation. The sizes of the experimental plots were 2m by 2m consisting of nine beds with 1m gap. The organic manures were apply at the rate of 1kg/plot for manufacture type and 5kg/plot for produced type two weeks before planting. Plant was done by using broadcasting method and the beds were watered thoroughly after planting. Hand hoeing was done as at when required to control weeds. Watering was done every day using watering can.

Data Collections

The data collected were:

I. Plant height: Determine by using ruler to measure the tip of the plant to the soil level in cm every two weeks.
II. Number of leaves /plant: It was determined by counting the number of leaves /plant every two weeks.
III. Shoot yield: It was determined by using a digital scale to measure the fresh weight of the shoot/plot
IV. Leaf yield: It was determined by using a digital scale to measure the fresh weight of the leaf /plot
V. Total cost: It was determined by adding all the money spent the production of the jute mallow using different organic manure
VI. Total return: It was determined by adding all the money realized after the sales of of the jute mallow using different organic manure

VII. Profit: It was determined by subtracting total return from total cost

Data Analysis

The data collected from different treatment were subjected to analysis of variance (ANOVA) and the mean separated using DMRT (Duncan Multiple Range Test).

RESULTS

Table 1 shows the effect of different types of organic manure on plant height of jute mallow. The effect was significant with throughout the experiment. The formulated organic manure had the tallest plant which was followed manufactured typed. The control had the least plant height. Table 2 shows the effect of different types of organic manure on number of leaves/plant of okra. The effect was significant with throughout the experiment. The formulated organic manure had the highest number of leaves/plant which was followed manufactured typed. The control had the least number of leaves/plant. Table 3 shows the effect of different types of organic manure on the shoot yield of jute mallow. The effect was significant with the produced organic manure having the highest shoot yield was followed by manufactured organic manure. The control had the least shoot yield.

Table 3 shows the effect Different types of organic manure on the leaf yield of jute mallow. The effect was significant and follow similar trend as shoot yield. The effect was significant with the produced organic manure having the highest leaf yield which was followed by manufactured organic manure. The control had the least leaf yield. Table 4 shows the total cost of using different types of organic manure in the production of jute mallow. The effect was significant with the produced organic manure and control having the same total cost. However, the manufactured total was cost higher due to the cost of buying the manufactured organic manure.

Table 5 shows the total return of using different types of organic manure in the production of jute mallow. The effect was significant with the produced organic manure having both the highest yield and return, this was followed by the manufactured organic manure. The least yield and return was recorded in the control. Table 6 shows the profit from using different types of organic manure in the production of jute mallow. The effect was significant with the produced organic manure having profit (N580) this was followed by the manufactured organic manure (N480). The least yield and return was recorded in the control (N390)

DISCUSSION

The result shows that different types of organic manure had the higher vegetative yield while the non fertilized jute mallow. However, the formulated organic manure had the more vegetative growth than the manufacture organic manure. The organic manure had N for vegetative growth. The result is in line with the works of Akanbi *et al* (2018) and collaborate the work of Olaniyi *et al.,* (2018). The result shows that produced organic manure had the highest shoot and leaf yield. The result is expected as organic manures had influenced both the shoot and leaf yield. However, the effect was higher in produced organic manure because the produced organic manure had more organic N than the manufacture organic manure. The result is in line with the works of Akanbi *et. al.,* (2018) and collaborate the work of Olaniyi *et al.,* (2018) The result shows that produced organic manure had the highest yield, return and profit. The result is expected as organic manures had influenced both the shoot and leaf yield. However, the effect was higher in produced organic manure this is because the produced organic manure had more organic N than the manufacture organic manure. This resulted in the jute mallow having more yield, return and profit than the manufactured organic manure. The result is in line with the earlier works of Olawepo *et al.,* (2018) and collaborate the work of Olaniyi, e*t al.,* (2018)

CONCLUSION

It can be concluded that different types of organic manure had significant effect on the vegetative and leaf yield in jute mallow. However, the produced organic manure had more vegetative yield than the manufactured organic manure. It can also be concluded that different types of organic manure had effect on the total cost, total return and profit in jute mallow production. However, the produced organic manure had more yield, total return and more profit than the manufactured organic manure.

ABSTRACT
This study was conducted to evaluate the effect of training on plantain/banana rapid multiplication techniques carried out at the National Horticultural Research Institute, Ibadan on stakeholders' productivity and welfare in Oyo state. Data were collected on types of technologies adopted, effects of technologies on welfare of trainees as well as constraints in application of technologiesusing structured questionnaire from 28 out of 58 trained participants and analyzed using descriptive statistics. Results revealed that most (85.7%) of the participants were males, married (89.3%), with tertiary education (77.6%), average age (52 years), years of experience in plantain/banana farming (10 years) and farm size (5.6±7.6acres). The result further showed that 82.1% adopted the technologies and 46.4% adopted technology related to sucker production. More than three-quarters of the trainees (85.7%) have applied the knowledge gained on types of suckers to use for rapid multiplication, while 57.1% have applied micropropagation techniques and specifically decapitation. Also, the result showed that 85.7% of the respondents agreed that the application of the technologies has increased the income, acquisition of household assets (82.1%), and financial contribution to children's fund (75.0%) with about 60-100%. Access to funds, irrigation and land are constraints to application of the technologies as opined by 46.4% of the trainees. The study recommends that training programmes be evaluated when the participants are expected to have been practicing and not only at the start or the end of the training.
***Keywords**: Applied technologies, Evaluation, Rapid multiplication techniques, Plantain/Banana*

INTRODUCTION

Training programmes are conducted with the aim of ensuring improved skills, knowledge and attitude as well as change in behaviour or performance of the trainees (Osei et al, 2005). Training evaluation is a means of obtaining relevant information from trainees on the effects of a training programme previously organized. An effective way of evaluating a training programme is to assess participants (trainees) when they are already on-the-job using what they were taught (Osei et al, 2005). Evaluating participants at the time of training is used to determine whether or not the objective of the training has been achieved (Neendoor, 2003). This provides an immediate evaluation of the training. However, having a follow-up study to determine how effective a training programme has been able to change participants' performance on-the-job offers adequate insight into how useful the training is to participants' work environment or situation (Osei et al, 2005).

Plantain is an important staple food crop, the fourth worldwide; which contributes to food security, decreased rural poverty and poverty alleviation. It is a raw material for many delicacies and snacks. Nigeria is a major producing country of plantains in the world (Ayanwale et al, 2016). There are different techniques for the propagation of this all-important staple plantain (including bananas), some of which are mother plant stripping, decapitation, corm technique, tissue and cell culture (Tumuhimbise and Talengera, 2018).

Rapid production of clean planting materials is important to ensure increased productivity and welfare of plantain farmers. It is also important, considering the contribution of the crop to food security, as well as reduced poverty alleviation. This study was therefore carried out to evaluate the effect of a training on rapid multiplication techniques for plantain/banana carried out at National Horticultural Research Institute, Ibadan on farmers (trainees) welfare.

Specifically, this study profiled:

- Personal characteristics of the trainees (participants)
- Training modules which the participants have applied to the plantain/banana production
- Technologies adopted by the trainees
- Perceived effect of application of the training on trainees' welfare
- Constraints to application of technologies by the trainees

METHODOLOGY

The study was carried out at NIHORT. Plantain producers were trained on rapid multiplication of plantain to produce clean and disease-free planting materials. The producers trained were part of NIHORT stakeholders in plantain value chain. A total number of 58 stakeholders were exposed to practical demonstration on the processes of rapid multiplication technology of plantain. After 2 years, a total number of 28 trainees were randomly selected and data were collected on the extent of adoption of the technology and effect on welfare as well as constraints in the application of technologies.

Data collected were analyzed using descriptive statistics.

RESULTS AND DISCUSSION

Personal characteristics of trainees

The results revealed that most of the trainees were males (85.7%), married (89.3%), with tertiary education (77.6%), only 28.6% had farming as primary occupation (Table 1). Furthermore, the average age of trainees was 52 years (51.6±14.3), with household members being on the average of 5 (5.3±2.7) and 10 years' (10.0±11.5) experience in plantain/banana production while their average farm size was5.6±7.6 acres.This implies that the trainees have the educational ability to apply the knowledge disseminated during the training as observed in their educational qualification. Most of the participants are not new to the plantain/banana enterprise; they have spent an average of 10 years in the enterprise and have sizeable farmwith an average of 5.6 acres where they produce.

Training modules which participants' have applied to their plantain enterprise

The results further revealed that most of the trainees have applied the knowledge gained from the training as regard the types of suckers (85.7%) suitable for plantain production (Table 2). Thus, they are able to select the best type of sucker available in their locality for rapid multiplication of plantain. More than half of them have also applied the knowledge transferred on macro propagation techniques and decapitation (57.1% respectively) while 46.4% have applied corm techniques as well as the use of macro chamber/propagator. This implies that useful knowledge which could be easily applied by the trainees was passed across to them during the training session. Moreover, application of the knowledge transferred during the training implies that there will be an improvement in the participants' plantain enterprises.

Adoption of technologies after training

Furthermore, the results showed that 82.1% of the trainees have adopted different aspects of the technology after their capacity was built (Table 3). They adopted technologies pertaining to sucker production (46.4%), decapitation methods (14.3%) as well as corm techniques (10.7%). The results have shown that not only were some training aspects applied by the trainees they have also adopted these technologies for use in their plantain enterprises.

Adoption of the training modules (aspects) taught is expected to increase the productivity and welfare of the plantain farmers (producers).

Effect of technologies on welfare of trainees

Trainees were asked to rate their opinion on how the training has impacted their lives (welfare). Table 5 showed that most of the trainees opined that there was up to 60-100% increase in their welfare considering increased income (85.7%), acquisition of household assets (82.1%), increased financial contribution to household and to children's education (75.0% respectively). Only 35.7% opined that the training has enhanced their decision-making power up to 60-100%.

Constraints in application of technologies

Despite the application of knowledge gained, 46.4% of the trainees opined that there were constraints to the application of technologies they were taught (Table 5). Some of the constraints include fund and access to irrigation (10.7%) as well as access to land (7.1%). This implies that knowledge gain is not the only factor required for participants to apply the technologies taught.

CONCLUSION

Most of the trainees have applied the knowledge gained from the training and were able to select the best types of suckers in their respective locality for rapid multiplication of plantain. Furthermore, the stakeholders have adopted technologies pertaining to rapid multiplication techniques of plantain multiplication. The study recommends that training programmes be evaluated when the participants are expected to have been practicing and not only at the start or the end of the training. This is to give an insight as to whether or not the training is achieving its ultimate aim of improved welfare for the trainees.

ABSTRACT
Despite an increasing focus on the health benefits of fruits and vegetables in human diet, their consumption is still far below the World Health Organization's recommended intake of at least 400g per day per capita in Nigeria. The study therefore assessed the perception of the health benefits of fruits and vegetables among households in southwestern Nigeria. A total of 450 households were randomly selected from the study area using a multistage sampling technique. Information was obtained from household heads with the aid of personal interviews and semi-structured questionnaire. Data were analysed using descriptive and inferential statistics. The perceived benefits of fruits and vegetables were assessed using a Likert 5 points rating scale of "Strongly Agreed", "Agreed", Undecided", "Disagreed" and "Strongly Disagreed". Results revealed that only 50.0% of the respondents had favourable perception of the health-related benefits of fruits and vegetables, while 45.0% and 42.8% of the household heads had unfavourable perception on the health-related benefits of fruits and vegetables, respectively. These findings implied that about half (50.0%) of the sampled respondents do not have positive perception of the importance of fruits and vegetables in human health. Hence the need for more enlightenment programmes and comprehensive nutrition education strategies on the health benefits of fruits and vegetables among household in south-western Nigeria.

IINTRODUCTION

Low fruits and vegetable consumption are associated with the most important causes of premature mortality globally, this is the reason many people in most countries have some form of malnutrition due to the inadequate unbalanced or excessive consumption of macro nutrients and micronutrients (Daniel et al., 2019). This has led to the spread of many of the non-communicable diseases that are the main cause of premature mortality globally. However, economic growth has been considered as one of the factors that can determine the consumption rate of fruit and vegetable According to Silva et al., (2017), consumption of fruits and vegetables is important for the provision of micronutrients to the body, as these food items are a rich source of vitamins and minerals required for the growth, development, and normal functioning of the human body. The micronutrients supplied by fruits and vegetables are also vital for the optimal functioning of the gastro-intestinal tract as they also enable the body to use other nutrients required for its normal function like energy from fats and carbohydrate (Ibe et. al., 2020).
Various reviews have associated low intake of fruits and vegetables with chronic diseases such as cardiovascular diseases, blood pressure, hypercholesterolemia, osteoporosis, many cancers, chronic obstructive pulmonary diseases, respiratory problems as well as mental health (Park et al., 2011; Payne et al., 2012; Habauzit et al 2014; Pem and Jeewon, 2015). Despite an increasing focus on the health benefits of fruits and vegetables, their consumption is below the recommended intake among adults in both developed and developing countries (Ruel et al., 2005; Morbidity and Mortality Weekly Report, 2010; Banwat et al., 2012; Ogundari and Arifalo, 2013). Price of vegetables, price of fruits, level of education and age are the factors greatly influencing demand for fruits and vegetables (Aturamu et al., 2021). Although, a considerable number of research has been done in Nigeria (Ogundari and Arifalo, 2013; Layade and Adeoye, 2014; Ibe et al., 2018; Adenegan et al., 2018; Obayelu et al., 2018) to ascertain the

factors influencing fruit and vegetable consumption/demand however, there is a dearth of information on consumers' perception of the health benefits and barriers of fruits and vegetables as well as the factors influencing their perception in Nigeria. Thus, this study was conducted to examine households' perceived benefits and barriers of fruits and vegetables and also analyze the relationship between their socio-demographic factors and perception in southwestern Nigeria.

MATERIALS AND METHODS

Description of the study area

This study was carried out in southwestern Nigeria which falls on latitude 6^0 to the north and latitude 4^0 to the south. It is marked by longitude 4^0 to the west and 6^0 to the east. It is bounded in the north by Kogi and Kwara States, in the east by Edo and Delta States, in the south by Atlantic Ocean and in the west by Republic of Benin. The zone is characterized by a tropical climate with distinct dry season between November and March and a wet season between April and October. The mean annual rainfall is 1480mm with a mean monthly temperature range of 18^0C – 24^0C during the rainy season and 30^0C – 35^0C during the dry season.

Method of data collection

A multistage sampling technique was used to select the respondents. The first stage was the random selection of two states (Ogun and Osun states) out of the six states which makes up the southwestern zone. The second stage involved the random selection of ten Local Government Areas (LGAs) from the selected states proportionate to the size of LGAs in the two states. In the third stage, one city and one village were randomly selected per each of the selected LGAs, while in the last stage 411 households were randomly selected from the selected communities proportionate to size.

Data were collected from household heads or their spouse using personal interviews and semi-structured questionnaire. Information was sourced on the socio-economic and demographic characteristics of household heads such as age, gender, household size, level of education, income level, occupational status as well as response to some statements on the perceived health benefits of fruits and vegetables.

Method of data analysis

Data obtained were analysed using descriptive statistics, inferential statistics and the Likert scale 5-point scale. In the scale, statement like "Strongly Agreed" (SA) was given a rating of 5 points, "Agreed" (A) 4 points, "Undecided" (U) 3 points, "Disagreed" (D) 2 points and "Strongly Disagreed" (SD) 1 point. The mean score (MS) was calculated as follows:

$$MS = (\Sigma\ (RP \times O) / \Sigma f)$$

Where RP is the rating points, O is the number of observations and f is the total number of sampled respondents.

RESULTS AND DISCUSSION

Socioeconomic characteristics of respondents

As shown in Table 1, about 86 percent of households sampled in the study area were male-headed with only 14.1% headed by female. The mean age of household heads was 45.09±13.54 years. This indicated that a larger proportion of the sampled household heads were in active and productive age. Furthermore, more than 40 percent of the respondents were within the age range of 20-40 years, married, educated, had between 1 and 5 household size, engaged in other occupation other than agriculture and earned less than N50,000 monthly. The fact that most of the household heads were educated implied that they are likely to aware of the health benefit of fruit and vegetable in human diet.

Households' perception on health benefits of fruits and vegetables

The results of analysis of households' response to certain statements on perceived health related benefits of fruits and vegetables using Likert 5-point scale rating are presented in Tables 2 and 3. The result showed that most of the respondents in the study area had positive perception on the health-related benefits of fruits and vegetables. This result is in line with the findings of Wolf *et al.,* (2008), where nearly all the respondents sampled in their study reported that there were health benefits related to eating fruits and vegetables. Respondents did not perceive time taken to prepare fruits and vegetables as a barrier. They perceived fruits and vegetables to be cheap, readily available, provide essential nutrients, help to maintain body weights and also lower the chances of illnesses such as cancer, high blood pressure, stroke and so on.

CONCLUSION

This study examined the perception of household heads in south-western Nigeria on the health benefits of fruits and vegetables in human health using primary data which were obtained with the aid of personal interviews and semi-structured questionnaire. Data were analyzed using descriptive and inferential statistics. Findings from the study revealed that about half of the sampled household heads sampled do not have positive perception of the importance of fruits and vegetables in human health. The positive perception of health benefits of fruits and vegetables among respondents would likely indicate their readiness in the purchase and consumption. Hence the need for more awareness and nutrition education programmes education (such as health talks, seminars, workshops and jingles) for households in south-western Nigeria on the nutritional value and major health benefits of fruits and vegetable when consumed in adequate proportion.

FUNGI TOXIC EFFECT OF *MORINGA OLEIFERA* LEAVES AND *ALLIUM SATIVUM* (GARLIC BULBS) EXTRACTS AGAINST ROT CAUSING FUNGI PATHOGENS OF CUCUMBER (*Cucumis sativus* L.)

Elum C.G*., Onyeanusi, H.C., Uwanaka, C.E., Orija, B. A., Obire, J
National Horticultural Research Institute, P.M.B 5432, Jericho GRA, Ibadan, Oyo State, Nigeria.

ABSTRACT
The Cucurbitaceous plant family is affected by several diseases caused by different formae of fungus Fusarium oxysporum. Two economically important fungi species F. oxysporum and F. verticillioides have been identified as a causative pathogens causing rot in Cucumis sativus L.(Cucumber). Samples were collected from symptomatic cucumber fruits expressing rot and were surface sterilized, cultured on solidified Potato dextrose agar and incubated at 28±2°C for 5 days. Sub culturing was done to obtain pure cultures of the isolates. Isolates were identified using cultural, microscopic and molecular characterization. The culture was viewed under the microscope and identified morphologically as Fusarium spp. The pathogenicity of F. oxysporum and F. verticillioides confirmed on healthy cucumber fruits revealed its capability to cause infection on healthy fruits. The growth inhibition of all the isolated fungi by extracts of Allium sativum (Garlic) and Moringa oleifera (Moringa) at different days of incubation. There was significant growth inhibition of the two isolated organisms but F. oxysporum had the highest inhibition occurrence followed by F. verticillioides. There was no significant ($p \leq 0.05$) difference in the growth inhibition between F. oxysporum and F. verticillioides all through the seven days of observation. The aqueous extracts gave better growth inhibition compared to the ethanol extracts. Growth inhibition of F. oxysporum was better than that of F. verticillioides
***Keywords**: Moringa oleifera, Allium sativum, Cucumis sativus, fungitoxicity.*

INTRODUCTION

Cucumber (*Cucumis sativus* L.), an important vegetable crop belonging to the family Cucurbitaceous. It is an annual monoecious creeping vine that bears large leaves that form canopy over its cylindrical fruits (Adetula and Denton, 2003). Cucumber, a popularly cultivated fruit in the gourd family has its origin traced back to ancient India and has been ranked the fourth most widely cultivated vegetable in the world after tomato, cabbage and onion (Wehner, 2007). In Nigeria, the cucumber plant will thrive well at any time of the year even though it has little or no tolerance to frost. During the raining season, the crop is grown under rainfed conditions and during the dry season using irrigation year (Eifediyi and Remison, 2009). It prefers conditions of high light, high humidity, high soil moisture, temperature and fertilizers in green-houses (El-Aidy et al., 2007).

Fruits generally, due to their high moisture content and nutrient composition are prone to pathogenic fungal attack which in addition to causing rots may also make them unfit for human consumption by producing mycotoxins. Gatto *et al.,* (2011) reported that fungal infections are the main cause of postharvest rots of fresh fruits and vegetables during storage and transport which cause significant economic losses in the commercialization phase. Infections caused during postharvest conditions lower shelf life of fruits and adversely affect the market value of fruits thereby having a negative impact on the economy. The contamination of fruits with mycotoxins has not only caused health hazards but also resulted in economic losses, especially for exporting countries. Presently, use of chemical fungicides serves as the primary means for controlling postharvest fungal decay of fruits and vegetables. Continuous use of fungicides is been frowned at as there is increasing public concern regarding contamination of fruits and vegetables with fungicidal residues and proliferation of resistance in the pathogen populations.

MATERIALS AND METHODS

Sample Collection

The experiment was conducted at the Plant Pathology Laboratory of the National Horticultural Research Institute, Ibadan, Nigeria. Cucumber fruits with signs of rot were obtained from a local fruit market in Ibadan. The diseased samples were packaged in a paper bag and taken to the laboratory for further research. The leaves of *Moringa oleifera* leaves were collected from a residential building at Oluyole Estate Ibadan, Oyo State while *Allium sativum* cloves were bought at Oje market in Ibadan.

Isolation and Identification of Fungi

The pathogenic organisms from the rotten cucumbers were isolated using a direct plating method. The cucumber fruit was washed under running water and surface sterilized with 70% ethanol for about three minutes and thereafter rinsing in three changes of sterile distilled water before blotting it dry on filter paper. A sterile scalpel was used to cut a section of tissue from the cucumber fruit moving from the healthy to the diseased portion where the fungus is likely to be more active. The cut portion is aseptically placed on a Petri dish containing 15ml of potato dextrose agar (PDA) and incubated at room temperature of 27^0C ± 2^0C in a laminar flow for seven days. The growth on the Petri dishes was observed and sub-culturing was done to get pure cultures.

Identification of Fungal Isolates

This was done based on the description of the morphological appearance of fungal colonies on Potato Dextrose Agar culture medium and the slide culture technique for microscopic evaluation according to method by Wantanabe (2002).

Pathogenicity Test

Healthy cucumber fruits were surface sterilized with 70% ethanol. Cylindrical plugs were cut from each cucumber fruit using a sterile 5mm cork borer. Pure culture of each isolated fungus was introduced into the holes in three replicates. The cylindrical plugs were placed back in the holes and sealed with sterile petroleum jelly. The fruits were incubated at room temperature (28±2oC) for7–10days while the control has no fungus. The cucumber fruits were examined after 7days to access and record the extent of rot and the pathogens were re-isolated from the inoculated cucumber fruits. The experiment was done in three replicates under sterile conditions.

Preparation f Plant Extracts

The leaves of *M. oleifera* and clove of *A. sativum* were washed under running water, air dried for weeks at room temperature and grounded into powdered form. The powdered samples were added to different conical flasks containing the extraction solvent (sterile distilled water and ethanol). For the aqueous plant extraction, dried plant materials were soaked in water for 24hours, stirred every 2 hours, sieved with muslin cloth and further filtered using Whatman filter paper. The aqueous filtrate was concentrated using a rotator evaporator at 50^0C. While for the ethanol extraction, dried plant materials were soaked in ethanol for 72hours with constant stirring every two hours after which solvent was collected using muslin bag. It was further filtered using Whatman filter paper and filtrate was evaporated to dryness using a rotatory evaporator set at 40^0C. After getting the crude extracts of each botanical, 0.25g of each extract was dissolved in 250ml of sterilized distilled water and it served as the stock solution. Further dilutions were made to get the 25, 50, 75 and 100%, a modified method of Akanmu *et al.,* (2013a).

Growth Parameter Measured

Data collected were limited to the length of the mycelia growth extension of the two fungal organisms. Radial growth was measured at 24 hours interval for seven days as the mean growth along the two axes on two pre-drawn perpendicular lines on the reverse side of the plate.

Fungi toxicity was expressed as percentage inhibition of mycelia growth using formula adopted from Onuh *et al.,* (2005);

$$F_P = \frac{F_1 - F_2}{F_1} \times 100$$

Where F_P = percentage inhibition of mycelia growth, F1 = mycelia growth in control plate

F_2 = mycelia growth in plate containing plant extracts.

Statistical Design and Analysis

The experiment set up was laid out in a Completely Randomized Design (CRD). The data collected were subjected to analysis of variance (ANOVA) using Generalized Linear Model (GLM) procedure of Statistical Analysis Software (version 9.1). The differences between means were separated using Duncan's Multiple Range Test (DMRT) at $p \leq 0.05$.

RESULTS

Fungi isolated from rotting cucumber

The fungi isolated and found pathogenic from the rotting cucumber fruits are *F. verticillioides* and *F. oxysporum* (Plate 1),

Growth inhibitions of the isolated fungi by *Moringa oleifera* and *Allium sativum* extracts

Table 1 shows the growth inhibition of all the isolated fungi by extracts of *A. sativum* (Garlic) and *M. oleifera* (Moringa) at different days of incubation. There was significant growth inhibition of the two isolated organisms but *F. oxysporum* had the highest inhibition occurrence followed by *F. verticillioides* . There was no significant ($p \leq 0.05$) difference in the growth inhibition between *F. oxysporum* and *F. verticillioides* all through the seven days of observation.

Table 1: Radial growth inhibition of the isolated fungi by *Moringa oleifera* and *Allium sativum* extracts (cm)

Organism	Day 1	Day 2	Day 3	Day 4	Day 5	Day 6	Day 7
Control	2.45^{a}	4.22^{a}	5.51^{a}	6.58^{a}	7.31^{a}	7.68^{a}	8.14^{a}
Fusarium verticillioides	0.53^{b}	0.78^{b}	1.03^{b}	1.29^{b}	1.48^{b}	1.66^{b}	1.83^{b}
Fusarium oxysporum	0.44^{b}	0.72^{b}	0.90^{b}	1.14^{b}	1.31^{b}	1.44^{b}	1.56^{b}

Means with different letters in a column are significantly different at $p \leq 0.05$

(A) (B)

Plate 2: Pathogenicity test for (A) *F. oxysporum* *and* *(B) F. verticillioides*

DISCUSSION

This research showed that cucumber fruits are prone to postharvest rot caused by fungal pathogens and that *F. verticillioides* and *F. oxysporum* were the fungal pathogens isolated from the rotting cucumber fruits as proved by pathogenicity tests. Onaebi and Chiejina (2013) suggested that these pathogens could have gained entry into the fruits through wounds or bruises created during harvesting and packaging of the fruits for delivery to the markets.

Results obtained from the *in vitro* study of the effects of *M. oleifera* and *A. sativum* at different concentration levels on *F. verticillioides*, and *F. oxysporum* showed that both extracts have antimicrobial potentials and this supports several reports on the fungicidal effects of plant extracts on different pathogens of crops (Amadioha and Obi, 1999; Olufolaji, 1999; Onifade, 2000; Okigbo and Ogbonna, 2006; Nwachukwu, E. O. and Osuji**,** 2008).

The significantly better result obtained with ethanol extract and *M. oleifera* in the individual assay supports the work of Chiejina and Onaebi (2016) who reported that ethanol plant extracts of *Chromolaena odorata* and *M. oleifera* significantly reduced the mycelial growth of the isolates *in vitro*.

CONCLUSION

The experiment shows that *M. oleifera* and cloves of *A. sativum* have fungi toxic potentials against fungi associated with rot of cucumber caused by *F. oxysporum*, *F. verticillioides* individually. Further work to evaluate the synergetic effectsof *M. oleifera* leaves and cloves of *A. sativum* for fungitoxic potentials against fungi associated with rot of cucumber will still be needed before credible assertions can be made on the phytotoxicity of the two extracts on the isolated fungi.

ABSTRACT
Hypertension, a major global health concern, affects millions of individuals and is a leading cause of cardiovascular diseases. In recent years, Camellia sinensis, commonly known as tea, has garnered attention for its potential anti-hypertensive properties. This review delves into the growing body of scientific evidence regarding the effects of tea consumption on blood pressure regulation. The chemical composition of Camellia sinensis is dissected, highlighting its diverse bioactive compounds, including polyphenols, caffeine, theanine, theaflavins and thearubigins among others. The mechanisms underlying the antihypertensive effects of Camellia sinensis are elucidated, encompassing actions such as vasodilation, antioxidant activity, and lipid profile modulation. Additionally, the review highlights the need for personalized recommendations and future directions for research in this field.
Keywords*: Hypertension, Camellia sinensis, blood pressure, vasodilation, antioxidant*

INTRODUCTION

Hypertension, often dubbed the "silent killer," is a widespread and potentially life-threatening medical condition characterized by elevated blood pressure (Bromfield and Muntner, 2013). Hypertension is a complex and widespread health issue with far-reaching consequences. It is crucial for individuals to be proactive in monitoring their blood pressure and adopting a heart-healthy lifestyle (Ettehad *et al.,* 2016). While conventional medications and lifestyle modifications play a vital role in managing hypertension, there is a growing interest in exploring natural remedies, particularly medicinal plants, as potential alternatives to pharmaceutical interventions (Ahmad *et al.,* 2015).

Plants have been used for medicinal purposes for thousands of years across different cultures and civilizations (Chukwuma *et al*., 2019). Medicinal plants owe their therapeutic properties to a vast array of phytochemicals, including alkaloids, flavonoids, terpenoids, polyphenols, and essential oils. These bioactive compounds exhibit a range of activities, from anti-hypertensive and antioxidant to antimicrobial and anticancer effects. The chemical diversity of these constituents contributes to the broad spectrum of medicinal plant applications in modern medicine (Mgbeahuruike *et al.,* 2017).

Camellia sinensis is a versatile and culturally significant plant that has shaped the world of beverages. Beyond its delicious flavors, *Camellia sinensis* continues to be a subject of scientific research for its potential health-promoting properties (Mazur *et al., 2021*). The antioxidant properties of tea polyphenols, particularly epigallocatechin gallate (EGCG), have been associated with reduced oxidative stress, inflammation, and the prevention of chronic diseases, including cardiovascular diseases, cancer, and neurodegenerative disorders. Additionally, the presence of theanine, caffeine and volatile compounds like terpenes in tea has been linked to improved cognitive function and alertness (*Izzreen and Fadzelly, 2013)*

Understanding Hypertension

Hypertension is a chronic medical condition characterized by consistently elevated blood pressure levels (Fagard *et al*., 2009). Blood pressure is the force exerted by blood against the walls of the arteries as the heart pumps it throughout the body. It is typically measured in millimeters of mercury (mm Hg) and is expressed as two values: systolic and diastolic blood pressure. Systolic blood pressure, represents the pressure in the arteries when the heart beats or contracts to pump blood, while diastolic blood pressure, represents the pressure in the arteries when the heart is at rest between beats. Normal blood pressure is typically defined as around 120/80 mm Hg. Hypertension is diagnosed when blood pressure consistently exceeds 130/80 mm Hg (Kjeldsen, 2018). Several factors contribute to the development hypertension. These include genetics, sedentary lifestyle, diet high in salt, alcohol consumption, smoking and underlying medical conditions (Ettehad *et al.,* 2016).

Bioactive Compounds of *Camellia sinensis*

The composition of tea's bioactive compounds can vary depending on factors such as the type of tea (green, black, white, oolong), growing conditions and processing methods. Tea is reported to contain the following compounds;

Polyphenols: Catechins are the most abundant polyphenols present in tea. The main catechins are epicatechin (EC), epicatechin gallate (ECG), epigallocatechin (EGC), and epigallocatechin gallate (EGCG). EGCG, in particular, is reported for its potential health-promoting properties. Besides catechins, tea contains other polyphenols such as quercetin, kaempferol, and myricetin (Samanta, 2022).

Caffeine: Caffeine, a natural stimulant, can improve alertness and cognitive function when consumed in moderation. The caffeine content varies depending on the type of tea and the brewing method (dePaula and Farah, 2019)

Theanine: Theanine is an amino acid that is found almost exclusively in tea leaves. It has a calming effect on the nervous system and can help reduce stress and anxiety (Li *et al.*, 2022).

Theaflavins and Thearubigins: These compounds are primarily found in black tea and are the result of the oxidation process that black tea leaves undergo. Theaflavins and thearubigins contribute to the colour, flavor, and aroma of black tea (Teshome, 2019).

Essential Oils: Tea leaves contain essential oils that give tea its characteristic aroma and flavour. These oils can vary in composition and contribute to the distinct profiles of different tea varieties (Chen *et al.*, 2014).

Antihypertensive Mechanisms

Several mechanisms have been postulated to explicate the mode of action of *Camellia sinensis* in blood pressure-lowering. *Epigallocatechin gallate* was reported to help prevent cardiac hypertrophy and hypertension by suppressing angiotensin II and pressure overload, reactive oxygen species generation and NADPH oxidase over-expressions (Li *et al*., 2006). Tea catechins, according to some research data, can stimulate the production of nitric oxide (NO) in the endothelium, leading to vasodilation, which helps lower blood pressure by reducing vascular resistance. For instance, in a study conducted by Ramirez-Sanchez *et al*., (2011), epicatechin contributes to blood pressure regulation via stimulation of NO production by endothelial NO synthase (eNOS) in endothelial cells.

Tea is renowned for its potential role as an antioxidant in the management of hypertension. One of the primary mechanisms by which tea exerts its antioxidant effects is by reducing oxidative stress. Hypertension is often associated with an imbalance between the production of reactive oxygen species (ROS) and the body's ability to neutralize them with antioxidants. Tea, rich in flavonoids such as catechins, acts as a scavenger of ROS. These compounds can donate electrons to unstable ROS, neutralizing their damaging effect (Nakagawa and Yokozawa, 2002).

Hypertension is often associated with unfavorable changes in blood lipid levels, such as elevated LDL cholesterol (Jia *et al*., 2010). Tea consumption has been linked to improvements in lipid profiles, including reductions in LDL cholesterol levels. This may contribute to reduced cardiovascular risk in hypertensive individuals. A possible mechanism for the aforementioned could be that, tea catechins increase micellar cholesterol solubilisation and thus inhibit the absorption of cholesterol from the intestinal contents (Koo and Noh, 2007).

Future Recommendation

There is a need for research that would investigate the potential interactions between *Camellia sinensis* and commonly prescribed anti-hypertensive medications to ensure their safe co-administration. In addition, awareness on the benefits of *Camellia sinensis* as a complementary approach to hypertension management within public health initiatives is needed. This would encourage individuals to incorporate tea consumption into their daily routines, alongside other lifestyle modifications.

CONCLUSION

The mounting scientific evidence discussed here underscores the multifaceted role that tea can play in regulating blood pressure and promoting cardiovascular health. However, research that would evaluate safe co-administration with other anti-hypertensive agents and effective awareness on tea consumption must accompany this review to ensure widespread access to the potential benefits of tea consumption.

ABSTRACT

Oyster mushrooms are widely grown owing to their simple and low production technology with high biological efficiency. Spawn is the planting material in mushroom cultivation, its quality is very key for a successful crop of any edible and medicinal mushrooms. The main objective of the study was to determine the best grain spawn for getting early colonization and high yield crop of oyster mushrooms. Different cereal grains namely, wheat (Triticum aestivum), Sorghum (Sorghum bicolor) and Millet (Pennisetum glaucum) were evaluated for spawn production of the following oyster mushrooms, Pleurotus ostreatus var columbinus (blue oyster), P. djamor (pink oyster), P.citrinopileatu (Yellow oyster), and P. pulmonarius (Indian phoenix mushroom). The results revealed that blue oyster mycelium showed preference for all the grain substrates evaluated with no significant difference in its vertical mycelia extension (8.55, 8.33 and 8.17cm) on Sorghum, wheat and millet respectively at p<0.05 while Indian oyster showed preference for wheat grains and recorded its longest mycelium, 9.22cm on wheat and least (8.17cm) on millet. Millet grains appeared to be the least preferred grain as all the mushrooms recorded their least growth on it. The study concludes that sorghum and wheat are the best spawn substrates for effective mycelia growth.

INTRODUCTION

Mushrooms are macro-fungi, unlike micro-fungi, they produce visible reproductive structure from which their spores are released into the atmosphere. These spores are microscopic, usually suspended in the air and beaten down during the rains, if they fall on a suitable substrate, they germinate into thread-like mycelium which may eventually develop into a mushroom primodium which matures into visible fruiting bodies (Stamets, 2000). Mushrooms are known for their organoleptic and medicinal values and are highly priced for this, they are also rich in high quality protein which contains all the essential amino acids as found in animals and are sources of vitamins and minerals (Chang and Miles, 2008).

A medium through which the mycelium of a fruiting culture has grown, and which serves as the inoculum or "seed" for the substrate in mushroom cultivation, is called the mushroom spawn. Failure to achieve a satisfactory harvest may often be traced to unsatisfactory spawn quality. Consideration must also be given to the nature of the spawn material, since this influences the rapidity of growth in the spawn medium, as well as the rate of mycelial growth, and the filling of the beds following (spawn running) inoculation (Ragunathan *et ai.,* 1996).

The success of mushroom cultivation is largely dependent on the quality of its planting material, a vigorous mushroom spawn will results in healthy fruiting bodies and high yield. In a situation where the spawn substrate is not preferred, the mushroom mycelia's growth is retarded or no growth results (Mahadavan and Shanmugasundaram, 2018). This study therefore evaluated the mycelia growth of six different mushrooms on three cereal seeds for preference by the various mushrooms.

MATERIALS AND METHODS

Cultures of *Pleurotus ostreatus var columbinus* (blue oyster), *P.djamor* (pink oyster), *P.citrinopileatus* (Yellow oyster), *Calocybe indica* (milky white), *Ganoderma lucidium* (reishi mushroom) and *P.*

*pulmonarius (*Indian phoenix mushroom*)* were prepared on potato dextrose agar and slants were maintained at 4^0C in a refrigerator until needed.

Seeds of wheat (*Triticum aestivum*), guinea corn (*Sorghum bicolor*) and millet (*Panicum miliaceum*) were purchased from Bodija market, a local food market in Ibadan. The seeds were rid of empty kernels and were separately soaked for eight hours and drained to about 60% moisture content. The soaked and drained seeds were separately filled into 200ml capacity glass bottles (3/4 way filled) The bottles were then plugged with cotton wool wrapped in aluminum foil and sterilized in an autoclave for 30minutes at 121^0C (Zadrazil, 1978). After cooling to room temperature, the bottles were seeded with mycelia-agar discs of the different mushrooms being evaluated. The bottles were then kept in a dark room within the laboratory for two weeks to allow for the mycelia to ramify the seeds. Mycelial growth was measured every other day from the day of inoculation (Fasidi and Ekuere, 1993) and mycelia density was visually done on a scale of +1 to +3 where +1 is moderate mycelial density, +2 is abundant mycelial density and +3 is very abundant mycelial density according to the method of Mahadevan and Shanmugasundaram (2018).

The experiment was a completely randomized design with four replications.

RESULTS

All the mushrooms grew on all the grain substrates tested, blue oyster mycelia showed preference for all the grain substrates evaluated with no significant difference in its vertical mycelia extension at $p<0.05$ while Indian oyster showed preference for wheat grains and recorded its longest mycelium, 9.22 on wheat and least on others. Millet grains appeared to be the least preferred grain as all mushrooms recorded their least growth on it. It was also observed that *S. bicolor* recorded the longest total mycelia growth of all the grain substrates evaluated. (Table1).

Figure 1 shows average daily growth rate of the mushroom mycelia, this result agrees with the report of Mahadavan and Shanmugasundaram (2018), who reported that *Sorghum bicolor* seeds as grain substrate, supported prolific growth of the mycelia of some oyster mushrooms above barley followed by wheat where millet ranked least in all the parameters considered. Therefore, this study concludes that sorghum and wheat are the best spawn substrates for effective mycelia growth.

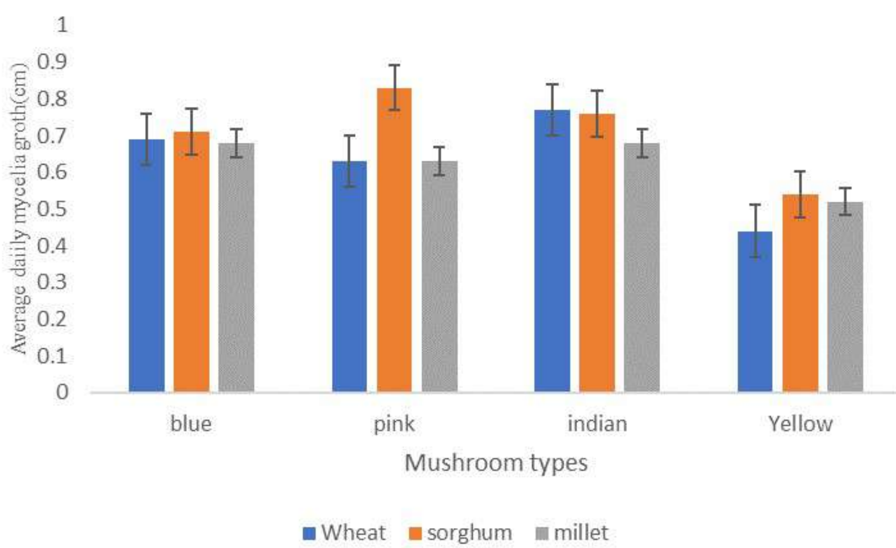

Fig 1: Mycelia growth of various mushrooms on three different spawn substrate types

Table 1: Mycelia growth and mycelia density of four oyster some selected on difrent grain substrates

Mushroom type	Blue oyster		Pink oyster		Indian oyster		Yellow oyster		Total mycelia growth (cm)
	Mycelia growth rate and mycelia density								
	Mycelia extension (cm)	Mycelia density	Mycelia extension (cm)	Mycelia density	Mycelia extension (cm)	Mycelia density	Mycelia extension (cm)	Mycelia density	Cumulative mycelia extension (cm)
Wheat	8.33^{a}	+3	7.50^{b}	+2	9.22^{a}	+3	5.33^{b}	+1	30.38^{b}
Sorghum	8.55^{a}	+3	10.00^{a}	+3	9.11^{a}	+3	6.42^{a}	+1	34.08^{a}
Millet	8.17^{a}	+3	7.52^{b}	+2	9.17^{a}	+3	6.25^{a}	+1	31.11^{c}

+1 moderate mycelial density, +2 is abundant mycelial density and +3 is very abundant mycelial density. Means followed by the same superscript letter(s) in each column are not significantly different (P>0.05) by Duncan's multiple range test.

ABSTRACT
The study investigated digitised horticultural news using the National Institute for Horticultural Research (NIHORT), Ibadan, as a case study. It employed the case study and descriptive research design. The data used for this article were obtained from the collection of all digitised news between the year 2007 and 2014. Using the descriptive statistics to present the data, the study revealed that a total number of 231 digitised horticultural news with The Guardian having the highest number of horticultural news that have been digitised. The study also shows that 88 news have been digitised under the ornamental news, 32 under the spices category, 59 under the fruits category, 35 under the vegetable category, 20 under the food security and health category and 7 under other crops. The article concludes that although digitisation of horticultural news has been ongoing, the number of digitised news are few therefore recommends that libraries should priotise digitising every news in every newspaper as a daily routine.

INTRODUCTION

Libraries and librarians have been tasked with the duty of adopting and ingraining the usage of technologies in library services and operations in view of the current breakthroughs in Information and Communication Technologies (ICTs) and the quickening rate of information explosion. Due to this, its current print materials now need to be converted into forms and/or mediums usable with various information and communication technologies. Digitisation refers to a wide variety of steps involved in the process of conversions and making of historical and other materials globally accessible through the application of digital processes (Otubelu and Ume, 2015). Libraries all over the world are quickly adopting digitisation procedures for their resources as a means of survival in order to strengthen their mechanisms and raise their relevance in this era of massive information explosion and accessibility mediums. Mohammed (2009) pointed out that libraries and the degree of service delivery to the community are more affected by the growth of ICTs and its subsequent integration in library and information services. In order to conserve the original item from destruction and to provide public access to resources that could otherwise be prohibited due to geographic differences, tangible information items must be transferred to digital format. This process is known as digitisation (Yaya and Adeeko, 2016).
Development, sustainable production, marketing, and use of high-value, intensively cultivated food and ornamental plants are all aspects of horticulture. It is both a science and an art. The Latin words hortus (garden plant) and culture (tilling the soil) are the source of the word. In horticulture, food and ornamental plants are produced with meticulous attention to detail, frequently in a small area as opposed to a large field (Michaels *et al*., 2022). As horticultural practices continue to evolve, access to historical horticultural news becomes invaluable for understanding the industry's evolution, the challenges it has faced, and the innovations that have propelled it forward. Digitisation offers a promising avenue to unlock this treasure trove of knowledge. As stewards of knowledge in the field of horticulture, National Horticultural Research Institute (NIHORT) library, nestled in the heart of Nigeria recognizes the critical need to preserve and disseminate its rich collection of horticultural news, ensuring that it remains accessible to future generations of scholars, researchers, and practitioners. This study explores the journey undertaken by NIHORT library to digitise its extensive collection of horticultural news.

Research Objectives

The major aim of the research is to assess the digitisation of horticultural news in NIHORT Library. The specific objectives are to:

i. Determine the number of horticultural news that have been digitised in the various newspapers subscribed to at NIHORT Library.
ii. Ascertain the number of horticultural news that have been digitised under various category of horticulture at NIHORT Library.

Research Questions

i. How many horticultural news has been digitised in the various newspapers subscribed to at NIHORT Library?
ii. What is the number of horticultural news that has been digitised under the various category of horticulture at NIHORT Library?

METHODOLOGY

The case study research design was employed for this study while a descriptive research design was used to gather broad quantitative data about the number of digitised news. The data was obtained from three newspapers that are subscribed to by the institute namely Nigerian Tribune, The Punch and The Guardian newspapers. The obtained data was analysed using descriptive statistics. The article relied on digitised news in the three newspapers obtained from the library between the year 2007 to 2014.

DISCUSSION

This study examined horticultural news that have been digitised using The Nigerian Tribune, The Punch and The Guardian Newspapers between 2007 and 2014. It was revealed that between the year 2007 and 2014, 46 digitised news were recorded in The Nigerian Tribune, 45 in The Punch Newspaper and 140 in The Guardian Newspaper which has the highest number (Table1). These statistics shows that 231 horticultural news have been digitised between 2007 and 2014. This reveals availability of digitised horticultural news in NIHORT library for use by researchers/users.

The study further delineates the digitised news under various category. The findings revealed that under Ornamental News, Nigerian tribune had the least number of digitised news with a total number of 3, The Punch had 4 while The Guardian being the highest number of digitised news (81) (Table 2). In the spices category with a total of 32 digitised news, The Punch had 3, the Nigerian Tribune had 13, while The Guardian had 16 digitised news. (Table 3) In the Fruits category with a total number of 59 digitised news, The Guardian has more digitised news with a total number of 24, The Punch had 23 digitised news followed by Nigerian Tribune which has the least with a total number of 12. (Table 4) Table 5 shows that The Guardian had a total number of 14 digitised news in the vegetable category, The Nigerian Tribune has 12 and The Punch with the least 9. While in the category of food, security and health news (Table 7) , the study found that few newspapers have been digitised with Nigerian Tribune having 4 digitised news, The Punch having 4 and The Guardian with 2 digitised news. A total of 10 horticultural news has been digitised under the food, security and health. In the category of other crops, the study found a total number of 7 digitised news with The Guardian having the highest number of 3 digitised new, The Punch had 2 and Nigerian Tribune had 2 (Table 6)

CONCLUSION

The digitisation of library materials has been discovered to be a crucial aspect in the growth of modern libraries. The delivery of library services has continued to change as a result of the current development. It is necessary for special libraries especially in horticultural institute, to step up their efforts to digitise their local content for preservation and simple access if they are to coexist with the rapidly expanding information technologies. The study was able to reveal that there is a need for horticultural libraries to digitise horticultural news by taking it as a daily routine to search for relevant information in newspapers and digitise them, thereby providing a robust resource base of the institutes and rendering better services to the researchers. When horticultural news are digitised, the information is preserved and researchers can make quick references to them regardless of their location.

RESPONSE OF PINEAPPLE (*Ananas comosus Var*.) TO SELECTED HERBICIDES

[1]Adebisi. J.K. and [2]Agbo. S. O.
[1]University of Tuscia, Vicerbo, Italy;
[2]Federal University, Oye Ekiti, Ekiti State, Nigeria

ABSTRACT
Pineapple plants show delayed maturation mainly because their superficial root system exposes them to intense competition with weeds for nutrients. This attribute contributes to delays in crop development and thereby reduces their overall yield and quality. For this reason, it becomes necessary to apply herbicides to control weeds. The objective of this study was to determine the response of different varieties of pineapple (Smooth cayenne, MD2, and Sugar loof) to various herbicides at their vegetative stage. The experimental setup consisted of four treatment categories, which includes the control and three herbicide treatments with each having five replicates. The control was hand-weeded, while the herbicide treatments were administered with tolerable levels of Atrazine, Glyphosate, and Paraquat. The physiological evaluations of pineapple leaves were used to assess potential adverse effects due to the applied herbicides. Based on these assays, we did not observe any substantial difference on the Atrazine treatment plots when compared to the control treated population within the exposure period of 70 days. However, paraquat-treated pineapples showed considerable physiological responses at a week or 7 days of treatment application. Further anatomical analysis of the Pineapples may reveal unexpected variations from the control population.
Keywords: *Atrazine, glyphosate, paraquat, pineapple, treatment.*

INTRODUCTION

Pineapple (*Ananas comosus*) belongs to the family Bromeliaceae, consisting of 50 genera and about 2500 known species. It has dagger-like leaves making it to be classified to the monocotiledonae family. In Nigeria, the most popular species of pineapple grown are Smooth Cayenne, Sugar loof, and MD2, a new strain from Costa Rica that is sweeter than the regular varieties, and always growing to a uniform size and ripening evenly. The MD2 is also referred to as golden yellow (FAO, 2010). Pineapple has a slow growth with a superficial rooting system, these are major factors that exposes it to intense competition with weeds, contribute to its delay of development, reduce its yield and quality (Reinhardt, 2002). It is recommended to keep the fields clean from weeds during the first five to six months of field establishment. It is pertinent to know that in pineapple fields, weed competition is exacerbated by the fact that the crop is small and grows very slowly, favoring water and nutrient uptake by weeds (Catunda, *et. al*., 2005). One of the alternatives to control competition is the use of herbicides, which allows less reliance on manpower. During the crop cycle, ten to twelve weeding may be needed, which leads to burdening the production cost considerably. Weed control with herbicides is a good alternative, especially in large fields and rainy periods when the grass grows quickly and hand-hoe weeding is not feasible.

In a report given by Leonardo, *et. al.,* (2012) on the growth, production, and quality of pineapple in response to herbicide use, the results obtained on the vegetative phase were that the use of herbicide on the treatment had no effect when compared to manual hoe weeding on the number of leaves. Considering the natural flowering, the same number of leaves was observed after the tenth month (July) in all treatments, being the peak during the fourteenth month (November). Catunda *et al*. (2005), evaluated the effect of herbicide semicarbazone on pineapple growth, cultivar 'Pérola', also did not obtain difference in the D-leaf growth, despite showing phytotoxicity symptoms at the beginning of the crop development, indicating that the damages caused in the first few days by the herbicides did not disturb the final growth of the crop. However, these authors compared the effects of the herbicide mixture diuron + paraquat on the crops; they reported severe damage to the pineapple plants, which caused their death 30 days after treatment (Catunda *et al*., 2005).

The application of these herbicides is where the issue arises since herbicides in recent days are termed lesser-known toxicants (US, EPA) that is, toxicants in our environment that attention is not paid to. Agrochemicals, such as herbicides, insecticides, pesticides, and may others. had been said to be lesser-known toxicants in our environments today. The effects of these toxicants in our environment cannot be over-emphasized since they do not only affect targeted organisms but also the non-targeted. Agrochemicals such as herbicides are generally used to control weeds (target organisms) in farmlands generally. The project will be focused on the effects of these herbicides, on pineapple plants (non-target organisms) during their vegetative phase. Also, to know the type of varieties that had high susceptibility or resistance to particular herbicide in Nigeria. Moreover, herbicides are toxicants that have negative effects on humans and their environments, it is important to know if these herbicides can have a negative effect on these pineapple varieties. The objectives of the study were:to know the effects of herbicides on pineapple plants during their vegetative phase based on their physical changes and to determine how the herbicides can affect pineapple plants in their vegetative phase.

MATERIALS AND METHODS

Description of the site

The experiment was conducted at an experimental site located at Federal University, Oye-Ekiti, Faculty of Science, behind the second makeshift lecture hall. The experimental site had the following geographic coordinates: N 07º46.616', E 005º18.916', Average temperature of 21-25 ^{O}C, average rainfall of;1000-1500 mm per annum relative humidity; 50-80 %. The topography of the area was an almost flat one. Physical characterization was done on the soil and it was discovered to be loamy soil. There was no specific type of land preparation (no heap or bed made) the pineapples were planted directly on the field And there was no fertilizer applicatio to the plants, while and the period of plant exposure to herbicides was carried out every thirty days (30). There was no need for wetting during the first few months of planting which fell in the rainy season.

Description of the plant materials

The pineapple suckers were gotten from National Horticultural Research Institute, Idi-Ishin Jericho Ibadan. The suckers were transported down to Oye-Ekiti by public transport on the 19th of May 2019 after which the site clearing was done and they were planted at exactly 1 week and 5 days of collection. The suckers were planted in the evening and the physical characteristics of the suckers were taken note of which includes the drying of the leaves that was obvious in the MD2 variety and weathering of leaves noticed in the Smooth Cayenne while the Sugar loof variety looks good (without any withering or drying of leaves). The period of acclimatization was for 3 months before treatment applications. The pineapples were expected to mature after 1 and a half years of planting.

Experimental design

1. The experiment had 4 weed control treatments which included the control (hand-hoe weeding = T_O) and 3 herbicide types (T_{1-3}), 3 varieties of pinneapples (MD2, Sugar loof, Smooth cayenne = V_{1-3}), each at 5 replicates per weeding treatment to give a total of 20 suckers for each variety, for a total of 60 suckers for the whole plot. Plant spacing of 60cm x 75cm was used with a space of 75cm in between the blocks. The concentration of herbicides used was such that it will not harm the plant since the study is a long-term exposure (chronic exposure) according to the United States Environmental Protection Agency. The blocks of treatment were labeled based on the herbicides used which include T_O (conruol) T_1 (Herbicide Atrazine), T_2 (Herbicide Glyphosate), and T_3 (Herbicide Paraquat dichloride) as the active ingredient and they were prepared at a concentration of 2.5g/L, 2.5ml/L, and 2.5ml/L respectively and dissolved in 1litre of water using a magnetic stirrer to ensure a homogenous mixture of the solvent and then transferred into bottles. The herbicides were sprayed on the field at an equal volume of 100ml in a 200ml herbicide dispenser (pushp). This hand sprayer was used to control dispersal by wind as well as the volume,

and hand weeding was used for the control. The application of the herbicides was performed on a weekly basis. The herbicides were applied for a period of 10 weeks and physical observations were taken note of at the different times they were applied.

RESULTS

Physical observation

Table 1 showed the records of observations taken and indicated that after the first week of treatmrnt applications, all plots were in good condition as there was no physical changes observed on the planted suckers. However, after the second application, the pineapples with Paraquat plot (T3) treatment began to dry up along with the weeds. After this was observed, the plot was left to recover from the shock which did not happen until the end of the treatment period. In contrast, , the pineapples treated with Atrazine (T1) showed no significant physical changes while the weeds started to dry up.With this trend, application of the treatment continued till the end of the experiment. Plot treated with Glyphosate (T2) recorded no casualty due to the treatment applied, hence, the application was continued., However, a yellowish coloration was observed on the weeds by the 3rd week of application. This similar observation made in T2 got changed by the 7th application. . There was increase in growth observed in both treatments T1 and T2, while the control plots were weekly hand-weeded and watered.

DISCUSSION

When comparing the physical response observed on the control pineapples plot with the pineapple varieties on the treatment plots, the treatments showed that after the first application of Atrazine (T1), the pineapples and even the weeds around were not affected, until the second application where the weeds responded to the herbicide treatment, revealing that the effect of atrazine concentration used can be seen on the weeds after two consecutive application of the herbicide but not on the pineapple varieties, as there was no evident effect of Atrazine on their physical appearance till the end of the experiment (Figure 1). The pineapple varieties with Glyphospahte treatment (T2) did not respond immediately to the herbicide treatment unlike the weeds, which began to give a yellowish coloration just after the second application which was later seen on the pineapple plants after the seventh application of the herbicide showing that the persistent application of Glyphosate at a concentration of 2.5 ml L^{-1} will elicit a response in the pineapple plants. In other words, when the pineapples on T2 were physically compared to the control, they were totally different from the control (Figure 2). Lastly, the pineapples treated with Paraquat (T3) responded to the treatment immediately after the first application, with all the pineapples on that plot responding to it equally and this is seen in the dry leaves they possessed. This indicates that pineapples will respond to Paraquat application at a concentration of 2.5ml L^{-1} of water. Since this was noticed the pineapple plants were left to recover and it was after the tenth application they all recovered (Figure 3). Also, this indicates that there is a big gap between the control and the treatment groups. This was in trend with reporsby Catunda, *et. al.* *2005) in which Paraquat and Diuron were mixed and this caused severe damage to the crops after which all the plants died 30 days after the treatment.

CONCLUSION AND RECOMMENDATION

The study showed that the vegetative production of the pineapple varieties upon the usage of atrazine was not disturbed as the pineapples did not respond to the herbicide treatment effect. This can also be said of the treatment with the use of Glyphosate, that with a wide interval of application, there will be no effect on the vegetative growth of the pineapple plants. In contrast to the above, the consecutive application of paraquat even at a very low concentration causes severe damage to the vegetative production and growth of the three pineapple varieties. However, the performing of an anatomical analysis of the pineapples will help to reveal the effects of the herbicides on the plant tissues, for a better insight into whether there was an effect that couldn't be seen on the physical appearance of the pineapples.

ABSTRACT
*The crop output or plant performance of any cultivated farmland is determined by its level of soil fertility. Hence, productivity of any farmer is directly proportion to the quantity of harvested crops from a given size of farmland. This study therefore assessed the preference of organic and inorganic fertilizers application among arable crop farmers in Ogbomoso Agricultural zone of Oyo State, Nigeria. Specifically, the study described the socio-economic characteristics of the respondents, examined the crop enterprise combinations, identified the sources of fertilizers available to the respondents and determined the level of preference of both organic and inorganic fertilizers among the respondents. Multistage sampling procedure was employed to select 158 arable crop farmers, while interview schedule was used to collect relevant information from the respondents. The data collected were analyzed with frequency counts, percentage and mean as the main descriptive tools, while Pearson Product Moment Correlation was used as inferential statistical tool. The results revealed that 77.2% and 22.8% sampled farmers were male and female, with mean age of 46.63 years, mean farm size of 2.40ha and mean of 7.99 years of farming experience respectively. Inorganic and organic fertilizers have weighted mean score of 1.5 and 0.74 and were ranked 1st and 2nd. The educational status (r=0.370**; p<0.000), farm size (r=0.250**; p<0.002) and years of farming experience (r=0.299**; p<0.000) exhibited significant relationship with the preference of fertilizers application among the arable crop farmers.*
Keywords: *Organic, Inorganic, Fertilizer, Application*

INTRODUCTION

It is no doubt that soil fertility level of any agricultural farmland would determine the crop yield and its harvest during a specific cropping season. As a result of declining soil fertility, farmers tend to remain productive by making necessary amendments in order to improve the soil fertility level through the application of either organic or inorganic fertilizers. A prominent constraint to higher productivity among farmers in the Sub-Saharan region, including Nigeria is "soil infertility" related mainly to low nutrient status of the soils and continuous cultivation without planned replenishment of depleted soil nutrients (Wanyama et al., 2009). The fact that, agriculture is important in the economy of Nigeria with crops of cocoa, oil palm, maize, rubber, yam and cassava produced for food and foreign exchange earnings, and providing employment for over 66% of the population (IFAD, 2014), it is also imperative that crop yield is encouraged and sustained through the application of amendment materials (fertilizers).

A contributing factor to insufficient food production is the low soil organic matter content, and consequently, the inherent infertility of soils in Nigeria and in sub-Saharan Africa (Shiyam & Binang, 2013). As a result, small scale farmers, who produce the bulk of food in Nigeria, have to embrace fertilizer application – organic and inorganic – in order to increase yield (FAO, 2013). According to IFPRI (2011), the production efficiency of farmers for most crops is low. Druilhe & Barreiro-Hurlé (2012) asserted that among the problems hampering arable crop yield is availability and affordability of inorganic fertilizers. However, Shiyam & Binang (2013) argued that inorganic fertilizer may increase yield in the short term but may be both uneconomical and environmentally unsound. They stated that organic fertilizer, unlike the inorganic options, is environmentally sustainable and able to achieve increased agricultural productivity.

In lieu of the above premise, this study therefore focused on the preference for organic and inorganic fertilizer application among arable crop farmers in Ogbomoso agricultural zone of Oyo State, Nigeria. Hence, the study described the socio-economic characteristics of the respondents, examined the crop enterprise combinations, identified the sources of fertilizers available to the respondents and determined the level of preference of both organic and inorganic fertilizers among the respondents. The study tested the significant relationship between the socio-economic characteristics of arable crop farmers and their preference of organic and inorganic fertilizer application.

Previous research has identified a few factors that affected the fertilizer usage by arable crop farmers in developing nations. In Nigeria, Amanze et al. (2010) shown that whereas gender, age, and household size had no effect on farmers' usage of fertilizer in the production of arable crops, crop output, education level, farm size, and fertilizer price did. In Kenya, Wanyama et al. (2009) demonstrated that the likelihood of farmers adopting fertilizer in maize production was significantly influenced by the presence of change agents (extension) visits, the percentage of land under maize production, the sex of the household head, and agricultural training. Conversely, the intensity of fertilizer application was significantly influenced by the employment type of the household head, the price of fertilizer, and the proportion of area allocated for maize cultivation. In Nigeria, Chianu and Tsujii (2004) discovered that farmers from the Guinea savanna zone, younger farmers, farmers with higher levels of education, and farmers who cultivate a variety of crops have a higher likelihood of using fertilizer.

Kelly (2006) investigated the factors influencing fertilizer demand in sub-Saharan Africa and found that the cost of fertilizer, crop output prices, and the cost of other inputs that can be used in place of fertilizer are the main drivers of fertilizer demand in the area. In Nigeria, research by Akpan and Aya (2009) revealed that factors such as family size, consumption spending, the number of chicken birds kept by farmers, the number of goats owned, and the perceived price of fertilizer all had a negative impact on the demand for fertilizer. Fertilizer demand is positively impacted by farmer education, farm size, income, extension agent contact, ability to forecast rainfall, availability of contemporary communication tools, and yield of maize and mixed crops planted with it. According to research conducted in Nigeria by Olayide et al. (2009), the amount of fertilizer used intensively rises with family labor and physical access to the fertilizer, but decreases with farm size and distance from homestead.

Minot et al. (2000) reported that fertilizer demand from farmers in Malawi and the Benin Republic. In the Benin Republic, it was found that the number of cattle owned, the size of the farm, the expenditures of the household head, the education level of the head of the household, and the size of the farm all significantly impacted the need for fertilizer. They deduced that the following factors influence fertilizer demand in Malawi: farm size, number of pigs owned, education of the household head, ethnicity, price of maize, expenditure of the household head, club membership, and vegetable plot. According to Staal et al. (2003), some of the key factors influencing farmers' decisions to use fertilizer in Kenya include population density, soil textures (clay, loamy, and sand), cash crop plots, pasture plots, extension services, education, and the number of adults per acre.

Fufu et al. (2006) discovered that age, farmers' perceptions of price changes, and expectations for rainfall are important factors that influence fertilizer usage among maize farmers in their empirical investigation on the drivers of fertilizer use on maize fields in eastern Ethiopia. The utilization of fertilizer by smallholder farmers was found to be highly influenced by various factors, including age, education, credit, presence of a cash crop, distance to fertilizer market, and agro-ecological potential, as confirmed by Olwande et al. (2009) in Kenya.

METHODOLOGY

This study was carried out in Ogbomoso Agricultural Zone of Oyo State. The zone is one of the four Agricultural zones in Oyo State. Ogbomoso Agricultural Zone comprises of five (LGAs). Multistage sampling procedure was adopted for this study. Firstly, purposive sampling technique was employed in the selection of three LGAs which includes Surulere, Ogo-Oluwa, and Oriire LGAs respectively due to their rurality in nature. During the second stage, one percent (1%) number of villages was considered from the list of registered villages in the selected LGAs. Thereafter, the use of random number table was employed in the selection of five (5) villages from Oriire LGA, three (3) villages from Surulere LGA, and two (2) villages from Ogo-Oluwa LGA respectively, which amounted to a total of ten (10) villages and thirty percent (30% = 158) of the registered arable crop farmers were randomly selected accordingly. Both descriptive (frequency counts, percentages, mean, rank) and inferential (Pearson Product Moment Correlation) tools were employed to analyzed the data and tested the formulated hypothesis of the study.

RESULTS AND DISCUSSION

Socio-economic characteristics

Table 1 revealed the mean age of the respondents to be 46.63 years which suggests that the respondents are adults. Their adulthood is expected to differentiate between organic and inorganic fertilizers and their relevance to crop production. Both male (77.2%) and female (22.8%) arable crop farmers were sampled for this study. This implies that males are more involves in farming compared to their female counterpart. It is also an indication that both genders are involved in arable crop production. It was also observed that majority (94.3%) of the respondent were married with only 5.7% single. The variation in the marital status may be due to differences in their age. The result on educational background showed that 79.1%, 11.4% and 7.0% were secondary, primary and tertiary school leavers. This implies that almost all the arable crop farmers are literate. The means farm size and years of farming experience were 2.40ha and 7.99. The result on farm size suggests that the arable crop farmers cultivate sizeable farmland and with a specific years of farming experience. The variation in the farm size cultivated may be due to difference the farmland ownership status and access to required production input such as capital, fertilizers, etc. The farm size is may also determine the fertilizer requirements of the respondents. Most (95.6%) of the respondents received extension contact. The respondents contact with extension services is expected to influence their arable crop production knowledge and preference for fertilizer application.

Table 1: Distribution of respondents by socio-economic characteristics

Variables	Frequency (Percentage)
Age (years

Crop enterprise combinations

Table 2 revealed the different combinations of crop types grown by the respondents which include sole maize (70.3%), sole cassava (61.4%), maize and cassava (100.0%), maize, yam and cassava (79.9%), maize, cassava and okra (100.0%), maize, cassava and tomatoes (62.0%), maize and okra (86.1%), maize and tomatoes (44.9%) respectively. This results implies that most respondents combines two or more arable crops at a time on the same farmland probably with the intention to maximize the use of available farmland, rainfall season, labour usage, food availability for household consumption (food security) and profit maximization.

Table 2: Distribution of respondents by crop enterprise combination

Crops	*Frequency (Percentage)
Sole Maize	111(70.3)
Sole Cassava	97(61.4)
Maize + Cassava	158(100.0)
Maize + Yam + Cassava	126(79.7)
Maize + Cassava +Okra	158(100.0)
Maize + Cassava + Tomatoes	98(62.0)
Maize + Okra	136(86.1)
Maize + Tomatoes	71(44.9)
Yam + Okra	142(89.9)
Leafy vegetable + Pepper + Tomatoes	69(43.7)

Sources of fertilizers

Table 3 revealed the sources of both organic and inorganic fertilizers available to the sampled respondents and 93.7% each indicated Agricultural Development Programme (ADP)/Government and market/poultry farm, only market (76.6%) and only poultry farm (17.1%), while only 35.4% indicated input dealers. The result implies that, the respondents' source for the fertilizers from different sources. The choice of source may be due to availability, nature of relationship between the source and the arable crop farmers, etc.

Table 3: Distribution of respondents by source of fertilizers

Sources	*Frequency (Percentage)
ADP/Government	148(93.7)
Market	121(76.6)
Poultry farm	27(17.1)
Market + Poultry farm	148(93.7)
Input dealer	56(35.4)

Source: Field Survey, 2023; *: Multiple Responses

Preference of organic and inorganic fertilizers

For this objective, 3-point rating scale of mostly preferred, preferred and not preferred was employed. Thereafter, weighted mean was computed and ranked accordingly (Table 4). Inorganic fertilizer had the highest weighted mean score (WMS) of 1.5 and was ranked first (1st), while organic fertilizer was ranked second (2nd) with WMS of 0.74. This result is in conformity with Olaleye et al. (2008), that 40.5% and 59.5% of the farmers preferred the use of organic and inorganic fertilizers. This result implies that most farmers preferred and applied inorganic fertilizer compared to organic fertilizer. Their preference for each fertilizer may be due to difference in their knowledge of advantage/purpose, convenience and availability of the two types of fertilizers.

Table 4: Distribution of respondents by preference of organic and inorganic fertilizers

Types of fertilizer	**Frequency (Percentage)**				
	Level of preference				
	Mostly preferred	**Preferred**	**Not preferred**	**WMS**	**Rank**
Organic	32(20.3)	54(34.2)	72(45.6)	0.74	2nd
Inorganic	97(61.4)	43(27.2)	18(11.4)	1.5	1st

Source: Field Survey, 2023; WMS: Weighted Mean Score

Test of hypothesis

The result of Pearson's product moment correlation (PPMC) revealed that educational status (0.370**; p<000), farm size (0.250*; p<002) and years of framing experience (0.299**; p<000) recorded a significant relationship with the level of preference of fertilizers among the respondents. This result implies that, the identified socio-economic variables have decisive influence on the preference of fertilizer application among the arable crop farmers. The results therefore reject the null hypothesis. This result corroborate Minot et al. (2000) and Amanze et al. (2010), reported that size of farm plot, household head expenditure, farm size, educational level, maize plot, rice plot, and number of cattle owned has significant effect on fertilizer application.

Table 5: Test of significant relationship between the socio-economic characteristics of respondents and their level of preference of fertilizers using PPMC analysis

Socio-economic variable	**Pearson correlation (r-value)**	**P-value**	**Result**	**Remark**
Age	0.094	0.240	NS	Accept H_0

CONCLUSION AND RECOMMENDATIONS

Conclusively, the study revealed that farmers of different socio-economic background such as age groups, genders, educational status, etc. are involved in arable crop production in the study area. The farmers cultivate numbers of arable crops both as sole and multi-cropping with majority having preference for inorganic fertilizer. It was observed that socio-economic variables influence the level of preference of arable crop farmers in the study area. The study therefore recommend the need to educate the arable crop farmers on the relevance of both types of fertilizers in relation to their side effects to both farmland and human health, it is also important to encourage arable crop production through extension service/training and timely provision of required production inputs especially fertilizers.

PROFILE DISTRIBUTION OF ORGANIC AND AMORPHOUS SESQUIOXIDES ALONG A TOPOSEQUENCE OF SOILS IN KWARA STATE, NIGERIA

Adefemi P.M., Raji B. A., Olasoji H.O., Ogunlade M.O.

ABSTRACT

The study was carried out in Kwara State to evaluate soil profile distribution of organic and amorphous sesquioxides (iron and manganese) along a toposequence. Three profile pits were established along the toposequence which were delineated into three topographic units, upper slope, middle slope and lower slope. The amorphous Fe and Mn had a total mean value of 0.02 and 0.05mg/kg^{-1} in the upper slope, 0.05 and 0.16mg/kg^{-1} respectively in the lower slope. Organic Fe and Mn in the upper slope showed a mean value of 0.02 and 0.01mg/kg^{-1}, while the lower slope showed a higher value of 0.03 and 0.02mg/kg^{-1} of Fe and Mn as compared to the upper slope. The result showed that amorphous sesquioxides are more available in the lower slope while it was negligible in the medium slope. Topography, soil chemical properties such as organic carbon play a significant role in the distribution forms of sesquioxides.

***Keywords**: Soils, toposequence, sesquioxides, Kwara State.*

INTRODUCTION

Iron (Fe) and manganese (Mn) found in soils are released during soil weathering and soil development. They are re-precipitated as amorphous or crystalline oxides, hydroxides or oxyhydroxides (Obi *et al.,*2009). Oxides, hydroxides and oxy-hydroxides of iron (Fe), manganese (Mn), are referred to as sesquioxides. They occur in soils mainly as amorphous and crystalline inorganic compound; however, a small fraction may be present in the organic complexes (Hassan *et al* 2015). The form and content of the oxides influence soil physicochemical properties such as phosphate retention, charge surface, specific surface area, aggregate formation and stabilization making it unavailable in highly weathered tropical soils, *(*Duiker *et al.,* 2003).

Hot climates areas are known to experience a lot of weathering processes, and weathering is a major factor that contribute to the distribution of sesquioxides. Weathering of primary minerals is more powerful in the tropics than in a temperate climate and it occurs to a greater depth. Consequentially, sesquioxides are formed during weathering of soils. Topography is a factor of soil weathering and soil formation processes; therefore, topography is a major factor contributing to the distribution of sesquioxides soils. Subardja and Buurman (1980*)* confirmed that elevation influenced soil properties, development and degree of weathering. The objectives of this research were to access some physical and chemical properties of the soils; investigate the forms, content and distribution of iron and manganese oxides along the soils; and compare the distribution of iron and manganese sesquoxides with other physical and chemical properties of the soils on the toposequence.

MATERIALS AND METHODS

Location of Study

The study was carried out at the University of Ilorin, in Ilorin South local government area of Kwara State, Nigeria. Ilorin South falls within latitude 8°26′29.8″N and longitude 4°405′48.7″E. The toposequence has an elevation ranging from 308 to 334m above sea level. The climate of the area is characterized with an average temperature of 29^{0}C, an average humidity level of 52%, with an average wind speed of 10km/h. The rainy season is between March and November with a brief break in August and the annual rainfall varies from 1200 mm to 1500 mm. Ilorin falls within the Guinea savannah belt.

Analytical Procedure

Soil samples were collected from profile pits in each of the topographic units. Three profile pits were dug and the toposequence was delineated into three topographic units: upper slope (UPS), middle slope (MS) and lower slope (LS). The samples collected were air-dried, sieved through a 2mm sieve. The samples for Fe and Al determination were further passed through 1mm sieve. Particle size analysis was performed by the hydrometer method and organic matter by the Walkey-Black method. Soil pH was determined both in water and KCl following (Mclean 1965) procedure. Total Nitrogen was determined by Kjelhdal distillation method (AOAC 1999) while the cation exchange capacity was by the summation method. Available phosphorus was by the Bray and Kurtz No 1 (1954) method. Amorphous oxides were extracted by ammonium oxalate extraction (McKeague and Day 1966). The organic oxides were extracted by tetra sodium pyrophosphate ($Na_4P_2O_7$) solution, (Mckeague, 1967). The oxides of Fe and Al were correlated with some soil properties using GenStat.statistical tool.

RESULTS AND DISCUSSION

Physical properties of the soils

The physical properties of the soil are shown in (Table 1). The three pedons UPS, MS, LS were deep; the profiles were 160cm, 170cm and 200cm deep respectively. Idoga *et al.,* (2006) reported that soil depth, increased with decreasing altitude or down slope, soils on the UPS and MS were weakly structured, while those at the LS were well developed. The soils were classified as Ultisols and they have relatively high percentage of sand. The MS profile was poorly drained, this could result to why the sesquioxides in the medium slope were very negligible as opposed to other profiles. The sand content decreased with soil depth except MS which showed an increase and a further decrease with soil depth. Udo (1980), noted that in poorly drained soils, iron reduction to a divalent state usually occur, inducing high solubility and the resultant loss of the element by leaching.

Table 1: Physical properties of the soil

Pedon	Depth(cm)	Sand (%)	Silt (%)	Clay (%)	Bulk density (g/cm)	Textural Class
UPS	0-43	88.40	4.40	7.2	1.61	Sand
	43-72	84.40	8.40	7.2	1.77	Sand
	72-95	82.40	6.40	11.20	1.68	Loamy sand
	95-160	82.40	6.40	11.20	1.65	Loamy sand
MS	0-20	92.40	0.40	7.20	1.59	Sand
	20-125	78.80	12.88	8.32	1.64	Sandy loam
	125-170	88.80	6.88	4.32	1.58	Sand
LS	0-33	84.80	10.88	4.32	1.56	Loamy sand
	33-110	82.80	12.88	4.32	1.49	Loamy sand
	110-200	80.80	14.88	4.32	1.54	Loamy sand

Chemical properties of the soils

Some of the chemical properties of the soil are shown in (Table 2). All the profiles had a soil pH < 6.8, this shows that the soils are acidic. The value of organic carbon at UPS ranged from 0.44 to 2.79%, 0.26 to 2.87%, 0.82 to 2.72% and in the upper, middle and lower slope respectively. The value shows that organic carbon decreased with increase in depth. The values of the available phosphorus (AP) at the upper, middle and lower slopes ranged from 0.75 to 1.02 mg kg-1; 0.83 to 2.06 mg kg-1 and 0.88 to 5.41mg kg-1 respectively. Available phosphorous exceeded 4 mg kg-1 in the lower slope profile, this shows that the lower slope profile is not a weathered soil like the upper and middle slope profiles. Duiker *et al.,* (2003) proves that phosphate is usually not available in highly weathered soils. This result proved that the Upper and the middle slope soil profiles are weathered soils.

The data on the forms of Fe and Al are shown in (Table 3). The amorphous Fe (ox) had a mean value of 0.06, 0.01 and 0.05 mg kg^{-1} in the profiles. Thus, it is deduced that the amorphous oxide of Fe is higher in the UPS. The organic Fe (p) has a mean value of 0.03, 0.05, and 0.03 mg kg^{-1} in the three profiles, the middle slope has the highest value, this could be as a result of weathering of the organic material. Amorphous Mn (ox) had mean values of 0.05, null, and 0.6 mg kg^{-1} across the three soil profiles. While the organic Mn (p) showed mean values of 0.01, null, 0.02 mg kg^{-1} across the three profiles. Manganese had an insignificant value in the middle slope for both the amorphous and organic forms.

Mg	0.598*	-0.539*	0.276	0.223
CEC	0.417	-0.247	0.282	0.171
pH (water)	0.641*	-0.488*	0.345	0.107
pH (KCL)	-0.245	-0.016	0.208	0.164
BS	0.063	-0.540*	0.812	0.236

The distribution of amorphous iron (Fe) had significant strong positive correlation with organic matter of the soil ($p<0.001$); significant moderate positive correlation with organic carbon, magnesium, CEC, pH (water), and base saturation ($p<0.05$); weak positive relation with pH (KCl); very weak positive correlation with potassium; and very weak negative correlation with available phosphorus and total nitrogen (Table 4). The distribution of amorphous manganese (Mn) showed significant strong positive correlation with base saturation ($p<0.001$); significant moderate positive correlation with organic matter ($p<0.01$); weak positive correlation with organic carbon; available phosphorus, total nitrogen, CEC, and pH (water); and very weak relation with potassium and pH (KCl). The distribution of organic iron along the toposequence had weak positive correlation with exchangeable acidity; and very weak positive correlation with total nitrogen, but significant strong negative correlation with organic matter ($p<0.01$); significant moderate negative correlation with pH (water), and base saturation ($p<0.05$); weak negative correlation with CEC; and very weak negative relation with organic carbon, available phosphorus, potassium, pH (KCl). Whereas, the distribution of organic manganese had
significant moderate positive correlation with available phosphorus ($p<0.05$); weak positive relation with total nitrogen; very weak positive relation with organic matter, CEC, and pH (KCl) but weak negative correlation with pH (water); very weak negative with organic carbon, potassium, and base saturation.
Seal *et al.* (2006) observed positive correlation of organic carbon with amorphous organic iron and negative correlation with amorphous iron. Ammari and Mengel (2006) inferred that soil organic matter played an important role in availability and solubility of iron. Juo *et al*., (1974) concluded that Nigeria has a relatively small amount of amorphous iron oxides in most Alfisols and Ultisols derived from acidic parent rocks. Maniyunda *et, al* (2015) confirmed that pedogenetic development and sesquioxides crystallization were significantly higher in the subsoil compared to surface horizons.

CONCLUSION

Based on the results, this study showed that the upper and the middle slope profiles have aged and weathered due to the high sesquioxides content present. The Clay and organic matter also had a strong influence on the movement and the distribution of the forms of organic and amorphous sesquioxides of Iron and Manganese in the soils.

ABSTRACT
Mushroom and ginger are high valued crops of immense health benefits and income potential. Mushroom is a prized delicacy with notable health benefits, a good protein substitute especially where other protein sources are not affordable. Ginger too is a health based crop used as accompaniment in the treatment of various health related issues. Although an increased awareness is being generated among the populace on the health and income benefits, it becomes necessary to have capacity of interested stakeholders developed for sustained production and utilization of the crops. Thus, a program was organized to train youths on mushroom and ginger production and utilization. Based on needs assessment in the community of focus, 80 respondents were selected as part of a Federal Government sponsored constituency project facilitating training for youths. Data was obtained through use of structured questionnaires and analyzed through frequency counts, percentages and t-test. Findings revealed that majority (80%) of the respondents were aged between 19 and 48 years. A sizeable proportion (58.8%) were males, married (75%), while 78.8% had education from primary to tertiary. Major occupation by 51.2% of respondents was farming. There was significant difference between the total post evaluation mean score and pre evaluation mean score (t=16.692, p=.000). In order to achieve a nationwide spread cultivation of mushroom and ginger processing both for local consumption and export,while also reducing youth unemployment, it becomes imperative to strengthen capacity of unemployed youths and other prospective stakeholders to maximally benefit from the potentials in the selected value chains for income generation and livelihood enhancement.
Keywords: *Farming, horticulture, mushroom, ginger, empowerment*

INTRODUCTION

Capacity building is the process of equipping individuals with the understanding, skills and access to information, knowledge and training that enables them to perform effectively in an informed society. Capacity building is necessary to equip both citizens and stakeholders with skills and competencies necessary in horticultural value chains to ensure sustainable agricultural development, improved income and economic empowerment (NIHORT,2020 and Berg,2016). Mushrooms are exotic functional foods with health benefits such as anti-viral, cholesterol-lowering, immune boosting anti-oxidant and anti-ageing properties (Bamigboye *et al*,2022). They can be converted to various forms of products such as mushroom biscuits, soup premix as health based food products. (Ogbo *et al*,2023). Nutritionally, mushrooms are rich sources of protein, fibre, vitamins and carbohydrates. Mushrooms help to prevent cancer and other life threatening diseases. Also environmental pollution can be reduced by mushrooms which convert and utilize organic wastes (Ayodele,2023). They also promote healthy skin complexion and hair, energy level, brain function, bone strength and overall low weight. (Oyetayo,2011). Different studies carried out on mushroom include perception and consumption of wild and cultivated mushroom in Port Harcourt, Nigeria. The survey revealed that 53.3% were conversant with wild mushrooms, and 27.8% with cultivated mushrooms. Although 58.9% indicated interest in mushroom consumption, and the relatively low consumption was attributed to its unavailability by 68% of the respondents (Adedokun and Okomadu,2017).

Ginger is an important cash crop in Nigeria, a flowering plant whose rhizome is frequently consumed as a spice, either fresh or dry, or used for a number of therapeutic purposes (US NCCIH, 2016). Ginger is available in different forms such as raw ginger, dry ginger, bleached dry ginger, ginger powder, ginger oil, ginger oleoresin and ginger candy. It is an important spice used for pickles and preservatives (Emmanuel, 2022). Ginger is one of the most widely used spices and herbs around the world, with a significant presence in the global food market and a substantial postharvest loss ((Malik *et al*, 2023) with storage loss estimated as high as 50 % (Rema and Rajeev, 2002). This underscores the need for processing into more stable forms for longer shelf life. Bamigboye,*et al* (2022), Adejo and Ademu (2018), Ndem and Martha (2016) advocated for training on mushroom production to facilitate its cultivation and consumption. Similarly, Omorefosa (2016) and Ayodele (2023) recommended massive cultivation of mushrooms and development of the mushroom value chain in Nigeria as a panacea to food scarcity, weapon for youth and women empowerment. This could provide 30 million skilled, semi-skilled and unskilled jobs for unemployed graduates, vulnerable youths and women, and contribute significantly to rural development and the country's GDP. It is against this background that a Federal Government sponsored constituency training program was conceived with the aim of reducing unemployment among the Nigerian youths, promote sustainable livelihood and economic empowerment by building their capacity in mushroom production and mushroom/ginger value addition. Specific objectives were to assess the knowledge uptake of the respondents and also profile their socio-economic characteristics.

METHODOLOGY

The study area was in Delta State, South-South part of Nigeria. The State is bordered on the north by Edo State, the east by Anambra and Rivers States, the south by Bayelsa State, and to the west by Bight of Benin. It has a projected population of 5,636,100 in 2022 with a land area of 16,986km^2 and lies at latitude 5^0 30'N and longitude 6^0 00'E (Delta State Government,2023). Delta State is blessed with a favourable natural environment (riverine and upland) and climatic conditions that warrant all year round farming activities. Wide variety of crops such as rice,yams, cassava, mangoes, pawpaw, rubber and oil palm are grown. There is availability of fertile land and water resources creating opportunities in vegetable and fish farming (Obekpa and Tasie, 2022). Agriculture comprised 13.2% of the State's GDP in 2020.

Needs assessment was carried out in Ndokwa/Ukwani Federal Constituency of Ndokwa West Local Government Area of Delta State. to determine preference of training programme and the commodity crops of focus. Population for the study were youths in Ndokwa West Local Government Area. A total of 80 male and female respondents randomly selected from 15 communities were trained under the Batch 2 segment of the training. Participants were exposed to theoretical and practical hands on experience training sessions in four training modules comprising: Mushroom production: Mushroom and ginger value addition: Economics, marketing and record keeping of mushroom production, and Economics, marketing and record keeping of ginger value addition. Data were collected through the use of structured questionnaires. Descriptive statistics such as frequency, percentages and means were used to describe the socio-economic characteristics of the respondents while t-test was used to compare the pre-evaluation and post-evaluation knowledge mean scores of the respondents.

RESULTS AND DISCUSSION

Findings from Table 1 revealed that majority (58.8%) of the trainees were males, married (75%) and involved in farming activities (51.2%). Eze, *et al* (2017) affirmed that males are the bread winners who have to engage in productive activities to provide for their family needs. A sizeable proportion (80%) of the trainees was within the age bracket of 19 and 48 years which is the active age while 45% had tertiary education. However, most (62.5%) of the trainees did not belong to any association. Asfaw and Admassie (2004) posited that education enhances the capacity of farmers to obtain and analyze information which may result to increased production. The results on Table 2 revealed that post training scores increased for each of the modules taught. Knowledge of participants before and after the training for each of the modules taught was assessed with paired sample t-test. Differences observed in the mean values were statistically significant at 1% level of significance as shown in the t-values (Table 3). These includes: Mushroom production (t= 12.377, p=.000), mushroom marketing and record keeping (t=9.032, p=.000), ginger processing (t= 15.999, p=.000), ginger processing and record keeping (t=8.364, p=.000). Overall, significant difference existed between total post knowledge score and total pre-knowledge score of participants (t= 8.364, p=.000). This implies that the participants' knowledge increased for each of the modules they were taught which were above the knowledge that they had before they participated in the training program, thus suggesting that exposure to the training improved the knowledge level of the participants.

CONCLUSION AND RECOMMENDATIONS

The study concludes that knowledge level of trainees improved after exposure to the trainings. Although majority of the trained youths did not belong to any agricultural association. The study recommends fully funded training by the Federal Government for unemployed youths to be domiciled in each senatorial district in Nigeria, with empowerment to facilitate integration into specific value chains, with formation of youth groups to explore both local and export market options.

TECHNICAL EFFICIENCY OF TOMATO PRODUCTION IN YAMALTU-DEBA LOCAL GOVERNMENT AREA OF GOMBE STATE

***Layade, A.A., Adeoye, P.O. and Idowu, O.O.**
National Horticultural Research Institute, P.M.B 5432, Idi-Ishin, Ibadan

ABSTRACT
The study investigated the level of technical efficiency of tomato farmers in Yamaltu-Deba Local Government Area of Gombe State. A multistage sampling technique was used to select eighty tomato farmers from the study area. Information was obtained from the sampled farmers through the use of a structured questionnaire. Stochastic Production Frontier Analysis (SPFA) with Cobb-Douglas functional form was used to analyze the technical efficiency of the farmers. The result revealed the tomato farmers in the study area were fairly efficient with mean technical efficiency level of 0.87. Fertilizer use, organic manure, pesticide and farm size enhanced tomato output and technical efficiency of the farmer at 1% and 10% alpha level. Return-to-scale of 0.32 was estimated, implying the farmers operate in the stage two of production where doubling the input lead to less than double in the output. Farmers should therefore pay attention to their input combination to avoid diminishing returns.
Keywords: *Production function, tomato, stochastic frontier, inefficiency*

INTRODUCTION

Tomato (*Lycopersion esculentum* mill) is one of the leading vegetable crops in Nigeria. The crop is high in nutritional values and it is rich in vitamins, mineral and fibre. It is widely used in varieties of dishes as raw, cooked or processed products in Nigeria. The production of tomato started experiencing increase from 1.79MT in 2010 until 2015 when it hit the production volume of 4.22 MT. However, the country could not sustain the increase as the production value declined to 3.57 in 2021 (FAOSTAT, 2021). The decline in production volume has raised an important policy question such as what factors are responsible for the dwindling production figure of tomato in the country. The answer perhaps could be in the technical efficiency of the farm or the farmers which is referred to as the ability of a farm to produce as much as output with the level of inputs, given the existing technology (Erena *et al*, 2021). The study therefore seeks to support literatures in production efficiency by analyzing the technical efficiency of tomato farmers in Yamaltu-Deba Local Government Area of Gombe State. Specifically, the study described the socio-economic characteristics of tomato farmers; estimated the determinants and levels of technical efficiency of tomato farmers in Yamaltu-Deba Local Government Area of Gombe State.

MATERIALS AND METHODS

Study Area

The study was carried out in Yamaltu-Deba Local Government Area (LGA), Gombe State. Yamaltu-Deba is one of the eleven Local Government Areas in the State with its headquarters in Deba. According to NBS (2009), the result of 2006 census indicated a population of 255,726 for Yamaltu-Deba LGA. The LGA covers an area of about 1,981 square kilometers and lies at latitude $11^0 31'$ N and longitude 11˚24' E with the temperature ranges from 20^0C to 31^0C and mean annual rainfall of 750mm. The soil is rich clay-loam, making it ideal for agricultural activities (Saleh *et al*., 2021). The LGA is known for cultivation of a wide range of vegetables, fruits and cereals. It hosts parts of the lake Dadinkowa and shares boundaries with parts of Borno State to the North, Balanga LGA to the South, Gombe and Akko LGAs to the East (Erie *et al*, 2019). The target population was tomato producers.

Sampling technique

A multistage sampling technique was used in the choice of individual respondent. The first stage was purposive selection of Yamaltu-Deba LGA from eleven LGA in Gombe state. Yamaltu/Deba was selected because it is known for production of tomato. The second stage was random selection of two belts within the LGA based on size of tomato production- Dadinkowa and Kwandon. The third stage involved random selection of forty tomato producers from each belt, making a total of eighty. However, data from seventy-seven respondents were found useful for analysis.

Data source and analysis

Primary data were used for this study. Data were collected by the use of well-structured questionnare. Respondents were asked to indicate socio-economic characteristics and production variables (quantities of inputs used and output).

Data analysis involved the use of descriptive and Stochastic Production Frontier Analysis (SPFA). The descriptive analysis was used to analyze socio-economic characteristics of farmers while SPFA with Cobb-Douglas functional form was used for estimating the determinants and levels of technical efficiency.

$$Y_i = f(X_i, \beta)e^{v_i - u_i} \text{...}(1)$$

$$\ln Y_i = \beta_0 + \beta_1 \ln X_1 + \beta_2 \ln X_2 + \beta_3 \ln X_3 + \beta_4 \ln X_4 + \beta_5 \ln X_5 + \beta_6 \ln X_6 + \beta_7 \ln X_7 + v_i - u_i \text{........}(2)$$

where,

Y_i= Observed individual *ith* farm output of tomato (Kg)

X_1=Farm size (ha)

X_2= Quantity of seeds (Kg)

X_3= Fertilizer (Kg)

X_4= Organic manure (Kg)

X_5= Herbicides (litres)

X_6= Pesticides (litres)

X_7= Labour (man days)

$\beta_{i's}$ =Technology parameters to be estimated

ln=Natural log

The v_{is} are random error variable that are assumed to have normal distribution $iid\, N(0, \delta_{vi}{}^2)$. The u_{is} are non-negative random variable having half of normal distribution $iid\, N^+(0, \delta_{ui}{}^2)$ which measures technical inefficiency effects.

Accordingly, Technical efficiency (TE) of individual tomato farmer is defined as the ratio of observed output (Y_i) to the corresponding frontier output (Y_i^*), conditioned on the level of input used by farm. Technical inefficiency is therefore defined as the amount by which the level of production is less than the frontier output. The model for TE will be expressed as:

$$TE = \frac{Y_i}{Y_i^*} = \frac{f(x_i;\beta).\exp(-u_i)}{f(x_i;\beta)} = \exp(-u_i) \text{...}(3)$$

where, Y_i is the observed and Y_i^* is the frontier output. Technical efficiency takes value between 0 and 1 i.e $0 \leq \text{TE} \leq 1$.

In addition, the study measured technical inefficiency, u_i , of the tomato farmers. The technical inefficiency effects are as follows:

$$\ln Y_i = f(\alpha + \beta) + e_i \text{...}(4)$$

$$u_i = \alpha_0 + \alpha_1 Z_1 + \alpha_1 Z_1 + \alpha_1 Z_1 + \alpha_1 Z_1 + \alpha_1 Z_1 + \alpha_1 Z_1 + \alpha_1 Z_1 + \alpha_1 Z_1 + v_i + u_i \text{..................}(5)$$

Where,

ui=technical inefficiency of equations 4 and 5 respectively

α_i=Vector of parameters
Z_1=Age of tomato farmers (years)
Z_2= Marital status
Z_3=Education (years)
Z_4=Household size of the farmer
Z_5=Membership of association: 1 if farmer belongs to association, 0 otherwise
Z_6=Extension visit
Z_7=Training
Z_8=Record keeping: 1 if farmer keeps record of farming activity, 0 otherwise
e=Random error
The u_i is non-negative random variable having half of normal distribution $iid\,N^+(0,\delta_{ui}^{\ 2})$.

RESULTS AND DISCUSSION

Socio-economic characteristics distribution of respondents

The distribution of socio-economic in table 1 revealed that most of the producers were within the age range of 20-39years with mean age of 37years. This is an indication that the farmers in the study area enjoys involvement of young persons in farming activities. About eighty-one percent of the respondents were male, indicating that men engage more in the tomato production in the study area. This is in conformity with finding of Saleh *et al,* 2021 (2021) and Usman and Bakari (2013) who reported the mean age of approximately 40years in their study areas. Over 68% of those engaged in tomato production were married with the mean household size of 11 persons, implying that most of the respondents have advantage of supply of family labour. The result is in line with Pius *et al*, 2006 who opined that farmers with sizeable family could engage them to their farm business. Eighty-three percent of the respondents had formal education, indicating that majority of respondents were literate and this could assist them in effective communication in doing their business (Asogwa and Okwoche, 2012). In term of experience, 54.6% had spent between 6 and 15 years the tomato farming, indicating a relatively high knowledge in tomato production. The greater the year of farming experience, the more knowledgeable the farmer is in minimizing costs and maximizing the profits.

Summary of quantity of input used by tomato farmers

A tomato farmer in the study area harvested an average output of 5,758.78kg from 1.08ha of land and about 5.63kg tomato seeds. The farmer applied an average of 130.24kg of fertilizer, 21.94litres of herbicides, 43. 37litres of insecticides and utilized average of 481.94mandays per hectare (Table2).

Table 2: Summary of quantity of input used by tomato farmers

Variables	Mean quantity
Average farm size for tomato (ha)	1.08
Seed (kg)	5.363
Fertilizer (kg)	130.24
Herbicides (litres)	21.94
Insecticides (litres)	43.37
Labour (manday)	481.94
Output (kg)	5,758.78

Maximum Likelihood Estimate for the Stochastic frontier

The result of stochastic frontier analysis and the inefficiency model are presented in table 3. The variance parameters for sigma squared (σ^2) and gamma (Υ) are 0.0304 and 0.978 respectively for tomato farmers and are significant. The sigma squared is an indication of goodness of fit and correctness of the distributional form assumed for composite error term while the gamma shows that about 97.8% of total variation is due to technical inefficiency and 2.2% accounts for random shocks.

The result further shows that the coefficient of the parameter estimates of farm size was positive and significant to output at 10%, use of organic and inorganic fertilizer was positive and significant at 1% and insecticide have positive significant influence on tomato output at 1%. While the coefficient of the parameter estimates of herbicide had negative and significantly effect on output at 10%. This implies that one unit increase in farm size, organic and inorganic fertilizer, and insecticide will increase tomato output by 0.016, 0.058, 0.072 and 0.162 respectively. However, a unit increase in quantity of herbicide will reduce the output by 0.119. The estimated elasticity of all the inputs are less than one, indicating decreasing returns to scale. This implies that the farmers operate in the stage two of production, and should be careful to know when to stop increasing input because increase in input combination by 1% will result to less than 1% increase in total output.

The lower panel of table 3, presents the estimated parameters of the inefficiency model in the stochastic frontier production function of tomato farmers. The signs of inefficiency model of the stochastic frontier production function had important implications on technical efficiency. The result revealed that only the coefficient of the parameter estimate of membership of association was positive and statistically significant to technical inefficiency which implies that membership of professional association reduces efficiency of the farmer. This is against the *apriori* expectation and may be due to the fact that some decisions being taken by the executives are having negative influence on the activities of the members. Although record keeping, training, household size and marital status were not statistically significant but had negative signs. The negative signs indicate parameters that reduce technical inefficiency of the farmer, and thus increase their efficiency.

Distribution of technical efficiency estimates for tomato farmers in the study area

Frequency distribution of technical efficiency of the farmers shows the efficiency of the farmers ranges from minimum value of 0.58 and maximum value of 1 with the mean technical efficiency value of 0.87 (Table 4). This shows that if the farmers with minimum efficiency are able to achieve the maximum level of efficiency, they would be able to save 42% of production resources. Likewise, the efficient farmers will be able to save 13% of their usual production input. The mean technical efficiency value also indicates that tomato farmers in the study area were fairly efficient.

Table 4: Frequency distribution of technical efficiency estimates for tomato farmers in the study area

Efficiency range	Frequency	Percentage
Less than 0.50	-	-
0.51-0.60	1	1.30
0.61-0.70	5	6.49
0.71-0.80	10	12.99
0.81-0.90	25	32.47

Minimum= 0.58		
Maximum= 1		
Standard deviation= 0.10		

Source: Computed from field survey data, 2021

CONCLUSION

Based on the findings, the study concludes that farmers were fairly efficient and could improve their output and efficiency through proper input combination. Fertilizer and pesticide contributed largely to output in the study area, the study therefore recommends policy that will encourage input distribution to farmers in order to boost tomato production. Training of farmers should be encouraged as this could improve their efficiency.

ABSTRACT
Mushroom cultivation is an economically feasible bio-technological process for conversion of various lignocellulosic wastes into edible protein. The aim of this study is to evaluate the suitability of waste paper in combination with sawdust for oyster mushroom production. From the National Horticultural Research Institute (NIHORT) Ibadan, the pure culture of blue oyster mushroom (Pleurotus ostreatus var columbinus) was obtained from Mushroom unit while the shredded waste paper was supplied by NIHORT management team. The mushroom was cultivated on paper substrate alone, sawdust substrate alone and in combination ratios of 1:3, 3:1 and 1:1. The experiment was laid out in a complete randomized design (CRD) in five replicates. Substrate ratio combination of 1:3 produced the highest number of fruits (13.00), BE (40.38%), PE (14.48%), days to full mycelial colonization and primordial initiation (26.00 days and 29.69 days respectively) and highest fruit weight (70.67 g). Substrate ratio combination of 3:1 had the largest width of pileus (9.90 cm) compared with others. Paper alone, sawdust alone and ratio 1:1 had comparable length of stipe while the shortest (4.80 cm) was observed on ratio 1:3. This study revealed that paper and sawdust combination (1:3) resulted in high BE and fruit bodies yield. Thus, waste paper is an alternative substrate for mushroom cultivation.
Key words: *Edible mushroom, Paper, Pleurotus ostreatus var columbinus*

INTRODUCTION

Pleurotus species (Oyster mushroom) has been widely cultivated and commercialized after *Agaricus bisporus* (Mshandete, 2011). It is a potential source of dietary fiber, contains approximately 100 bioactive compounds and rich in protein, carbohydrates, lipids, minerals and vitamins but with low fat and calories contents (Deepalakshmi and Mirunalini, 2014). Oyster mushrooms are the least expensive and easiest to grow commercial edible mushrooms as a result of their ability to recycle agricultural or horticultural wastes due to its multilateral enzyme system that can biodegrade a large range of lignocellulosic wastes (Mshandete, 2011), convert crop residues to food protein, serve as source of food production and security, employment opportunities and source of income (Banik and Nandi *et al*., 2004). Various substrates reported in the cultivation of mushrooms include cassava wastes, cottonseed hull, rice and wheat straw, leaves, paddy straw, barley straw, beans straw, corncob, sawdust and sugarcane baggase (Sharma *et al*., 2013; Sonnenberg *et al*., 2015; Otunla *et al*., 2016). Mushroom cultivation can play an important role in ensuring food security, diversifying business and employment opportunities, both in urban and rural areas (Tesfay *et al*., 2020).

Sawdust and waste paper are incinerated, disposed openly in fields and burnt, leading to environmental and or air pollution. Papers composed of primarily cellulose, hemicellulose and lignin (Tesfay *et al*., 2020) and a number of colleges and offices dispose waste papers. If this can support the growth of mushrooms, it may help to transform this waste into an acceptable edible biomass of high market value and serve as a cheap source of substrate for mushroom growers. Therefore, the current study was aimed at evaluating waste paper, in combination with sawdust, for the cultivation of mushroom.

MATERIALS AND METHODS

***Source of higher fungus* (*mushroom spawn*)**

Pleurotus ostreatus var columbinus spawn (seed) used for this research study, was obtained from the pure culture collection from the Mushroom unit mycology laboratory of the National Horticultural Research Institute (NIHORT), Idi-Ishin, Jericho, Ibadan, Oyo State.

Substrates collection and composting

The sawdust used for this experiment was collected at Sanngo sawmill within Ibadan, Oyo State while the shredded waste paper was obtained from NIHORT, Ibadan. They were composted for a month at the mushroom unit substrate composting room as follow; paper alone, sawdust alone and in the combination ratios of 1:3, 3:1 and 1:1.

Mycelia ramification on substrates

Each of the substrate (500 g) was packed into heat-resistant transparent polythene bags, replicated five times and the bags were of the size 35 x 10 cm. The necks of the bags were tucked with a cotton plug and were sterilized in an autoclave at 121ºC for 15 minutes. Aseptically in the inoculating room, the bags were separately inoculated with the mushroom spawn on cooling and later transferred into the vegetative room (temperature and relative humidity of 28-30 ºC and 82-85% respectively) to allow mushroom mycelia ramification.

Cropping and harvesting of mushroom

The cropping or fruiting house was maintained at 24-28 ºC and relative humidity at 84-87%. Inoculated substrate bags fully ramified with mushroom mycelia were moved out of the vegetative room into the cropping house where fructification took place. Mushroom fruit bodies were harvested manually by twisting them from the base without leaving any remnant. The following parameters were observed and recorded; number of fruits, fruit weight, width of pileus, length of stipe, days to full mycelia colonization and primordia initiation while Biological and Production Efficiencies were calculated.

***Research* Design**

In five replicates, the experiment was laid out in a complete randomized design (CRD).

Data Analysis

Data collected was analyzed using ANOVA while significant means were separated using Duncan's multiple range test.

RESULTS AND DISCUSSION

It was observed that the substrates, singly and in combinations, showed remarkable growth and yield of the mushroom species. *Pleurotus* species are known to be able to degrade lignocellulosic agricultural and or horticultural wastes (Mshandete, 2011). The mushroom must have secreted hydrolyzing enzymes to degrade the components of the substrates for easy accessibility of the component nutrients.

***Days to full mycelial colonization*:** The shortest number of days to full mycelial colonization (16.00 days) was recorded on paper substrate alone followed by substrate ratio of 3:1 (18.67 days). Substrate ratio combination of 1:1 was significantly different (22.67 days) while the longest number of days was recorded in substrate combination of ratio 1:3 which was comparable to what was observed in sawdust substrate alone (26.00 days and 25.00 days respectively). This was similar to the work of Girmay *et al*. (2016) that reported 14.00 days, Shah *et al*. (2004) that reported 2-3 weeks and Kumari and Achal (2008) that reported 20.00 days after inoculation. This may be due to the substrate nature, ability to retain moisture and differences in environmental condition. Temperature of 30 ºC is optimal to the growth of *Pleurotus ostreatus* (Marino *et al*., 2003).

***Primordia initiation*:** This was first observed in substrate ratio combination of 3:1 (24.00 days). This was followed by what was recorded on paper alone which however was not significantly different from what was observed on substrate ratio 1:1 (26.33 days and 26.67 days respectively). The longest number of days was recorded on substrate ratio combination of 1:3 which was comparable to sawdust substrate alone (29.69 days and 29.00 days respectively) (Table 1). Various researchers reported different number of days for primordia initiation. This was in consonance with the report of Oei (2003) that materials with high quality lignin and cellulose will have longer number of days for primordia initiation. Substrate with higher amount of waste paper had longer time. This could be attributed to the lignin and cellulose content of waste paper.

***Number of fruits*:** The highest number of fruits (13.00) was recorded in paper and sawdust combination of ratio 1:3. This was followed by ratio combination of 1:1 (8.00) which however, was not significantly different from what was harvested on the sawdust substrate alone. The least (5.67) was observed on paper substrate alone (Table 1).

***Fruitbody weight*:** The heaviest fruit weight of 70.67 g was recorded on paper/ sawdust combination of ratio 1:3. This was followed by 60.00 g fruit weght harvested on paper substrate alone. The least (51.67 g) was observed on paper/ sawdust combination of ratio 1:1 which however, was not significantly different from what were recorded on substrate combination of ratio 3:1 and sawdust substrate alone (Figure 1). The growing season, environmental condition and variation in the nutrient composition are attributable to the variation in the fruit weights. There was availability of carbon from the sawdust while the paper provided cellulose, hemicellulose and lignin and also created crevices within the substrate combination for effective and efficient mycelia remification.

***Width of pileus*:** The widest width of pileus (9.90 cm) was observed in substrate ratio combination of 3:1 followed by ratio combination of 1:3 but this was not significantly different from what was recorded on paper substrate alone and other substrate ratio combinations (8.33 cm, 8.33 cm and 7.23 cm respectively) and sawdust alone (7.53 cm). This was longer than what was reported (3.8-5.2 cm) by Gume *et al*. (2013) but similar to an earlier report by Idowu and Otunla (2021). The size is a function of the amount of light and the aeration of the inoculated substrate bags in the cropping room (Kivaisi *et al*., 2003).

***Length of stipe*:** The longest length of stipe (6.77 cm) was recorded on substrate ratio combination of 1:1 which was comparable to that of paper substrate alone and sawdust substrate alone (6.33 cm and 6.07 cm respectively). This was significantly different from what was observed on substrate ratio of 3:1 which was also comparable to what was observed in ratio 1:3 (Table 1). Width of pileus and length of stipe vary on different substrates due to the structure, compactness and the physical properties of the substrate (Tesfay *et al*., 2020).

***Biological and Production Efficiencies*:** Both followed the same trend; substrate combination of ratio 1:3> paper alone> sawdust alone> 3:1> 1:1 respectively (Figure 2). One part of paper to three parts of sawdust gave the highest biological and production efficiencies, I opined that the sawdust served as a better source of carbon as earlier reported by Shah *et al*. (2004).

CONCLUSION AND RECOMMENDATION

Days to full mycelia colonization on paper substrate was shortest and with the greatest mycelia density. However, the harvested fruit weight was less than that of substrate ratio combination of 1:3 due to low nutrients in the paper. Therefore, paper could be employed to create crevices within the sawdust substrate to enhance mycelia ramification and be optimized for its cellulose, hemicellulose and lignin contents for maximum mushroom fruit bodies yield.

ACKNOWLEDGEMENT

Our appreciation goes to NIHORT management team for releasing the shredded waste paper used in this research studies. Furthermore, kudos to the following mushroom unit staff members Mrs F.O. Akinrinsola, Mr J.A. Abass, Mrs G.A. Majekadegbe, Mr M.O. Daropale and Mr Solomon M.K. for their immense support.

ABSTRACT
An experiment was carried out in the screen house of the National Horticultural Research Institute, Ibadan Nigeria. The study was carried out to determine the effect of different growth media on the seed germination and seedling growth of tomato (Lycopersicum lycopersicum L.). Viable seed of tomato were planted in different growth media: T1: coco peat, T2: coco peat and topsoil (1:1), T3: spent mushroom compost, T4: spent mushroom compost and topsoil (1:1), T5: sawdust, T6: sawdust and topsoil (1:1), T7: rice husk, T8: rice husk and topsoil (1:1) and T9: sole topsoil (control). Data were obtained on the number of leaves, plant height, stem girth and at the termination of the experiment, data on root length, fresh and dry weight were observed. It was observed that the growth media with sole cocopeat has the highest plant height (7.01 cm) and was significantly different from other treatments while the least plant height of 3.20 cm was observed in rice husk treatment.
Keywords*: Growing media, Lycopersicum lycopersicum L., seed germination, seedling growth*

INTRODUCTION

Tomato *Lycopersicum lycopersicum* L., holds a preeminent position as the most widely consumed vegetable worldwide. Its popularity stems from its ubiquitous presence as a fundamental ingredient in an extensive array of dishes, whether consumed raw, cooked, or processed. Belonging to the Solanaceae family, which encompasses various commercially significant species, the tomato is a staple crop cultivated globally for both local consumption and export purposes. In 2014, the global cultivation of tomatoes encompassed an expansive 5 million hectares of land, yielding a bountiful production of 171 million tonnes. Among the major tomato-producing nations, the People's Republic of China (hereafter referred to as "China") and India played pivotal roles in contributing to this substantial production (FAOSTAT, 2017). The versatility of tomato cultivation is evident in its ability to thrive in diverse geographical zones, whether in open fields or controlled environments such as greenhouses. Harvesting of tomatoes can be achieved through manual labor or mechanized means. While under specific conditions such as rejuvenation pruning, weeding, irrigation, and frost protection, the tomato plant can exhibit perennial or semi-perennial characteristics, it is predominantly regarded as an annual crop in commercial agriculture (Geisenberg and Stewart, 1986).

The concentration of tomatoes fluctuates as the fruit undergoes the maturation process, a feature that significantly contributes to the taxonomy of this species. This aspect proves invaluable in the domain of crop breeding for cultivated tomatoes, as recognized by esteemed bodies such as the Organisation for Economic Co-operation and Development (OECD, 2008), and researchers like Spooner, Anderson, and Jansen (1993). The nutritional profile of tomatoes is enriched with lycopene, a potent antioxidant and carotenoid, renowned for its ability to protect cells against oxidants associated with cancer development. Categorized as a climacteric fruit, the tomato exhibits a unique ripening process characterized by an escalation in both respiration and ethylene production as it matures. Understanding these physiological intricacies is critical for optimizing harvesting and storage practices.

In the context of plant cultivation, the term 'growth medium' pertains to the material employed in containers to nurture plants. It could be a solid, liquid, or semi-solid substrate specifically designed to sustain the growth of a population of microorganisms or cells, including small plants like moss (Physcomitrella patens). Different types of growth media are tailored to suit the needs of diverse plant species. Modern cultivation practices have also embraced "soilless culture," a system where plants are grown without traditional soil in situ (Gruda, 2009). In these systems, solid rooting media, often referred to as "growing media" or "substrates," play a pivotal role. These materials serve as a surrogate for soil, offering essential anchorage for the root system, supplying water and nutrients to the plant, and ensuring adequate aeration in the root zone (Gruda et al., 2006).
The choice of growth medium emerges as a critical factor influencing seedling quality in nursery settings (Baiyeri and Mbah, 2006). It acts as a reservoir for essential nutrients and moisture (Grower, 1987). Effective management of growth media is deemed vital in ensuring the production of high-quality seedlings capable of withstanding seasonal challenges encountered in the field (Khan et al., 2006). While numerous organic materials can be utilized as constituents of growth media, only a limited subset has been thoroughly investigated. This research seeks to evaluate sustainable practices for cultivating selected vegetable crops in nurseries through the utilization of different growth media.

MATERIALS AND METHODS

The experiment was set up during the rainy season between June and August 2023. The experiment was laid out in CRBD with seven (7) treatments replicated twice. The crops were tomato and pepper. The media were cocopeat (CB), cocopeat and topsoil (CBTS), spent mushroom (SM), spent mushroom and topsoil (SMTS), sawdust (SD), sawdust and topsoil (SDTS) and topsoil. The growth media were measured in 2kg for sole media (spent mushroom, cocopeat, and sawdust) properly mixed with water and evenly spread on a planting tray while other combined media were measured in a ratio 2:1 (2kg of the media mixed with 1kg of topsoil) evenly mixed. The seeds were evenly planted in the trays of media. 50 seeds of tomato and pepper were planted in the media. Emergence data were taken on all the crops with respect to the growth medium starting from 4 days after planting, and at 2 weeks after planting (2WAP), agronomy data were taken on all the crops for a period of 3weeks after which destructive samples were also taken for further analysis.

RESULTS AND DISCUSSION

Table 1 shows the vegetative growth parameters of the tomato seedlings with respect to the different sowing media. It is observed that the growth media with sole cocopeat has the highest plant height (7.01 cm) and was significantly different from the height in coco peat and topsoil; spent mushroom compost and topsoil (1:1). The least plant height of 3.20 cm was observed in rice husk treatment. The highest stem girth of 1.7 mm was observed in rice husk and topsoil treatment at ratio 1:1 and it was significantly higher than other treatments. The least stem girth was observed in sawdust treatment.

Table 1: Vegetative growth of *Lycopersicum lycopersicum* (Ibadan local) in response to different growth media at five weeks after sowing

	Tomato (Ibadan Local)	
	Plant Height (cm)	Stem Girth (mm)
Treatments	5 weeks after sowing	
T1	7.01	1.1
T2	6.17	1.2
T3	5.98	1.1
T4	6.05	1.2
T5	3.33	0.6
T6	5.00	0.9
T7	3.20	0.7
T8	5.23	1.7

T9	4.90	0.9
$LSD_{0.05}$	0.64	0.23

T1: coco peat, T2: coco peat and topsoil (1:1), T3: spent mushroom compost, T4: spent mushroom compost and topsoil (1:1), T5: sawdust, T6: sawdust and topsoil (1:1), T7: rice husk, T8: rice husk and topsoil (1:1) and T9: sole topsoil (control)

CONCLUSION

From the results, it can be concluded that cocopeat is a good media for the growth of *Lycopersicum lycopersicum*: however, rice husk and topsoil treatment in 1;1 ratio support healthy stem girth in the seedling growth.

ABSTRACT
This study was conducted to determine the effect of different growth media and he germination and growth of queen palm (Syagrus romanzoffiana), the most popular ornamental palm in Nigeria. Different growth media and their combinations were used, which include: Topsoil + Manure (1:3), Topsoil + Manure (2:2), Topsoil + Manure (3:1), Topsoil + Sawdust (1:3), Topsoil + Manure (2:2), Topsoil + Manure (3:1), manure alone, sawdust alone, and topsoil alone as the control. Results obtained showed that Topsoil + sawdust (3:1) produced 100% of germinated seeds while Topsoil + manure (1:3) produced significantly higher palm heights (32.17cm), fresh shoot weight (5.43g), fresh root weight (2.53g) and dry shoot weight (3.11g). Palms grown with manure produced the highest dry root weight.
Keywords: *Queen palms, groth media, seed germination, manure, sawdust*

INTRODUCTION

Queen palm (*Syagrus romanzoffiana*) is a popular ornamental palm tree species popularly used in landscaping and garden designs in Nigeria. Queen palms are known for their graceful, feather-like fronds, which can reach lengths of up to 3 m. They have a slender trunk that can grow up to 12 m tall and is usually topped with a symmetrical crown of fronds. Queen Palms are native to South America but have become popular ornamental trees in various parts of the world, including Nigeria, where they are commonly used in landscaping. **They** are known for their tolerance of a wide range of soil types and their ability to withstand drought conditions once established. They thrive in tropical and subtropical climates. It also has ecological importance due to its sweet fruits and being consumed by parrots and other animals (Laindorf *et al*., 2018; Weirich Neto *et al*., 2020). It is easily adapted to different types of soils and climates.

Growth media play a crucial role in determining the germination and subsequent growth of queen's palm (Salamat *et al*., 2019; Junior *et al*., 2013). Several growth media including soil, peat moss, vermiculite, and their combinations has been reported to impact the germination and growth of queen palms (Al-Khayri and Naik, 2017). These authors reported that choice of growth media significantly influenced the germination rate and subsequent growth of queen palm. Different growth media have varying properties, including water-holding capacity, aeration, and nutrient content, which has some impact on germination rate and subsequent growth, vigour, and sustenance of plants (Nath & Singh, 2012; Mir *et al*., 2021). The objective of this study is to determine the effect of different growth media on the germination and growth of queen palms.

MATERIALS AND METHODS

Ripe, matured, sorted seeds of queen palms were collected from the Floriculture Garden, National Horticultural Research Institute, NIHORT, (7˚25″N and 3˚52″E) Ibadan, Nigeria. The seeds were pregerminated by soaking for two weeks in water. The water was drained every other until two weeks and then, the seeds were de-pulped, washed and soaked in 2% sodium hypochlorite for 1 hour, thereafter, rinsed in running water for 5 minutes. After pre germination treatment, the seeds were selected and used for germination and growth experiment. Growth media used in the study was Topsoil + Manure (1:3), Topsoil + Manure (2:2), Topsoil + Manure (3:1), Topsoil + Sawdust (1:3), Topsoil + Manure (2:2), Topsoil + Manure (3:1), manure alone, sawdust alone, and topsoil alone as the control. Growth media were measured into jute bags (20L each on volume basis) and arranged in a completely randomized design with five replicates.

Queen palm seeds were selected based on good appearance and colour. Twenty seeds were planted in each media and monitored for germination. Agronomic practices were maintained, and the pots watered at least three times every week to field capacity. Data taken include the number seeds, the heights of seedlings, the number of leaves, the shoot fresh shoot and root weights and the dry shoot and root weights. Data were collected from 3 weeks after planting with the emergence of the plumule. Data collection was done every two weeks after emergence. Data collected were analyzed using SAS 2000 software, mean separation was by the least significant difference.

RESULTS AND DISCUSSION

Highest germination percentage (100%) was produced with the use of Topsoil + sawdust (3:1) after 7 weeks (Table 1), which was significantly from the germination percentage obtained with the use of manure (61.25%). Apart from Topsoil alone, Topsoil + sawdust (3:1) had significantly higher germination percentage than the other growth media. Use of this growth media could be explored in palm seedlings nursery. Other authors reported a 1:1 mixture by volume of peat moss and perlite for palm seeds germination (Meerow and Broschat, 2017). Furthermore, Topsoil + manure (1:3) produced the highest heights of palms. This could be adduced to the presence of manure in the media. Shokalu *et al* (2021) also reported that growth attributes of pines were improved with organic soil amendments. The fresh shoot weight (5.43g), fresh root weight (2.53g) and dry shoot weight (3.11g) was also obtained with the use of Topsoil + manure (1:3) while manure grown seeds had the highest dry root weight (1.64g). This could be attributed to the environment being favourable to root initiation of the queen palms.

CONCLUSIONS

The germination and growth queen palms were enhanced with the use of different growth media. Results obtained showed that Topsoil + sawdust (3:1) has great potentials in its use for germination of ornamental palms seedlings, while Topsoil + manure (1:3) and manure has great potentials in the provision of proper growth and establishment of the palms seedlings. It is recommended that further studies be carried out to verify and validate the value results obtained in this study.

Table 1: Effect of different growth media on number of germinated seeds and height of queen palms

	Number of Seeds germinated			Height of Germinated Plants (cm)

ABSTRACT

Eggplant is a fruit or leafy vegetable crop cultivated for food and medicinal purpose. Viral Diseases impose significant constraints on both yield and quality of eggplant production. A field trial conducted at the research farm of the National Horticultural Research Institute, Ibadan, Nigeria in 2021 cropping season to evaluate the virus disease response, growth and yield of 10 eggplant accessions. The experiment was laid out in a randomized complete block design and replicated three times. Data on virus disease incidence and severity, plant height (cm), were collected bi-weekly, after transplanting (WAT), Data on fruit yield were collected. The data was analyzed using analysis of variance (ANOVA) and means were separated using the Duncan Multiple Range Test (DMRT). The disease incidence at 8 WAT for accession V9 (10.0%) and V1 (23.3%) were significantly lower (p<0.05) than the other varieties, disease severity in accession V1 (2.00), V8 (2.00) and V9 (1.33) at 8 WAT were also significantly lower (p<0.05) than the other varieties. Accession V1, V8 and V9 significantly (p>0.05) had the taller plants (47.10cm, 45.30cm and 44.74cm) while V2 had the least plant height (28.3cm). The highest fruit yield was obtained from accession V1 (55.33 t/ha) followed by V9 (36.900 t/ha) and V8 (32.83 t/ha) respectively which were significantly (p>0.05) higher than accession V2 (13.23 t/ha) that produced the least fruits. The study concluded that since accession V1, V8 and V9 had reduce virus incidence, severity and gave better fruit yield of eggplant, this has given more insight which will be helpful for national breeding for virus resistance in eggplant.

INTRODUCTION

Eggplant (*Solanum gilo*) is a very important vegetable crop in Nigeria especially in the eastern part of Nigeria which has developed a high popularity and has become one of the most consumed vegetables. Eggplant is of significant importance to the culture and tradition of the locals in the Eastern part of Nigerian (Onuoha, 2005). The crop is mainly cultivated for food, medicine and represents the main source of income for many rural household in Nigeria. Eggplant are perennial crop but are grown commercially as an annual crop and thrive well in rich, deep, well drained, sandy loamy soils. It is well adapted to the tropical climate (Rao and Subramanian 1994.). Eggplant is a very good source of dietary fibre, potassium, copper, small amounts of protein, vitamins (vitamin B and C), minerals, starch and other nutrients. The leaves are excellent sources of vitamins A and B (particularly riboflavin), calcium, phosphorous, and iron (USDA, 2009). Most small scale farmers are dependent on the production of the fruits and leafy vegetable as means of livelihood and income generation. Eggplant is exposed to many pathogens, including threatening fungi, bacteria and viruses (Beemster and Rozendaal, 1972; Hanˇcinský *et al*., 2020).

Plant viruses are among the principal disease-inducing agents affecting crop as they are transmitted through vegetative propagation, by contact between infected and healthy plants and by different vectors, including insects and nematodes (Banttari *et al*., 1993). Some of these viruses, such as the *Cucumber mosaic virus* CMV, (Bagewadi *et al*., 2015), *Tomato spotted wilt virus* TSWV, (Kamberoglu and

Caliskan, 2009) and *Eggplant mottled dwarf virus* EMDV, (Martelli 1969). Despite its importance, eggplant farmers face several adverse conditions in growing the crop throughout the tropics on a large scale due to its susceptibility to a large number of pathogens. Among the factors responsible for low yield of eggplant, viral diseases are considered to be the most serious, preventing the crop from achieving it genetic potentials (Fajinmi *et al.*, 2012). Studying the impact of *these* viruses on the growth and yield of eggplants will help to determine to what extent the damage done by this virus and also to justify the need to invest on the control measures. Hence the objective of this study was to determine the growth and yield response of 10 accessions of eggplant to viruses.

MATERIALS AND METHODS

The trial was conducted at the experimental field of National Horticultural Research Institute, Ibadan, Nigeria during the planting seasons (June to September) of 2021. The genetic materials comprised of 10 eggplant variety was obtained from the seed unit of National Horticultural Research Institute. These varieties are new purified lines developed from two cycles of selfing and selection from eggplant germplasm collected from farmers` field in South Western Nigeria. Seeds used in this study were derived from seeds harvested from selected individual segregants from earlier generations having farmers preferred traits such as high number of fruits per plant, intermediate plant height with appropriate fruit size and shape.

The experimental design was randomized complete block design and replicated three times. The eggplant seeds were sown in bowls filled with sterilized top soil, kept in an insect-free and insect screened cages in the nursery for 6 weeks. The seedlings were transplanted to the field.

Data Collected

Disease evaluation

The disease incidence (DI) was calculated as the number of plants showing virus symptoms expressed as a percentage of the total number of plants in the plot using the formula below,

Where;

$$\text{Disease incidence (\%)} = \frac{\text{Number of infected plants}}{\text{Total no of plant sampled}} \times 100$$

Virus Severity

This was determined from the 2nd to 8th week after transplanting. The disease severity of the virus was determined using a disease severity scale based developed by Arogundade *et al.*, (2012) and Ayo-John *et al.*, (2012): where; 1= no visible symptoms, 2= mild symptoms (less than 10% of total leaves) such as mosaic, mottling, yellowing, vein banding or necrosis, 3= moderate symptoms greater than 10% but less than 50%, 4= severe symptoms greater than 50% but less than 75% accompanied with reduced leaf lamina or distortion, 5= severe symptoms greater than 75% plus leaf distortion and general stunting of the plant.

Growth parameters measured

Data on growth parameters was taken bi-weekly from 2 to 8 weeks. The collected data were on (i) Plant height, by measure plant height from soil level to the apex (ii) the yield data.

Statistical analysis

All data collected were subjected to analysis of variance (ANOVA) and means were separated using the Duncan Multiple Range Test (DMRT).

RESULTS AND DISCUSSION

Virus disease incidence of 10 eggplant accessions

The performances of ten accessions of the eggplant to viruses on the disease incidence showed that, at 2 WAT there was no significant difference ($P \geq 0.05$) among the accessions (Table 1). At 4 WAT V1, V8 and V9 had significantly ($P \leq 0.05$) lower virus incidence ratings of 4.2%, 8.4% and 4.2% respectively than other accessions. The same trend was observed at 6 WAT and 8 WAT where V1, V8 and V9 disease incidence ratings were 12.5%, 10.5%, 8.4% and 23.3%, 25.5%, 10.0% respectively compared to other accessions (Table 1).

Virus disease severity of 10 eggplant accessions

At 2 and 4 WAT there were no significant difference (P≥0.05) among the all the accessions (Table 1). Disease severity significantly varied at 6 WAT where the highest disease severity was recorded in V5, V6, V7 and V10 with a score of 3, 3, 3 and 3 respectively. Disease severity at 8 WAT in V5 and V7 was 4 and 5 respectively having the highest disease severity, while V1, V8 and V9 were all significantly (p≤0.05) lower in disease severity with 2, 2 and 1. (Table 1).

Plant height of 10 eggplant accessions response to virus

The performance of ten accessions of eggplant on plant height showed that, there were no significant difference (P≥ 0.05) among the accessions at 2 WAT. At 4 WAT the trend was the same but at 6 WAT the V2 recorded the lowest plant height 13.4 cm. At 8 WAT there was significant difference among the accessions where V1, V8 and V9 had the highest plant height of 48.8 cm, 47.1 cm and 45.3 cm respectively (Table 2).

Effect of virus on the yield/ha parameters on eggplant

The number of fruits produced showed that there was significant difference (p≥0.05) among the accessions in eggplant fruits. The V2, V5 and V7 produced the lowest number of fruits with (13.2 kg), (14.3 kg) and (17.9 kg) respectively (Table 2). However, V1, V8 and V9 gave the highest fruit yield (55.3 kg, 32.8 kg and 36.9 kg respectively). (Table 2).

Table 1: Virus disease incidence and Virus disease severity of 10 eggplant accession

Accessions	Virus disease incidence %				Virus disease severity			
	2WAT	4WAT	6WAT	8WAT	2WAT	4WAT	6WAT	8WAT

Means within each column followed by the same letter(s) are not significantly different at P≤0.05 using the Duncan Multiple Range Test (DMRT). WAT=Weeks after transplanting

DISCUSSION

The eggplant varieties exhibited virus symptoms such as mosaic, mottling, vein clearing, stunted plants, fruit deformation and leave curl. Similar observations of these were made by Achiangia *et al*. (2013) on pepper varieties sampled in the Western highlands of Cameroon. Viral symptoms are thought to be spread by aphids as a result of their feeding activities. The result showed that lower disease incidence have significant relationship with yield of crop in any environment and this correspond positively with the findings of Kumar *et al*. (2014), Awasthi *et al*. (2014) and Sharma *et al*. (2017). The virus severity has been found to have a variable effect on crop yield potential, because of the damage caused on the plant and probably the loss of the crop. Disease severity enhance fruit yield, because the higher the proportion of plants with greater disease severity, the greater the expected yield loss. This showed that crop loss was a function of severity of diseased plants and this correspond with the findings of Assabgui and Hall (2016).

ABSTRACT
Bambara groundnut (Vigna subterranea [L.] Verdc.) is a valuable but underutilised legume crop grown in sub-Saharan Africa. The objective of this study was to evaluate the yield and yield components of eight Bambara groundnut accessions obtained from the National Root Crops Research Institute in Umudike, Nigeria. The experiment was conducted at the Teaching and Research farm of the University of Uyo, Uyo Southern Nigeria during the 2021cropping seasons, using a randomised complete block design with three replications. Growth, yield and nutritional parameters were collected and subjected to analysis of variance, correlation and principal component analysis. Plant height, number of leaves, and leaf area were all significantly different (P<0.05) among the accessions three months after planting. Number of pods per plant, seed weight, and 100-seed weight differed significantly (P<0.05). Caly PSC (2853 kg/ha), Caly SK 46 (2803 kg/ha), Zeina (2538 kg/ha), and BNT (2488 kg/ha) were the top yielders among the accessions. Yields of Bambara groundnut differ significantly (P<0.05) between accessions studied, ranging from 1624.67 kg/ha to 2853.33 kg/ha. Principal component (PC) analysis identified eight influential components, two of which, PC1 and PC3, contributed 27% and 17% of the total variation, respectively. In this study, the correlation analysis revealed that plant height and petiole length, plant height and number of seeds per plot were all negatively correlated. The leaf area and the number of pods per plot, the number of seeds per pod and the fibre content, the leaf area and seed weight, and the plant height and seed weight were all positively correlated. The nutritive value of the eight Bambara groundnut accessions varied significantly (P<0.05). The mean protein levels of eight Bambara nut accessions studied ranged from 18.82 to 20.39%. Findings from this study clearly indicate that Bambara groundnut is suitable for production in Uyo, Akwa Ibom State. High yielding accessions identified in this study are recommended for increased production in Akwa Ibom State
***Keywords**: Accessions, Bambara groundnut, Proximate, Yield, Uyo*

INTRODUCTION

The Bambara groundnut (*Vigna subterranea* (L. Verdc) belongs to the *leguminosae* family and has been believed to have originated in the Sahel region, which is now West Africa. Bambara groundnut is a staple food in some semi-arid regions of Africa (Gonné *et al.,* 2013). It is an underutilised food legume (Azam-Ali *et al.,* 2001) that plays an important role in initiatives to maintain food security in Sub-Saharan Africa (Koné *et al.,* 2015). Bambara groundnut is an herbaceous, short-leaved annual crop plant that grows to a height of about 15 cm and has numerous nitrogen-fixing nodules on the roots that help to improve the soil (Yakubu *et al.,* 2010). Its edible seeds are high in calories, vitamins, and vegetable proteins (Minka and Bruneteau, 2000). In addition to nutritional benefits, the roots, leaves, and seeds are used in traditional medicine (Maphosa and Jideani, 2016). This leguminous crop is well adapted to the tropics and can thrive in a variety of environmental conditions, including marginal soils where other leguminous crops cannot be grown (Abejide *et al.,* 2017). Bambara groundnut cultivation has declined in Nigeria's Sahel and Sudan Savannah zones over the last 20 years. Bambara groundnut contains a substantial supply of minerals such as phosphorous, calcium, zinc, and iron, enabling it to be a complete diet and people can easily survive by feeding specifically on Bambara groundnut diet or providing all of their nutritional requirements. Bambara is used to make a variety of dishes, including a local dish known as 'okpa' in Nigeria (Oluwole and Oluremi, 2012). The seed contains approximately 24% protein, 64% carbohydrates (53% starch, 10% dietary fibre), and 6% total fat, providing nutrition and a balanced diet for humans (Azman *et al*., 2019). However, one of the drawbacks of most underutilized and neglected crop species, including Bambara groundnut, is a lack of established breeding programmes; as a result, landraces of Bambara groundnut have remained the primary source of planting materials used by farmers (Mayes *et al.,* 2015). Despite the vast genetic diversity of Bambara groundnuts, Akwa Ibom State has not fully utilized this unique resource in terms of variety selection and development. It is necessary to assess its yield potential in Akwa Ibom State and determine the nutrient quantities of the selected accessions. This study will make a significant contribution by identifying high yielding Bambara groundnut accessions that are adaptable to Akwa Ibom State for increased production in Akwa Ibom State.

MATERIALS AND METHODS

Experimental site

The experiment was conducted at the Teaching and Research farm of the University of Uyo, Uyo Southern Nigeria during the 2021cropping seasons. Uyo lies between latitude 15^o 02′ North and longitude 07^{o}56′ East of the Greenwich meridian and altitude 38m above sea level. It is located in the humid high rainfall area of Southern Nigeria, with an annual rainfall of over 2500mm and an average daily sunshine of 3 hours 31 minutes. Throughout the year, the temperature ranges from 23^{o}C to 34^{o}C. (Ndaeyo, 2003).

Plant materials, field layout and data analysis

Three replications of each treatment were used in the randomised complete block design (RCBD) of the field experiment. Eight accessions of Bambara nuts were obtained from the National Root Crops Research Institute in Umudike: Zeina 22, Regal green 27, Caly SK 144, BNT 89, Caly PSC 6, Caly SK 46, SDR 21 and Caly 4. Each replication was divided into 9m^2 plots (3m x 3m). Each block had 8 plots, and twenty-four seeds were sowed in each plot to a depth of 5 cm. There were 30 cm between seeding locations. Data were collected on various agro-morphological parameters from the five (5) plants in the middle of each plot and the growth and harvest stages served as the basis for the evaluation and. Data collected were subjected to Analysis of Variance (ANOVA) and the means were separated using the Least Significant Difference (LSD) test at a 5% level of significance.

Sample collection

Mature and dried *Vigna subterranean* (L.) Verdc seeds used for this study were harvested from the experimental site, dried in the sun, carefully removed from their hulls, ground into powder using a mortar and pestle, and stored in a plastic bag ready for analysis.

Proximate composition

The moisture content was determined by drying 5 g of powdered sample to constant weight in a 105 ^{o}C oven. The moisture content of the seed was calculated as the difference in weight between before and after drying (AOAC, 2006). Ceirwyn (1998) described a method for determining ash content that involved dry ashing in a muffle furnace at 600 ^{o}C until greyish white ash was obtained. According to the AOAC (2006) method, crude lipid content was determined using a soxhlet apparatus and n-hexane as the solvent. The crude protein of the sample was calculated by multiplying the value obtained from Kjeldahl's nitrogen analysis by a protein factor of 6.25 (AOAC, 2006). Available carbohydrate was calculated by subtracting the sum of the percentages of ash, crude lipid, crude protein, and crude fibre from 100%. The calorific value was calculated using the equation described by Asibey-Berko and Taye (1999).

$$Available\ Carbohydrate\ (\%) = 100 - (\%\ ash + \%\ protein + \%\ lipid\ \%\ fibre)$$

$$Energy\ (kcal/100g) = (crude\ protein\ x\ 2.44) + (crude\ lipid\ x\ 8.37) + (available\ carbohydrate\ x\ 3.57)$$

RESULTS AND DISCUSSION

Variation among growth characters of eight Bambara groundnut accessions

Table 1 shows the mean values of various growth parameters for the eight Bambara groundnut accessions three (3) months after planting. The results in Table 1 indicate that plant height, number of leaves, and leaf area differed significantly (P≤ 0.05) among the eight accessions, but petiole length did not. The tallest plant was Caly SK 144 (56.50 cm), followed by BNT 89 (39.00 cm) and SDR 21 (37.80 cm). These three accessions had plant heights greater than the grand mean (37.52 cm), while Caly PSC had the shortest plant height (29.78 cm) at 3 MAP (Table 1). At 3 MAP, the number of leaves of the various accessions studied differed significantly. BNT 89 had the most leaves (533.40), followed by SDR 21 (37.80) and Caly PSC (449.80), while Caly SK 144 had the fewest leaves (171.00). The petiole length of the Bambara groundnut studied did not differ significantly at 3 MAP, as shown in Table 1. Caly 4 had the longest petiole length (2.90 cm), followed by Caly PSC (2.50 cm), and Regal green 27 had the shortest (2.04 cm). Table 1 also showed that the leaf area of the accessions studied varied significantly (P0.05) at 3 MAP. The leaf area's grand mean was 25.03 cm^2. SDR 22 had the largest leaf area (33.20 cm^2), followed by Caly 4 (27.40 cm^2), and Zeina 22 had the smallest leaf area (19.75 cm^2).

Table 1: Mean values of growth parameters of eight Bambara groundnut accessions at 3 MAP

Accessions	Plant Height	Number of leaves	Petiole Length	Leaf Area
SDR 21	37.80	498.80	2.30	33.20
Caly 4	36.20	432.25	2.90	27.40
Caly PSC	29.78	449.80	2.50	25.55
Caly SK 144	56.50	171.00	2.10	25.12
Grand mean	33.76	423.57	2.26	25.03
Regal green 27	32.50	410.60	2.04	24.30
Caly SK 46	34.38	432.00	2.10	24.20
BNT 89	39.00	533.40	2.20	20.68
Zeina 22	34.02	413.60	2.30	19.75
Grand mean	37.52	423.57	2.30	25.03
LSD (P≤ 0.05)	4.43	188.76	NS	7.42

Yield and yield related traits variation in eight Bambara groundnut accessions

The mean values of different yield parameters of eight Bambara groundnut accessions at harvest are shown in Table 2. The number of pods, weight of dried pods, seed weight, weight of 100 seeds, and dry matter of Bambara groundnut accessions differ significantly (P<0.05). There was a significant difference (P<0.05) in the number of pods per plant among the Bambara groundnut accessions. Caly SK 144 had the most pods per plant at harvest (110.00), followed by Zeina 22 (83.33) and SDR (77.33). Caly SK 46 produced the fewest pods per plant (66.33). At harvest, the weight of dried pods varies significantly among Bambara groundnut accessions. Caly 4 had the highest dried pod weight (115.33 g), followed by Caly SK 114 (111.00 g) and Caly SK 46 (103.00 g). Regal green had the smallest weight of dried pods (56.00 g). The yield (seed weight) of the Bambara groundnut accessions differed significantly (P<0.05). Caly PSC had the highest yield (2853.33 kg/ha), followed by Caly SK 46 (2803), Zeina 22 (2538.67 kg/ha), BNT 89 (2488.67 kg/ha), and SDR 21 (2357.33 kg/ha). The seed weights of these five accessions were greater than the grand mean (2331.00 kg/ha). Regal green had the lowest yield (1624.67 kg/ha). The weight of 100 seeds of the Bambara groundnut accessions differed significantly (P<0.05). Zeina 22 had the highest 100 seed weight (86.00 g), followed by Caly SK 46 (83.00 g) and Caly 4 (82.00g). Caly PSC had the lightest weight of 100 seeds (66.67 g). Table 2 also showed that there was a significant difference (P<0.05) in dry matter between Bambara groundnut accessions. Regal green had the highest dry matter

(128.00%), followed by Caly 4 (85.33%) and Caly PSC (84.00%). Caly SK 46 had the least dry matter (43.00%).

The objective of this study was to identify high yielding and stable Bambara groundnut accessions that are adaptable to Uyo production environments, as well as to determine the relationships between the traits (plant height, grain yield, hundred grain weight, leaf area, and petiole length). Plant growth traits (plant height, number of leaves, and leaf area) showed highly significant ($P< 0.05$) differences three months after planting. This demonstrates that the climatic conditions in the Uyo production environment were variable. Bambara groundnut grows best in climates with abundance of sunlight, high temperatures, and rain (Mabhaudhi and Modi, 2013). The yield in this study ranged from 1624.67 kg/ha to 2853.33 kg/ha, which was considerably higher than the yields reported by Unigwe *et al.* (2016) and Shegro *et al.* (2013). Their yields ranged from 9.90 to 126.03 kg/ha and from 13.33 to 191.73 kg/ha. This suggests that the Bambara groundnut genotypes used in this study were capable of adapting to the production environments in Uyo, Akwa Ibom State. Temperature, altitude, rainfall, soil type, and genetic constitution are all factors that influence Bambara groundnut growth (Shegro *et al*., 2013). According to Sagoe *et al.,* (2021), environmental conditions and genetic constitution are the two most important factors influencing crop yield performance. Among the accessions evaluated, four accessions; Caly PSC (2853 kg/ha), Caly SK 46 (2803 kg/ha), Zeina (2538 kg/ha) and BNT (2488 kg/ha) were top yielders. According to Ellah and Singh (2008), Nigeria has the highest Bambara groundnut yield potential of any African country, ranging between 500 and 2600 kg/ha. According to Unigwe *et al.* (2016), Bambara groundnut is very adaptable compared to other crops and grows well under harsh environmental conditions (high wind, heavy rain, and cold temperature), despite the fact that Uyo, Akwa Ibom State, is located in Nigeria's humid rainforest zone, which experiences seasonal heavy rain. In most crops, yield and other yield traits are reported to be highly influential parameters for crop improvement (Khan *et al*., 2020). Grain yields per hectare ranged from 115.34 kg/ha to 1446.67 kg/ha. Light, temperature, water, moisture, rainfall, soil texture, and nutrition are all environmental factors that affect plant growth (Mabhaudhi and Modi, 2013). Berchie *et al.* (2010) reported pod and seed yields of 4173.05 and 3084.43 kg/ha, respectively, in Ghana. Researchers have found significant variation in grain yield and other traits among landraces (Alake *et al.,* 2015). This suggests that Bambara groundnut grown in Uyo, Akwa Ibom State, can produce high yields. There was a significant difference in hundred seed weight among the accessions in this study. In this study, the 100-seed weight ranged from 66.67 to 86.00 g. According to Akpalu *et al.* (2012), these findings demonstrate the significance of seed quality in determining seed yield. Seed size can be used to predict seed vigour, which is a component of seed quality (Mandizvo and Odindo, 2019). In the evaluation of morphological traits, hundred seed weight has been cited as an important yield enhancing trait (Unigwe *et al.* 2016). It is an important yield measure and an appropriate indicator for observing the tradition of quantitative traits influenced by genotype and environment (Rogé *et al.,* 2016). Interestingly, phenotypic variation among genotypes was significant in the study, indicating that accessions had high genetic diversity for the traits of interest.

Table 2: Mean values for yield characters of the eight accessions of Bambara groundnut

Parameters	Number of pods per plant	Weight of dried pods	Seed weight (kg/ha)	100 seeds weight	Dry matter

Nutritional qualities of Bambara groundnut accessions

The results presented in Table 3 show the proximate analysis of Bambara groundnut accessions. Table 3 shows that the proximate composition of the eight Bambara groundnut accessions tested differed significantly (P<0.05). Table 3 shows that there was a significant difference (P<0.05) in the moisture content of the Bambara groundnut accessions. Regal green 27 had the highest moisture content (7.91%), closely followed by Caly SK 46 (7.80%) and Caly SK 144 (7.58%). BNT recorded the lowest moisture content (6.39%). Furthermore, there was a significant difference (P<0.05) in the crude fat content of the Bambara groundnut accessions. SDR 21 had the highest crude fat content (6.60%), followed by Caly SK 144 (6.48%), and Regal green (6.38%). Caly SK 46 had the lowest crude fat content (5.80%). The crude fibre of the Bambara groundnut accessions differed significantly (P<0.05). SDR 21 had the highest crude fibre content (5.59%), followed by BNT 89 (5.48%) and Caly PSC (5.42%). Caly SK 46 had the lowest crude fibre content (4.60%). The total ash of the Bambara groundnut accessions differed significantly (P<0.05). BNT 89 had the highest ash content (3.92%), followed by Caly 4 (3.88%) and Caly PSC (3.82%). SDR 21 had the lowest total ash content (3.51%). The protein content of the Bambara groundnut accessions differed significantly (P<0.05). Caly PSC had the highest protein content (20.39%), followed by SDR 21 (20.21%) and BNT 29 (19.87%). Caly SK 46 had the lowest protein content (18.29%). The available carbohydrate of the Bambara groundnut accessions differed significantly (P0.05). Caly SK 46 had the highest available carbohydrate content (60.24%), followed by Zeina 22 (59.62%) and Caly 4 (59.49%). Caly PSC 6 had the least available carbohydrate (56.81%). The current study examined into the variations in the proximate analysis of Bambara groundnut seed during the rainy season. The nutritive value of the eight Bambara groundnut accessions differed significantly. These findings were similar to those reported by Abdalla Saleem *et al*. (2012) when investigating the nutritive value of three Grewia species' leaves and fruits. The proximate and mineral results clearly show the potential of Bambara groundnut as a source of scarce nutrients such as protein. Under proper management, location, and planting season, Bambara groundnut protein content can reach 24. 02%, which compares favourably with that reported for more conventional legumes such as faba beans (Musalam *et al.,* 2004), but is higher than the records of Nworgu (2004) which was 18.3%, Aletor and Omodara (1994) which was 10.4%. The protein content of the Bambara groundnut seed investigated in this study ranged from 18% to 20%, which was higher than the 7% minimum crude protein level required for optimum rumen function (van Soest, 1994; Fasakin, 2004). The current study's high ash content could be attributed to high concentrations of minerals that are precursors to proximate formation. The ash content in this study was less than 8%, as reported by Gohl (1981), who concluded that ash content greater than 8% indicates fat contamination. Abdalla Saleem (2012) added that high ash contents are also indicative of low organic matter. The moisture content of the eight Bambara groundnut accessions studied in this study was less than 8%, which is considered low. Bambara nut seeds are known for their low moisture content, which indicates that they have good storage qualities. The storage value is reduced when there is a high moisture content. Okonkwo and Opara (2010) obtained a similar result for the same plant.

Table 3: Proximate analysis of Bambara groundnut accessions

Accessions	Moisture (%)	Crude Fat (%)	Crude Fibre (%)	Ash (%)	Protein (%)	Carbohydrate (%)
Caly SK 46	7.80	5.80	4.60	3.55	18.29	60.24
Zeina 22	6.80	5.96	4.71	3.58	19.35	59.62
Caly 4	6.74	5.91	4.65	3.88	19.34	59.49

Pearson correlation coefficients (r) between the growth and yield traits of twelve accessions of Bambara groundnut

Table 4 displays the Pearson correlation coefficients (r) between the evaluated agronomic traits and nutritional qualities of the Bambara groundnut accessions. The correlation coefficient of the Bambara groundnuts accessions studied showed both positive and negative associations with yield and yield-related traits (Table 4). Plant height had a positive but significant association (r = -0.421*) with leaf area. Plant height recorded a positive and highly significant correlation (r = 0.526**) with weight of hundred seeds. Number of pods per plant recorded a positive association (r = 0.178) with seed weight. Weight of dried pods recorded a negative and significant relationship (r = -0.426*) with protein content. Weight of hundred seeds had a positive correlation (r = -0.135) with seed weight. Fibre had a positive and highly significant association with fat content (r = 0.942**). Protein had a negative but highly significant relationship (r = -0.574**) with moisture. Also, protein recorded a positive and significant (r = 0.453*) relationship with fat as well as a positive and highly significant relationship (r = 0.575**) with fibre. Carbohydrate had a negative but highly significant correlation (r = -0.730**) with protein. The specific coefficient, according to Silva *et al.* (2016), is a correlation estimate for the purpose of selection for direct and indirect breeding because it indicates how closely two or more traits are genetically and non-genetically related. In this study, plant height and petiole length were negatively correlated, while leaf area and number of pods per plot, number of seeds per pod and fibre content, leaf area and seed weight, plant height and seed weight were positively correlated. The positive correlations among and between the various traits indicate that selecting for any of these traits in a Bambara groundnut improvement programme will have a positive influence on selecting for related traits (Unigwe *et al*., 2016). It is critical for breeding programmes to develop vegetative growth and yield collections (Gao *et al.,* 2020). Selecting for these traits may be useful in breeding Bambara groundnut for future production (Alake and Ayo-Vaughan, 2017).

Principal component analysis for agronomic traits and nutritional qualities of Bambara groundnut accessions.

Results presented in Table 5 shows the principal component analysis of agro-morphological traits and nutritional qualities of the Bambara groundnut in this study. The first five principal components (PCs) with Eigen values greater than 1.0 jointly accounted for 74.37% of the total variation in the accessions (Table 5). The traits of importance for the first component involved agronomic traits and nutritional qualities of agronomic interest. Principal component one (PC1), with eigen value of 4.17, contributed 27.81% of the total variability. PC2, with eigen value of 2.62, accounted for 17.52% of total variability. PC3, with eigen value of 2.00, accounted for 13.34%, PC4, with eigen value of 1.23, accounted for 8.20%, while PC5, with eigen value of 1.12, accounted for 7.47% of total variability observed among the eight Bambara groundnut accessions. In PC1, the traits that accounted for most of the 27.81% observed variability among the eight accessions of Bambara groundnut included fat (0.86), fibre (0.91) and protein (0.77). In PC2, the traits that accounted for most of the 17.52% observed variability among the eight accessions of Bambara groundnut included ash (0.73). In PC3, the traits that accounted for most of the 13.34% observed variability among the eight accessions of Bambara groundnut included plant height (0.71) and weight of dried pods (0.65). In PC5, the traits that accounted for most of the 7.47% observed variability among the eight accessions of Bambara groundnut included number of pods per plant (0.60). Shegro *et al.* (2013) demonstrated the merits of principal component analysis (PCA) in predicting trait relationships in Bambara groundnut accessions. Ntundu et al (2006) found a strong association between landraces as well. A plant with this strong relationship grows and produces a high yield (Chijioke *et al.,* 2010). In general, the PC analysis of the 15 traits revealed that PC1 was made up of a number of traits that contributed the most variation, followed by PC3. Ntundu *et al.* (2006) reported that leaf morphology, seed size, and colour were morphological criteria used by Tanzanian farmers during selection. PC1 and PC3 made significant contributions to trait association in this study and were responsible for high Eigen values.

CONCLUSION

Findings from this study indicate that Bambara groundnut is adaptable to the Uyo environment in Akwa Ibom State. The agronomic characteristics of the accessions in this study varied significantly. Caly PSC (2853 kg/ha), Caly SK 46 (2803 kg/ha), Zeina (2538 kg/ha), and BNT (2488 kg/ha) were the top yielders among the accessions evaluated. These accessions may be suitable for population development as well as for Bambara groundnut production in Uyo, Akwa Ibom State. The genetic potential of the accessions in this study can aid in the selection of desirable parental lines and increase the efficacy of Bambara groundnut breeding programmes. This study revealed that Bambara groundnut grown in Uyo, Akwa Ibom State, and a good source of nutrients. It is recommended that the experiments be repeated in more locations and seasons with more Bambara groundnut accessions of superior traits for high production.

ABSTRACT
Tomato which is a fruit vegetable and known to possess great nutritional and economic benefits among farm families was assessed for level of preference and production share, on-farm in Akure north LGA. One hundred and twenty-six tomato farmers were assessed for production and preference information in two communities (Oba-ile and Ogbese) within Akure north LGA Ondo state, Nigeria. These farmers were interviewed using a well-structured questionnaire which captured the socio-economic characteristics and preference indices for the selected tomato attributes. Data were analyzed using descriptive statistics, cross tabs and regression analysis. Results showed that eighty-three percent of the farmers were male with most been middle-aged (43%). Production activities were carried out by at least 6 members of each farming household and the average number of years for educational attainment was twelve (12) years. However, about 33 percent of the farmers had access to extension services while only 13% had access to credit facilities. Farmers in the study area mostly preferred the yield attribute of tomato while the price attribute was least preferred, as in economic terms, the higher the price of a good, the lesser the quantity demanded of the good. The regression analysis revealed age, primary occupation, total farm size and age squared as socio-economic factors influencing the share of tomato cultivated on-farm. However, for a farmer to fully maximise the available scarce resources at his disposal, measures should be put in place to address the low cultivation of tomato in south west Nigeria and greater measures put in place by crop experts to inculcate farmers preferences for tomato attributes that will endear them to cultivate the crop thereby boosting farm income and improving the livelihood of the farm family.
Keywords: *Tomato, Preference, Attributes, Regression, Akure North local government area*

INTRODUCTION
Fruit vegetables are vegetables with a pulpy, seed-rich body which grows on a vine. They are used as vegetables, are higher in calories than leafy vegetables and rich in vitamin C (Segen's Medical Dictionary, 2012). Examples of fruit vegetables include tomato, okra, bell pepper, red pepper, eggplant, water melon amongst others. Tomato (Lycopersicon esculetum) is one of the most widely consumed vegetables in the world today. Nigeria ranks highest in Africa in terms of tomato production, 879,000 t/annum (Ibeawuchi *et al.,* 2015). There are different varieties of tomatoes found in Nigeria today among which are; Roma, Betterboy, Grape, etc. just to mention a few, Oladitan and Oluwasemire (2018) revealed that Tomato production in Nigeria is mainly concentrated in the northern part of the country, however there is some production in the middle belt and south-western part of the country as well. Tomato production in Nigeria plays an important role in enhancing food and nutrition security (Schreinemachers *et al.,* 2018) as it provides food and raw material for industries, employment for smallholder farming households, and income from sales within the urban, peri-urban and rural areas of the country (Bello and Abdulai, 2016; Food and Agriculture Organization, 2017). The production preferences of farmers are initialized by the traits or attributes of crops they cultivate, which are described as the physiological and phenological characteristics of crops that their physical environment and management practices can influence (van Vliet and Giller, 2017). The preference for a variety of tomato is primarily based on the yield of the crop, socio-economic characteristics, attitude and behaviour of the farmers, risks perception, and climatic factors (Oye, 2014; Adegboye *et al.,* 2021). Hence, an increase in fruit vegetable productivity will enhance food nutrition security of both rural and urban households in Nigeria while also addressing the basic needs of the poor rural horticultural farmers.

Over the past ten years in Nigeria, tomato yields have remained very low at an average of 5.47 tonnes/ha relative to the world average yield of 38.1 tonnes/ha (Izuaka, 2020). This could be attributed to differences in climatic factors, lack of good high yielding varieties and inadequate good agricultural practices to the crop on the field. In the humid west to southern regions, production of the crop has been limited majorly by climatic factors, which include low temperature, high humidity and high rainfall (Oladitan and Akinseye, 2014; Oladitan and Oluwasemire 2018). Hence, the need to sensitize farmers in the south and equip them with the needed incentives towards improved tomato production to bridge the demand and supply gap, increase farmers' income, and enhance food nutrition security. It is against this backdrop that this research work was carried out to determine the factors influencing tomato production in Akure North LGA, Ondo state while assessing their preferences for selected tomato attributes.

METHODOLOGY

This study was carried out in Akure North Local Government Area of Ondo state. The Local Government Area (LGA) comprises of five (5) major communities, Iju , Ita-Ogbolu, Oba-ile, Igoba and Ogbese in Akure North LGA. These communities are located between latitudes 5°45' and 7°52' and longitudes 4°20'and 6°05' and the farmers within the communities cultivate a wide range of fruits and vegetable including tomatoes. Two (2) communities (Oba-ile and Ogbese) were randomly selected from the five (5) communities within the LGA based on the prominence of tomato production in the communities. Primary data for the study were obtained with the aid of a well-structured, pre-tested questionnaire distributed randomly to a selected number of farmers in the two communities via sampling proportionate to size thereby, giving a total sample size of 130 respondents, however only 126 were found useful for analysis which captured the socio-economic characteristics and preference of selected tomato attributes among farmers in the study area. Data generated was analyzed using descriptive statistics, cross tabs regression analysis to capture socio-economic characteristics, preference for tomato attributes and factors affecting Percentage of tomato cultivated on the farm.

Regression analysis was used to determine the level of relationship/significance between percentage of tomato cultivated on the farm (dependent variable) and demographic characteristics and production characteristics (independent variables). The regression model is specified in the general form:

$$Y = f(x_1, x_2 ---- x_{10}) \qquad 1$$

Where: $Y =$ Percentage of tomato cultivated on the farm %

x_1 = Age (years)

x_2 = Sex (Male = 1; 0 otherwise)

x_3 = Marital Status (Married = 1; 0 otherwise)

x_4 = Years of schooling (Years)

x_5 = Household size (actual number)

x_6 = Age squared (Actual years)

x_7 = Primary Occupation (Farming 1, 0 otherwise)

x_8 = Extension accessibility (Binary 1/0)

x_9 = Total farm size (actual figure)

x_{10} = Credit access (Binary 1/0)

The attributes of tomato selected for this study were culled from literature and from interaction with farmers. They include but were not limited to; fruit size, tolerance to pest and disease, yield, shelf-life and price of tomato seeds, respectively. The fruit size of tomato can be either medium sized or big for appreciable market value. The tolerance to pest and disease level must be mildly tolerant or tolerant for a farmer to have appreciable gains on his farm. The average yield of tomato in the south west is about 5tons/hectare, therefore to gain an appreciable yield double the volume of status quo, a farmer has to aim at 10/15tons per hectare. The shelf-life of tomato fruits is very paramount to the existence of the tomato enterprise as tomato fruits are highly perishable. The shelf-life can be categorized into fair and good shelf-life respectively. Finally, the price of tomato seeds to cultivate a hectare can range from N20, 000 to as high as N50, 000 depending on the variety and the accessibility of the seeds to the farmers.

RESULTS AND DISCUSSION

Socio-economic Characteristics of Farmers

The summary statistics showed in Table 1 revealed that about 83% of the farmers were male while the average age of farmers was approximately 43 years. The average years of formal education for the entire sample size was approximately 12 years while the tomato farming activities were supported by an average of six members of each farming household. On average, a farmer had an annual income of N241, 580 from previous harvest and 89 percent of the farmers were mainly involved in farming activities. A sizeable (33%) proportion of the farmers had access to extension services while minute (13%) proportion had access to credit facilities for their farming enterprise. Also, about 13% of the farmers on average were in good proximity to source of input (seed) supply and 59 percent had easy access to output market to sell their produce on time.

Farmers' preference for selected tomato attributes

The preference for tomato attributes such as Fruit size, tolerance to pest and disease, yield, shelf-life and price with respect to socio-economic characteristics of the farmers is as shown in Fig 1. 52.38% of the farmers in the LGA did not prefer the fruit size of tomato attribute possibly going by their status quo while 61.90% of farmers did not agree with the price of seed attribute. This may be due to the high cost of seed (inputs) which creates a set- back for farmers when trying to break even in their farming enterprise. About 64.28% of farmers had an interest in the attribute shelf-life of tomato. This depicts that tomato farmers in the study area are seeking for solution to fast deterioration of harvested tomato fruits and seeking for a way to reduce post-harvest loss by the breeding of tomatoes with good shelf-life properties. 57.14% of the farmers showed interest in the attribute tolerance to pest and disease of tomato depicting that after good shelf-life, tolerance to pest and disease is an attribute most farmers in the study area considered. However, yield (65.87%) was the highest sought attribute of tomato by the farmers and this is in line with the study by Kassie *et al.,* 2017 where yield was considered a priority attribute by maize farmers in rural Zimbabwe.

Factors influencing share of tomato planted on-farm

The regression results in Table 2; revealed age, age squared, primary occupation and total farm size as socio-economic variables influencing share of tomato production on-farm. The age of the farmers within the study area had a positive and significant influence on the share of tomato planted on-farm. This is expected as most of the farmers are middle aged and able-bodied men who are still in their active years and productive in farm engagement. The primary occupation of the respondents was also positive and significant at $p \leq 0.05$ signifying that most of the respondents were into full time farming activities and very few diversified their source of income. The variables total farm size and age squared were significant but negative depicting that as total farm size of the farmer increases, the percentage of tomato cultivated decreases. This can be attributed lack of information or awareness on the nutritional or economic benefits of cultivating tomatoes. Most of the farmers in the study area would rather cultivate staples and pulses to achieve food security whilst neglecting nutrition security. The significance of age squared variable explains the law of diminishing returns. The older the farmer gets the less productive they become. Hence, an increase in the age of the farmer, decreases the percentage of land allotted to tomato production due to exigencies of old age and the possibility of dearth in technological know-how.

CONCLUSION AND RECOMMENDATION

Most tomato farmers in the study area were middle aged men with secondary school level of education. The preference for selected tomato attributes by the farmers, showcased yield as the most preferred tomato attribute, followed closely by good shelf-life and then tolerance to pest and disease of tomato attributes, respectively. The factors influencing the percentage of tomato to cultivate positively or negatively on- farm were; age, total farm size, primary occupation of farmer and the age squared of farmers. Therefore, to promote tomato production in Akure north LGA,, there should be awareness on the nutritional and economic benefits inherent in tomato production and subsequent consumption in order to boost the demand and inadvertently the supply of this fruit vegetable in the study area.

ABSTRACT
To determine characteristics that contribute to the yield of carrots under the influence of irrigation interval, nitrogen levels, and intra-row spacing, field trials were conducted during the 2010/2011, 2011/2012, and 2012/2013 dry seasons at the Federal College of Horticulture Research Farm, Dadin-Kowa, Gombe State. The treatments consisted of three irrigation intervals (5, 7, and 9 days), four nitrogen rates (0, 50, 100, and 150kg N/ha), and three intra-rows spacing (5, 1,0, and 15 cm). The treatments were combined and laid in a split-split-plot design with irrigation interval in the main plot, and nitrogen levels in sub-plots while intra-row spacing was assigned to the sub-sub-plots. The treatments were replicated three times in each season. The characters studied are plant height, number of leaves per plant, fresh weight of shoot per plant, dry weight of shoot per plant, root length per plant, root diameter per plant, fresh weight of root per plant, dry weight of root per plant, cracked root per plant, carotene content and root yield. All characters studied were found to be positively and highly significantly correlated with root yield in all three years of investigations. This study has confirmed that all the growth and yield characters considered had a positive association with root yield. And thus, made a significant contribution to root yield. Therefore, they should constitute important traits when breeding for high-yielding carrot varieties.
Keywords: *correlation, path analysis, characters, irrigation, nitrogen, spacing and carrot*

INTRODUCTION

The carrot (*Daucus carota* L.) is an important vegetable because of its high nutritive and medicinal value. It is valued as food because of its high carotene content and vitamin A, which is important in protecting against blindness in children. Carrot has a long storage life compared to many other perishable vegetables. Accurate information on the yield of carrots in Nigeria is difficult to come by, however, yields of about 4 t/ha have been reported by (Hamma *et al.,* 2012) under irrigation conditions in Zaria, Nigeria. This is low when compared to a yield of 20-40 t/ha obtained in Mauritania and Niger Republic, 25-45 t/ha in Senegal and the Cape –Verde, and 40-50 t/ha in Chad (Lannoy, 2001). This low yield may be attributed to complex issues such application of adequate amounts of water for irrigation, the application of nitrogen, and optimum population and plant density. Hence the objective of this research is to determine the influence of irrigation interval, nitrogen levels, and intra-row spacing on the growth and yield of Carrot under irrigated conditions in Dadin-kowa, Yamaltu Deba L.G.A, Area of Gombe State, Nigeria. Parts of the results obtained in this study showed that application of water at every 5-day interval and application of 150 N/h combined with 15cm intra-row spacing resulted in optimum growth and yield of carrots in Yamaltu Deba L.G.A, area of Gombe State, Nigeria (Mahmoud *et al.,* 2019). To determine characters that contribute to the yield of carrots under the influence of irrigation interval, nitrogen levels and intra row spacing correlation and path analysis were carried out. This is because the estimation of a simple correlation between various agronomical characteristics may provide good information necessary for crop production when selection is based on two or more traits simultaneously. Mukhtar (2009), Sadek *et al.* (2006), and Babaji *et al*. (2007) observed that association among traits might be measured by genotypic or phenotypic coefficients of correlation depending on the types of studied material, crops, and the kind of experimental design. Therefore, information obtained from correlation coefficients for growth and yield characters could also be useful as an indicator of the more important parameters under consideration.

MATERIALS AND METHODS

Field trials were conducted during the dry seasons of 2010/2011, 2011/2012, and 2012/2013 at the Teaching and Research Farm of the Federal College of Horticulture Dadin-Kowa, northern Guinea savanna ecological zone of Nigeria (Latitude 11°30" N, Longitude 10° 200" E and 240m above sea level). Soil samples from the study area were taken randomly to a depth of 0-30 cm using a tubular auger. The samples were mixed thoroughly in a container after which a representative sample was scooped out from the bulk and analyzed to determine the initial soil fertility levels using standard procedures as described in the report by (Mahmoud *et al.,* 2018 and 2019) and the result of the analysis is presented in Table 7. The treatments, which were laid in a split-split plot design with three replications consisted of three (3) irrigation interval (5, 7, and 9 days) and was assigned to the main-plot, four (4) nitrogen levels (0, 50, 100 and 150kg/ha) which were assigned to the sub-plot and three (3) spacing (5, 10 and 15cm) assigned to sub-sub-plot treatments. The experimental plots were properly ploughed and harrowed twice to obtain a fine tilth. A furrow of 75cm in between a strip of 2m was dug and used as a distributor channel. Later, the strips were encircled with raised bunds, into basins of 2-meter length. Land preparations were carried out in early October. Drainage channels were constructed at the tail end of the field. The variety used for this research is Nantes. A dose of half the nitrogen rate and a full dose of phosphorus as well as a full dose of potassium were applied at two weeks after sowing. Urea (46%N), muriate of potash (60% K_2O_5), and single superphosphate (18%P_2O_5) were used as sources of nitrogen, phosphorus, and potassium, respectively. The second dose of nitrogen was applied as a side dressing at six weeks after sowing. Weeds were properly controlled by hand hoe. Three hoe weeding were carried out in each season. No incidence of pests and diseases was recorded throughout the period of experimentation in all seasons.

The characters studied are plant height, number of leaves per plant, fresh weight of shoot per plant, dry weight of shoot per plant, root length per plant, root diameter per plant, fresh weight of root per plant, dry weight of root per plant, cracked root per plant, carotene content and root yield. The growth parameters assessed at 9WAS were plant height, length, and number of leaves. Five plants were selected randomly from each plot and were tagged at 3 WAS for recording various growth and yield parameters. Plant height was recorded from the base of the root to the top of the plant and the average plant height was then expressed in cm. The length of leaves was measured from the base to the tip of the leaves expressed in cm. The number of leaves in five tagged plants was counted and the average value was worked out. The yield parameters assessed at harvest were the length of the carrot, carrot diameter, carrot fresh weight, and carrot yield per ha. The length of the carrot was measured in five randomly selected plants from the base of the root to the top of the root and the average carrot length was expressed in cm. The circumference of five carrots selected randomly was recorded at the basal portion of the root with the help of thread and scale and the average carrot diameter was expressed in cm. The fresh weight of five carrots selected randomly after harvest was recorded and the average fresh weight of carrot was expressed in grams/plant. The total root yield was computed from the yield of the net plot and expressed in kg per ha. The data was subjected to analysis of variance (ANOVA) and the means were separated using Duncan's Multiple Range Test (Duncan, 1955). All statistical procedures were done as described by Gomez and Gomez (1984). The strength of the relationship between growth and yield parameters was studied using correlation coefficient analysis (Little and Hills, 1978 Babaji *et al.,* 2007).

RESULTS AND DISCUSSIONS

Simple Correlation matrix involving root yield, growth, and yield parameters of carrot

The simple correlation matrix between root yield, some growth, and yield components during three years of investigation were presented in Tables 1,2, and 3 for the 2010/2011, 2011/2012, and 2012/2013 dry seasons respectively. The characters studied are plant height, number of leaves per plant, fresh weight of shoot per plant, dry weight of shoot per plant, root length per plant, root diameter per plant, fresh weight of root per plant, dry weight of root per plant, cracked root per plant, carotene content and root yield. All characters studied were found to be highly significantly correlated with root yield in all three years of investigations. It was also noted that the relationship between plant height, mean number of leaves per plant, fresh weight of shoot per plant, dry weight of shoot per plant, root length per plant, root diameter per plant, fresh weight of root per plant, cracked root per plant and carotene content were all found to be positively in all the three years of study as shown in Tables 1, 2 and 3.

The Direct and Indirect Contribution of Growth and Yield Parameters of Carrot to Root Yield

The partitioning of the total correlation into direct and indirect effects of some growth and yield characters on the root yield of carrots was positive throughout the period under consideration. The highest individual contribution was from the fresh weight of root per plant while the highest combined contributions were from the fresh weight of root per plant combined with root length per plant and from the fresh weight of root per plant combined with root diameter per plant as shown in Tables 4,5 and 6.. The significant and positive correlations between pod yield and growth characters indicated the importance of good vegetative development as being necessary for high yields. This is in conformity with the work of Wright (1934) who noted a highly significant positive relationship between yield and vegetative characters. The positive significant relationship between yield and yield characters indicates that these characters are important yield indices (Mukhtar *et al.*, 2013; Babaji *et al.,* 2005; Babaji *et al.,* 2007). All the direct and indirect effects were positive throughout the period under consideration. This suggests that these characteristics are important in root yield and the higher the direct or indirect effect the more critical the determinant in yield and thus constitute important characteristics that the breeders should consider when breeding for high-yielding varieties.

CONCLUSION

Based on the results of this work, it can be concluded that all the growth and yield characters considered in this work made significant contributions to yield and thus constitute important characters when breeding for high-yielding varieties.

Economics Section Cocoa Research Institute of Nigeria

Corresponding author: yetunde.oladokun@gmail.com

ABSTRACT
Nigeria produces about 50% of the world's kolanut and it is mostly consumed within. This study examined Kolanut processing for quality improvement among kolanut processors in Ogun State of Nigeria. The study was carried out in Ogun state, Nigeria. One hundred and eight (108) kolanut processors' information was used for analysis. Descriptive statistics was used as analytical technique. The mean age of kolanut processors in the study area was 59 ± 14. Ninety four percent of the processors are female. In the study area 42.6% of the processors do not have formal education while 47.4% have a level of education (primary/secondary). Majority (96.3%) of the processors in the study process more of gbanja/goro type of kolanut. One hundred percent of the processors affirmed that they process their raw kolanut to avoid spoilage. Also 48.1% of the processors reported that to reduce the bitter taste of kolanut they store the nut for a long time or allow it to be well dried Eighty percent of the processors use leaf to preserve kolanut. They use this to avoid spoilage (33.3%), to enhance the appearance of kolanut (27.8%) and to avoid being heated (20.4%). On the other hand, 77.8% of the processors use nylon to preserve kolanut and some of the reasons why they use it is to make it airtight thus avoiding spoilage, it also enhance storage for a long time. Majority (96.3%) of the processors use chemical to preserve their nut. This study recommended that the right processing techniques should be put in place to reduce its bitterness and sensitization on the non usage of chemicals to preserve kolanut.

INTRODUCTION

Kola an evergreen tree and a member of sterculiaceae familyis an important commodity crop in West Africa and other tropical regions of the world (Onaolapo and |Onaolapo, 2019). It is native to tropical Africa with its center of diversity in West Africa especially Cote d'Ivoire and Ghana (Gestrich *et al*. 2021). Among about 40 Cola species in West Africa, the Cola nitida and Cola acuminata are the species of real economic importance (Asogwa *et al*.2011; Adesida *et al.* 2021). They are important economic crops in the forest areas of West and Central Africa, Caribbean Islands, Mauritus, Sri Lanka and Malaysia (Adesida *et al*. 2021). Although Cola nitida is of more economic importance in Nigeria especially in the north, Cola acuminate has its origin and is consumed mainly among the Yoruba tribe of Western part of Africa.Kolanuts are extremely popular due to their high caffeine content. Kolanuts have a bitter taste and contain between 1-1.5% caffeine by weight (Clayon, 2002). They are also a source of antioxidants and contain small amounts of theobromine, d-catechin, L-epicatehin, kolatin, phlobaphens, antioxidant pigment, betaine and protein. Kola extract isa popular ingredient in fat loss supplements. It suppresses hunger, aids digestion of food and acts as a diuretic.

Cola acuminata: The processing of *cola acuminata* begins with a meticulous inspection to separate healthy pods from those afflicted by weevils, diseases, or deformities. Following this, the seed coat or testa of the nuts from the healthy pods is removed. This is done by immersing the nuts in clean water for 24 hours to encourage rotting, after which the nuts are peeled and rinsed in fresh water.The rinsed nuts are then gathered in wide, flat baskets to allow excess water to drain before being placed in a room at ambient temperature for three days for curing. During this curing process, defective or infested nuts are identified and removed, and there might be some moisture reduction through sweating.Finally, the nuts are sorted by size and stored in large baskets for proper storage.

Cola nitida: For Cola Nitida, the testa or seed coat of the fresh nuts can be made to rot by placing them on the bare ground with intermittent moistening, covering them with jute bags for 3-4 days. This method causes the nuts to become wet and turn black while also aiding the maturation of premature nuts. Alternatively, the testa of fresh nuts can be soaked in water for 24 hours. After soaking, the nuts are peeled, rinsed, and collected in baskets to drain excess water. During this process, defective and infested nuts are removed.Next, the nuts are cured in flat baskets for three days. Throughout this period, they are subject to regular inspection to eliminate any remaining defective or infested nuts.For storage, the nuts can be transferred to baskets lined with polythene sheets, followed by layers of paper (such as old newspapers) and fresh leaves from specific plant species. These layers are replaced during weekly inspections. Alternatively, the nuts can be stored in jute bags lined with thin transparent polythene sheets, layered with paper and fresh leaves. After two months, the frequency of inspections can be reduced to intervals of 2-3 weeks.These processing techniques are crucial for maintaining the quality and safety of cola nuts for various purposes, including their use in the production of cola-flavored beverages.

Nigeria is the leading world producer of Kolanut (Amon-Arma *et al.* 2021). It is estimated that Nigeria produced 171428.8 metric tonnes of fresh nut in 2021 (FAOSTAT, 2021). Kola has numerous socio-economic as well as nutritional importance. Kola nut is an important article of trade in West Africa and in the trans-Saharan trade routes for many centuries. Kola nut was harvested in 257114 hectares in 2021 (FAOSTAT, 2021). Kolanut is majorly consumed within Nigeria thus efforts must be put in place to increase its consumption through post harvest processing to reduce its bitter taste (Asogwa *et al*. 2012). This study thus seeks to examine Kolanut processing for quality improvement among kolanut processors in Ogun State of Nigeria

METHODOLOGY

The study was carried out in Ogun state, Nigeria. Shagamu town was purposively selected because of the high concentration of kolanut marketers/processors in this area. One hundred and fifteen (115) processors were randomly selected and after sorting out for missing data one hundred and eight (108) kolanut processors' information was used for analysis.

Analytical techniques

Descriptive statistics was used to analyse the data retrieved from the information collected.

RESULTS AND DISCUSSION

Table 1 presented the socio economic characteristics of kolanut processors in Ogun state. The mean age of kolanut processors in the study area was 59 ± 14years. Kolanut processors in the study area are middle aged thus they are still active and could be sensitized and trained on the right processing techniques to improve the taste of kolanut. Ninety four percent of the processors are female.This finding is in conformity with Oluyole *et al*. 2023 which confirmed that men are more into production of tree crops while women are into processing and marketing. In the study area, 42.6% of the processors do not have formal education while 47.4% have a level of education (primary/secondary). Kolanut processors do not really need formal education for their trade, most times they get trained informally from marketers who have been in this trade for a while (Source??).

Table 1: Socio Economic Characteristics of Kolanut Processors in Ogun State

Variable	Freq(108)	%
Age (years)		
<30	1	1.9

Educational Status		
No formal education	46	42.6
Primary	44	40.7
Secondary	18	6.7

Source: Field Survey, 2021

Table 2 presented the quality improvement among kolanut processors. Majority (96.3%) of the processors in the study process more of gbanja/goro type of kolanut.Gbanja/goro is *cola nitida* and it is one of the most popular specie of economic importance in Nigeria (Odo *et al*. 2023). One hundred percent of the processors affirmed that they process their raw kolanut to avoid spoilage. Also 48.1% of the processors reported that to reduce the bitter taste of kolanut they store the nut for a long time or allow it to be well dried. Good post harvest processing techniques could also reduce the bitter taste of kolanut to enhance its consumption. Eighty percent of the processors use leaf to preserve kolanut. They use this to avoid spoilage (33.3%), to enhance the appearance of kolanut (27.8%) and to avoid being heated (20.4%). On the other hand, 77.8% of the processors use nylon to preserve kolanut and some of the reason they use it is to make it airtight thus avoiding spoilage, it also enhance storage for a long time. Majority (96.3%) of the processors use chemical to preserve their nut. They use chemicals such as Gamallin 20 and Phostocin to prevent weevil infestation on kolanuts. They use the two chemicals together probably to make preservation more effective. Eighty three percent of the processors affirmed that they ferment their kolanut before peeling. The reasons for this were to ease peeling, to enhance long term storage and to enhance the appearance of the nut.

Table 2: Quality Improvement among kolanut processors

Variable	Freq(N=108)	%
Type of Kola processed		
Local Kolanut	4	3.7
Gbanja/Goro	104	96.3
Why do you process your kolanut

Do you use leaf to preserve kolanut?	86	79.6
Reasons for using leaf		
To enhance the appearance of the kolanut	30	27.8
To dry up the nut quickly	8	7.4
To be used as airtight	8	7.4
To preserve the nut to avoid spoilage	36	33.3
To improve taste (to reduce bitterness)	4	3.7
To avoid being heated	22	20.4
Do you use nylon to preserve your nut	96	77.8
Why do you use nylon to preserve kolanut		
Nylon is airtight and avoid spoilage of nut	54	50.0
Nylon saves labour and does not need to be changed regularly as leaf	6	5.5
Leaf makes kolanut to burn	4	3.7
Nylon moistens nuts	6	5.6
Nylon enhances storage for a long time	34	31.4
Leaf dries up quickly	2	3.8
Do you use chemical to preserve your nut?	~~104~~	~~96.3~~
Yes	??	??
No	??	??
Chemicals used to preserve kolanut		
Gamallin 20 and Phostocin	84	80.8
Gamallin 20 alone	10	9.6
Phostocin alone	10	9.6
Do you ferment your kolanutbefore Peeling?	~~90~~	~~83.3~~
Yes		
No		
Why do you ferment before peeling?		
To ease peeling	36	40
To enhance long term storage	36	40
To enhance colour	8	8.9
To enhance the appearance of the nut	10	11.1

Source: Field Survey, 2021

CONCLUSION

In the context of this study, kolanut processing reduces the bitter taste of kolanuts, especially, when the kolanuts are stored for a long time or allow it to be well dried. The use of leaves to preserve kolanuts avoid kolanut spoilage; it enhances the appearance of kolanuts and it avoids kolanuts from unnecessarily being heated. It is quite disheartening that majority of the processors still use chemicals such as gamallin 20 and phostocin to preserve kolanuts against insecticidal infestation. The study therefore recommended that sensitization on the non-usage of chemicals to preserve kolanuts should be intensified.

ABSTRACT
Tomato (Solanum lycopersicum) production is challenged by a wide range of biotic and abiotic stresses, which are the most important constraints for the plant yield and productivity. Sterilization of explants is a pre-requisite step for carrying out any plant tissue culture work for further biotechnology applications. In this study, various concentrations of sodium hypochlorite (NaOCl) with a drop of Tween 20 (T20) were used as surface sterilization treatments, 3.5% NaOCl+ T20 for 20mins, 1.0% NaOCl for 25mins, 10% NaOCl for 5mins, 2.5% NaOCl for 10mins, and 5.25% NaOCl for 10mins. The tomato seeds were thereafter rinsed with sterile double distilled water at least five times to remove traces of sterilant and further blotted on sterile filter paper before culturing. Seeds sterilized with 3.5% solution of sodium hypochlorite for 20mins and 2.5% solution of sodium hypochlorite for 10mins with a drop of non-ionic surfactant (Tween 20) had the highest mean number of leaves (14 ± 0.58) and (12 ± 1.15) which is essential for regeneration purposes using aseptic cotyledonary leaf as explants. The lowest percentage of seed germination were recorded while using the 10% of sodium hypochlorite for sterilization. Therefore, the reported sterilization treatments could be useful for carrying out any biotechnological applications including the clonal propagation of high-value commercial cultivars, virus-free plants and genetic transformation in tomato crop improvement programme.
Keywords*: Sterilization, In vitro Regeneration, explant, Tomato.*

INTRODUCTION

Tomato *(Solanum lycopersicum L.)* belonging to the family *Solanaceae* has a much lower sugar content than other edible fruits and considered as a fleshy vegetable *(Bhatia et al; 2004)*. The fruits are essential source of nutrition for substantial portions of the world's human population because this vegetable crop is widely cultivated and consumed extensively as both fresh vegetable and concentrated processed products *(Beecher, 1998)*. Tomato is grown in tropical, sub-tropical and temperate areas. From the socioeconomic outlook, tomato is well-known as 'Red Gold' in the farming community due to its prominent economic status. However, its productivity is weakened by a wide range of biotic and abiotic stresses which are most important constraints for plant yield and productivity. Abiotic stress conditions such as drought, salinity and heat have been studied in agricultural plants due to the economic losses that they cause every year worldwide *(Martinez et al. 2018)*. Likewise, biotic stresses caused due to pathogen attack such as., bacteria, fungi, virus and nematodes etc. also stimulate adverse effects on plants. Therefore, there is a pressing need for biotechnological interventions to increase the productivity of this crop. The *in vitro* culture of tomato has been successfully used in the different biotechnological applications including the clonal propagation of high-value commercial cultivars, virus-free plants and genetic transformation *(Namitha and Negi, 2013)*. The introduction of qualitative traits into commercial tomato cultivars is substantial, the aim being to ameliorate their nutritional value, productivity, abiotic stress resistance and application in molecular farming *(Gerszberg et al., 2015)*. These crop species exhibited extraordinary nutritional value that's why it is considered to be preventive food *(Raiola et al., 2014)*.

Recently, this crop has gained huge popularity due to its anti-cancer and antioxidant characteristic (*Khuong et al., 2013*). Tomato is rich in vitamins such as vitamins A and C, fiber and considerable quantities of antioxidants such as flavonoids, zeaxanthin, β-carotenes, lutein, and lycopene *(Hobson and Davies, 1971)*. The compound lycopene protects cells and organs in the human body from harmful oxygen free radicals; therefore, they decrease the risk of cancers *(Rao and Agarwal, 2000)*. Tomato is a predominantly inbreeding species and its genetic variation tends to decrease. So, these problems hamper to improve tomato characters through conventional breeding program.

A major limitation to aseptic culture establishment is microbial contaminants which may be introduced into the culture medium from explants and affect the potential of plant regeneration *(Jeffery 2005)*. Surface sterilization of explants is therefore an important precondition in any tissue culture experiment to minimize the chances of contamination. Since, surface sterilization requires the use of chemicals that are, toxic to microorganism but nontoxic to plant material preferably at low concentrations, and in order to find an optimized protocol for sterilization of a specific tissue, three factors are to be taken into consideration viz., sterilant, its concentration and the treatment duration. Maintaining an aseptic or sterile condition has been identified as a pre-requisite step in successful tissue culture procedures *(Badoni and Chauhan, 2010)*. The sterilizing agents used for optimization of in vitro sterilization protocol are ethanol, sodium hypochlorite (NaOCl), calcium hypochlorite, mercuric chloride (HgCl2) and hydrogen peroxide which have been reported toxic to the explants used in plant tissue culture. Therefore, their appropriate minimal concentration and exposure time of sterilants to the explants is an essential step before culturing to achieve maximum survival rate for regeneration purposes.

Proper concentrations of surface sterilizer and explants responsive hormones along with time period are limiting factors for a successful regeneration of tomato plants *in vitro*. So, it is necessary to develop a reproducible *in vitro* regeneration protocol of tomato. Considering all above aspects, the present study was undertaken to determine suitable concentrations and accurate exposure time of surface disinfectant to drastically reduce contamination, thereby increase germination rate in tomato for high frequency plantlet for regeneration and fruit setting.

MATERIALS AND METHODS

Plant materials collected

Seeds of tomato (*Solanum lycopersicum*) (UC82) were obtained from the gene bank of National Horticultural Research Institute (NIHORT) Ibadan, Nigeria. This research work was carried out in the Biotechnology Laboratory of the institute.

Regeneration media

The regeneration media was prepared and adjusted to pH 5.8, melted in a microwave oven. About 50-100 ml of the medium was dispensed into each previously sterilized culture jars, autoclaved at 121°C at 15 psi for 15 min. The efficiency of sterilization was ascertained using Bowie-Dick auto clave tape which changed from blue to black. The preparation was allowed to cool overnight before inoculation process. The seeds were inoculated onto sterile, cooled and solidified regeneration medium (RM). The various constituent of the media used are:

RM1 = MS + 30 g L-1 sucrose + 8 g L-1 agar gel *(Cortina et al., 2004)*
RM2 = MS + 30 g L-1 sucrose + 2 g L-1 phytagel *(Cortina et al., 2004)*

Surface Sterilization

Seeds of UC82 tomato were soaked in distilled water for 30-45mins in order to identify and discard non viable seeds. Various concentrations of sodium hypochlorite (NaOCl) with a drop of Tween 20 (T20) was used as surface sterilization treatments for the presumable viable seeds, duration of treatment was also taken into consideration.

Table 1: Treatment concentration

Sterilants	Reagents	Treatment Duration (mins)
S1	3.5% NaOCl + T20	20
S2	1% NaOCl + T20	25
S3	10% NaOCl + T20	5
S4	2.5% NaOCl + T20	10
S5	5.25% NaOCl+ T20	10

The seeds were rinsed with sterile double distilled water at least five times to remove traces of sterilant and further blotted on sterile filter paper before culturing. It is worthy of mention that the study was carried out in triplicate for each sterilant, 5 seeds in each culture jar, totaling 15 seeds for each sterilant concentration used, also two different gelling agents were used which are agar and Phytagel.

Tomato seed Germination

In-vitro tomato seedlings were produced according to the methods described by (*Cortina et al. 2004)*. Surface-sterilized tomato seeds were inoculated on germination medium (GM). Each culture jar containing germination medium was inoculated with 15 sterilized seeds and were covered to be in the dark at 25 ± 2°C for 3 - 5 days to germinate and then exposed to a 16/8 hrs light photoperiod with light intensity of 1500 lux for 7 - 10 days at the same temperature. Data were taken 12-14 days after inoculation.

RESULTS

Table 2: Plant Parameters obtained from RM1

Sterilants	Treatment Duration (mins)	Number of seeds inoculated	Number of germinated seeds	Germination percentage (%)	Number of Leaves	No. of Leaves ± S.E	Average plant height(cm)
S1	20	15	14	93.3	42	14 ± 0.58	5.47
S2	25	15	3	20.0	9	3 ± 3.00	7.00

Figure 2: Media with Agar

DISCUSSION

In the present study, effect of different concentrations on sodium hypochlorite and drop of T20 on efficiency of seed germination to produce aseptic cotyledonary leaves for regeneration was evaluated. It was observed from the study that is (Table 2), 3.5% NaOCl for 20mins (S1) was found to be the best concentration for sterilization, seeds that were sterilized with S1 has the highest germination rate of 93.3% which signifies no contamination in the culture jars, 1.0% NaOCl for 10mins has the lowest germination rate of 20.0% due to contamination. S1 also has the highest number of leaves 42(14 ± 0.58) which is essential for regeneration purposes using aseptic cotyledonary leaf as explant.

However, from (Table 3), 2.5% NaOCl with drop of T20 for 10mins (S4) had no contamination thereby having the highest number of leaves 32(12 ± 1.15), S1 which had the highest germination rate in table 1 recorded no germination in one of the culture jars which in turn narrowed the germination rate to 60%.

Among the different concentration of sodium hypochlorite (NaoCl) used for surface sterilization, the maximum aseptic germination was achieved at 3.5% and 2.5% respectively in both RM1 and RM2, While the lowest percentage of seed germination were recorded while using the 10% of sodium hypochlorite for sterilization, Inhibition of seeds germination at higher concentration might be due to peroxiding action of chloride atoms and ions that combines with proteins causing the death of biological organisms *(Pauling, 1955)*. In contrast to our observations, many researchers have previously recorded different treatment combinations and concentrations of sterilants for different durations such as 70% ethanol for one minute followed by soaking in 4% NaOCl *(Soundarajan, 2015)*, 70% ethanol for 30 minutes and 20% NaOCl for 20 minutes *(Manawadu et al., 2014)*, 70% ethanol for 10 seconds followed by continuous shaking *(Chandra et al., 2013)* and 0.1% HgCl2 for 3 minutes, respectively.

CONCLUSION

The study has shown that contaminant free cultures could be obtained with an efficient sterilization protocol as well as the derivation of aseptic cotyledonary leaves for in vitro regeneration for indirect shoot and root organogenesis from local tomato cultivar which could be useful for crop genetic improvements and micro propagation purposes. All the concentrations of sodium hypochlorite solution (NaOCl) used for surface sterilization has significant effect on seed germination.

ABSTRACT

This study investigates the consumption patterns, level of awareness of the health benefits of processed ginger and factors influencing processed ginger's purchase decision among households in Ido local government Area of Ibadan, Oyo state. The respondents for the study were selected through two-stage sampling techniques. Data was collected with the use of structured questionnaire. Descriptive statistics and probit regression were used for data analyses. Result showed that average age of respondents was 42 years and most (95.0%) of them were aware of processed ginger's health benefits. About (38%) of the respondents obtained their information by word of mouth. About 46% of the respondents prefer to consume ginger as herbal tea/drink, Household size, education, training on the health benefits of processed ginger are factors with statistically significant influence on processed ginger's purchase decision. It is recommended that training sessions on health benefits and marketing campaigns should be implemented on its main usage as an herbal tea or drink to increase regular consumption.

Keywords*: Consumption patterns, Processed ginger, Ido local government, Food processing*

INTRODUCTION

Unhealthy dietary patterns and poor eating habits have been identified as primary promoters of major diseases including heart disease, stroke, chronic lung disease, cancer, and diabetes on a global scale (WHO, 2011). The growing interest of consumers in achieving optimal health, prolonging life expectancy, and enhancing their quality of life has led to a renewed focus on the consumption of functional foods, which are commonly recognized for their medicinal and health-enhancing properties (Kotilainen *et al*., 2006). Ginger, scientifically known as *Zingiber officinale Rosc*., is a root and spice crop that belongs to the Zingiberaceae plant family. The name "Zingiber" is derived from the Greek word "Zingiberis", which originates from the Sanskrit name "Singabera". Ginger has been used as a medicinal remedy since ancient times and continues to be a crucial cooking spice worldwide. Processed ginger products offer a level of convenience and satisfaction that fresh ginger lacks. In today's fast-paced world, consumers are drawn to the ease of incorporating ginger into their diets without the hassle of peeling, grating, or chopping fresh ginger rhizomes. Processed ginger products like ginger paste and ginger powder are readily available and save valuable time in meal preparation. According to Anita *et al*. (2020), processed ginger in the form of ginger candy can reduce the vomiting rate in pregnant women during their first trimester.

According to Onwusiribe *et al*. (2020), Ginger is perishable and given the poor state of storage and other infrastructural facilities in Nigeria, post-harvest losses are massive, thus, there is market glut during harvest periods and marked scarcity during off-seasons. This phenomenon makes the need for value addition (such as processing and packaging) very pertinent to improve the shelf life of fresh ginger and to attract a fair price to the farmers. From an economic point of view, the importance of reducing food wastage is often emphasized to enhance resource efficiency. Processed ginger products, such as ginger paste, ginger powder, and ginger-infused oils, have longer shelf lives compared to fresh ginger. This increased shelf life translates into reduced food waste, which is not only economically advantageous for consumers but also aligns with sustainability goals by minimizing resource wastage.

Numerous studies have substantiated the advantageous effects of ginger products on human health. Despite the increasing recognition of its consumption and health benefits, the level of awareness remains notably inferior in comparison to other spices such as onion and locust bean, as highlighted by Oguntoye *et al*., (2020). Furthermore, limited research has been conducted on the consumption of processed ginger, the extent of awareness regarding its health benefits, and the factors that influence the decision to purchase processed ginger. These factors serve as the basis for conducting the present study.

MATERIALS AND METHOD

The study was conducted in Ido local government. Ido local government is one of the thirty-three local governments in Oyo state. It was carved out of Akinyele local government in 1989. According to the 2006 census, it has an area of 986 km^2 and a total population of 103,261. The major towns within the local government are Ido, Apata, Ijokodo, Omi adio, Akufo, and Apete.

A two-stage sampling procedure was used to select 80 respondents for the study. The first stage of the sampling involves a purposive selection of Ido local government of Oyo state, after which twenty respondents was randomly selected from each of the four major towns in Ido local government which are: Ido, Apata, Omi adio and Apete which will make a total of eighty respondents.

METHODOLOGY

Descriptive statistics

Descriptive statistics was used to analyze the socio-economic characteristics of the respondents, consumption patterns and level of awareness of the health benefits of processed ginger.

The Probit Model

Probit regression was employed in the analysis of factors influencing processed ginger's purchase decision. The probit model is as specified: $yi^* = Xi\,\gamma + ui$

Where:

yi^* = latent variable that defines the rule as to whether a household would decide to consume ginger or not

Xi = a vector of exogenous variables

γ = coefficients associated with the repressors (X) including the constant term

ui = error term assumed to be normally distribution with zero mean and unit variance

RESULTS AND DISCUSSION

Table 1: Socio-economic characteristics of the respondents.

Variables	Category	Frequency	Percentage	Mean
Gender	Male	25	31.3	
	Female	55	68.8	
Religion	Islam	45	56.3	
	Christianity	35	43.8	
Marital status	Single	12	15.0	
	Married	62	77.5	
	Divorced	2	2.5	
	Widow	4	5.0	
Age	≤ 30	22	27.5	
	31- 40	12	15.0	
	41- 50	21	26.3	42
	51- 60	19	23.8	
	> 60	6	7.5	
Education level	Primary education	1	1.3	
	Secondary education	24	30.0	
	Tertiary education	55	68.8	
Household size	1-3	22	27.5	
	4-6	54	67.5	4
	≥ 7	4	5.0	
Monthly income	≤ 30000	11	13.8	
	30001 – 70000	27	33.8	
	70001 – 110000	34	42.5	75775
	110001 - 150000	4	5.0	
	150001 - 200000	4	5.0	
Monthly food expenses	≤ 4000	15	18.8	
	4001 – 8000	29	36.3	
	8001 – 12000	25	31.3	8678
	12001 – 16000	8	10.0	
	16001 – 20000	3	3.8	

Monthly expenses on processed ginger	≤ 300	15	18.8	
	301 – 600	43	53.8	123
	601 – 900	21	26.3	
	901 – 1200	1	1.3	

Source: Field survey, 2023

The result revealed that most of the respondents were female (68.8%) with a mean age of 42 years which signifies that they are in active age group which means level of consumption and awareness about the health benefits of processed ginger will be high. The mean household size was 4 persons. Most of the respondents had tertiary education level (68.8%) which could be of a great factor to their level of consumption and awareness about the health benefits of ginger. About 43% of the respondents had average monthly income of ₦75775, about 36% of the respondents spends between ₦4001 to ₦8000 monthly on food with average monthly food expenses of ₦8678. About 54% of the respondents spends between ₦301 to ₦600 monthly on processed ginger with average monthly expenses on processed ginger of ₦123

Table 2: Respondent's awareness about the health benefits of processed ginger

Awareness about the health benefits of processed ginger	Frequency	Percentage
Aware	76	95.0
Not aware	4	5.0
Total	80	100.0

Source: Field survey, 2023

Ginger has a lot of health benefits which includes aiding of food digestion, relieves nausea, serves as antioxidant and it boosts the immune system. The result shows that most (95.0%) of the respondents were aware about the health benefits of processed ginger. This is a relatively high level of awareness which is expected to stimulate consumers towards its consumption.

Table 3: Sources of information about the health benefits of processed ginger

Sources of information about the health benefits of processed ginger	Frequency	Percentage
Social media	18	22.5
Electronic media	18	22.5
Print Media	5	6.3
Doctor or Nutritionist	9	11.3
Word of mouth	30	37.5
Total	80	100

Source: Field survey, 2023

There are many sources of information about the health benefits of processed ginger, these sources includes social media, electronic media, print media, doctor or nutritionist and word of mouth. From the result, it was found that most (38%) of the respondents obtained their information by word of mouth which is closely followed by social media and electronic media (23%).

Table 4: Respondent's consumption patterns of processed ginger

Consumption pattern	**Frequency**	**Percentage**
Cooked with food	24	30.0
As herbal tea/drink	37	46.3
Mix with pap	18	22.5
Sauce	1	1.3
Total	80	100.0

Source: Field survey, 2023

Processed ginger is consumed in different forms which includes cooking with food, consumption as an herbal tea or drink, mixed with pap and as a sauce. Most (46%) of the respondents consumed processed ginger as an herbal tea or drink; about 30% consume it by cooking it with food while about 22.5% consumed it with pap while 1.3% of the respondents consumed it as a sauce.

Table 5: Factors influencing purchase decision of processed ginger

Consumption	Coef.	Std. Err.	Z	P>z	[95% Conf.	Interval]
Age	.0089008	.0150626	0.59	0.555	-.0206214	.0384229

_cons	-5.617547	2.1272	-2.64	0.008	-9.786782	-1.448313

Source: Field Survey (2023)

Number of obs = 80, LR chi^2 (8) = 34.65, Prob > chi^2 = 0.0000, Log likelihood = -37.73, Pseudo R^2 = 0.3147

Table 5 shows the results of probit regression analysis carried out to identify the socio-economic determinants of processed ginger's purchase decision. The Log-likelihood function of the estimated model is -37.73 with the associate Chi-square value (34.65) is statistically significant ($P < 0.000$), implying that the probit model can be relied upon to predict the factors influencing processed ginger's purchase decision. Household size, education, training on the enlightenment of health benefits of processed ginger are factors with positive and statistically significant influence on processed ginger's purchase decision. This is in support of the study of Phuah *et al*. (2015) who found statistically significant influence of education and household size on their purchasing behaviour towards functional foods. The positive signs of the coefficients of the significant variables suggest that the variables can substantially enhance the likelihood of consumer decision to purchase processed ginger in the study area.

CONCLUSION AND RECOMMENDATION

Findings reveals that the awareness about the health benefits of processed ginger is relative high in the study area, with most consumers consuming it as herbal tea/drink. Consumer's household size, education, training on the enlightenment of health benefits of processed ginger are strong influencers of processed ginger's purchase decision. Their age, gender and income play little role in explaining ginger's purchase decision. Based on empirical findings of this study, it is recommended that educational programs and training sessions should be implemented to increase awareness about the specific health benefits of processed ginger. These programs should focus on both the methods of processing fresh ginger and the broader health advantages of consuming processed ginger. Also, marketing campaigns on its main usage as an herbal tea or drink should be created and tips on how to incorporate processed ginger into their daily routines should be provided to encourage regular consumption.

ABSTRACT
Yellow ficus (Ficus retusa 'Nitida') as an hedge plant is used for landscaping. To optimize the propagation technology for this important hedge plant, this study was conducted to evaluate the residual effect of organic materials in the varying growth media utilised in the propagation of yellow ficus at the nursery stage. The growth media utilised were topsoil, sawdust, topsoil + cow dung (4:1), topsoil + poultry manure (4:1), cow dung + sawdust (1:4), sawdust + poultry manure + topsoil (1:1:3) and sawdust + cow dung + topsoil (1:1:3). The experimental design was Completely Randomized Design (CRD) with three replications. At initial planting, at 13 weeks after planting (WAP), under nursery conditions, there was significant difference in yellow ficus plants grown in the media sawdust, cow dung and topsoil S+C+T (1:1:3) (26.92) and Topsoil (T) alone (27.13) as they supported greater leaves production though similar in their support, with medium sawdust, poultry manure and topsoil S+P+T (1:1:3) (24.18) closely following, in comparison with Sawdust (S) alone (9.78). At residual planting, Sawdust (S) alone support for leaves production was the poorest from 7WAP till the end of the study. Medium T+C (4:1) performed excellently well and maintained gradual increase in the highest leaves produced throughout the residual planting period. At 13WAP, medium T+C (4:1) supported production of the highest number of branches at both initial and residual plantings. At 13WAP initial planting, S+C+T (1:1:3) (6.72) supported longest branch length in yellow ficus while at residual planting, longest branch length was supported by Topsoil alone (8.27) with S+C+T (1:1:3) (6.78) closely following. Positive significant difference in C+S (1:4) (1.00) influence on branch girth was observed at initial planting while widest branch girth was supported by S+C+T (1:1:3) at residual planting. At initial planting, sawdust alone (32.39) supported longest root length closely followed by topsoil alone (26.48). In residual planting, highly significant difference was observed as topsoil alone (14.31) supported longer root lengths of yellow ficus. From this study, the media T+C (4:1), S+C+T (1:1:3) and S+P+T (1:1:3) in this order are recommended for residual use in yellow ficus planting at the nursery stage.
Keywords: growth media, nursery, organic materials, residual, yellow ficus.

INTRODUCTION
Yellow ficus is an economically important and attractive ornamental hedge plant used in landscaping that is relatively hardy when fully established. It is a species of evergreen woody plant in the fig genus, native to the Malay Archipelago and Malesia floristic region and Indochina floristic region, and the Indomalaya ecozone, i.e. of India, Malaysia origin (Gilman and Watson, 1993). It is ornamental plant made up of different species and cultivars and about 70 species of Ficus are found naturally in West Africa. According to Henley *et al*. (2009), Yellow ficus (formerly Ficus microcarpa L.f., now Ficus nitida) also known as Ficus retusa 'Nitida', the Cuban laurel fig, belongs to the genus, Ficus. The plant is 'difficult-to-root but sawdust + cow dung + topsoil (1:1:3) is a medium that most favorably supported establishment and sustenance of yellow ficus plants (Adeoluwa *et al*., 2014) as it encourages early rooting and establishment. Alternative products as components of media mixes for horticultural use are becoming important. Selection of substrates for horticultural use is often based on cost, availability, ease of handling, and consistency. Factors such as transportation costs, consistency of product, disease and insect infestation, and availability of such alternative materials remain the main concerns for growers. Development in the landscape industry leads to new opportunities for use of different types of alternative materials. In recent times, some common organic by-products are marketed to the horticultural industry. They include animal wastes such as poultry litter, poultry manure, cow dung, etc.
As important as the use of topsoil is in raising ornamental plants, the continuous use of topsoil alone in raising ornamental plants in the nursery till maturity or till they are sold off could lead to land degradation over time which may pose a threat to environmental sustainability (Akintoye *et al*., 2012). What is considered a waste by someone, can be another person's material for use; "One man's waste is

another man's treasure" (Sibley *et al*., 2013). This is applicable to agricultural waste materials we find useful for various horticultural purposes. Natural, farm and forestry by-products/ wastes are often abundant and readily available. They could be utilised as components of growth media mixes in ornamental plants production, especially, at the nursery stage. However, the reuse of growth media could be a means of reducing the quantity of topsoil used in raising plants in the nursery, reduce environmental degradation, while ensuring sustainability and preservation of the environment. Removal of plants, bagging them bare root with minimal media, moving them particularly over a long distance and planting them in desired location is possible without loss of plants. This is also done with yellow ficus seedlings ready to be transplanted. This indicates that media from which these nursery plants are removed can be reused. Therefore, this study is aimed at utilising some agricultural waste materials and determining their residual effects in the propagation of yellow ficus at the nursery stage.

MATERIALS AND METHODS

The experimental site was the screen house of the National Horticultural Research Institute, (NIHORT), Ibadan, Oyo State, Nigeria (30 52'E and 70 25'N) between early season May to August, 2022 (initial planting) and late season July to October, 2022 (residual planting). Yellow ficus (Ficus retusa 'Nitida') cuttings with eight (8) nodes each were planted in black polythene nursery bags filled with different growth media. Each nursery bag had a cutting of yellow ficus planted in it. The nursery bag was 10cm by 12cm and medium sized. The growth media utilized in this study include: topsoil alone, sawdust alone, topsoil + cow dung (4:1), topsoil + poultry manure (4:1), cow dung + sawdust (1:4), sawdust + poultry manure + topsoil (1:1:3) and sawdust + cow dung + topsoil (1:1:3). Equal measurement of these different growth media was put in the nursery bags. Each medium had three replications. Topsoil was obtained within NIHORT, Ibadan, Oyo state, Nigeria. Sawdust was obtained from the processed wood from the Wood Processing department of Forestry Research Institute (FRIN), Ibadan, Oyo state, Nigeria. The trees lumbered from which the sawdust were obtained were matured (>20 years). Cured poultry manure from birds raised in battery cages were utilized in this study. Growth media samples were collected prior planting and analysed according to standard procedure (IITA, 1979).

The experimental design was Completely Randomized Design (CRD) with three replicates. Mist propagation technique (Brown, 2011) was utilised to encourage the rooting of the cuttings. Plants were uncovered after three (3) weeks. 450ml of water per plant per week was applied in the course of the trial. Necessary nursery and other agronomic practices were carried out. No insecticide application during the study. Data collection on number of leaves commenced three weeks after plants were uncovered. Data on number of branches and branch length was taken at ninth week after plants were uncovered; and every forth night thereafter. Data collection on branch girth and root length was at the termination of the experiment. On termination of first planting, and at commencement of the residual study, the ficus plants were removed from each medium and fresh cuttings were planted in each following the same procedure as utilised in the first planting. Data collected were subjected to one-way analysis of Variance (ANOVA) using SAS 1999 package to determine the difference in means and Least Significant Difference (LSD) at $p < 0.05$ probability level was used to compare the treatment means (SAS, 1999).

RESULTS AND DISCUSSION

Media analysis

The results of the physical and chemical analyses of the media utilized in this study are presented in Tables 1a and 1b.

Soil Analysis

The topsoil was sandy loam in texture with pH 7.7. The available N=0.03%, P=8.2%, K=9.59cmolkg-1, Na=35cmolkg-1, Ca=42.16cmolkg-1, Mg=4.64cmolkg-1; Fe=0.79mgkg-1, Zn=2.92mgkg-1 and Mn=58.6mgkg-1.

Growth media initial and residual plantings effects on yellow ficus plants

(i) Root length in yellow ficus as influenced by growth media at initial planting and the residual effects

At initial planting, Sawdust alone (32.39) supported roots production as well as longest root length in yellow ficus plants production and growth in the nursery (Table 2). Positive significant difference was observed in the root length of plants in the medium sawdust alone (32.39) compared with those in C+S (1:4) (7.10) and T+P (4:1) (8.67). Plants in this medium (sawdust alone) most likely had earlier rooting and longer roots (Table 2). This is supported by Olosunde (2003), that the medium in which a plant is grown do have an effect on the percentage of rooting and quality of root such plants will have. Also, growing and penetrating roots can easily move sawdust aside as it is light (Adeoluwa *et al*., 2014) and such allows the roots movement towards available water and nutrients resulting in longer roots. The heavier or more compact the soil or medium, the more difficult for roots movement resulting in compact and shorter roots. Akinyele (2010) corroborated that using sawdust as the rooting medium resulted in seedlings with longer root lengths compared to those in topsoil as rooting medium. However, it is suggested that in this study, due to lack of adequate nutrients, over time, sawdust alone could not sustain the growth and development of the yellow ficus plants as evident in the plants' poor number of leaves and branches produced, branches length and girth. No significant difference was observed between T+P (4:1) (8.67) and C+S (1:4) (7.10).

All the other media showed similarity in their influence on root development of the yellow ficus plants (Table 2). They include topsoil alone (26.48), S+P+T (1:1:3) (17.81), S+T+C (1:1:3) (11.25) respectively. This shows the degree of their influence in supporting root development, establishment, growth and survival of the yellow ficus plants.

Residual effects

The medium Topsoil alone supported longer root lengths of yellow ficus, 14.31 compared to C+S (1:4) (3.33) and T+P (4:1) (3.00) (Table 2). This could be as result of the sandy loam texture of the topsoil. T+P (4:1)) and C+S (1:4) influence on root length was not significantly different from each other at residual planting.

(ii) Number of branches production in yellow ficus as influenced by growth media at initial planting and the residual effects

At initial planting, there were no significant differences in the influence of the various growth media on the number of branches produced by the yellow ficus cuttings planted in them from the 9WAP to 11WAP in this study (Table 3). However, at 13WAP yellow ficus plants in the medium T+C (4:1) 7.53 produced the highest number of branches, outperforming the other media but closely followed by those in Topsoil alone (6.47), T+P(4:1) (6.25) and S+C+T (1:1:3) (5.58) respectively (Table 3). There was positive and highly significant difference between T+C (4:1) 7.53 and C+S (1:4) 3.83 (Table 3). C+S (1:4) medium least supported branching in yellow ficus under nursery conditions throughout the experiment, closely followed by sawdust alone.

Residual effects

There was no significant media influence on branches production within the 11 weeks of planting. At 13WAP, T+C (4:1) (3.30) highly significantly supported number of branches produced compared with the other growth media but closely followed by S+C+T (1:1:3) (2.73) (Table 3). Plants in sawdust alone (1.50) performed least in branches production. This could be as a result of a low and eventual depletion of nutrient content in the medium over time. The other media were similar in their support for branch production.

(iii) Branch length in yellow ficus as influenced by growth media at initial planting and the residual effects

At 9WAP, no significant difference in the influence of the media on branch length of yellow ficus plants was observed at initial planting (Table 4). However, at 11WAP, S+C+T (1:1:3) and topsoil alone, in a similar manner supported the growth of longest branches in yellow ficus plants. Furthermore, at 13WAP in the same trend, S+C+T (1:1:3) (6.72) supported longest branch length in yellow ficus in comparison with sawdust alone (2.92) medium. C+S (1:4) 3.40, and sawdust alone (2.92) significantly least supported branch length increase throughout this study.

Residual effects

No significant difference was observed on influence of the planting media on branch lengths of yellow ficus seedlings (Table 4).

(iv) Branch girth in yellow ficus as influenced by growth media at initial planting and the residual effects

At initial planting, positive highly significant difference in C+S (1:4) (1.00), influence on branch girth compared with the media S+P+T (1:1:3) (0.29) and T+P (4:1) (0.26) which show similarity in their influence on yellow ficus under nursery conditions was observed (Table 5). No significant difference observed in S+C+T (1:1:3) (0.18), topsoil alone (0.16), T+C (4:1) (0.16) and sawdust alone (0.15) support for branch girth (Table 5).

Residual effects

In the residual studies, S+C+T (1:1:3) (0.15) highly significantly supported branch girth of yellow ficus plants and were wider than those in T+C (4:1) (0.12) (Table 5). C+S (1:4) (0.05), S+P+T (1:1:3) (0.06) and T+P (4:1) (0.05) were similar in their influence on branch girths of the yellow ficus plants in them. C+S (1:4) (0.05) and T+C (4:1) (0.12) media were absolutely different in their support for branch girth of yellow ficus plants in them despite they both contained cow dung as a source of nutrients. Medium C+S (1:4) indicated a limitation in available nutrients due to sawdust content compared to the topsoil advantage in medium T+C (4:1) which eventually affects the branch girths development of yellow ficus plants. Also, highly significant difference was observed in influence of S+T+C (1:1:3) (0.15) on branch girths of yellow ficus plants compared with S+P+T (1:1:3) (0.06) despite they both contained cow dung and poultry manure respectively as complementary source of nutrients. This suggest that cured cow dung as constituent of growth media supports yellow ficus growth as earlier reported by Adeoluwa *et al*. (2014). Sawdust alone least supported branch girth in yellow ficus growth under nursery conditions at both plantings.

(v) Leaves production of yellow ficus as influenced by growth media at initial planting and the residual effects

At 3WAP, the medium topsoil alone supported leaves production best in comparison with all the media at initial planting (Table 6). At 7WAP and 11WAP, there was no significant difference in media influence on the number of leaves produced by yellow ficus plants in this study. However, at 9WAP, all media influenced increased number of leaves production and performed similarly except T+P (4:1) (18.08) which supported highest number of leaves production, closely followed by S+C+T (1:1:3), (16.92), Topsoil alone (16.07) and T+C (4:1) (15.40) respectively. The medium sawdust alone least supported yellow ficus leaves production from 7WAP till the termination of the experiment.

At 13WAP, Yellow ficus plants performance in the various media varied as observed in this study (Table 6). The media topsoil alone (27.13) and S+C+T (1:1:3) (26.92) supported greater leaves production though they performed similarly in their support of yellow ficus survival and growth under nursery conditions. There was no significant difference in plant performance between media T+P (4:1) and T+C (4:1) in their influence on leaves production (Table 6). This suggests that either of these media could be used in planting yellow ficus in the nursery. Presence of cow dung or poultry manure in these media will provide nutrients for the plants; as organic materials improve soil structure and aeration thereby making air and water necessary for plants growth, improves water holding capacity (Onemli, 2003), lessens evaporation (Kushwaha *et al*., 2001). Nutrient is made available to the plants in a slow-releasing manner ensuring early rooting and survival of this difficult-to-root plant.

Residual effects

At residual planting, no significant difference on leaves production in yellow ficus seedlings were observed amongst the media at 3WAP, 5WAP and 9WAP in this study. More variations in growth media support for leaves production was observed as the weeks after planting increased. At 7WAP, the media C+S (1:4) (15.67) and S+C+T (1:1:3) (15.00) showed similar influence in their support for leaves production in yellow ficus seedlings compared with the other media. Sawdust alone support for leaves production was the poorest from 7WAP residual planting till the end of the study. At 11-13WAP, S+C+T (1:1:3), S+P+T (1:1:3), T+C (4:1) and T+P (4 :1) all performed and maintained positively significant support of leaves production in yellow ficus plants planted in them in a similar trend across the weeks. However, at both periods, T+C (4:1) 21.32 and 22.37 at 11WAP and 13WAP respectively, outperformed and were significantly different from all other media in supporting leaves production of yellow ficus plants at residual. It was closely followed by S+C+T (1:1:3) 16.90 and 18.70; C+S (1:4) 16.47 and 16.87 and S+P+T (1:1:3) 14.73 and 16.87 across 11WAP and 13WAP respectively. These aforementioned media (T+C (4:1), S+C+T (1:1:3), T+P (4 :1), S+P+T (1:1:3), and C+S (1:4) compared with topsoil alone indicated the advantage of the presence of poultry manure, cow dung and sawdust in improving soil structure and texture; growth media porosity and aeration. According to Carter (2002), organic matter even in small amounts have effects on the soil/medium physical, chemical and biological properties. The extra source of nutrients and slow-nutrient releasing ability of poultry manure and cow dung in the media ensures availability of the required nutrients to the plants despite the soil was planted in previously. This availability of the required nutrients to the plants gradually will ensure more leaves production which is a vital part in hedge plant growth. Therefore, either of these media could be utilised for production in the nursery for a longer period and for residual use in yellow ficus propagation and growth.

CONCLUSION AND RECOMMENDATION

In conclusion, the media T+C (4:1), S+C+T (1:1:3), S+P+T (1:1:3) and T+P (4 :1) in this order are recommended for residual use in yellow ficus planting at the nursery stage. It is of note that each of these growth media has manure in them. However, cow dung is favored in media mixes for yellow ficus production based on their influence and support of the plants in the nursery and residual plantings. Cow dung which is often plant based will encourage easier rooting and establishment with available nutrients for a longer period.

ABSTRACT
Cashew, Anacardium occidentale, belongs to the Anacardiaceae family of plants. Although, Cashew is a tropical crop of economic importance which is mostly cultivated in many agro-ecological zones in Nigeria. Its growth is majorly hindered right from the nursery as a result of poor depleted soils Hence, the need to evaluate the response of organic fertilizers as an alternative to chemical fertilizer which was carried out in the nursery for cashew seedlings growth. Poultry droppings (PD) and palm kernel cake (PKC) were applied to supply 5kgN/ha and 10kgN/ha to the cashew seedlings. Large cashew nut size was planted into 2.5kg topsoil (0 – 30cm) obtained from Cocoa Research Institute of Nigeria (CRIN) using completely randomized design at three replicates. Data on plant height, stem diameter, leaf area and number of leaves were taken. All data were subjected to analysis of variance using GENSTAT with means separated using LSD values. The results indicated poultry manure and palm kernel cake at four tons/ha significantly (p> 0.05) increased the growth parameters considered at twelve weeks after sowing. It could therefore be concluded that optimal and sustainable growth performance of cashew seedlings can be attained by the use of organic fertilizer materials especially those of rather than total dependence on costly and scarce chemical fertilizers.
***Keywords**: Cashew, palm kernel cake, poultry manure*

INTRODUCTION

Cashew trees are spread throughout the tropics. The cashew tree is easily cultivated and grows with minimum of attention where more than 65% of the farming families who are small holder farmers depends on the crop as a major source of income (CBN, 2005; Aikpokpodion, *et al*., 2009). Cashew is a prime tree crop of economic importance in Nigeria. Cashew is grown majorly for its edible nuts and the oil contained in the shells. Cashew nuts are edible when roasted and used extensively in the confectionery and baking trade.It is an important commodity crop with great potentials as foreign exchange earner and source of industrial raw materials. Cashew production in Nigeria is faced by a number of problems ranging from urbanization, years of abandonments due to poor appleand nut pricingand poor soil. The establishment of cashew is often affected by poor soils (Topper, 2001). Cashew requires fertile soils and needs soil fertility amendmentlike other tree crops for optimum cashew seeding growth andoptimal production of nuts and apples. (Ibiremo, 2008). Tropical soils are highly leached and low in exchangeable bases; N, P, water holding capacity and organic matter. Hence, most of the essential nutrients found in them are below the critical level (Egbe and Chude, 1987) and there is need for amendment. Most farmers cannot afford inorganic fertilizers due to its high cost and scarcity, coupled with its negative effects on the environment therefore the need for research into low cost, internally sourced, cheap and adoptable organic materials that can serve as fertilizer in cashew seedlings. Poultry manure and Palm kernel cake (PKC) are examples of organic materials easily available for use as soil ammendment.

One of the largest and fastest expanding agro-based industries in the world is the poultry sector (Power and Dick, 2000; Kelleher *et al*., 2002; Sharpley *et al*., 2007). Manure usage is an essential component of sustainable agriculture. Poultry manure has been used as a fertilizer in organic crop development for centuries and has long been regarded as one of the most desired natural fertilizers due to its high nitrogen content. (Sloan *et al*; 2003), it has the potential to be recycled on agricultural land. Beneficial usage is based on their ability to improve soil properties such as plant nutrient availability, soil reaction (pH), organic matter content, cation exchange capacity, water holding capacity, and soil tilt. Poultry waste contains all important nutrients, including micronutrients, and has been proven to be an excellent source of plant nutrients. (Kelley *et al*., 1996; Williams *et al*., 1999; Chan *et al*., 2008; Harmel *et al*., 2009). Poultry manure has a high nitrogen and nutrient content. It has been proven that chicken manure contains

1.8% nitrogen, 1.5% phosphate, and a nitrogen-phosphorus-potassium (NPK) ratio of 2:2:1. (Sloan *et al*; 2003).

Palm kernel cake from agro-processing industries is an excellent source of nitrogen (Kolade *et al*., 2006). Palm kernel cake is a significant byproduct derived from the residuals of the monocotyledonous oil palm (Elaeis guineensis Jacq.) (Mohamed *et al*., 2012). In the oil palm sector, 3% the fresh fruit bunch is palm kernel cake, according to Rupani *et al*. (2010). Therefore, programs for soil amendment can employ the use of these nutrients, which are frequently allowed to go to waste. Therefore, the application of PKC could be a method for improving the fertilizer value of manure. This is because oilcakes is known to have higher nutritional contents, specifically nitrogen (5.20% N and 0.77% P), than manure (0.50% N and 0.06% P). (Opoku, 2011). The aim of this research was to assess growth response of Cashew seedlings to applied agricultural waste on a depleted soil in Ibadan.

MATERIALS AND METHODS

The experiment was conducted at the screen house of the Cocoa Research Institutes of Nigeria (CRIN)from 23rd June – 18th September, 2023**.** Composite soil samples was collected within the CRIN premises, which was air dried, crushed and sieved with a 2mm sieve, and thereafter, representative samples of both the soil and the treatment used, were taken to the laboratory for pre-cropping physical and chemical analysis using standard procedures: soil pH was determined in distilled water at soil to water ratio 2:1, total N by Kjedahl method, available P using Bray-P1extraction and molybdenum blue colorimetry, exchangeable K, C. The experiment was arranged in a Completely Randomized Design (CRD). There were five treatments which were: Poultry droppings (PD) at two levels, Palm Kernel Cake (PKC) at two levels, PD+ PKC at two levels and Control and replicated three times to give eighteen experimental units.

Poultry droppings (PD1), Palm Kernel Cake (PKC1) and PD1+PKC1 were measured to supply 10kgN/ha to each 2.5kg polythene, while PD2, PKC2 and PD2+PKC2 were measured to supply 5kgN/ha. Two each of 15kg large cashew nut size gotten from CRIN nursery unit was sown into each treatment including the control. Parameters measured during the experiment were: plant height, number of leaves, stem girth, stem diameter and leaf area at 4, 6, 8, 10 and 12 WAS respectively. Data obtained were subjected to analysis of variance (ANOVA) using GENSTAT and the significant means differences were separated using LSD at 5% level of probability.

RESULTS AND DISCUSSION

Some physical and chemical properties of the soil used for the experiment are presented in Table 1. The soil is slightly acidic (pH 6.3), this falls within the acceptable range of 5.5 -7.5 for tree crops (Egbe *et al*., 1989). The total N, available P, K and Ca values were below the required value for optimum cashew production since they are lower than the critical level determined for cashew in Nigeria (Egbe, *et al*., 1989). The organic carbon content of the soil was low as well. The deficiency of essential macro – nutrient elements of the soil suggest that the soil will require the use of soil amendments for better crop performance. The use of organic materials in form of poultry manure and palm kernel cake however will help increase the nutrient content of the soil since they are rich in both micro and macro nutrient elements (Table 1). Poultry manure (PD1) gave the highest plant height at twelve weeks after sowing compared with other treatments sources used in this experiment and this was significantly different from the other treatments (Table 2). Number of leaves in the soil amended with PD1 was significantly higher than the control (Table 3). Stem diameter was highest in PKC_1, this was closely followed by PD_1+PKC_1, though only PKC_1 was significantly higher than the control at twelve weeks after sowing (Table 4). These results were consistent with the earlier works of Adeniyan and Ojeniyi (2005) and Akanbi *et al*, 2013 who reported that organic manure improved the growth performance of cashew seedlings significantly. Table 5 shows that PD_1 and PKC_1 gave the highest leaf area which were significantly higher than the control.

CONCLUSION

It can be deduced from the studies that poultry manure (PD) performed better than PKC and can be used alone or in combination with PKC for cashew seedling production. Also, the study could be extended to six months to ensure proper mineralization of the organic materials.

ASSESSMENT OF SOIL FERTILITY STATUS OF SOME SELECTED KOLA PLANTATIONS IN OSUN STATE, NIGERIA

Taiwo N., Adebowale L.A and Akanbi O. S. O.
Cocoa Research Institute of Nigeria (CRIN), P.M.B 5244 Ibadan. Oyo state

Corresponding author: nnennataiwo@gmail.com

ABSTRACT
The study was carried out to evaluate the soil fertility status of some selected kola plantations in Osun state so as to improve the productivity. Ten core soil samples at 0-15cm and 15-30cm depth were randomly collected in each plantation using soil auger and bulked into composite samples to obtain representative soil samples. The soil samples were air dried, sieved through 2mm sieve and some physico- chemical properties were determined following standard laboratory technique. Results showed that the pH of the soil ranged from 6.60- 6.90 in Ife south L.G.A and it was 6.4-6.5 at Odo- Otin L.G.A. Soil organic carbon was moderate and Nitrogen contents were low compared to critical level .While the soil exchangeable cations (K+, Ca, Mg) and Available Phosphorous were found adequate for optimal kola production in Nigeria.The plantations would need N based fertilizer augmentation for sustainable kola production.
Keywords*: Soil fertility, Kola, Plantation*

INTRODUCTION
Kolanut is an important economic cash crop to a significant proportion of Nigeria population who are involved in kolanut farming, trading and Industrial utilization. There is also increase in demand for its usage in pharmaceutical industries and for production of soft drinks, wines and candles. Its uses have inevitably created a high demand in excess of its production (Oladokun 1985). While the demand is rising, Nigeria Kolanut production remains low because many of the trees are unfruitful and have very low yield due to the old age, incompatibility and soil nutrient depletion. The removal of essential plant nutrient through kola pod harvesting over a long period without any nutrient addition to kola farms have also led toa steady decline in yield. Tree crop farming in Nigeria has been based on the exploitation of fertility build up by the forest. It is, however, important to note that nutrient are removed annually from the farm through crop harvests. The calculated amounts of N, P, K removed from one hectare of kola soil per year were 130.9kgN, 10.3KgP and 138.74kgk respectively through harvesting of pods (Ayodele, 1989). There is a need to increase plantation acreage and nut yield per tree. These can be achieved through detailed study of existing conditions of the farms (Adebowale *et al*, 2021). Ndagi 2012, Adebowale and Odesanya 2015, observed that old kola nut trees need adequate soil amendment as a result of nutrient mining through harvesting of kola pod without replacement via fertilizer application. Therefore, the objective of this study was to investigate the soil nutrient fertility status of kola plantation in some selected local government area of Osun State to improve kola productivity.

MATERIALS AND METHODS
Soil samples were collected from kola plantations in two local government areas of Osun State namely (Ife south and Odo Otin L.G.A). In each of the plantations visited ten core soil samples at 0-15cm and 15-30cm depth were randomly collected using soil auger and bulked into composite samples to obtain the representative soil samples for each kola plantation. The labelled samples were brought to the laboratory for processing and analysis. The soil samples were air dried, sieved through 2mm sieve and some physical and chemical properties determined following standard procedure (IITA, 1979).

RESULTS AND DISCUSSION
Particle size and pH
Table 1 and 2 indicates the results of soil analysis for both locations selected in Osun State. The results showed that the sand, clay and silt contents at 0-15cm depth were 672.2g/kg, 212g/kg and 112.8g/kg respectively at Ife South L.G.A while at Odo Otin L.G.A, the sand, clay and silt contents were 695.2g/kg, 172g/kg and132.8g/kgsoil. At 15-30cm depth the values were695.2g/kg, 172g/kg and 122.8g/kg sand, clay and silt at Ife south while 675.2g/kg, 192g/kg and 132.8g/kg were recorded at Odo Otin L.G.A. This

observation similar with results of Adebowale et ai,2021, who reported that soil values decreased with depth at Odo Otin L.G.A. Meanwhile it was opposite side at Ife South L.G.A. The soil of both site evaluated is texturally classified as sandy loam. The soil pH ranged from 6.6 -6.9 with a mean value of 6.8 at Ife South L.G.A and 6.4 -6.5 with a mean value of 6.45 at Odo Otin L.G.A respectively. The soil pH values of both locations evaluated fall within the range required for optimal kola production.

Organic Carbon (OC)

The soil organic carbon contents at 0-15 cm depth in Ife south LGA ranged from 14.8g/kg and 21g/kg with an average value of 17.9kg/soil while it was 9.3g/kg to 21.1g/kg with a mean value of 15.2g/kg at Odo Otin L.G.A. The organic carbon content was 21g/kg and 21.2kg/g at both locations assessed. The value is moderate however it is below the critical level of 30g/kg required for kola production in Nigeria (Egbe *et al*1, 1989). The soil organic carbon contents decreased down the soil profile. The higher organic matter content at the upper depth (0-15cm) may be attributed to accumulation and decomposition of large amount of leaf litters falls over the years (Iloyanomon and Ogunlade, 2011).

Total Nitrogen (N)

The soil nitrogen contents at the upper depth (0-15cm) for both locations assess ranged from 0.7g/kg to 0.8g/kg with an average value of 0.75g/kg in Ife South and 1.0-1.5g/kg with average an value of 1.25g/kg in Odo Otin L.G.A respectively. These values obtained fall below the critical value of 10g/kg soil required for sustainable kola production in Nigeria as reported by (Egbe *et al*,1989). The N contents decrease with increase in depth with higher N found at Odo Otin soil (1.5g/kg) compared to N at Ife south (0.8g/kg) soil. Therefore, there will be need for N application in all kola plantation evaluated in Osun State.

Available Phosphorous

The soil available phosphorous contents were higher at the topsoil(0-15cm) with a value of 15.17mg/kgP at Ife South and 19.11mg/kgP in Odo Otin soil respectively. Soil available P contents of the study area were adequate and well above the critical level of 6.0mg/kg required for kola production (Egbe *et al*,1989). This result is similar to the report of Iloyanomon *et al*, 2011, that high P in the soil as a result of the fast decomposition of the kola leaves. There is no need of phosphorous fertilizer application.

Exchangeable Potassium (K)

The exchangeable potassium (K) in soil contents of the locations was found to be adequate for kola. The upper depth (0-15cm) of the soil in Ife South had 0.13cmol/kg soil, while the soil potassium value at Odo Otin is 0.25cmol/kgsoil. The soil K^+ in Odo Otin L.G.A was higher than the K contents at Ife South. These values obtained were higher than the critical value of 0.12cmol/kg soil as reported by Egbe *et al*, (1989). This could be as a result of possible fixation of potassium in the study site which makes it easier for the roots to absorb nutrients as reported by Adebowale *et al*, 2021.

Exchangeable Calcium (Ca)

The calcium contents of the soil ranged from 13.28 to 15.46cmol/kg with a mean value of 14.37cmol/kg at Ife South and 12.97- 13.28cmol/kg with a mean value of 13.13cmol/kg at Odo – Otin L.G.A. Ife South recorded the highest calcium with a values of 15.46cmol/kg at 0-15cm depth, while the least value of 12.97cmol/kg was recorded at Odo Otin L.G.A. However, calcium content was higher than the critical level of 0.8cmol/kg required for sustainable kola cultivation as reported by (Egbe *et al*,1989). The calcium contents in Ife South soil decreased with increasing depth.

Exchangeable Magnessium (Mg)

The magnesium contents of the two locations evaluated were found suitable for kola production. Soil Mg contents at the topsoil (0-15cm) in Odo Otin was higher with value of 2.07cmol/kg while the least value 1.03cmol/kg Mg was recorded at Ife South L.G.A. The Mg contents were adequate and well above the critical level of 0.08cmol/kg required for optimal kola production. There is no need for magnesium fertilizer at both locations evaluated. The magnesium contents decreased with increasing depth at both locations. This is in contrast to the report of Adebowale and Odesanya (2012) which observed that there was gross deficiency of Magnesium contents in kola soil at Odogbolu L.G.A in Ogun state.

Sodium (Na)

The Na contents of the soil ranged from 0.89-0.92cmol/kg at Ife South and it was 0.89-0.95cmol/kg in Odo Otin. The mean value of 0.95cmol/kg was recorded in Ife South while a mean value of 0.92cmol/kg was recorded at Odo –Otin L.G.A. The mean Na contents values of both locations assessed were similar with the findings of Adebowale *et al*, 2021.

CONCLUSION

The study was carried out in two local government areas of Osun State (Ife South and Odo Otin L.G.A) to evaluate the soil nutrient status of some selected kola plantations in the areas for optimal kola production. The soil pH in both study locations were suitable for sustainable kola production. Soil organic carbon contents was moderate and total N contents is not adequate for kola cultivation. While soil Available P and exchangeable cations (K, Ca, Mg) were adequate for kola plantations evaluated in both sites. In conclusion, Nitrogen based fertilizer would be required to improve the soil N loss in evaluated site in order to enhance kola productivity and yield**.**

ABSTRACT
A nursery experiment was conducted at Teaching and Research Farm, Federal Polytechnic, Ile-Oluji, to examine the effects of organic soil-less substrates on the performance of two varieties of carrot (Daucus carrota, L): Thelma F1 (SMTH) and Finger F1 (SMFIN). The organic substrates materials (SM) was made up of the following proportions: cocoa pod husk (CPH) 25%, Stone dust (SD) 5%, cocoa dry leaves (CDL) 10%, poultry manure biochar (PMB) 20%, pig biochar (PB) 15% and fallow top soil (FTS) 25%. The materials were milled and made up to 25kg which was allowed to stand for twenty one (21) days in an air tight bag before it was used to fill the seed trays. The experiment consisted of four treatment combinations; SMTH, SMFIN, CTH, and CFIN. The experimental design used is Completely Randomized Design (CRD). Arrangement of the seed trays at the nursery followed space of (3x1) m^2. Twelve (12) plots were used for this factorial experiment with six hundred seedlings (600) representing one treatment combination. The total seedlings used were two thousand four hundred (2,400). Data were collected on growth characters of carrot from twenty (20) plants in each cell given a total of two hundred and forty (240) plants sampled. Data collected were subjected to analysis of variance (ANOVA) while significant treatment means were separated using Least Significance Difference (LSD) test at 5% level of probability using Gentstat software. The result from this investigation confirmed that organic soil-less substrates improved growth characters of cucumber at all stages of the experiment compared to control. The use of this organic package is suggested for carrot farmers in Ile-Oluji, Nigeria.

INTRODUCTION
Soil-less is the practice of growing crops without using soil. The practice is used to control soil related problems emanated from agricultural land use and high price of haulage of top soil in our society (Agbona *et al,* 2023). Some of the soil-less materials that can be use as organic substrates for growing crops are; sawdust, coco peat, peat moss, woodchips, fleece, marc, bark etc. (Agbona *et al*, 2023). The nutritional value of carrot merits special attention. It is a rich source of vitamins A and E. Both hot and sweet carrots contain more vitamin C to prevent flu colds than any other vegetable crop (Bosland and Votava, 2010).

MATERIALS AND METHODS
The experiment was conducted at the nursery site of the Teaching and Research Farm, Federal Polytechnic, Ile-Oluji, Ondo State, between September and December, 2022. The organic waste used for this Research project was sourced from Teaching and Research Farm, Federal Polytechnic, Ile-Oluji, and the seeds from aggro-allied shop located in Akure. The varieties used for the experiment is; Thelma F1and Finger F1 carrot which was placed on a seed sourcer, dressed with dressed seed fungicide and sprinkled with moderate water to give the seeds damp condition for quick germination. (Agbona *et al*, 2020).

Preparation of experimental site, soil-less material & filling of seed trays
The site for the experiment was cleared, and fumigated to prevent insect attack on the seedlings. The seed trays and other necessary equipment needed for the experiment were washed and dried in the sun for three days before the commencement of the experiment. The soil-less materials (cocoa pod husk) CPH, (stone dust) SD, (cocoa dry leaves) CDL, (pig biochar) PB, and (poultry manure biochar) PMB. All were

milled separately and allowed to stay for three days before been mixed together in the ratios below (Agbona *et al*, 2023):

Table 1: soilless materials in different mixing ratios in 25kg bag

S/N	Soilless Materials	Percentage (%)	Mixing ratio	Quantity (Kg)
1	CPH	50	50/100 x 25	12.5
2	SD	5	5/100 x 100	1.25
3	CDL	10	10/100 x 25	2.5
4	PB	20	20/100 x 25	5
5	PMB	15	15/100 x 25	3.75
	Total			25

The materials were later allowed to stay in a mildly perforated rice bag covered completely for 21 days. This is to allow all the micro-organisms in the materials to mix and react together. Later, the material gave rise to soilless organic material formulated for this trial experiment. A total of six seed trays were filled with the soilless materials and wetted to field capacity after standing in the bag for 21 days. The seed trays were left to stand for 14 days to allow the micro-organisms full establishment under irrigation for the two weeks. Water was applied every three days for three times before planting of seeds.

Treatments, experimental design and allotted technique

The treatments and the variety of the carrot was replicated three times given a total of nine replications. A set of seed trays contained 200 cells and three trays will give rise to 600 cells for each treatment variety. A total of 20 seedlings was sampled randomly from each seed tray which was arranged in Completely Randomized Design (CRD) in the nursery. For each variety of carrot a total of two hundred and forty (240) seedlings were sampled.

Crop establishment

The carrot seeds were placed on a seed sourcer wetted lightly and planted in the seed trays in the evening and they were placed on two days wetting regime (Oyewusi *et al*, 2020). The seed trays were later arranged in their respective plots for the commencement of the research.

Other agronomic practices

Watering was done twice a week throughout the period of the experiment. Weeds were controlled through the hand picking. Kaocide was used to control leaf rot, a fungus and nematicide for soiless materials treatment before planting.

Growth parameters measured

The parameters measured in the course of this experiment are; Germination count, germination percentage, plant height, numbers of leaves, stem girth, fresh shoot weight, fresh root weight and total biomas. Others include total water utilization and dry matter yield of pepper.

Chemical analysis of the soil.

Soil samples were collected from the field using soil auger. The soil was sieved with 2mm sieved range before being subjected to laboratory analysis. The samples were collected and analyzed for routine chemical analysis as described by Carter (1993). The samples were air dried and sieved using a 2mm sieve before making the determinations. Soil organic matter was determined by the procedure of Walkley and Black using the dichromate wet oxidation method (Nelson and Sommers, 1996)., total N was determined by micro-Kjeldahl digestion method (Bremner, 1996)., Available P was determined by Bray-1 extraction followed by molybdenum blue colorimetry (Frank *et al*, 1998). Exchangeable K, Ca, Mg were extracted using 1.0N ammonium acetate. Thereafter, K was determined using a flame photometer and Ca Mg were determined by EDTA titration method (Hendershot and Lalande, 1993). The pH was determined in water (1/2) medium using the digital electronic pH meter.

Statistical analysis

Data collected were subjected to analysis of variance (ANOVA) while significant treatment means were separated using the Least Significance Difference (LSD) test at 5% level of probability using Genstat software.

RESULTS AND DISCUSSION

Chemical composition of the soilless materials

Samples of the six soilless materials used for the purpose of this experiment were taken and analysed as presented in the tables 2 and 3. On table 2, chemical composition of the substrates that made up the soilless package shows that the components contained the needed nutrients such as: N, P, Na, Ca, Mg, %C, N that is higher in values than the composition of top soil and sand stone powder on table 3 and 4.The pH of the soil-less growth media is 5.57 in value which is considerably good for vegetable production.

Table 2: Chemical composition of the soil-less materials

Effects of soilless organic growth media on growth parameters of carrot in the nursery.

Tables 5,6, and 7 shows the effects of soilless organic growth media on carrot's growth characters in the nursery. The effects on plant height, and stem girth were all significant at all the stages of the experiment. This may be as a result of moderate nitrogen value of 1.65 (Table 3) of the substrates. However, number of leaves was not significant as a result of slow nature of the plant to produce leaves. But in all the stages of the experiment, Finger F1 variety performed better than Thelma variety in terms of plant height, numbers of leaves and stem girth. (fig. 2,3,4 and 5).

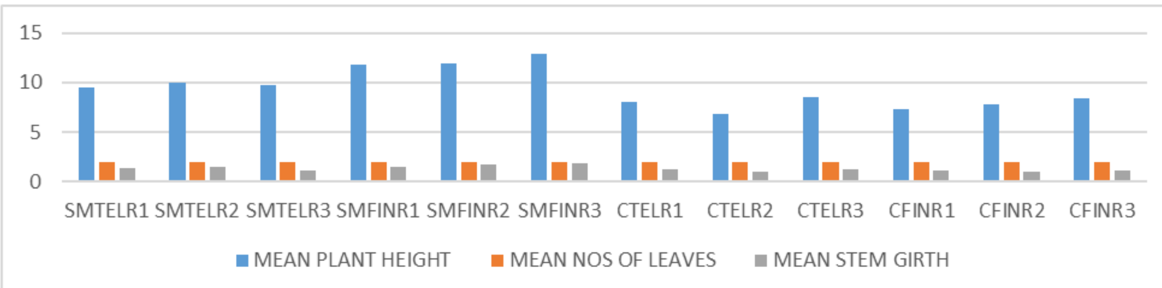

Fig. 4: Bar chart showing the effects of soilless organic growing media on growth parameters of carrot in the nursery at 23 days after planting.

EFFECTS OF ORGANIC SOILLESS GROWTH MEDIA ON YEILD COMPONENTS OF CARROT.

The experiment was terminated at 30 days after planting and the results obtained shows that Thelma variety performed better than Finger F1 variety. (Fig.5). This may be as a result of fast and high germination count and percentages recorded for the varieties grown on the growth media 9 days after planting.

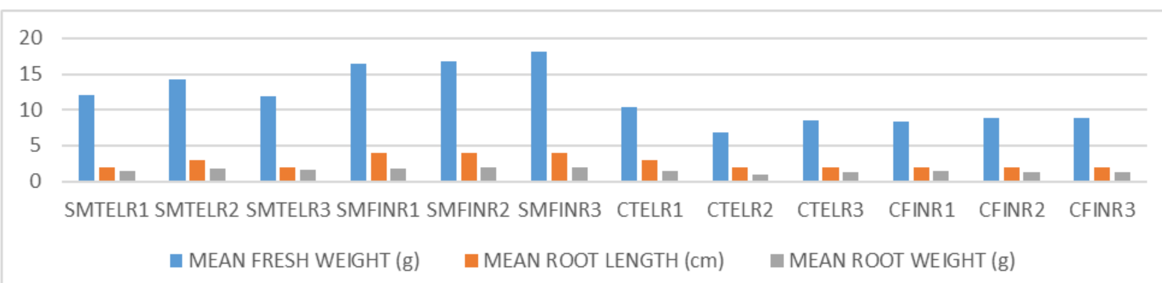

Fig. 5: Bar chart showing effects of soilless organic growth media on yield components of carrot at termination stage 30 days after planting

CONCLUSION AND RECOMMENDATION

The results obtained from this project affirmed the fact that soil-less organic growth media improved growth and yield component of carrot. In all, Finger F1 variety performed better than Thelma variety. It is therefore recommended that soil-less organic growth media with the proportions used in this experiment (Table 1) is good for raising Finger F1 carrot variety in the nursery in Ile-Oluji this was in line with the increase in performance of tomatoe raised on soil-less materials in the nursery.

ABSTRACT

African eggplant (*Solanum aethiopicum*) is known for its multiple purpose as the fruits can be consumed raw or prepared as sauce; and the leaf as vegetable and it is also a good source of mineral nutrients. Despite this socio-economic importance, there is paucity of information on the genetic diversities of its species thereby creating gaps in selection and adoption for scientific research. Thirty-three accessions of African eggplant were evaluated for qualitative and quantitative traits to provide necessary information for genetic improvement most especially on earliness in fruiting and yield for this important but less utilized fruit vegetable. The experimental design was Randomized Complete Block Design (RCBD) in triplicates. Variability of studied traits was evaluated by Analysis of Variance (ANOVA) which revealed significant differences ($p < 0.05$) among the accessions for all the traits studied. Nhep2101 exhibited highest number of branches (7.26) and Nhep2142 gave the least (3.50). Number of fruits per cluster was highest in Nhep2115 (6.17) and the least was recorded in Nhep2142 (1.83). The highest number of harvested fruits were observed in Nhep2123 (113.67) while the lowest number of fruits was recorded in Nhep2142 with 20 fruits. Accessions Nhep2104, Nhep2110 and Nhep2115 were ranked as the top three superior accessions useful in breeding for earliness while accessions Nhep2123, Nhep2124 and Nhep2121 will give more income to farmers by weight. The wide range of variations observed could be a good tool when making selection in future breeding programme for desired traits and farmers adoption.
Keywords: Accession, Agronomic diversity, *Solanum aethiopicum*, African eggplant

INTRODUCTION

The genus Solanum belongs to the family Solanaceae which is a large family that has been the source of many morphologically different domesticated species (Sharmin *et al*., 2011). Out of about 2300 species that have been identified in the family, nearly one-half of them belongs to the genus Solanum according to Agnieszka *et al*., (2007) who reported detailed taxonomic audit of the genus Solanum. The common name 'eggplant' encompasses three closely related cultivated species endemic to Africa, belonging to the genus Solanum L., subgenus Leptostemonum (Dunal) Bitter. Two sections exist in this subgenus namely: Section Melongena and Section Oliganthes. Section Melongena comprises two species which include *S. melongina* and *S. macrocarpon* while Section oliganthes has only one species named *S. aethiopicum*. This species is further grouped into different ecotypes which are Aculetum, Gilo, Kumba and Shum group as revealed by similarities in genotypic characterization through varied phenotypes in existence (Sharmin *et al*., 2011).

Some authors, however, have argued that the four groups in *S. aethiopicum* be treated as different species since they all display varied phenotypes and genotypes using a combination molecular marker (Nunome *et al*., 2003; Sifau *et al*., 2014). Apart from the four species mentioned above, taxonomists have also identified and reported other Solanum species including *S. incanum, S. scabrum, S. dasyphyllum* and *S. erianthum* (Agniezka *et al*., 2007; Osei *et al*., 2010; Aguoru *et al*., 2015; Mariola *et al*., 2014; Sifau *et al*., 2014) while many species are yet to be identified, named and classified systematically (Agniezka *et al*., 2007). The various species are known for their ethnobotanical uses most especially as food and trado-medicine. The African eggplant (*S. aethiopicum* L.) is the third most consumed fruit vegetable in tropical Africa after tomato and onion both in quantity and value and this is followed by okra. The high nutritive value of the leaves and the high leave and fruit yield (*S. macrocarpon*), as well as high resistance to pests and diseases make the crop interesting for development (Bonsu *et al*., 1998). Consumer preference for a variety of African eggplant is based on among others such as size, form, colour and taste (sweet or bitter). The leaves, fruits and roots have a variety of medicinal uses (Bukenya-Ziraba *et al*., 2004). *Solanum aethiopicum* are used as a medicine to treat diarrhea, hypertension etc. (Adeniji and Aloyce, 2012).

The selection of many diverse cultivars of African eggplant by small scale farmers as well as existence of germplasm collections have not improved breeding activities, instead, the long period of selection by these peasant farmers has resulted in several landraces which gave rise to different traits being exhibited by the crops. This includes earliness, colour, size and sweetness. In essence, the African eggplant has long been neglected by formal crop improvement programmes except in breeding programmes where it is used as a source of specific trait(s). Systematic characterization of African eggplant varieties or lines using morphological traits is needed to fuel breeder's efforts in improving species (AVRDC, 2003). There is therefore the need to characterize *S. aethiopicum* germplasm collected from different eco-geographical zones in Nigeria for the development of a new variety. Despite its socio-economic significance, local genetic varieties of this species are still less known, while the adopted enhanced varieties introduced constitute a serious threat to the local ones (Bationo-Kando *et al*., 2015).

Determination of existence of morphological and yield related traits among the accessions will help in laying foundation for better management, improvement, and germplasm expansion. The objective of this research, therefore, is to investigate the variations that exist among the thirty-three accessions of *S. aethiopicum* and to assess their flowering and yield performance to generate information that will help in breeding new varieties as well as assist in expansion and conservation of the existing germplasm.

MATERIALS AND METHODS

Thirty-three accessions of *Solanum aethiopicum* (African eggplant) were sourced from the genebank of National Horticultural Research Institute (NIHORT) headquarters, Idi-Ishin, Jericho Reservation area, Ibadan, Oyo State for characterization and evaluation of both qualitative and quantitative traits. The experiment was carried out at the Research field of NIHORT, Ibadan, Latitude 7.4028ºN and Longitude 3.8152ºE. Seeds of the African eggplants were sown in seedling trays filled with steam sterilized loamy soil and raised in the screenhouse of Genetic Resources Unit of NIHORT for five weeks. Plants were transplanted to the field using a Randomized Complete Block Design (RCBD) with three replications. The plot size was 2 m^2. The row-to-row distance was 0.6 m and plant-to-plant distance was 0.5 m. Each accession was planted in a separate plot to make 33 plots per replicate and a total of 99 plots with ten plants per plot. Cultural practice of manual weeding was carried out during the experimental period to reduce the competitiveness of soil nutrients between the plants and the weeds and to reduce the insects and rodent infestation during the period. Fertilizer was not added to assess the performance of each accession to utilize optimally available soil nutrients and productivity when planted by resource-constrained farmers. However, Laraforce with active ingredient of Lambda-cyhalothrin was applied at the rate of 20 ml/20L of water as and when due to prevent defoliation as well as cross pollination by insects.

Data collection and analysis

Data were collected from five randomly tagged plants per plot for seven agronomic traits {days to flowering, days to 50% flowering, number of branches per plant, plant height (cm), stem girth (mm), petiole length (mm) and peduncle length (mm); five yield related traits {number of fruits per cluster, number of fruits harvested per plot, weight of fruits harvested per plot, fruit length (mm) and fruit width (mm)} and ten qualitative related traits (stem colour, petiole colour, leaf hairs, sepal colour, fruit colour, fruit shape, fruit position, fruit-end shape, presence/absence of stripes) using IBPGR descriptor (1990).

Statistical analysis

The qualitative data collected were subjected to analysis of variance while significant means were separated using minitab 19 software. Correlation among the quantitative traits were also estimated using Pearson correlation coefficient.

RESULTS AND DISCUSSION

The results of this study showed significant variations for all the observed traits at 5 % ($p < 0.05$) level of probability. This creates a great scope for making selection in future breeding work especially in those areas of interest that will benefit the African eggplant farmers (Table 1). Phenotypic assessment of the accessions revealed that 100 % of the accessions have green stem colour, green petiole colour, green sepal colour, white petals colour, direct fruit position and presence of stripe. Three separate fruit colours were observed among the accessions, 45.45 % white, 9.09 % light green and 45.45 % lemon green. Three different fruit shapes were also observed, and these include oval (51.51 %), long (30.30) and round (18.18 %) while 69.69 % have pointed end shape and 30.30 % flat end shape (Table 2). These results confirm the report of Osei *et al*., 2010 who observed existence of distinct variations among the twenty-eight (28) African eggplants characterized for morphological traits in Tanzania. The number of days to flowering varied from 90.67 to 105.00. The mean for number of branches is 5.45 and the extreme values are 3.50 and 7.27 while the mean for plant height is 53.49 cm and the range varied from 41.17 cm to 74.50 cm (Table 3). The genetic variability exhibited by the accessions is very important for germplasm expansion and breeding advancement and this agrees with the work of Plazas *et al*., 2014 who discovered diversity and variability among different varieties of Solanum studied.

For the earliness, Nhep2104 was the earliest accession which flowered at 91 days followed by Nhep2110 and Nhep2115 at 93 days. Accessions of Nhep2115, Nhep2128 and Nhep2141 had the highest number of fruits per cluster 6 which were not significantly different from one another. The highest number of harvested fruits per plot (114 fruits) was recorded in Nhep2123 followed by Nhep2124 and Nhep2121 with 95 and 94 fruits per plot respectively. In terms of weight of harvested fruits per plot, accession Nhep2150 gave the maximum weight of 2283g followed by Nhep2139 and Nhep2121 with 2166g and 2150g respectively. Variations observed among the studied accessions are tools when making selection for breeding. Nhep2115 flowers early and have highest number of fruits per cluster, therefore, cross between Nhep2115 and Nhep2123 will produce a hybrid for earliness and high yield (Table 4). This result is comparable to what was obtained by Bationo-Kando *et al*., 2015 who reported 68.4 – 94.0 of days to flowering and 1.3 – 5.3 number of fruits among the Solanum aethiopicum studied in Burkina Faso.

Correlation coefficient between pairs of twelve quantitative traits is as shown in Table 5. This is used to show the relationship between variables. There is a significant positive relationship between number of fruits harvested per plot and number of branches per plant, number of fruits per cluster and weight of fruits per plot. Petiole length also exhibited positive correlation with fruit length. High negative correlation was observed between fruit width and number of fruits harvested. Bationo – Kando *et al*., 2015 reported both positive and negative correlations among the accessions in their work which is similar to the result of this study. The correlation will help to facilitate identification of reliable traits during selection by breeders.

CONCLUSION

The study showed a high level of variability among the traits studied. The variations exhibited among all the accessions was a useful tool when making selection based on those traits for advancement in future breeding programmes for a particular trait. Accessions, Nhep2104, Nhep2110 and Nhep2115 are to be considered for early flowering while accessions, Nhep2123, Nhep2124 and Nhep2121 were high yielders with relation to numbers of harvested fruits per plot. Hybridization between these accessions especially, Nhep2123 and any of the early flowering accessions will give a high yield and better income for farmers. However, there is need to engage our farmers in participatory varietal selection to give an output of their desire.

PRELIMINARY FIELD EVALUATION OF PASSION FRUIT LINES FOR AGRONOMIC PERFORMANCE AND DISEASE EXPRESSION

Ajose, T.E., Matthew, J.O., Fajinmi, O.B. and Arogundade, O.*
Fruits Research Programme, National Horticultural Research Institute, Ibadan, Nigeria.

*Corresponding author: arogundade_olawale@yahoo.co.uk

ABSTRACT
Passion fruit industry is gradually growing in Nigeria. To this effect, there is need to assess the available germplasm of the crop in a natural open-field environment to determine the productivity potential of each genotype and identify prevalent diseases causing significant damage to the crop. Four Passion fruit lines (LY, PK, WR and YK) were assessed. Line PK was consistently inferior in terms of agronomic performance to lines LY and YK, which are promising. A fungal pathogen (Sclerotia rolfsii), causing damage to the fruit was identified macro-and micro-scopically.

INTRODUCTION

Passion fruit plant (Passiflora spp.), belonging to the family Passifloraceae, is an important woody vine grown in the tropics and subtropics, partly for fresh consumption and more importantly for industrial production of juice, jelly and ice cream (Samyor *et al*., 2020). Passion fruit juice, in addition to its characteristic aroma and flavour, serves as a good source of vitamins, proteins and minerals like K, Ca, P, Fe, Na, Mg, S and Cl (Appleby, 2014). The seed contains piceatannol and Scirpusin B which have strong antioxidant activity that promotes cardiovascular health benefits (Sano *et al*., 2011). Among the diverse species of Passion fruit from which several genotypes are usually obtainable (Nobrega *et al*., 2022), Passiflora edulis Sims (purple) and Passiflora edulis f. flavicarpa Deg. (yellow) are well known and edible. In Nigeria, recent research works have focused extensively on boosting the productivity potential of the crop in an organic system. Ndukwe *et al* (2021) worked on the effect of poultry manure application rate, time and method on the growth and yield of 1-2 genotypes of yellow passion fruit. Similarly, Joseph-Adekunle *et al* (2022) assessed the effect of varied application rates of an organic fertilizer on a genotype of yellow passion fruit. However, there are scarce reports of studies on assessment of performance of several genotypes of Passion fruit simultaneously in the country.

The major aim of evaluating several genotypes of a crop species is to precisely predict future performance (Smith *et al*., 2002). Vilela *et al*. (2022) studied the performance of 32 genotypes of sour passion fruit, identifying the promising lines for productivity, fresh consumption and industrial purpose. The assessment of numerous genetic materials in a specific environment provides information about the adaptability and stability of the concerned material as well as resistance to stress factors, especially biotic (Forster *et al*., 2013). Unlike in temperate region where crops are minimally attacked by diseases, the principal constraint to sustainable productivity of passion fruit tree in the tropics and subtropics is multiple disease infestation (Amata *et al*., 2009). Diseases in the root system and aerial part of the plant, resulting from the presence of fungal, bacterial and viral pathogens are common, causing premature death, defoliation, delayed fruiting, low pulp yield and decreased quality, which has implication for economic losses (Cerqueira-Silva *et al*., 2015). Hence, this research work was carried out to understudy the agronomic performance of four lines of Passion fruit and accurately identify diseases affecting the crop in a natural field environment of National Horticultural Research Institute, Ibadan, situated in South-West, Nigeria.

METHODOLOGY

The experiment was carried out in an open field at National Horticultural Research Institute, Ibadan (latitude N7º24ꞌ36.246 and longitude E3º50ꞌ492ꞌꞌ) between 2020 and 2021.

Seed Propagation

A total of four passion fruit cultivars, including three from Kenya and one from Nigeria were used in this study. These cultivars are Yellow Kenya (YK), Pink Kenya (PK) and Wilt Resistance (WR) from Kenya and a Local Yellow (LY) which is indigenous to Nigeria. Seeds were extracted from matured fruits and thoroughly depulped, after which they were rinsed under tap water and dried at room temperature for 48 hours before they were sown in nursery trays. At 6-leaf stage, seedlings obtained were transplanted into potting bags containing 1.5kg of well drained, sterilized sandy-loam soil for 1 month and afterwards moved to the field. The experiment was laid out in a Randomised Complete Block Design with 3 replicates. The experimental units were established at 2 m × 2 m spacing on field for evaluation of performance and adaptability of the four lines. Agronomic data and disease expression were observed. Data were collected for 8 months on vine length (VL, cm), vine girth (VG, mm), number of branches and only once for yield (kg). Data collected were analysed using descriptive method.

Collection of infected fruit samples

Passion fruits exhibiting visible disease symptoms were sampled on the field. Infected fruits with characteristic yellowing, soft rot and white mycelial growth were brought to the Pathology laboratory of National Horticultural Research Institute, Ibadan, for mycological study.

Isolation of fungus pathogen from infected fruits

The infected fruits were thoroughly rinsed under a running tap. The affected tissues were cut into pieces of 3-5 mm, surface sterilized in 70% ethanol and then rinsed thrice in sterilized distilled water. The samples were blotted dry using Whatman No 1 filter paper. Potato Dextrose Agar (PDA) was used to culture the fungus pathogen(s). Thirty-nine grammes of the medium was dissolved in 1L of distilled water and sterilized by autoclaving at 1210C and 1.5 psi for 15minutes. The sterilized medium was allowed to cool to temperature between 45-500C and then amended with chloramphenicol (60µg /L). The surface-sterilized fruit tissue sample was then picked using sterilised forceps and placed aseptically on 9mm diameter petri-dishes containing the solidified ammended PDA. Incubation was done at 28±2°C for 3-5 days. Sub-culturing of the fungal mycelium was done till pure culture was obtained. The cultural and microscopic morphology of the isolate was studied for identification.

Pathogenicity Test

Pathogenicity test was done according to Koch's postulate (1890). Healthy, matured Passion fruits were used in this study. Fruit surfaces were sterilized with 70% ethanol and punches made on them with the aid of sterilized cork borer, followed by inoculation with 8mm PDA disk of mycelia of the isolated fungus grown for 5 days. Inoculated fruits were covered with the initially cut off fruit parts and incubated in a dessicator under high relative humidity at room temperature for 3-5 days.

RESULTS

Agronomic and Yield Parameters

The evaluation of the four Passion fruit lines was conducted throughout the production cycle. Overall, the lines were observed to be different in their agronomic performance under field condition. Line LY had the highest vine length at 1MAT, followed by YK and then, WR while PK had the least. This trend continued throughout the period of data collection. The highest vine length data (215.7cm) was obtained at 4 MAT on line LY. From 6MAT, there was no record of line PK any longer. Line PK gave the least vine girth from 1-5MAT while line WR consistently ranked third from 1-7MAT. At 1MAT, line YK had the highest vine girth, followed by line LY, and then, WR. At 2-7 MAT, line LY had the highest vine girth, followed by line YK, then WR. At 8MAT, line LY had higher vine length than YK.

Line PK consistently gave the lowest no of branches from 1 to 5MAT while at 3 to 7MAT, WR ranked third with respect to number of branches. At 1MAT, line YK and WR had the highest number of branches, which was followed by line LY. At 2MAT, line YK and LY had the highest number of branches, followed by line WR. At 3-4MAT, line LY had the highest number of branches, followed by line YK and then WR. At 5-7MAT, line YK had the highest number of branches, followed by line LY and then, WR. Yield obtained at harvest for Line YK and LY were 157 g and 165 g respectively while fruits were not recovered from lines PK and WR because they were lost before the end of the season.

Identification of the isolated fungus and Pathogenicity test

The isolated fungus was identified as *Sclerotium. rolfsii* using both cultural and microscopic features according to Barnett and Hunter (1972). The fungal mycelium obtained from infected Passion fruit was first white in colour (Plate A) and afterwards, brown with the presence of bead-like structures (Sclerotia) (Plate B). Hyphae were observed to be hyaline, branched, septate and have clamps. Pathogenicity test revealed that *S. rolfsii* produced the same symptoms, initially observed on infected passion fruit collected from the field. Fruit soft rot and white mycelial growth were observed on inoculated fruits while the uninoculated were healthy, showing no visible disease symptoms.

DISCUSSION

Productivity is an important attribute for selecting genotypes of a crop species for cultivation, whether in organic or conventional farming system (Kokare *et al*., 2014). Passion fruit productivity is considered to be generally low. This has been attributed to many factors, including the cultivation of inappropriate cultivar, genetics of the planting material, biotic stresses and environmental factors (Nogueira 2016; Faleiro *et al*. 2011). This has necessitated research works aimed at selection of superior lines targeted at meeting pre-determined need of end-users. Increased productivity, good fruit quality and resistance to diseases are some of the important traits that passion fruit breeding programs address most times.

In open field cultivation system, evaluation of planting lines for agronomic performance in the scenario of biotic stresses is necessary. Line PK, though in the same environment as lines LY and YK, performed poorly throughout the period of the experiment, with respect to the agronomic parameters evaluated. There are reports of Purple passion fruit, to which Line PK belong, being more vulnerable to diseases and losses eventually (Mwirigi *et al*., 2016). The seemingly good performance of line LY could be a function of adaptive advantage, having been cultivated over the years in Nigeria. Moreira *et al*. (2018) similarly identified two inferior and three superior genotypes with respect to productivity while evaluating some Passion fruit lines. *Sclerotium rolfsii* has diverse host range of more than 500 plants in the tropical, subtropical and warm temperate areas (Wydra, 1996). The sclerotia constitute the primary inoculum of the pathogen and major means of dispersal. Through them, the fungus survives adverse environmental conditions (Okereke and Wokocha, 2007). Management strategies such as crop rotation, weed control and soil processing should be employed against infection of *S. rolfsii* on passion fruit plantation in NIHORT environ.

ABSTRACT
Persea americana M. (Family: Lauraceae) grown in tropical and subtropical areas, has several health-related phytonutrients properties including antioxidant, anti-cancer, anti-inflammatory, and anti-neurogenerative effects. Additionally, it contains vitamin C, which helps to boost the immune system and promote healthy skin. In this study, the antioxidant potential of the absolute (100%) and aqueous (80%, 80:20 v/v) methanol extracts of seeds of Persea americana Mills was examined through three models using 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical scavenging assay, FRAP, and TAC. The total phenolic contents of the methanol extracts ranged between 2.36 ± 0.01 to 2.89 ± 0.05 mg GAE/g. The results of total flavonoid contents of the seed extracts ranged from 19.22 ± 0.14 to 70.34 ± 0.62 mg CE/g. Furthermore, the absolute methanolic seed extracts were able to scavenge the DPPH assay than the aqueous methanol extracts. Also, as the concentration of the methanolic seed extracts increases, the results present an increase in the absorbance value of the reducing power assay (FRAP). The absolute methanol extracts of seeds of Persea americana showed the highest value of total phenols, flavonoids and most significant antioxidant activities. Therefore, this study demonstrated that methanolic extracts from avocado seeds are a good source of bioactive components that implement antioxidant properties.

INTRODUCTION
Free radicals are highly reactive and unstable molecules which are produced spontaneously by the body as a result of normal metabolism. Free radicals can accumulate in cells and harm other molecules like DNA, lipids, and proteins (Martemucci *et al*., 2022). This damage may raise the likelihood of developing cancer and other disorders. When there is an accumulation of excessive free radicals in the body, it generates a phenomenon known as oxidative stress. Excess free radicals can cause a variety of illnesses and cell damage (Tsatsakis *et al*., 2019). However, in small-moderate amounts, free radicals aid in the proper functioning of the body and the regulation of cell processes (Sharifi-Rad *et al*., 2020). Free radicals are majorly caused by external factors such as radiation, excessive smoke, industrial pollutants, and ozone. Antioxidants are essential for neutralizing the effects of free radicals and oxidants as well as reducing the risk of degenerative diseases (Rahman *et al*., 2022).
The avocado seed is a natural antioxidant with high nutritional content and bioactive substances such as fibre, phenolic compounds, vitamins C and E, and carotenoids that benefit human health (Siol & Sadowska, 2023). It has phytonutrients and antioxidants, such as vitamin C, that can strengthen immunity (Lyu *et al*., 2023) and have digestive benefits for treating ulcers and diarrhoea brought on by intestinal parasites. In addition to other medical uses, it is used to treat skin eruptions, dry skin, swelling brought on by inflammation, and other health conditions. Avocado seed contains phytochemical compounds with hydroxybenzoic acid that play antioxidant activity. Furthermore, avocado seeds, which include active compounds such as flavonoids, phenolics, tannins, and alkaloids, are the main source of antioxidant activity. Therefore, the objectives of this research were to examine the avocado seed extract's potential as a source of antioxidant activities, total phenol (TP), and total flavonoid (TF).

MATERIALS AND METHODS
Preparation of avocado seed extract
The fresh, dark avocado fruits were purchased from NIHORT Farm. Extract preparation starts at the sampling stage by separating the seed from the fruit pulp, peeling off the flesh and removing the pulp.

The seed was washed and cleaned with water, cut into pieces, dried in a place not exposed to direct sunlight, and then ground to powder and sieved to obtain fine particles. The seed powder was defatted with n-hexane in a soxhlet extractor and dried. Extracts were made by weighing 10 g of the powdered sample into 100 mL of solvents (100% methanol and 80% methanol) in different maceration containers. The mixture was stirred occasionally in the maceration container for 12 h at room temperature. It was then filtered using Whatman No 4 filter paper to separate the filtrate and residues. The residues were re-extracted with the same amount of 100% and 80% methanol as the solvent; re-extraction ended when the filtrate was clear. The filtrate was then evaporated using a rotary evaporator, dried, and weighed using an analytical scale.

Determination of total phenol and total flavonoid

Total phenol content was measured according to David *et al*. (2022) with minor modifications. The results were expressed as mg of gallic acid equivalents (GAE) per gram of sample ($R^2 = 0.9995$) using a spectrometer (T80 Series UV/Vis Double Beam Spectrophotometer, PG Instruments Ltd). The total flavonoid was determined by using the aluminium chloride method of Turco *et al*. (2016) with modifications. The results were expressed as mg of catechin equivalents (CE) per gram of sample ($R^2 = 0.9998$).

Antioxidant assay

The DPPH scavenging assay was performed according to Fadly *et al*. (2020) with minor modifications. The FRAP assay was estimated using the method of Vijayalakshmi & Ruckmani, (2016) with some modifications. A modified method by Elkhamlichi *et al*. (2017) was used to determine the total antioxidant capacity assay using the phosphomolybdenum method with modifications.

Statistical analysis

All analyses were done in duplicates, and data obtained from the results were processed and then analyzed statistically using SPSS (Statistical Package for Social Sciences).

RESULTS AND DISCUSSION

The results of total phenol and total flavonoid contents carried out *in vitro* were determined for 100% and 80% methanol extracts of seeds of *Persea americana* Mill are presented in Table 1. The total phenolic contents in different extracts expressed as mg gallic acid equivalents (GAE) per gram of extract, varied between 2.36 ± 0.01 to 2.89 ± 0.05 mg GAE/g. The highest phenolic contents were found in 100% methanol extracts (with 1 mg/mL extract concentration). Then, the total flavonoid contents values also tend to be at the same level as total phenolic contents. That is, the total flavonoid contents of 100% methanolic seed extracts were notably higher than 80% seed extracts. The results of total flavonoid contents determination of the examined seed extracts (in different extracts) ranged from 19.22 ± 0.14 to 70.34 ± 0.62 mg CE/g. The 100% methanolic seed extract had the highest value with 70.34 ± 0.62 (with 1 mg/mL extract concentration) which is in line with that reported by Folasade *et al*. (2016). Phytochemical substances such as phenols and flavonoids act as free radicals scavengers and serve as inhibitors to enzymatic reactions within the body (Mbinda & Musangi, 2019). Therefore, flavonoids which are considered a strong antioxidant found to be effective against a variety of ailments and other cardiovascular diseases, are actively present in various parts of avocado fruit.

Table 1: Total phenol and Total flavonoid contents of methanolic extracts of avocado seeds

Parameter	Results	
	100%	**80%**
Total phenol (mg GAE/g extract)	2.89 ± 0.05	2.36 ± 0.01
Total flavonoid (mg CE/g extract)	70.34 ± 0.62	19.22 ± 0.14

DPPH radical scavenging assay

The DPPH radical scavenging assay is shown in Fig.1. The absolute solvent extracts revealed stronger scavenging activity than the aqueous solvent extracts; also, as the concentration of the seed extracts increases at wavelength, λ = 517 nm, the activity increases. DPPH is an antioxidant assay that measures an antioxidant's ability to scavenge a stable radical. This stable free radical has an odd electron and absorbs strongly between 515 and 528 nm. When DPPH reacts with an antioxidant, it absorbs an electron from the antioxidant scavenger molecule, making the DPPH molecule more stable. At room temperature, this stable radical is decreased and decolourized from purple to pale yellow (Rahman *et al*., 2015). The 100% methanolic seed extracts showed great antioxidant activity, being able to scavenge more than 80%

of the DPPH radical assay at a concentration of 1000 µg/mL which displayed the highest activity than 80% methanolic seed extracts.

Ferric Reducing Antioxidant Power (FRAP)

The FRAP antioxidant assay is based on the reduction and inactivation of oxidation, and this can be described as redox reactions (which involve electron transfer between two species). The principle of reducing power assay is based on the ability to reduce ferric cyanide (Fe^{3+}) to form a ferrocyanide (Fe^{2+}) complex under low pH conditions in the presence of sample extract (Irshad *et al*., 2012). Fig. 1 presents the reducing abilities of the avocado extracts. The reducing power of seed extracts measured for the concentration from 0.25 to 1 mg/mL showed a general increase as the concentration of extracts gradually increased.

Total Antioxidant Capacity (TAC)

The TAC assay is presented in Fig 1. The phosphomolybdenum assay was used for total antioxidant capacity, the assay is based on the reduction of molybdenum (VI) to molybdenum (V) complex by antioxidant, which in turn forms a green solution. From the results, the 100% methanolic extracts have the highest TAC value at a concentration of 1000 µg/mL with 6.63 mg AAE/g, and the lowest was observed in 80% methanolic extracts at a concentration of 250 µg/mL with 1.14 mg AAE/g. Folasade *et al*. (2016) indicated that the total antioxidant capacity for the avocado seed extracts based on different extracting solvents showed the most effective antioxidant activity in the absolute solvents than the aqueous solvent. Furthermore, Alkhalaf *et al*. (2019) reported that avocado seed showed much greater total antioxidant capacity than pulp.

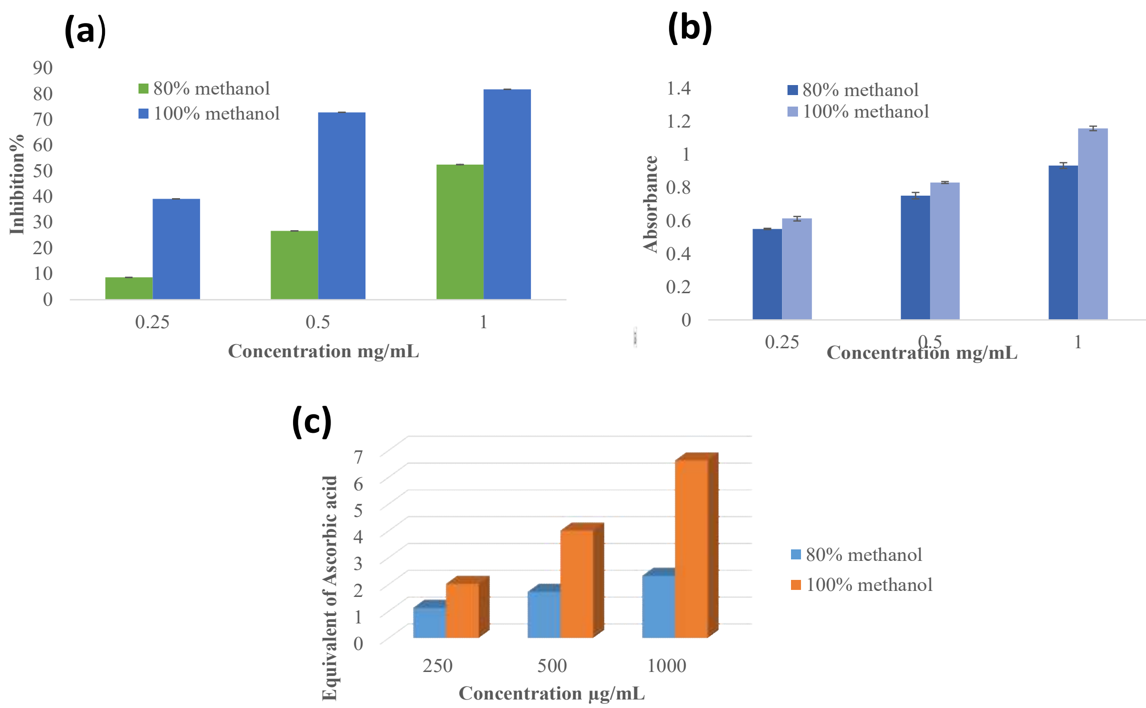

Figure 1: Antioxidant activities of methanol extract from *Persea americana* seeds using **(a)** DPPH assay **(b)** FRAP **(c)** TAC.

CONCLUSIONS

The three models' antioxidant potential (DPPH, FRAP, and TAC) examined in this study with methanolic seeds extracts followed the same trend as the total phenols and total flavonoids with 100% methanolic extracts being the highest in all and showed the highest antioxidant potential. Avocado seeds have significant polyphenol content, which may explain their high antioxidant activity. As a result, avocado fruit seed has been found as a source of phytochemicals that aid in antioxidant activity. More research should be done to develop the drying of avocado seed into tea bags for human consumption rather than being a by-product waste because it has antioxidant, anti-inflammatory, anti-ageing, and anti-cancer properties.

USE OF LIBRARY BY RESEARCHERS IN AN HORTICULTURAL RESEARCH INSTITUTE

***Anjorin, S.O and Fagbola, B. O.**
National Horticultural Research Institute, P.M.B 5432 Ibadan Oyo State

*Corresponding author: anjorinsarah2@gmail.com

ABSTRACT
The library is an important conduit of knowledge and information that gives birth to improvement in research and quality of life. Therefore, it has become imperative for research institutes to pay much attention to the provision of library services to their immediate patrons. However, there is a need to understand the library use patterns and material preferences of the researchers in order to efficiently provide these services. This article employed a collective case study method to study the use of library by researchers in horticultural research institute using the National Institute for Horticultural Research (NIHORT), Ibadan as a case study. The data used for the article was obtained from the daily statistics sheet kept by the library and a time frame between 2019 to 2023 was chosen. The study found that there was a high level of use of library among researchers in NIHORT, which is not abnormal for a research institute. The study also found that the researchers use more of books and journals than other library materials. The article concludes that researchers in NIHORT use the library as frequent as possible and they consult more of print materials. It is therefore recommended that the researchers should be introduced and encouraged to use electronic resources.
Keywords: *Horticultural research, Use of Library, Research institutes, Library resources, Researchers*

INTRODUCTION

A nation's agricultural, economic, scientific, and technological development can be guided in the right direction by agricultural research libraries. Examining how agricultural researchers, particularly those at the horticultural research institute, use libraries has become important at a time when the Federal Government of Nigeria is determined to increase agricultural productivity in the nation. A library is regarded as the hub of all research activities and a necessary component of an effective research system. It serves as a breeding ground for fresh concepts and ideas while also providing an account of earlier intellectual endeavors (Majid, Tamara, and Anwar, 1999). A science and technology institution's research capacity and sophistication can be gauged using the resources and facilities in the library (Gooch, 1994). The primary purpose of agricultural research libraries is to connect groups of students, professors, researchers, and scientists who are committed to exchanging knowledge and cooperating to solve agricultural and scientific problems and make use of available resources. Horticultural libraries may be defined as a collection of knowledge materials, especially books, journals and reports pertaining to horticulture. This collection may be a definite entity as in many agricultural research institutions, or within a larger library collection as in a university library (Aguolu, 2000). The library is essential to advancing scientific and technological research, which has numerous applications in agriculture and subsequently speeds up innovation. For the advancement of agriculture, the economy, society, and science, information is a vital resource.

The government has established a number of agricultural institutes, colleges, and universities over time, many of which have complementary agricultural libraries or collections. This has been done to advance agricultural research, teaching, and study. These institutions and their libraries produce and disseminate agricultural information or knowledge to government policymakers, researchers, teachers, students, farmers, and extension agents. According to Aguolu (200), agricultural data may be encoded or unencoded. The efficient utilization of libraries by researchers in horticultural research institutes plays a pivotal role in advancing scientific knowledge, fostering innovation, and promoting sustainable agricultural practices. However, despite the critical importance of libraries in supporting research endeavors, there is a noticeable gap in our understanding of how researchers in horticultural research institutes utilize library resources and services. This knowledge gap hinders the ability of these institutes to optimize their library facilities, tailor their collections, and enhance the overall research productivity of their staff. The expectations from agricultural libraries to play a major role in the dissemination of knowledge has necessitated a study to first determine the use of library by researchers in horticultural research institutes, using the National Institute for Horticultural Research (NIHORT), Ibadan as a case study.

Research Objectives

The major aim of the study is to examine the use of library by researchers in NIHORT. The specific objectives are to:

i. Examine the frequency of library use by researchers in NIHORT
ii. Investigate the type of library materials consulted by the researchers

Research Questions

i. How frequently do researchers at NIHORT use the library?
ii. What are the types of library materials consulted by researchers in NIHORT?

METHODOLOGY

The case study research design was employed for this study, while the collective case study method was preferred. This is because this method allows the researcher to study a group of people in a certain setting in order to explain their actions and behaviours in order to develop additional ideas and study questions that can be explored in future studies (Cherry, 2022). The population for the study consists of all researchers in the various departments of NIHORT who are users of the institute's library, irrespective of cadre. Only researchers who used the library within the specified period were used for the study. This article relied on data obtained from the daily statistics sheet of the library between year 2019 and 2023. The obtained data was analyzed and the results presented in charts using descriptive statistics.

RESULTS AND DISCUSSION

This study found that the use of library among NIHORT researchers is on the high side (fig. 1), which is expected of a research institute. However, it was observed that the institute library recorded the highest number of users in the year 2019. The study found that a good number of the researchers use the library on a daily basis, with a high number of them using the library at least once in a week. This is somewhat similar to the findings of Mugwisi (2014) that the majority of agricultural researchers in Zimbabwe use the library at least once a month, with those who use the library at least once a week coming closely behind. It however slightly negates the findings of Ezeala and Yusuff (2011) who found that researchers of agricultural research institutes in Nigeria use the library occasionally.

The study also found that the most preferred library materials by the researchers are books (fig 2-4) as they account for the highest number of library materials used monthly by the researchers. This may be an indication that the researchers prefer to seek knowledge from books as a primary source. The study also found journals to be the second preferred library material by the researchers in terms of frequency while reference materials were the least consulted materials. This is in consonance with the findings of Idiku et al. (2022) that print and book materials recorded 64% of library information sources consulted by users of an agricultural research library. It however contradicts the findings of Mugwisi (2014) who found that journals and government publications were the most consulted library materials by researchers in Zimbabwe agricultural research institutes.

CONCLUSION

Researchers are information seekers which makes it imperative for research libraries to provide replete necessary materials that are germane to the researchers in horticultural research institute. Although the study established that researchers use the library frequently and consulted more of books than other library materials, there is a need to sensitize the researchers about other materials and encourage them to use e-resources.

Based on this usage pattern, the institute should allocate enough funds to the library so that it can update its collection with new books and other materials. Additionally, access to cutting edge research resources, which are accessible on numerous local and worldwide internet databases, will motivate researchers to visit the library. This study therefore strongly suggests that libraries in horticultural research institutes should prioritize investments in e-resources, conduct frequent user training and sensitization programs to encourage researchers to use more e-resources for their research, and maximize the quest for knowledge as demonstrated in the use of library materials.

ABSTRACT

This study explores the diverse attributes of three Cucurbita pepo; pumpkin varieties; Casper white, Orangetti and Connecticut field cultivated in the National Horticultural Research Institute, Ibadan Nigeria, aiming to enhance awareness of their nutritional values. Pumpkin belonging to the Cucurbitaceae, are globally cultivated and have various applications based on their unique properties. The study reveals significant differences in colorimetric values, with all varieties tending towards darkness but lacking the typical bright orange hue due to carotenoid content variations. The research revealed that while all three varieties showed similar lightness values (L), the Orangetti variety exhibited the highest carotenoid content, contributing to its hue. Conversely, Casper White with its distinctive pale coloration, displayed the lowest carotenoid concentration. For Brix values, Orangetti was found to be the highest while the other two varieties (Casper white and Connecticut field) had lower Brix values, suggesting potential suitability for diabetic patients due to low sugar content. Additionally, Orangetti and Connecticut Field exhibit stronger DPPH antioxidant activity compared to Casper White, suggesting better potential for neutralizing free radicals. The study enhances understanding of these pumpkin nutritional and culinary potentials, and underscores the importance of considering these diverse pumpkin varieties in aiding informed consumer choices and further research.*

Keywords*: Pumpkin, Carotenoids, Color, Antioxidant activity, Awareness*

INTRODUCTION

Pumpkin (*Cucurbita pepo*) belongs to the family *Cucurbitaceae* and it is grown all over the world, with Cucurbita pepo, Cucurbita moschata, Cucurbita maxima being the most popular ones (Kulczyński *et al.*, 2020). The word pumpkin comes from the Greek word *pepon* meaning "large melon" (Dhiman *et al.*, 2009). They originated in Central America, playing roles in history, mythology, and cuisines worldwide (Kapek., 2022). Today, pumpkins are celebrated in fall festivals, Halloween traditions, and diverse culinary traditions (Kapek., 2022). They are considered among the top 10 vegetables worldwide (Balkaya *et al.*, 2010). Pumpkin (Cucurbita spp.) is one of the cucurbitacous fruit vegetables consumed and relished by most local people in Nigeria and in the sub-Saharan Africa. (Aruah *et al.*, 2012). According to Hussain Dar *et al*, pumpkins are rich in carbohydrates, thus making them a good source of calories. Additionally, it is abundant in ß-carotene, which gives pumpkins their distinctive yellow-orange color, making pumpkins a potential source of vitamin A which the body needs for healthy eyes, normal growth, and disease defense. It also contains a lot of fiber, lycopene, vitamin C, and vitamin E (Blessing *et al.*, 2011). Pumpkins are cultivated on over 3 million hectares worldwide, which yields over 27 million tons annually. China is the world's highest pumpkin producer with about 58% annual production (Hosen *et al,* 2021). The annual production of pumpkin has increased by over 5000 hectares compared to the past two decades according to a study by Wittstruck *et al*, 2020.

East African regions have lower pumpkin production projects due to their large reliance on other staple crops like rice, cassava, maize, sorghum and millet and this has led to lack of attention towards conserving plant genetic materials of other nutritious vegetables like pumpkin which has now resulted in decreased interest among small scale farmers in the production of pumpkin (Immaculate *et al.*, 2019). In Nigeria, a great number of the population are unaware of the nutritional benefits of Cucurbita, instead it is seen as a traditional food mostly for low income earners. This information gap may discourage high income earners and urban-dwellers from including this crop in their diet (Blessing *et al.*, 2011). This research aims to raise awareness of the nutritional values of three (3) different pumpkin varieties cultivated at the National Horticultural Research Institute, Ibadan, Nigeria. This knowledge can help increase awareness and encourage a wider population to include pumpkins in their diet.

Figure 1: Showing pumpkin varieties used A) Casper white B) Orangetti C) Connecticut field

METHODOLOGY

Source of material

Three pumpkin varieties of Cucurbita pepo used in this study were obtained from National Horticultural Research Institute. The pumpkin fruit was washed and peeled to remove the outer layer. The seeds were separated from the flesh and then the flesh was cut into smaller pieces and kept for further analysis.

Colour: Colour determination was carried out using a colourimeter (3NH NR60CP, Shenzhen, China) based on the CIE L*a*b* colour system.

Total carotenoid: The total carotenoid content of the pumpkins was determined using the method by De Carvalho *et al*, 2011.

DPPH Scavenging Activity: The antioxidant activity using DPPH was determined using the method by Baliyan *et al*, 2022.

Brix: Brix determination was carried out using a refractometer (PAL_1 Atago pocket refractometer).

RESULT AND DISCUSSION

Table 1: Shows the color values for three different *Cucurbita Pepo* varieties expressed using the L*a*b* color system.

Variety	L*	a*	b*	c*	Hue
Casper white	35.95 ± 0.48^{b}	1.92 ± 0.11^{a}	1.72 ± 0.74^{a}	2.61 ± 0.56^{a}	40.37 ± 11.34^{a}
Orangetti	36.23 ± 0.19^{b}	3.33 ± 0.45^{b}	2.54 ± 0.06^{ab}	4.20 ± 0.32^{b}	37.59 ± 4.64^{b}
Connecticut field	35.18 ± 0.19^{b}	4.44 ± 0.25^{c}	0.97 ± 0.16^{b}	4.55 ± 0.28^{b}	12.30 ± 1.40^{a}

Colour: The color values are an important parameter when trying to determine the visual quality of any fruit. The colorimetric values (L*, a*, and b*) are standard measurements in food science to understand the color of food products. L* values suggest lightness, with lower values tending towards darkness. The three pumpkin varieties showed no significant differences for L* values. The fact that all three pumpkin varieties displayed similar L* values, tending toward darkness, is intriguing. This result supports the assertion that these varieties lack the dominant orange hue commonly associated with high carotenoid content. Pongjanta *et al.* (2006) observed similar findings in pumpkin powder, emphasizing that not all pumpkin varieties will have the stereotypical bright orange hue. The a* values for all three varieties showed significant difference. The a* values were all positive and tends towards redness. Also, the three varieties were significantly different from each other. For the b* values, Connecticut field was significantly different from Casper white. However, there was no significant difference between Orangetti and Casper white and Connecticut field. For Chroma, variety Orangetti and Connecticut field had no significant difference while Casper white was significantly different. The hue angle values observed in this study were low and range between (12.30-40.37).

Table 2: Total carotenoid content, antioxidant activities and total soluble solid content of three (3) pumpkin varieties.

Variety	Total carotenoid(μg/g)	DPPH (%)	Total Soluble Solid (Brix (°))
Casper white	1.00±0.27^{a}	50.09±0.65^{b}	1.47±0.06^{a}
Orangetti	13.79±0.5^{c}	59.13±0.45^{a}	4.60±0.26^{b}
Connecticut field	8.79±0.16^{b}	59.52±0.91^{a}	2.00±0.43^{a}

Carotenoids: Carotenoid content of the pumpkin varieties observed in this study as showed in Table 2 indicate significant differences in all three varieties. However, highest total carotenoid content was observed in Orangetti as compared to other varieties. The Connecticut Field variety showcases a moderate level of carotenoids. Although this is lower than that of Orangetti, is considerably higher than Casper White's concentration, indicating a balanced carotenoid profile. Casper White variety has the lowest carotenoid content among the three. This low carotenoid presence is expected and consistent with its pale, almost white coloration, which often signifies reduced carotenoid concentrations. The carotenoid content of the pumpkin varieties ranged from 1.00-13.79 μg/g. The values obtained in this study compares favorably with those reported by Itle and Kabelka (2009) for Cucurbita pepo (1.9-14.7 μg/g) . Carotenoids bring extra benefits to foods, like antioxidants, anti-cancer properties, sun protection, heart health and reducing inflammation (Antonela Nincevic Grassino *et al*, 2023). High carotenoid levels can contribute to health benefits, given their antioxidant properties and their role as precursors to Vitamin A.

DPPH: From table 2, it was observed that the Orangetti and Connecticut Field varieties were not significantly different from each other. However, Casper White is significantly different from Orangetti and Connecticut field. Based on the results, Orangetti and Connecticut Field exhibit higher DPPH antioxidant activity compared to Casper White. This suggests that Orangetti and Connecticut Field may have a stronger capacity to neutralize free radicals, which are associated with oxidative stress and various health issues. The DPPH values of the pumpkin varieties in this study ranged from 50.09±0.65^{b} - 59.52±0.91^{a}. The values obtained in this study are lower than that of Lotfy *et al.* (2017).

Brix: A higher Brix value generally correlates with a sweeter taste in fruits and vegetables. The variation in Brix values among the three pumpkin varieties could have potential implications for consumer preference. Helyes *et al*. (2003) emphasized the importance of Brix measurements in determining the potential applications and consumer preference for fruits and vegetables. Findings from this research showed no significant difference in Brix value for Casper White and Connecticut. However, they were significantly different from Orangetti. It was also observed that all three varieties have low Brix values. This makes all varieties analyzed in this research ideal for diabetes patients.

CONCLUSION

In conclusion, the provided analysis sheds light on the varying physicochemical properties of different Cucurbita pepo varieties cultivated in the National Horticultural Research Institute, Ibadan, Nigeria. Building on the foundation laid by previous scholars, this study contributes to more understanding of the nutritional and culinary potentials of these pumpkins. Future research might delve deeper into other components like mineral content and texture.

INTRODUCTION

Spices are a group of horticultural crops that are used primarily for enhancing taste, flavor and appeal of food and beverage. They are not usually cultivated like other horticultural crops and staples as they are mostly gathered from the wild in their natural habitats (Adelaja and Fasidi 2012). While some have been deliberately cultivated by resource-poor farmers they still remain largely neglected, under-utilized and under-estimated in spite of the several roles they are able to play in nutrition, health and in livelihood security of households. Some of these spices are perennial crops with sustainable high yields spanning several decades with the potential of high income generation for producing households; some have short life cycles that generate multiple harvests from the same unit of land. The rich agro-ecological diversity in Nigeria favors the production of different types of spices. The longer rainy season and fertile lands of the southern parts of Nigeria favors production of several indigenous and perennial spices that are adapted to forest conditions while the drier Northern parts of the country with semi-arid and dry humid features favor production of short duration and drought-tolerant spices. The production of spices is beneficial in several ways such as provision of employment; on-farm and off-farm, provision of income, nutrition security, household subsistence, individual and household wellbeing. As reported by Adewale and Oladeji (2022), gains accruable to thriving spices production includes ability to grow in marginal conditions, eradication of hunger and poverty as a result of multiple harvests and high incomes earned, job creation, environmental sustainability as well as improved food security and nutrition. As parts of research efforts to ensure that spices as crops that are already endangered do not continue to face the threat of extinction and ensure that households are able to obtain nutritious diets through adoption of more diversified and sustainable food production systems, the study was conducted to assess gender involvement in spices production in south western and north central zones in Nigeria with the following objectives:

1. Identify socio-economic characteristics of spices farmers;
2. Ascertain production patterns- types and varieties of spices cultivated in the zones,
3. Identify constraints associated with spices production;

METHODOLOGY

Multistage sampling technique was used to select respondents for this study. Oyo and Kwara states were selected at the first stage for their intensity of cultivatable and wild spices. The second stage involved a purposive selection of Local Government Areas (LGAs) that are renowned for spices production. Akinyele, Ona ara and Ido LGAs were selected from Oyo State while Asa LGA was selected from Kwara state. The third stage was a random selection of communities within the LGAs. The final stage involved a random selection of farmers involved in spices production; a total of sixty (60) farmers were purposively selected for the study. Descriptive statistics- percentages and frequency counts were used to assess gender involvement in spices production.

RESULTS AND DISCUSSION

Socio-demographic characteristics of spices farmers in Nigeria.

The results of socio-demographic characteristics on Table 1 include sex, marital status, religion, household size, educational attainment, main occupation and social network. The results showed that respondents were predominantly females as 60.0% were females while 40.0% were male. This signifies that spices production is largely female-oriented. This agrees with the assertion of Nakwe et al., (2018) that rural women despite their lack of skills are the main producers of secondary, neglected, under-utilized crops such as spices. Majority (71.7%) of respondents were married, 18.3% were single and 10.0% were widowed. Also, majority (73.3%) were of the Islamic faith while 26.7% practiced

Christianity. The farming system in the areas revealed a predominantly labor-intensive pattern as family size of majority (60.0%) of farmers was in the range 1 – 5 persons in the household, 33.3% had between 6 and 10 persons and only 6.7% had family size with more than 10 persons. As reported by Anyanwu (2013), large family size among farmers contributes to the household workforce to generate income and as insurance against old. The results also showed that majority (66.7%) had no formal education while 20.0% had primary education and 13.3% had attained secondary education. This result show that most of the farmers have basic education and therefore would be able to comprehend and adopt technologies that would enable them expand and earn more from spices production. Most respondents (81.7%) were farmers, 8.3% were artisans, 6.7% were civil servants and 3.3% were traders. Respondents belonged to different social groups- 61.7% were members of farmer association, 60.0% belonged to women groups, 55.0% belonged to cooperative societies and 51.6% were members of religious societies. Also, majority (66.7%) inherited their farmlands while 21.7% leased and 11.7% purchased the farmlands. Majority (55.0%) had less than 10 years' experience in spices farming while only 3.3% had more than forty years' experience. This shows that farmers have ample knowledge of spices production which is likely to translate into better production capabilities with repeated production activities. Family and hired labor were basically the types of labor used in the areas as majority (51.6%) used family source of labor and 35.0% used hired labor for spices production activities.

Table 1: Socio-demographic characteristics of respondents

Variables		**Frequency**	**Percentage**
Sex	Male	24	40.0
	Female	36	60.0
Marital status	Single	11	18.3
	Married	43	71.7
	Widowed	6	10.0
Religion	Christianity	16	26.7
	Islam	44	73.3
Household size	1 – 5	36	60.0
	6 – 10	20	33.3
	➢ 10	4	6.7
Educational	Non-formal	40	36.7
	Primary	12	16.7
	Secondary	8	13.3
Main occupation	Farming	49	81.7
	Artisan	5	8.3
	Civil service	4	6.7
	Trading	2	3.3
Social group	Farmers association	30	50.0
	Cooperative society	7	11.7
	Religious society	6	10.0
	Women group	7	11.7
Land acquisition	Inheritance	40	66.7
	Purchased	7	11.7
	Leased	13	21.7
Experience in spices	**< 10**	33	55.0
	11 – 20	4	6.6
	21 – 30	13	21.7
	31 – 40	8	13.3
	➢ 40	2	3.3
Labor source	Family	31	51.6
	Hired	21	35.0
	Both	8	13.3

Production Practices among Spice Farmers

A wide range of both indigenous and exotic spices are cultivated in the different localities. Turmeric and hot pepper were predominantly cultivated by 70.0% of the farmers. Ginger and lemon grass were cultivated by 66.7% and 63.4% respectively. Ethiopian pepper was cultivated by only 30.0% of farmers.

Similarly, locust bean, alligator pepper, clove and African nutmeg were cultivated by only 30.0%, 28.3%, and 3.3% respectively. Spices which used to exist only in the wild are now been cultivated by some farmers. While this shows that the zones are favorable for the production of diverse classes of agricultural crops -spices inclusive, it further reveals that with awareness and public enlightenment, knowledge gaps can be removed and spices production can be promoted. This confirms the position of Padulosi *et al*., 2013, that enlightenment and capacity build can enhance farmers production and utilization of neglected and under-utilized crops such as spices. Different types of farming systems were practiced; 8.3% of farmers practiced sole spices cultivation, while a very high proportion (91.6%) of farmers intercropped their spices with other crops. Majority (88.3%) intercropped spices with vegetables while some farmers planted cassava, yam, maize alongside these spices. Majority (50.0%) of farmers sold their spices in heaps, 38.3% sold in bags and 11.7% sold in baskets. While a few (8.3%) of farmers sell directly to consumers, majority sell spices beyond the farm gate to a host of buyers, 58.3% sell to wholesalers; 16.6% sell to retailers and agro-processors respectively, this minimizes transaction time and costs and as reported by Pingali et al., (2019); reduction in transaction time and costs improves market infrastructure and enhances income of agricultural households.

Table 2: Spices Production Practices

Variables		Frequency	Percentage
Spices produced	Turmeric	42	70.0
	Hot pepper	42	70.0
	Ginger	40	66.7
	Lemon grass	38	63.4
	Ethiopian pepper	18	30.0
	Locust bean	18	30.0
	Alligator pepper	17	28.3
	Clove	2	3.3
	African nutmeg	2	3.3
Type of cropping pattern	Sole	5	8.3
	Intercropping	49	91.6
Plant intercropped	Vegetables	53	88.3
	Cassava	3	5.0
	Yam	2	3.3
	Maize	2	3.3
	Others	4	6.7
Mode of sale	Heaps	30	50.0
	Bags	23	38.3
	Basket	7	11.7
Buyers	Retailers	10	16.6
	Wholesalers	35	58.3
	Agro-processors	10	16.6
	Consumers	5	8.3

Constraints to Spices Production

Constraints associated with spices production are presented in Table 3. The study shows that majority (70.0%) of respondents encountered the problem of pest and disease incidence as the most critical constraint. Incidence of pest and disease on farms limit production and is the major cause of yield loss and food insecurity. A large proportion (68.3%) of respondents had the problem of weather fluctuations such as drought, changing rainfall patterns with resultant decline in crop production, 65.0% complained of lack of credit facilities which supports the position of Peter-Onoh (2014) that without credit facilities, expanding agricultural production remains a huge challenge as purchasing inputs and use of modern technologies would remain difficult. Also, 53.3% of respondents complained of insufficiency of extension contact. Similarly, 53.3% of respondents were confronted with the menace of grazing animals; 51.6% of respondents had the problem of inadequate market information which confirms the position of Baliyan (2009) who positioned that lack of market information hinders the potentiality of large scale production of horticultural crops such as spices. While 48.3% of respondents were faced with the problem of insufficient market channels; the high cost of labor was the challenge of 46.6% of respondents. Also, 43.3% of respondents complained of theft of harvestable spices, while 41.6% complained of low market price. 40.0% were confronted with high transportation costs and 38.3% had the problem of glut. The least constraints to spices production were seeds and seedlings and the land tenure system. If these constraints associated with spices production are tackled, it will further promote spices production will enhance farmers income and wellbeing.

Table 3: Constraints to spices production

Constraints	Percentage (%)
Pest and disease incidence	70.0
Weather fluctuations	68.3
Lack of credit facilities	65.0
Insufficient extension contact	53.3
Grazing animals	53.3
Inadequate market information	51.6
Insufficient market channels	48.3
Labor cost	46.6
Theft	43.3
Low market price	41.6
High transportation costs	40.0
Glut	38.3
Seeds and seedlings	30.0
Land tenure	18.3

CONCLUSION AND RECOMMENDATION

The study revealed that a larger proportion of spices farmers are women, have large household size and are members of social organizations. A wide range of exotic spices were cultivated along with previously wild, semi-domesticated spices that are now been cultivated by a number of farmers. It further identified pest and disease incidence as the main limiting factor to increased production of spices which constitutes the primary cause of low quality spices and reduced yields. The land tenure in the area affords ease of land use that could promote large scale production of spices in the areas as seeds and seedlings are readily available. The study concludes that with improved access to extension services, increased enlightenment and capacity development farmers would take advantage of the several benefits of spices, include them largely in their production systems to enrich their income generating capacities, enhance biodiversity and household well-being.

ABSTRACT
Integrated nutrient management (INM) refers to the maintenance of soil fertility and plant nutrient supply at optimum levels to sustain desired productivity using all sources of organic, inorganic and biological components in an integrated manner. There is however a dearth of information on practice of INM among mango farmers in producing areas. This study was conducted to ascertain current issues and challenges to INM use among mango farmers in Nasarawa state. The data collected from 66 mango farmers were analyzed; results indicated that majority (84.8%) were male, the average family size was 8 persons/household. A large proportion (59.1%) had less than two acres of mango farm and only 30.3% used grafted mango seedlings. A large proportion (37.9%) had less than 10 years' of experience in mango farming. Varieties of mango cultivated included Julie, Kent, Alphonso, Tommy Atkins, Saigon and Edward; Julie and Kent were cultivated by 84.8% and 59.1% of farmers respectively and were preferred for traits such as- marketability (78.8%), taste (63.6%), yield (42.4%) and size (28.8%). A greater proportion (53.0%) and (56.1%) of respondents did not apply fertilizer to their mango and were not aware of INM respectively. Constraints to mango production in order of importance were pest and disease infestation, insufficiency of credit facilities, inadequate market channels, bad roads and inadequate transportation system. It is recommended that the components and benefits of INM should be promoted among mango farmers to sustain higher yields, ensure yield stability while maintaining soil fertility and health.
***Keywords**: INM, Julie, Kent, Mango, Soil health*

INTRODUCTION

Mango has vast nutritional and economic importance to urban and rural households as the trees produce fruits with great diversity in size, form, color and quality. These fruits are put to diverse uses; ripe mango fruits are eaten raw and made into juices while unripe fruits are processed into pickles and chutney (Ali, Islam, Hassan *et al*., 2015). A key shortcoming to production of fruit trees is the steady decline of soil fertility which is usually further aggravated by continuous, long-term cultivation which results in soil nutrient mining. As most Nigerian soils are usually low in nutrient content as a result of total removal of crop residues from farm lands; other factors such as low fertilizer usage, inappropriate soil conservation and cropping systems contribute to the low nutrient content of the soils. The continuous use of chemical fertilizers especially NPK has impaired soil fertility and decreased soil factor productivity; therefore use of best horticultural techniques are required that will allow farmers have access; choose appropriate, efficient and cost-effective technologies for their enterprise; it is also important for farmers to participate in the development of the technologies and become knowledgeable about managing fertility in order to capture the diverse opportunities offered by the intervention.

There are many efforts in the form of researches and projects aimed at improving the livelihood of smallholder farmers to reverse the fertility status of soils which will increase productivity per unit area of land. Integrated nutrient management (INM) refers to a set of soil fertility management practices that necessarily include use of fertilizer and organic inputs combined with the knowledge on how to adapt these practices to local conditions with the aim of maximizing agronomic use efficiency of applied nutrients as well as improving crop productivity. It involves the use of chemical fertilizers in conjunction with organic manures, crop residues, bio-fertilizers and locally available resources in a cropping system. It further aims at reducing the uncontrolled use of chemical fertilizers, restore organic matter content in soils and increase nutrient use efficiency. INM also ensures the maintenance of the physical, chemical; and biological properties of soils and maintains the nutrient balance between supplied nutrient and nutrient removed by plants which aims at improving soil health and productivity on sustainable basis.

The goal of INM is to integrate the use of all natural and man-made sources of plant nutrients in order to ensure that crop production increases efficiently without compromising the soil productivity potentials of future generations. INM is thus crucial in sustainable agricultural productivity as it requires that natural resources be incorporated to generate increased output and incomes for farmers, (Dolker et al., 2017). In view of this, the study was conducted to ascertain constraints and opportunities associated with INM in mango production in Nasarawa state, Nigeria. Specifically, the study identified socio-demographic characteristics of mango farmers, characteristics of the mango production enterprise and constraints associated with mango production in the state.

METHODOLOGY

The study population comprised of mango farmers in Nasarawa state, Nigeria. Multi-stage sampling technique to select respondents. The first stage involved a purposive selection of Nasarawa state in the North-central zone of Nigeria for the intensity of mango production. The second stage involved a purposive selection of Local Government Areas (LGAs) in the state noted for mango production. Lafia, Kokona and Akwanga LGAs were selected. The third stage involved a random selection of communities within the LGAs- Akwaba community was selected from Lafia LGA; Maraba Kokona, Marke and Masauri kokona communities were selected from Kokokna LGA while Nongi, Endetu, Ubbe and Akwanga communities were selected from Akwanga LGA. The final stage involved a random selection of 66 respondents from the communities based on probability proportionate to size. Structured questionnaires were used to elicit information from citrus farmers in the selected communities. The information collected was statistically analyzed and results interpreted with frequencies, percentages and mean ranking.

RESULTS AND DISCUSSION

Personal Characteristics of Mango farmers

The personal attributes of mango farmers is shown in Table 1 It reveals that majority (84.4%) of mango farmers in Nasarawa state of Nigeria were male and only 15.2% were female signaling male dominance in mango production. Also, majority (68.2%) of the farmers were within the 19 and 41 age bracket revealing that most of these farmers are in the prime and active phase of their lives where they can give full and adequate attention to their livelihood security. While only 12.1% were single, majority (84.4%) were married. Marriage provides several benefits such as access to labor as married households usually have greater access to labor for agricultural activities than non-married households. The study further revealed that majority (60.6%) of respondents was Muslims practicing the Islamic religion. While only 18.2% had no formal education, 50.0% had basic education and 31.8% had tertiary education, this distribution reveals a largely literate population. With this varying literacy level, farmers are likely to adopt innovations such as INM faster than a largely illiterate population. Majority (71.2%) had more than 5 persons in their household signaling large household size; this might be attributed to polygamy as reported by Owoo (2018) which is the practice among Muslims in the northern part of Nigeria that encourages large household sizes coupled with the fact that children are considered as an essential part of the households work force as farm labor, to generate household income and as insurance in old age.

Table 1: Socio-Demographic Characteristics of Mango Farmers (n=66)

Variables	Categories	Frequency	Percent
Sex	Male	56	84.4
	Female	10	15.2
Age (Years)	<18	6	9.1
	18 – 41	45	68.2
	42 - 64	10	15.2
	65 and above	4	6.1
Marital status	Single	8	12.1
	Married	56	84.8
	Widowed	2	3.0
Religion	Islam	40	60.6

Mango Production Characteristics

Production characteristics of mango farmers are shown in Table 2. It revealed that mango farmers in the state were predominantly smallholder farmers as majority (59.1%) of farmers had mango farms less than 2 acres. A large proportion (37.9%) of farmers have less than 10 years' experience in mango farming while about 33.3% had between 10 and 20 years' experience in mango farming. The findings of this study further revealed that only 30.3% establish their mango farms with grafted seedlings while majority (69.7%) use mango seedlings. This non-use of improved planting materials among Nigerian farmers reduces their yields with a resultant negative influence on their livelihoods. Mango varieties predominantly cultivated by farmers included Julie (84.8%), Kent (66.6%), Alphonso (57.6%) and Tommy Atkins (43.9%) with Julie and Kent been the most preferred. Framers revealed reasons for preference of these varieties to include marketability (78.8%), taste (63.6%), yield (42.4%) and size (28.8%). The mango orchard system is not common among farmers in Nasarawa state as majority (65.2%) practice intercropping mango with crops such as cassava, maize, beans and yam. The result of this study also showed that majority (53.0%) of farmers in Nasarawa state do not apply fertilizers to their mango trees; this could be attributed to the fact that fertilizer use in tree crop production is very low in Nigeria as farmers rely on native soil nutrients for the completion of the life cycle of the plants. Consequently, yields are sub-optimal and usually below world average. Also, majority (56.1%) of mango farmers in the state are not aware of INM fuelling the position of Cheraja et al., (2021), that INM is a recent and emerging strategy that results in higher yields, sustained productivity, improved soil health with environmental benefits.

Table 2: Mango Production Characteristics (n=66)

Variables	Categories	Frequency	Percentage

Constraints to Mango Production

Several constraints challenge mango production in Nasarawa state as shown in Table 3. Pests and diseases infestation with 92.4% ranked first. This agrees with the findings of Ajayi and Nyishir (2006) that pest and disease incidence was the most challenging problem encountered by mango producing farmers in Nigeria. Lack of credit facilities and inadequate market channels ranked 2nd respectively with 90.9% while bad roads and inadequate transportation system ranked 4th respectively with 87.9%. This is in consonance with the position of Ibeawuchi et al., (2015) that Nigerian farmers are challenged by infrastructural constraints which include inadequate transportation systems and poor road networks. High post-harvest losses ranked 6th with 86.4% and fluctuating weather conditions ranked 7th with 84.8%. Inadequate storage facilities ranked 8th with 83.3% while insufficiency of labor and low market price ranked 9th respectively with 81.8%. Inadequacy of extension services, shortage of processing facilities and shortage of start-up / expansion capital ranked 11th respectively with 78.8%. Others are fruit theft and large number of middlemen..

Table 3: Constraints to Mango production (n=66)

Constraints	Percent	Rank
Pest and disease infestation	92.4	1st
Lack of credit facilities	90.9	2nd
Inadequate market channel	90.9	2nd
Bad roads	87.9	4th
Inadequate transportation system	87.9	4th
High post-harvest losses	86.4	6th
Fluctuating weather conditions	84.8	7th
Inadequate storage facilities	83.3	8th
Insufficient labor	81.8	9th
Low market price	81.8	9th
Inadequate extension contact	78.8	11th
Shortage of processing facilities	78.8	11th
Shortage of start-up capital	78.8	11th
Fruit theft	75.8	14th
Large number of middlemen	75.8	14th

Source: Field survey, 2022

CONCLUSION AND RECOMMENDATION

Based on the results obtained from this study, majority of mango farmers in the study area were male and a large proportion of these farmers had basic education. The study also showed that the farmers maintained a large household size which is an attribute of agrarian rural families as source of farm labor. The farmers are small holder farmers as small land holdings characterize their mango production enterprise and mango is planted as intercrop alongside other crops. The use of un-grafted mango seedlings characterized mango production in the study area as use of grafted seedlings is not common among mango farmers in Nasarawa state of Nigeria. A large proportion of farmers in the state are still not aware of integrated nutrient management as a strategy that will result in optimal yield of citrus, maintain and improve the physic-chemical properties and health of soils using different sources of plant nutrients.

ABSTRACT
Citrus, the most important fruit crop based on international trade is mostly produced in Benue state, Nigeria. Quantities produced annually are however less than yield potential and are attributed to a range of factors including low soil fertility, lack of knowledge of nutrient sources and inappropriate use of fertilizers. Integrated nutrient management (INM) is a strategy that combines chemical fertilizers, organic manure and certain microbes for higher crop yields, sustained productivity and improved soil health. This study was conducted to ascertain current issues and challenges to INM among citrus farmers in Benue state. The data collected from 76 citrus farmers were analyzed. Results indicated that majority (71.1%) were male, the average family size was 8 persons/household. Majority (84.2%) had less than three acres of land and 77.6% used budded citrus seedlings. A large proportion (39.5%) had between 10 and 20 years' experience in citrus farming. Varieties of citrus cultivated included sweet orange, tangerine, tangelo, lemon, grape fruit, lime. Sweet orange was cultivated by majority (84.2%) of farmers and was preferred for traits such as-taste (52.6%), marketability (35.5%) and yield (21.1%). Majority (93.1%) and (86.8%) did not apply fertilizer on their citrus and were not aware of INM respectively. Inadequate extension contact (86.8%), funds for inputs such as fertilizers (85.5%) and storage facilities (84.2%) were prevailing constraints challenging citrus production in the study area. Consequently, it is important to promote the potentials of INM through extension services to farmers as well as the benefits inherent in nutrient sources other than chemical fertilizers.
Keywords: *Benue state, Extension service delivery, INM, Sweet orange*

INTRODUCTION

Citrus is a large group of fruits which includes oranges, limes, lemons, tangerines, and grapefruits and is one of the world's most important fruits. It is a highly nutrient-responsive perennial fruit crop by its avid nutrient-absorbing capacity (Srivastava, 2012). Nutrient management is of importance in production of fruit trees such as citrus in order to promote growth, quality and fruit yield. Productivity in citrus steadily declines over-time due to deficiency in secondary and micronutrients. As reported by Srivastava *et al*., 2008; citrus requires 16 essential elements for normal growth therefore sub-optimum production due to prevalence of nutrient constraints is well established in citrus production. Conventional farming system involves use of fertilizers to enhance soil nutrients and improve productivity. Chemical fertilizers are one of the most commonly applied inputs in citrus production. In addition to the high cost of acquisition, their continuous application hampers soil health, soil productivity, the environment, quality of produce and is deleterious to the health of humans who consume them (Tarai and Ghosh, 2016).

However, supplementing chemical fertilizers with organic sources of nutrients for large scale production for long periods is impractical as organic sources provide little amounts of essential nutrients and are required in very large quantities that might not be readily available. Maximum fruit yield and adequate tree volume is attainable through combined use of fertilizers. An integrated supply of nutrients from all possible sources is therefore needed to enhance yield and productivity of citrus. Integrated nutrient management is an approach which involves the combined use of inorganic, organic and biological sources of essential plant nutrients to sustain optimum crop yield and improve or maintain physic-chemical properties of soil. INM aims at meeting the social and economic needs of farmers without harming the natural resource base of agricultural production for future generations. According to Dolker et al., 2017, INM aims at generating higher output and incomes for farmers through an integrative use of all natural and man-made sources of plant nutrients that will ensure efficient increase in crop productivity without compromising the potentials of the soil for future generations. The study was conducted to ascertain issues and challenges in INM among citrus farmers in Benue state. Specifically, the study identified the socio-demographic characteristics of citrus farmers, the characteristics of their citrus enterprise and constraints associated with citrus production in the state.

METHODOLOGY

The study population comprised of citrus farmers in Benue state, Nigeria. Multi-stage sampling technique to select respondents. The first stage involved a purposive selection of Benue state in the North-central zone of Nigeria for its predominance in citrus production. The second stage involved a purposive selection of Local Government Areas (LGAs) in the state noted for citrus production. Gboko, Otukpo and Ushongo LGAs were selected. The third stage involved a random selection of communities within the LGAs- Mbaiyon, Nongou and Apkacher communities were selected from Gboko LGA; Otobi Akpa, Upu, Otobi Onobi and Amla Otobi communities were selected from Otukpo LGA while Tse alu and Alu Mbayem communities were selected from Ushongo LGA. The final stage involved a random selection of 76 respondents from the communities based on probability proportionate to size. Structured questionnaires were used to elicit information from citrus farmers in the selected communities. The information collected was statistically analyzed and results interpreted with frequencies, percentages and mean ranking.

RESULTS AND DISCUSSION

Socio-Economic Characteristics of Citrus farmers

Majority (71.1%) of respondents were male while 28.9% were female (Table 1) resonating the position of Obayelu et al., (2019) that the Nigerian agricultural landscape is male-dominated. Citrus farmers were largely in their active phase of life as majority (82.9%) of respondents was between 18 – 64 years age bracket. As also shown in Table 1, majority (76.3%) of respondents were married; this fuels the assertion that marriage is highly respected in rural communities. Majority (93.4%) of respondents practiced Islamic faith; this reveals Islam as the predominant religion in Benue state of Nigeria. While only (2.6%) of respondents did not have any formal education, a large proportion (68.4%) of respondents had basic education. With this level of educational attainment, citrus farmers would be able to understand and adopt innovations related to their enterprise such as integrated nutrient management (INM) with relative ease. The findings of this study also showed that a large proportion (60.5%) of respondents had between 6 and 10 persons in their households. This is representative of rural families who maintain large household sizes for on-farm and off-farm agricultural activities.

Table 1: Socio-Economic Characteristics of Citrus Farmers (n=76)

Variables	Categories	Frequency	Percent

Citrus Production Characteristics

Production characteristics of citrus farmers are shown in Table 2. Small holdings characterized citrus farming in Benue state as majority (84.2%) of respondents had citrus farms that were less than 3 acres where 2.7% of respondents had between 20 and 40 citrus trees while 30.3% of respondents had more than 80 trees. Also as shown in Table 2, a large proportion (39.5%) of respondents had citrus farming experience that spanned between 10 and 20 years. This indicates that respondents have acquired significant experience in citrus farming. Majority (86.8%) acquired their citrus farmlands through inheritance signifying that inheritance land tenure system is the predominant practice of land-holding in the state as it is in most rural communities. The study further revealed that majority (77.6%) established their citrus farms with budded citrus seedlings. Varieties of citrus produced in the state are- Sweet orange (86.8%), Valencia late (10.5%), Tangerine (9.2%) and Lemon (3.9%) with Sweet orange, Valencia late and Tangerine been the most preferred. Citrus farmers revealed that these varieties are preferred for traits such as taste (30.4%), marketability (78.8%), yield (42.4%) and size (28.8%). Citrus is intercropped by majority (77.6%) of farmers with cassava, beans, maize, yam, vegetables, maize, water melon and soya beans indicating that orchard system of citrus farming is not popular among farmers as only 22.4% practiced sole citrus cropping. A large proportion 39.5% and 34.2% sold their produce at the farm gate and on trees respectively, while only 14.5% and 13.2% of respondent sold their produce at rural and urban markets signaling farmers preference for using pick-up buyers than incurring transport costs of taking to markets as posited by Mayala amd Bamanyisa (2018). Fertilizer use is common among citrus farmers in the state as 59.2% of respondents applied fertilizers to the trees on a yearly basis while 9.2% of respondents applied fertilizers more than one a year; however, INM is still not a popular practice among citrus farmers in the state as majority (86.8%) were not aware of INM.

Constraints to Citrus Production

A number of barriers to optimum production of citrus were identified in Benue state (Table 3). Inadequate extension contact and insufficient funds to purchase inputs were the most predominant constraints with 86.8% and were ranked 1st. Lack of credit facilities was ranked 3rd with 85.5%. inadequate storage facilities ranked 4th with 84.2%. Pests and diseases infestation with 82.9% ranked 5th. As reported by Inienger and Udoh (2020), pest and disease incidence in citrus is particularly challenging as it easily spreads from tree to tree and eventually reduces productivity. This has a huge resultant effect on farmers livelihood and household income. Bad roads and shortage of start-up capital ranked 6th with 81.6% respectively. The inaccessibility of rural areas where large amounts of citrus are produced due to bad road network is a problem for citrus farmers as the fruits spoilage is common due to the long hours of travel spent along the bad roads. Unavailability of funds and lack of start-up capital for investment is a major constraint of citrus farmers in Nigeria. Inadequate processing facilities, lack of sufficient market information, inadequate marketing and low market price channels ranked 9th respectively with 80.3%. High post-harvest losses and inadequate transportation systems ranked 12th with 77.6% respectively. High tolls, glut, land use tenural arrangements and fruit theft were other constraints that challenged citrus production in Benue state.

Lack of credit facilities and inadequate market channels ranked 2nd respectively with 90.9% while bad roads and inadequate transportation system ranked 4th respectively with 87.9%. This is in consonance with the position of Ibeawuchi et al., (2015) that Nigerian farmers are challenged by infrastructural constraints which include inadequate transportation systems and poor road networks. High post-harvest losses ranked 6th with 86.4% and fluctuating weather conditions ranked 7th with 84.8%. Inadequate storage facilities ranked 8th with 83.3% while insufficiency of labor and low market price ranked 9th respectively with 81.8%. Inadequacy of extension services, shortage of processing facilities and shortage of start-up / expansion capital ranked 11th respectively with 78.8%. Others are fruit theft and large number of middlemen.

Table 3: Constraints to Citrus production (n=76)

Constraints	Percent	Rank
Inadequate extension contact	86.8	1st
Insufficiency of funds for inputs	86.8	1st
Lack of credit facilities	85.5	3rd
Inadequate storage facilities	84.2	4th
Pest and disease infestation	82.9	5th

Source: Field survey, 2022

CONCLUSION AND RECOMMENDATION

The results of the study showed that majority of citrus farmers in Benue state, Nigeria are male, with some level of formal educational attainment. Citrus in the state is mostly established with un-budded citrus seedlings with citrus largely planted as intercrop with other crops. Establishment of large orchards is encouraged as the orchard system is not popular in the state. Citrus production was challenged by a range of constraints such as inadequate extension services and contact with farmers, limited capital for inputs and access to credit facilities. Lack of developed and organized markets and value chains also challenged citrus production as inadequate marketing information, outlets for marketing, low market pricing, glut and high post-harvest losses were identified by farmers as constraints to citrus production in the state. Accordingly, capacity development activities and research-extension linkages should be promoted to enhance farmers' knowledge of benefits and components of integrated nutrient management and fertility resources in citrus production to improve production and productivity among farmers in Nigeria.

ABSTRACT
In recent days, artificial ripening techniques for fruits are widely used worldwide due to commercial value and consumer acceptability of attractive fruit color. This study was carried out to compare the use of biological and chemical ripening agents on the physical and chemical properties of Banana. The treatment included Apple, Avocado, Oilpalm fruits, Mango, (Biological agents) Calcium carbide and potash (Chemical agents) while the variety used (BITA 3) was obtained from Agricultural Development Programme (ADP) Benin City, Edo State Nigeria. All treatments were purchased from New Benin market, Benin City, Edo State. The experiment was conducted from April to June 2021. The experiment was laid out in a Completely Randomized Design (CRD) with three replications. Data were collected on physical and chemical properties of ripe banana. Results indicate thatthere was significant difference in both physical properties and Chemical composition of ripen banana except pulp percentage. Apple treated banana ripened within three dayspulp pH of 5.7, pulp to peel ratio of 0.1% and Chemical analysis was observedto be 12% and 2.1% for fat and zinc respectively. On the other hand calcium carbide treated banana ripened within 4 days, a pulp pH of 6.0, pulp to peel ratio of 0.1%and chemical analysis was observed to be 12% for fat, 1.3% for Zinc respectively. The study concluded that natural ripening agents especially Apple was better compared to artificial ripener like calcium carbide and Potash and they may be devoid of any Potential health risks.

INTRODUCTION

Banana fruit of the genus Musa of the family Musae is one of the most important fruit crop in the world. The banana is grown in the tropics, and though it is widely consumed in those regions, it is valued worldwide for its flavour, nutritional value, and availability throughout the year. Dessert bananas are most commonly eaten fresh, though they may be fried or mashed and chilled in pies or puddings. They may also be used to flavor muffins, cakes, or breads. A ripe fruit contains as much as 22% of carbohydrate and is high in dietary fiber, potassium, manganese, and vitamin B6 and C (Ahmed *et al*., 2019). Bananas are climacteric fruits which are artificially ripened regularly. Ripening process of banana can be divided into three distinct phases namely the pre-climacteric or 'green life' stage, the climacteric and ripening stage and finally eat-ripe and senescence stage.During ripening process banana undergoes different physiological, biochemical, and organoleptic changes that lead to a soft and edible ripe fruit. Ripening is a biochemical process which involves a series of physiological changes in colour, aroma, flavor and texture. Once harvested it is highly perishable, with short shelf life leading to high post-harvest losses of about 20-50% dueto poor handling and quality deterioration (Ajayi and Mbah, 2007).
Ripening agents are substances which hasten the ripening process, and it comes in different forms. These include ethylene gas, ethephon, ethylene glycol, etherel and calcium carbide (Singal *et al*., 2012); African bush mango fruit (Irvingia gabonesis) and leaves, palm nut, cassia leaves, yellow pawpaw leaves, torch light battery, calcium carbide, potash and ash (Ajayi and Mbah, 2007). African mango fruits, calcium carbideand newbouldia leaves were also reported by Adewole and Duruji (2010). According to Singal *et al*., (2012), the commercial practice is to use these ripening agents to artificially ripen the fruits at the destination market before retailing. Ethylene gas is expensive to produce so low cost indigenous ripening technologies involving the use of hazardous materials are used (Singal *et al*., 2012; Ajayi and Mbah, 2007). The adverse potential of calcium carbide as a ripening agent has been established (Singal *et al*.,2012) while other chemical ripening agents like ethepon, etherel and ethylene glycol are also considered hazardous to health and they have to be used withinrecommended safe

limits (Hakim *et al*., 2012). The use of toxic and suspicious ripening agents is of great concern as the activities of human beings have been said to contribute to exposure of food materials to heavy metal contamination (Orisakwe *et al*., 2012). This present study was therefore carried out to compare the use of biological and chemical ripening agents on the physical and chemical properties of banana.

MATERIALS AND METHODS

Freshly harvested bunch of green but mature unripe banana (BITA 3) was bought from the improved banana varieties field collections of the Agricultural Development Programme (ADP), Benin City, Edo State. The ripening agents used were also bought from new Benin Market, Benin City and these were Calcium carbide, Potash, Apple, Mango, Avocado (Pear) and Oil palm fruits. The experiment was conducted (21st April to 30th April) 2021 at the Main Laboratory of the Faculty of Agriculture, University of Benin, Benin City, Nigeria. In a very clean and conducive environment with room temperature of 30^0C. The treatments *include;* Calcium carbide, Potash, Apple, Mango, Avocado, Oil palm fruits, Control under Open Air, and Control Under bag. The banana bunch was separated into hands with a sharp knife and each hand was made up of 12 banana fingers of approximately same size each. The weight of each banana hand made up of 12 fingers was taken using a sensitive electronic scale (Analytical weighing balance) on weighing, the banana handswere placed in black polythene bags. The calcium carbide and Potash were wrapped in polythene before being dropped into the black polythene bags containing bananas, the following treatments Apple, Mango, Avocado (Pear) and Oil Palm fruits were each placed respectively in polythene bags containing the banana. The control in bag was banana placed in black polythene bag without any ripening agent, while the last batch was control under open air, in which the bananas were not placed in black polythene bag. All the bags were tied up and stored on top of a table in the laboratory. The treatments were arranged in a completely randomized design (CRD) in 3 replicates.

Data Collection

Days to 50% ripening.

The days to 50% ripening was taken when about 6 out of the 12 fingers used for each experiment have ripened. Apple on day 3, Calcium carbide on day 3, while the untreated banana Control Open Air and Control under bag day 5 respectively, Avocado day 5, *Potash Day* 6. Oil palm day 6.

Days to full ripening (100%)

Apple day 4, calcium carbide day 5, potash day 6, Avocado day 6, *Mango Day* 7, ControlOpen Air and control bag day 7, oil palm fruit day 7.

Temperature in bags.

Each treatment, Apple 31^0C, Potash 31^0C, Control Open Air 30^0C, control under bag 32^0C, Mango 31^0C, Oil palm fruit 32^0C, Avocado 33^0C, Calcium carbide 32^0C.

Pulp to peel ratio

The division of weight of pulp to the weight of peel results in the pulp to peel ratio. Ripe banana was peeled using sharp edge knife. Then both pulp and peel were separated and individual weights were taken using a digital weight balance. Pulp to peel ratio is determined by using the formula given below.
Pulp to peel ratio =

Pulp percentage

The pulp percentage weight was *taken*, using the weight of Pulp all over the weight of peel and pulp which was then multiplied by 100.

pH of ripe fruit

The pH of the following fruits *was* recorded Calcium carbide and Mango had pH of 6 And 6 each. Potash and control open air 5.2 each. Oil palm 5.9 and control under bag was the least which is 5.1.

Laboratory Analysis

The physiochemical properties of the ripe bananas were determined according to the standard methods of AOAC (1990).

RESULT AND DISCUSSION

The effects of chemical and biological agents on physical properties of banana is showed in Table1. Result indicated that temperature reading ranges from 30^0C to 32^0C. Control Open Air Ripened at a temperature of 30^0C and Calcium carbide 32^0C there were changes in the pH of Calcium carbide and Mango with a pH of 6, Potash and control *o*pen air 5.2 each. Oil palm 5.9 and control under bag was observed to have the least of 5.1. These results were highly significant. The pulp topeel percentage ranges from 0.1- 2.2% respectively. Apple have 0.1% and Oil palm fruit treatment having 2.2%. Calcium carbide can induce ripening within 3 days and the fact that it is cheap makes it to be a popular ripening agent among banana marketers especially in the developing countries (Ajayi and Mbah, 2007).

Table 2 shows the effects of chemical and biological agents on chemical composition of ripe banana. The result shows that the use of biological and chemical agents greatly enhanced the ripening of banana. This result agrees with most research work in literature that ripening agents do accelerate ripening faster than when done naturally (Adewole and Duruji, 2010; Hakim *et al*, 2012 and Singal *et al*, 2012). This is also in agreement with Adewole and Duruji (2010) who observed a reduction in the protein content during ripening which may be due to reduction of nitrogen during ripening. However, it does not agree with Sen *et al* (2012) who stated that proteins increases during ripening. The differences in the protein values during ripening of bananas may be due to varietal differences (Mohapatra *et al*, 2010).

CONCLUSION.

Marketers are recommended to use biological ripening agents to ripen banana rather than chemical ripening agents because of the health hazards they cause.

ABSTRACT
This research was conducted to examine the growth and yield response of sunflower (Helianthus annuus L.) varieties to varying intra-row spacing in the Sudan savannah zone of Nigeria. The trial was conducted in two different locations, Kano University of Science and Technology (KUST) research farm and Binyaminu Usman Polytechnic (BUPOLY) Hadejia practical farm during 2019 raining season. Four varieties of sunflower (SSL803, SSL806, SSL807 and SSL809) were planted at varying intra-row spacing of 20, 30, 40, 50 and 60cm. Split plot design was adopted for the research, with variety allocated to the main plot while intra-row spacing to sub plots, treatments were replicated three times. Data were obtained on the plant growth and yield parameters. Data were subjected to statistical analysis of variance and mean differences separated using LSD at p=0.05. The result of the experiments shows that both variety and spacing revealed insignificant statistical difference in most of the growth characters assessed at both locations.
Key word: *Growth response, Sunflower, Varieties and Spacing*

INTRODUCTION

Sunflower (*Helianthus annuus* L.) belongs to the family (Compositae) Sunflower originated from Western North America; it is thought to have been domesticated around 1000 B.C. by Native Americans. Spanish explorers brought the sunflower to Europe in 1510. Sunflower is one of the most important oilseed crops containing high quality edible oil (Bakht *et al.,* 2010). Sunflower is currently the world's fourth largest oilseed crop (Rodriguez *et al.,* 2002). It is mainly used for oil production because of the high quantity of oil in the seeds (about 50%), (Severine *et al.,*2002). Sunflower seed was the third largest sources of vegetable oil worldwide, following cotton seed and soybean, sunflower oil is generally considered a premium oil because of its light colour, high level of unsaturated fatty acids and lack of linolenic acid, bland flavor an high smoke points, the primary fatty acids in the oil are oleic and linolenic (Typically 90 % unsaturated fatty acids), with the remainder consisting of palmatic and stearic saturated fatty acids (Anon.,1987). The economic importance of sunflower cannot be over emphasized as an important oilseed crop worldwide. The fresh green plants can be fed as silage or fodder to livestock. The seed which can be eaten raw or roasted contains 36 - 45% oil depending on the variety and can be used in salad, cooking oil, margarine, lubricant, paint vanishes and soap production. The decorticated seed cake is a good source of protein (35%) for livestock, especially when made from whole seed. The crop is also a good source of nutrition which is used in food preparation, feeding livestock and poultry (FAO, 2010).

Plant population based on row and plant spacing is a major part of agronomic practices leading to optimum productivity. Beg *et al.* (2003) found that high populations, from 80,000 to 100,000 plants, produced significantly higher yields. Agronomic practices in addition to high yielding varieties are the two most important items for higher productivity of the sunflower crop. Plant spacing is one of the most important agronomic practices that affect seed production and fatty acid composition of sunflower oils. It has been found to have positive influence on days to 50% flowering (Awais, *et al.,* 2013); stem diameter, head diameter, thousand seed weight, seed weight /plant and seed yield (Basha, 2000; *Ali, et al.,* 2014) as well as oleic and linoleic unsaturated fatty acids composition of oil (Ibrahim, 2012; Cucci, *et al.,2012*). On the other hand, it has been found to have negative influence on plant height (Ibrahim, 2012) and seed oil content (Faith, 2004; Ibrahim, 2012; Cucci, *et al.,2012)*. This work was conducted to evaluate growth and yield response of sunflower (*Helianthus annuus* L.) varieties to varying intra-row spacing in the Sudan savannah zone of Nigeria.

MATERIALS AND METHODS

The research was conducted at Bagauda research farm at Bagauda village, Kano state which lies between latitude 11 40'N and longitude 8 16' E and Binyaminu Usman Polytechnic Hadejia research farm, Hadejia town Jigawa state which lies between latitude 12 26' 59''E and longitude 10 02' 39'' E. Both locations were within the Sudan savannah ecological zone of Nigeria. The treatments consisted of variety SSL803, SSL806, SSL807 and SSL809 which were allocated to the main plots and intra-row spacing of 20, 30, 40, 50 and 60cm that were allocated to subplots. Split plot design was selected involving three replications, where each replication consists of four main plots each of 4.5m x 3m represented by 6 ridges. Five (5) selected plant samples were tagged for data collections on growth and yield characters at regular intervals and at harvest.

RESULTS AND DISCUSSIONS

The results of plant height, number of leaves and stem diameter at both locations were shown in Table 1 Plant height, number of leaves and stem diameter were not affected by variety and intra-row spacing at Hadejia, while at Bagauda, the plant height and stem diameter were significantly affected by both variety and intra row spacing, while the number of leaves was not significantly affected. Table 2 shows the results of Leaf area/plant, dry weight and days to 550% flowering and showed that none on the parameters were significantly affected by both the variety and the intra-row spacing in either of the locations, while only days to 50% flowering was significantly affected by variety at Bagauda. Results of Crop growth rate as affected by variety and intra-row spacing at both locations and sampling periods at 4th and 7th weeks after sowing, (Table 3) shows that spacing did not affect CGR significantly at both locations. However, the results shows that CGR was significantly affected by variety at 4th week after sowing at both locations, while at 7th week after sowing, CGR was not significantly affected by sunflower varieties. The interaction between variety and intra-row spacing showed non-significant statistical difference on all the characters assessed in either of the locations.

CONCLUSION

This study examined the growth and yield of sunflower as affected by variety and spacing at Bagauda and Hadejia locations. Based on the findings effects of variety and spacing on most of the characters assessed were not statistically significant at both locations, this implies that the differences observed were just by chance. Hence any of the varieties tested can perform very well in the experimental sites with good management.

ABSTRACT
Crop cultivars with enhanced weed suppressive abilities could play a key role in Integrated Weed Management (IWM) strategy. A field experiment was conducted at the National Horticultural Research Institute, Ibadan to evaluate the Weed Suppressive Abilities (WSA) of fluted-pumpkin Telfairia occidentalis Hook F. accessions. Thirty-eight accessions from all the major fluted-pumpkin production areas in Nigeria were evaluated. The experiment was laid out in Randomised Complete Block Design with three replications. Data were collected on weed species composition, weed density, weed biomass, weed ground cover and fluted-pumpkin canopy cover. Results indicated that 57% of the weed species were broadleaves, 33.3% were grasses while 9.1% were sedges. Results also indicated significant differences in weed density, weed biomass, weed ground cover, and fluted-pumpkin canopy cover ($p < 0.05$). Accession 38 had the lowest weed density, weed biomass and weed ground cover. The result suggested that the accessions with high canopy cover could suppress weeds and hence reduce weed completion with fluted-pumpkin.
Keywords: *Accession, Fluted-pumpkin, weed density, weed biomass, canopy-cover.*

INTRODUCTION

Fluted pumpkin (*Telfairia occidentalis*), commonly known as iroko or ugu in Yoruba and Igbo languages respectively in Nigeria is an important vegetable crop belonging to the plant family Cucurbitaceae. (Prota, 2006). It is a nutritious vegetable of tropical West Africa widely cultivated for its leafy shoots and immature edible seeds (Akoroda, 1990). The leaves are rich in iron and used to cure anaemia while also being high in protein content (Okoli and Mgbeoku, 1983). Weed competition is a major limiting factor to its production as weed competition with the crop adversely affects the crop. Although fluted pumpkin is a poor competitor with weeds, the variation in its genetic composition could play an important role in integrated weed management. Weed competitiveness comprises of the major elements namely Weed Tolerance (WT) and Weed Suppressive Ability (WSA). Weed Tolerance is the ability of a crop to maintain high yields in the presence of weeds while weed suppressive ability is the ability to suppress weed growth (Rodenburg *et al* 2009). The major objective of this paper therefore is to evaluate the Weed Suppressive Ability of fluted-pumpkin accessions.

MATERIALS AND METHODS

The field trial was conducted around vegetable nursery building of the National Horticultural Research Institute headquarters, Ibadan in the 2022 cropping season between March and November. The experimental site was slashed, ploughed and harrowed with tractor-mounted implements. The plot size was 2 m by 2 m (4 m^2) with 38 fluted-pumpkin accessions. The seedlings were transplanted at a spacing of 1 m x 0.5 m, making a population of 20,000 plants ha^{-1}. The experiment was laid out in Randomized Complete Block Design (RCBD) with three replications. At 4 weeks After Transplanting (WAT), inorganic fertilizer (NPK 20:10:10) mixed with organic fertilizer (poultry manure) was applied at 100 and 300 kg ha^{-1} respectively to supply the necessary nutrients to the plants as the site has been in use for planting fluted-pumpkin over many years. Staking was also done at 4 WAT using teraga or table method and the crop was trailed appropriately using rope. Weed removal was done at intervals of 4, 8, 12 weeks after transplanting when crop canopy had been fully formed, and prior to pod harvesting. Data were collected on weed species composition, weed density, weed biomass, weed ground cover and fluted-pumpkin canopy cover. Weed species composition, density, and biomass were obtained from two 50 cm x 50 cm quadrats randomly thrown in the diagonal transects of each plot. Weeds within each quadrat were counted and cut with sharp knife, sorted by species, and bulked together to form a sample. The samples collected were oven-dried at a temperature of 80^0C for 48 hours to obtain weed biomass. Weed ground cover and fluted-pumpkin canopy cover were obtained using the Line Intercept Method (LIM) used in vegetation assessment (Coulloudon *et. a*l. (1999). Statistical analysis of the data collected was performed using GenStat release 4.23 Discovery Edition Statistical software package. Means were separated using Least Significant Difference (LSD) at 5 percent probability level.

RESULTS

Nineteen weed species were frequently (more than 10%) observed in the plots. The most dominant ones were *Cleome viscosa, Mitracarpus villosus, Euphorbia heterophyla, Commelina benghalensis, Peuraria phaseoloides, Panicum maximum, Paspalum scrobiculatum and Tridax procumbens.* Of the weed species observed, 57.1% were broadleaves, compared to grasses and sedges which were 33.3 and 9.5% respectively. This observation corroborates the findings of Olorunmaiye *et al*. 2010 that broadleaves are dominant in vegetable fields. Weed density differed significantly among the accessions at 4, 8, and 12 WAT (table 1).

WAT-Weeks after transplanting. LSD- Least Significant Difference, **Significant P at 0.05, NS Not significant

At 2 WAT, accession 15 had the highest weed density which is significantly similar to that obtained in accession 1, 5, 10, 27, and 28. The lowest weed density was obtained in accession 38. At 8 WAT, the highest weed density was obtained in accession 22 while the lowest was obtained in accession 38. At 12 WAT, the highest weed density was obtained in accession 32 and it differed significantly from all other accessions (LSD = 47) while the lowest weed density was obtained in accession 38. Weed biomass also differed significantly among the accessions at 8 and 12 WAT but did not differ at 4 WAT. At 8 WAT, the highest weed biomass (367.2 g m^{-2}) was obtained in accession 25 which is significantly higher than those obtained in all other accessions. Accessions 8, 22, and 29 had similar weed biomass (293, 255, and 276 g m^{-2} respectively). At 12 WAT, accession 29 had the highest weed biomass while accession 38 had the lowest. By implication, accession 38 is the most superior accession in weed suppression while accession 25 is the weakest accession in weed suppression. The differences in the variation in weed suppressive abilities of the accessions could be attributed to the differences in the weed and fluted-pumpkin's canopy cover (Table 1).

ABSTRACT
The aspect of organic amendments often overlooked was the residual release of nutrients which improve soil productivity. This research was to investigate the residual effect of different organic manure (biochar and cow dung) on the early growth of Pterocarpus soyauxii seedlings. Fifteen treatments were applied and replicated four times. Collar diameter, height and number of leaves were data collected per plant at 3weeks for 18 weeks. Result obtained for collar diameter and number of leaves reveals the residual effect of application of biochar (B11 and B12) which has the highest number of 4.83mm and 58.25mm when compared with control of 3.85mm and 44.25mm respectively. Length of height shows the highest at (B+C4) of 29.62cm when compared with the control 20.75cm. There was no significant correlation among the growth parameters but there was a significant correlation between the use of both cow dung and biochar to improve plant and soil quality.
Keywords: *Pterocarpus soyauxii, treatment, residual effect, organic manure, growth parameters.*

INTRODUCTION
The maintenance of soil productivity is a significant barrier to tropical agriculture. Typically, crop cultivation is rotated across fields so that it can rely solely on fertile soils for a few years while not using fertilizers (Akande *et al.,* 2010). However, this cannot be sustained to meet increased demand of an increasing population. Erosion and poor soil fertility in tropical soils have detrimental effects in deteriorating the nutrient status and changing the population of soil organisms (Atijegbe *et al.,* 2014). However, nutrients contained in manures are released more slowly and are stored for a longer time in the soil ensuring longer residual effects, improved root development and higher crop yields (Abou El Magd *et al*., 2005, Yang *et al.,* 2015). *Pterocarpus soyauxii* belongs to the family *Fabaceae- Papilionoideae*, is a tree 27-34 m tall with bole length up to 17 m, girth up to 3.3 m with an undivided stem. The English name include (redwood, large fruited camwood, Gabon padouk, barwood, African padouk, African coral wood) (Orwa *et al.,* 2009). Pterocarpus is a genus with approximately 60 species, 20 of which may be found in African nations like Nigeria, Cameroon, Sierra Leone, and Equatorial Guinea.

Organic matter improves the physical and chemical characteristics of soil and prolongs the release of nutrients. The Organic fertilizers/manure like, cow dung on the other hand is readily available in rural areas of the country since most of the rural farmers rearing cattle for fattening, production of milk, and for ploughing their agricultural fields. Moreover, farmers around the nation are becoming aware and embrace the usage of organic manure, which is readily available, toxic-free, and inexpensive (Thakur *et al.,* 2021). Biochar is produced from biomass by pyrolysis, the thermal decomposition of biomass in absence or limited oxygen (Bridgewater *et al.,* 2003). Biochar is very porous material (George *et al.,* 2012) and thus it decreases soil bulk density and simultaneously increases water holding capacity (Brewer *et al.,* 2012). Several research works have been conducted on the complementary effect of organic manure and chemical fertilizers on different tree species, little information is available on the effect of cowdung and biochar on soil properties, nutrient uptake and growth of *Pterocarpous soyauxii*. The primary aim of this research is to investigate the residual impact of various organic manures (biochar and cowdung) on the early growth of *Pterocarpus soyauxii.*

MATERIALS AND METHODS
The experiment was carried out at the Trees Improvement Section Screen house of Forestry Research Institute of Nigeria, Jericho Ibadan, located on Longitude 3° 9'E and Latitude 07° 25'N. The annual temperature ranges from 25.4^0C-31.6^0C with a mean rainfall of about 1300-1500mm and average relative humidity of about 79.4% (FRIN Meteorological station). River sand was collected at the Asanmagbe

river bank in Forestry Research Institute of Nigeria. The soil was washed and sterilized at 200°C for one hour. The sterilized soil was bagged in 3kg polyethylene bags. Organic manure was then added and allowed to decompose for 3weeks before the seedlings was transplanted. The seed was sourced from the seed section Sustainable Forest Management Department, Forestry Research Institute of Nigeria. The study was carried out in a Completely Randomized Design (CRD) with 15 treatments replicated 4times. The experiment consists of B+C (10t/ha+90kgN, 135kgN and 180kgN), B+C (20t/ha + 90kgN, 135kgN and 180kgN), B+C (30t/ha + 90kgN, 135kgN and 180kgN), Biochar (20t/ha, 30t/ha), Cowdung (90kgN, 135kgN and 180kgN) and control. Viable seedlings transplanted were of uniform age of two months after transplanting and data were collected for 18weeks on plant height (cm), collar diameter (mm) and number of leaves at 3weeks intervals. The seedlings were further transplanted to the field for further research. All data obtained were subjected to statistical analysis using Genstat Statistical Software and were subjected to Analysis of Variance. Means were separated using Duncan's Multiple Range Test (Duncan, 1995) at 5% probability level.

There was significant difference among treatments from 3-9 WAT (HI to H3). At 3, 6 and 9WAT B+C3 was significantly different from B+C6 and the plots that receives no treatment (control CLT 15). However, at 12-18WAT, no significant differences were observed among the treatment used. The highest plant height was observed at B+C4 with a mean value of 29.62cm when compared with control (20.75cm) while B+C1 recorded the least mean value of 20.88cm.

There were no significant differences among the weeks after transplanting (WAT) except at week 15 and 18. At 15WAT, residual application of B+C3 and B+C4 with mean value 3.85mm and 3.81mm were significantly correlated than B+C6 which had the least performance with mean value 2.98mm when compared with control (3.02mm). At 18WAT residual application of B+C14 was significantly higher than B+C6 and the highest diameter was observed at B11 with a mean value of (4.83mm) while the least was recorded with B+C6 (3.49mm) respectively.

Table 5: Residual effects of organic manure on the Number of Leaves (NL) of *Pterocarpus soyauxii*

	Weeks after Transplanting (WAT)					
Treatment NL	(3) NL	(6) NL	(9) NL	(12) NL	(15) NL	(18)
B+C1	12.25a	15.25a	27.50a	30.25a	38.50a	44.25a
B+C2	11.50a	16.75a	28.25a	32.75a	40.00a	45.75a
B+C3	13.02a	18.75a	28.75a	34.01a	46.75a	45.01a
B+C4	13.01a	19.02a	28.25a	32.51a	49.01a	65.51a
B+C5	12. 25a	18.01a	20.05a	30.0a	45.75a	52.50a
B+C6	10.75a	14.25a	21.01a	27.01a	39.51a	36.51a
B+C7	13.02a	19.51a	27.52a	31.75a	42.25a	47.75a

B+C9	11.25a	15.75a	24.25a	27.75a	39.25a	53.51a
B10	12.25a	16.75a	28.02a	30.25a	41.01a	47.02a
B11	12.03a	15.25a	23.51a	28.75a	40.03a	52.01a
B12	14.25a	16.50a	28.02a	30.51a	47.25a	58.25a
C13	12.52a	17.51a	26.25a	32.25a	48.25a	56.75a
C14	11.25a	14.02a	24.75a	29.25a	43.50a	55.01a
CTL15	11.75a	14.5a	24.0a	28.0a	36.0a	44.25a

There were no significant differences among the treatment. At 18WAT the highest mean value of number of leaves was 51.3 while at 3WAT has the lowest mean value was 12.3. At 18WAT (B12) has the highest number of number of leaves of 58.25 while compared with control of 44.25.

DISCUSSION

The experimental soil was sandy soil and the pH was slightly acidic. The total nitrogen (N) and available phosphorus (P) content were high when compared with the critical value of 0.15% for N and 0.85mg/kg for available P (Ayodele and Agboola 1985) obtained for soil in south western Nigeria. Using the critical level of 0.16cmol/kg exchangeable Potassium (K) was low (Agboola and Ayodele 1987) and increase in N content in soils amended with cow dung and biochar suggests the ability of these amendments to supply N because of their fairly high N content. The results also suggest increased mineralization of river soil N was due to the priming effect after application of these amendments as a result of enhanced growth of soil microorganisms (Munda *et al.,* 2018). The adsorption of phosphorus in soil is pH dependent. With the increase in soil pH, solubility of P will also increase when biochar is added (Schneider 2012). The micronutrients (Cu, Mn, Fe and Zn) ranges from medium to high conforming with Ayele *et al.,* (2013). The medium to high values of these micronutrients may be due to long period of fallow of the land which has not been under cultivation for many years, according to Nigeria Country Profile (1997), the Country's soils are found to be of medium to high potentials.

It has also been suggested that organic amendments particularly biochar have considerable potential for soil improvement because of its unique physical, chemical, and biological properties and their interactions with soil and plant communities (Lehmann *et al.,* 2011; Amlinger *et al.,* 2007; Elad *et al.,* 2011). Fertilizer requirement of species, differ and such effort must be made to identify the appropriate fertilizer preferences of any species. Although some studies have reported only a limited effect of biochar and other organic amendments on plant growth (Lehmann *et al.,* 2011; Jones *et al.,* 2012), a number of others, using a range of plant species, have reported similar results (Ahmad *et al.,* 2014; Husk and Major 2011; Elad *et al.,* 2011). Our findings, however, suggested that cow dung played only a minor role in the increment of the growth variables, while biochar had significant effect on the growth of *Pterocarpus soyauxii* as a result of a longer time it takes to decompose and remains in the soil.

CONCLUSION

Combined use of organic amendments had shown a positive effect on soil condition and the growth response. A significant growth response (height) was found, where combined biochar/cow dung were applied. It also shows that there is positive response of biochar on collar diameter and number of leaves when applied solely. Therefore, the use of both cow dung and biochar to improve plant and soil quality can be recommended.

ASSESSMENT OF YOUTH INVOLVEMENT IN PLANTAIN VALUE CHAIN IN OYE LOCAL GOVERNMENT, EKITI STATE, NIGERIA

***Adebisi- Adelani O[1], Rufus M. D[2], Adebisi M. O[1], and Adewale M.O[1]**
[1]National Horticultural Research Institute, Ibadan,
[2]Federal University, Oye Ekiti

*Corresponding author: adelanidotol@yahoo.com +2348059221500

ABSTRACT
Agriculture has the potential to offer numerous productive employment opportunities for young people, provided there is an increase in investment and a favorable legal and policy environment. The plantain value chain involves the production, processing, transporting, marketing, and post-production of this horticultural crop, hence, the study aimed to assess the involvement of youth in all these processes in Oye local government, Ekiti state, Nigeria. Multi-stage sampling technique was used to arrive at the total of one hundred (100) youths. Data were collected using a well-structured questionnaire and was analyzed using descriptive statistics. The study reveals that the majority (62.0%) of the youth falls between the age of 25 and 44 years and about 58.0% were male. The study found that youth were moderately involved in plantain value chain, they make use of plantain production, processing, or marketing as a side hustle or secondary job. Also, it was observed that many of the respondents were educated which was concluded to be a major cause for the moderate and partial involvement of youth in Plantain value-chain. To encourage youths to participate more in active farming there is a need to encourage incentives that could make commercial agriculture enticing.
Keywords: *Plantain, Non- Agricultural, Agriculture, Horticulture, Young people*

INTRODUCTION

As reported by the Food and Agriculture Organization in 2021, Agriculture is the foundation of Nigeria's economy, contributing 22.35% to the GDP and serving as the main source of livelihood for most Nigerians, despite the presence of oil. The agriculture sector is made up of four sub-sectors which are: - Crop Production, Livestock, Forestry, and Fishing. Unfortunately, Nigeria's agricultural sector is bedeviled with several challenges such as lack of access to markets and credits, low level of technology especially mechanization, inadequate post-harvest infrastructure (storage, processing, transport), low uptake of research findings by stakeholders, and limited availability of improved technological packages especially planting materials and certified seeds (Ministry of Agriculture, 2007). This has made agriculture unattractive and non-lucrative, resulting in declining youth participation in agriculture (Muhammad-Lawal, Omotoesho, & Falola, 2009). According to Aphunu & Atoma (2010), in Nigeria, the farming population is aging. They noted that it is practically impossible for this aged generation dominating the agricultural sector to deliver the expected productivity required to meet the food demands of the growing population.

The National Policy on Youth Development in Nigeria states that individuals aged between 18 and 35 are considered youth (African Union). Most of these youth, both male and female, reside in rural areas where there are limited opportunities for productive employment (Allen., et al. 2016). However, because of their youth, resourcefulness, and entrepreneurial nature, they have a lot of untapped potential to revolutionize the agricultural industry. (Betcherman., et al. 2015). It is worth noting that Nigeria has one of the largest youth populations globally, with a staggering 13.9 million unemployed young Nigerians as of the second quarter of 2020. Unfortunately, this unemployment rate is on the rise in tandem with the growth in the youth population (NBS, 2020). According to the National Bureau of Statistics (NBS), Nigeria's youth population stands at 40 million, with only 14.7 million of them in full-time employment, and another 11.2 million without jobs. Agriculture has the potential to offer numerous productive employment opportunities for young people, provided there is an increase in investment and a favorable legal and policy environment. Nevertheless, the youth seem to be turning away from farming in search of more lucrative and business-oriented occupations (Girard, 2016).

Engaging more young people in the agricultural sector is one of the approaches to addressing the unemployment crisis among African youth. While most of the world's food is produced by (aging) smallholder farmers in developing countries, older farmers are less likely to adopt the new technologies needed to sustainably increase agricultural productivity and feed the growing world population while protecting the environment. Hence, we need to re-engage youth in agriculture. Plantain is a highly significant horticultural crop, ranking among the top ten food security crops that nourish people worldwide (USDA, 2012). It has long been a staple food for both rural and urban communities. Plantain is a versatile ingredient in the kitchen and serves as a primary ingredient in many popular delicacies and snacks. (Aina et al, 2012). The plantain value chain involves the production, processing, transporting, marketing, and post-production of this horticultural crop, all of these stages have employed different categories of persons in Nigeria and, therefore, have the capacity to solve the problem of unemployment, which is why this study aims to assess the involvement of youth in all these processes, to know how involved the youths are in Oye Local Government of Ekiti state. Ekiti State being among one of the plantain-producing States in Nigeria. In view of these, the objectives of the study were to:

1. Identify the socioeconomic characteristics of the youth in the study area;
2. Describe the major involvement of the youth in the plantain value chain;
3. Identify the non-agricultural business practiced by the youth of the study area;

METHODOLOGY

The study was conducted in Oye Local Government Area of Ekiti state. It was carved out from the defunct Ekiti North Local Government on 17 May 1989. Oye Local Government is bounded by Ilejemeje Local Government to the North, Irepodun/Ifelodun to the South, Ikole local Government to the East, and Ido/Osi Local Government to the West. A Multi-stage sampling technique was used to arrive at a total of one hundred (100) youths from two of the fifteen districts Oye and Ilupeju Ekiti which was purposively sampled based on 10%. Followed by random sampling of the communities in the two districts and finally by random sampling of a total of fifty youths in each of the two districts. It should be noted that the youth group in each community was identified through the village head. Descriptive statistics (mean, frequency, pie-charts, bar-charts and percentage distribution) were used to analyze the data.

RESULT AND DISCUSSION

Respondents' Socioeconomic characteristics

The result in Table 1 revealed that the majority (57.0%) of respondents are in the range of 35-44 years category. Thirty one percent are younger adults under 35 years, while only 12% are older, 45-54 years bracket. This indicates a relatively youthful sample, with most respondents in their mid-30s to early 40s. Looking at gender, there is a fairly even split between males (58.0%) and females (42.0%). This result is supported by the study carried out by (Tijani et al., 2009; Ekunwe &Ajayi in 2010), who found that Men were more involved in Plantain production, although considering that the differences were not so much we can infer that women are now getting involved in the value chain. For religious belief, an overwhelming majority (78%) identified as Christian, with far fewer identifying as Muslim (21%) or holding Traditional beliefs (1%). Ayinde et al., also reported that there were more Christians involved in the plantain value chain. Occupation-wise, civil service is the most common job (34.0%), followed by farming (30.0%), teaching (15.0%), trading (10.0%), and unemployment (11.0%). The prevalence of civil service jobs is high which can be associated with the presence of a tertiary institution in the Local Government, while farming and trading suggest some rural inhabitants are also represented. Only a few are unemployed from the sample which implies that they are involved in one activity or the other. In all, the respondents are relatively educated. Finally, a strong majority (76.0%) identified as indigenous to the area, versus 24.0% non-indigenous.

Table 1: Percentage Distribution of Socio-Demographic Characteristics of Respondents

VARIABLE		FREQUENCY	PERCENTAGE
Age	< 25 – 34 Years	31	31.0%
	35-44Years	57	57.0%
	45-54Year	12	12.0%
Sex	Male	58	58.0%
	Female	42	42.0%
Religious Belief	Christianity	78	78.0%
	Islam/ Traditional	21/ 01	21.0%/ 1.0%
Primary Occupation	Civil Servant/ Teaching	15/34	15.0%/ 34.0%
	Trading/ Farming	10/ 30	10.0%/30.0%
	Unemployed	11	11.0%
Educational Qualification	No formal education/ ND/NCE	02/ 40	2.0%/ 40.0%
	HND/ B.SC	23/35	23.0%/ 35.0%
Are you an indigene?	Yes/ No	76/24	76.0% / 24.0%

Source: Field Survey, 2023

Involvement of Youth in the Plantain Value Chain

The results in Table 2 revealed the involvement of the respondents in the plantain value chain. Regarding the production activities, the majority (63.0%) of the respondents were rarely involved in sucker production while 52.0% of the respondents were involved in plantain production. This is in agreement with the result obtained by Ayinde et al., (2022) and Akinyemi et al., (2010) where there was low involvement in plantain production. This can be as a result of the stress related to the production of plantain and their suckers. This imbalance raises sustainability concerns, as replanting is crucial for maintaining productivity over time. Also, regarding the processing, it was split into Flour, Chips, and fried plantain products. Findings revealed that more than half (60.0%) of the respondents were highly involved in the processing of plantain into flour, 32.0% of the respondents were involved in the processing into chips while 78.0% of the respondents were involved in the processing into fried plantain (Dodo), this result on processing negates the finding of Ayinde et al., in 2022 that observed that only 23% of the population were highly involved in plantain processing. Fifty seven percent of the respondents were highly involved in the distribution process of plantain, this result supports the finding of Adeoye et al., 2012 which identifies a lot of intermediaries in the transport or distribution of plantain. This points to potential opportunities for enhancing youth skills and engagement in additional plantain value-added products that have strong market demand. Regarding the marketing of the plantain, the result reveals that 43.0% of the respondents were highly involved in wholesale, 46.0% were moderately involved as retailers and 55.0% were rarely involved as consumers. This implies that respondents' participation further down the value chain in transportation, small-scale vending, and retail is less pronounced.

Table 2: Percentage Distribution of the Respondents on their Involvement in the Plantain Value Chain

Activities	Rarely Involved	Moderately Involved	Highly Involved	Mean
Production activities				
Sucker Production	63(63.0%)	21(21.0%)	16(16.0%)	0.950
Fruit Production	32(32.0%)	16(16.0%)	52(52.0%)	0.800
Processing into:				
Flour	40(40.0%)	10(10.0%)	50(50.0%)	0.960
Chips	68(68.0%)	10(10.0%)	22(22.0%)	0.540
Dodo	22(22.0%)	30(30.0%)	48(48.0%)	0.740
Distribution	10(10.0%)	33(33.0%)	57(57.0%)	1.470
Marketing				
Wholesales	16(16.0%)	41(41.0%)	43(43.0%)	1.270
Retail	32(32.0%)	46(46.0%)	22(22.0%)	0.900
Consumption	55(55.0%)	(0.5%)	45(45.0%)	0.900

Source: Field Survey,2023

Non-Agriculture Business Practiced

Table 3 is on the percentage distribution of the respondents on non-agriculture business practices, the findings revealed that the majority (77.0%) of respondents were not involved in businesses like tailoring and driving, 54.0% were highly involved in teaching while 46.0% were highly involved in trading. From the findings, it could be seen that most of the respondents have other businesses they engage in apart from farming which can help their income and livelihood sustainability as youths. This is supported by Daudu et al., (2023) who noted that youth would rather be involved in other activities than solely on farming.

Table 3: Percentage Distribution of the Respondents on Non-Agriculture Business Practiced

Non- agriculture Business	Rarely Involved	Moderately Involved	Highly Involved	Mean
Trading	11(11.0%)	43(43.0%)	46(46.0%)	1.320
Bike Riding	44(44.0%)	34(34.0%)	22(22.0%)	0.780
Mechanic	45(45.0%)	44(44.0%)	11(11.0%)	1.390
Tailoring	77(77.0%)	23(23.0%)	-	0.230
Driving	77(77.0%)	20(20.0%)	03(3.0%)	1.400
Teaching	3(3.0%)	43(43.0%)	54(54.0%)	1.400

Source: Field Survey, 2023

CONCLUSION AND RECOMMENDATION

From the study, we concluded that many of the youths were moderately involved in one plantain value chain or the other, however, it is not the sole or primary business of the youths in Oye Local Government. Many use plantain production, processing, or marketing as a side hustle or secondary job, while others as a subsistence form of agriculture. Also, it was observed that many of the respondents were at least educated which can be a major cause for the moderate and partial involvement, as youth in recent times would prefer to work in offices and other Jobs than farming which was also seen in the number of respondents that are employed into the civil service, as many youth sees farming as strenuous. This can also be linked to the increase in the number of respondents that participate in transporting and marketing the plantain in the value chain. It is obvious that there are a number of opportunities in the plantain value chain that has not been utilized, to encourage youths to participate more in active farming there is a need to encourage incentives that make commercial agriculture enticing as the population currently involved in farming are aged and this is not sustainable considering the increasing population of the country as well as ensuring food security.

IMPACT OF GAS FLARING ON COCOA SOIL FERTILITY IN NDOKWA LOCAL GOVERNMENT OF DELTA STATE

Asowata F. E.
Cocoa Research Institute of Nigeria

frankasowata@crin.gov.ng, frankasowata@gmail.com, +2348052645769

ABSTRACT
Gas flaring is common in the Niger Delta region of Nigeria to dispose of associated gas. Gas flaring is the burning of natural associated gas and other petroleum hydrocarbons at flare stacks during oil field operations and the basic components include methane, ethane, propane, iso-butane, n-butane, iso-pentane, n-pentane, n-hexane, CO_2, H_2S, He, and N_2 and soot etc. The threat to human, fauna and flora life posed by pollution due to gas flaring cannot be over-emphasized. Soil samples was collected from cocoa farms close to gas flare stack at Asemoku community in Ndokwa local government Area of Delta state at varying distances from the flow stations at a depth of 0-30cm using hand auger. Soil samples was collected at distance of 100m, 300m, 500m, 700m and control in cocoa farm away from the flow station. Soil samples were analyzed using standard laboratory procedures. The soil pH, a useful indicator of nutrient availability, presence of heavy metals in soils, the pH values ranged from 4.0 to 6.2.
Keywords: *Cocoa, hydrocarbon, gas, flaring, metals soils*

INTRODUCTION
Nigeria produces about 290,163*MT* (Statista., 2023 and in the first quarter of 2022, she earns some N22.89bn from exporting raw cocoa beans and other cocoa products (National Bureau of Statistic, 2022). The output of Nigeria cocoa beans for three years; 2014/15 to 2016/17 was about 620,000 metric tons and Niger Delta oil and gas producing states accounted for 546,822 metric tons which is about 88% as revealed by Cocoa Value Chain Assessment Report of the Foundation for Partnership Initiative in the Niger Delta (Aljazirah., 2019). Gas flaring is common in the Niger Delta region of Nigeria to dispose of associated gas (Akpojivi *et al*., 2005). Gas flaring is the burning of natural associated gas and other petroleum hydrocarbons at flare stacks during oil field operations and the basic components include methane, ethane, propane, iso-butane, n-butane, iso-pentane, n-pentane, n-hexane, CO_2, H_2S, He, and N_2 and soot etc. The threat to human, fauna and flora life posed by pollution due to gas flaring cannot be over-emphasized. These acid gases are carried downward as acid deposition (wet and dry depositions) onto cocoa vegetation, soil, and water bodies in communities close to the flare sites. This work was carried out in Ndokwa LGA, to study the impact of gas flaring on the fertility of cocoa soils.

MATERIAL AND METHODS
Soil samples was collected from cocoa farms close to gas flare stack at Asemoku community in Ndokwa local government Area of Delta state at varying distances from the flow stations at a depth of 0-30cm using hand auger. Soil samples was collected at distance of 100m, 300 m, 500m, 700m and control in cocoa farm away from the flow station. Soil samples were analyzed using standard laboratory procedures.

RESULTS AND DISCUSSION
Table 1: physical properties of cocoa growing soils in gas flared areas in delta state

S/n	Sand %	Clay %	Silt %
1	79.52	9.2	11.28
2	77.52	7.2	15.28
3	35.52	13.2	51.28
4	45.52	23.2	31.28
5	77.52	11.2	11.28
6	73.52	13.2	13.28

The physical properties of soil analysis is presented in tables 1 above and table 2 below. The textural classes of the soil samples is sandy-loam, and well suitable for cocoa cultivation. The soil pH, a useful indicator of nutrient availability, presence of heavy metals in soils, the pH values ranged from 4.0 to 6.2.

Table 2: Physical properties and pH of cocoa growing soils in gas flared areas in the Niger Delta

S/n	Distance (m)	pH	Temp. (O^{o}C)	Moisture (%)
1	100	4.0	60	16
2	300	4.2	48	27
3	500	4.4	34	32
4	700	5.7	30	30
5	control	6.2	30	45

The pH values increased away from the gas flare site along the cocoa plantation this is due to the deposits of acidic gas from gas flaring during oil and gas production and acid rains around cocoa farms close to flow station. the effect acid rain on vegetation and crops results in the decline of productivity and growth of some major food crops in the region such as; cassava, maize, plantain and cash crops like rubber, cocoa and oil-palm has also been documented. The recommended pH is 5.5-6.5 for cocoa growing soils, however cocoa has thrived in some lower pH soils of 4.5-5.5. The percentage moisture contents increased away from the gas flaring point, the soils of the cocoa plantation closer to the flare stack drys faster, this is certainly as a result of the continuous heat generated by continuous burning of petroleum gases (CO_2, H_2S, He, and N_2 and soot) etc.

Table 3: Chemical properties of cocoa growing soils in gas flared areas in the Niger Delta

S/n	Ca Cmol/kg	Mg Cmol/kg	K Cmol/kg	Org C %	N **%**	P mg/kg
1	2.45	1.18	0.12	1.32	0.09	1.27
2	1.15	2.97	0.26	1.76	0.21	2.86
3	2.15	2.34	0.24	2.60	0.18	2.40
4	4.67	2..63	0.36	4.60	0.90	1.64
5	2.86	1.52	0.24	0.80	0.06	4.32
6	3.43	1.82	0.22	1.08	0.06	8.52

The results of the chemical analysis is presented in table 3. Nitrogen content was adequate at sampling points closer to the flow station but wasn't up to the critical value of 0.09% at 700m and control which are further away from the flare points. This also confirm the present of nitrogen gas during gas flaring. The available P was inadequate across all sampling locations and far below the critical value of 10mg/kg recommended by Egbe (1989) as shown in table 4

Table 4: Critical levels of some soil properties for cocoa cultivation by Egbe (1989)

N %	P Mg/kg	K Cmol/kg	Ca Cmol/kg	Mg Cmol/kg	Zn Mg/kg	OM %	pH
0.09	10.0	0.3	5.0	0.8	2.80	3.0	5.5

The K content was also inadequate except at sampling point 5 and all samples was inadequate for Ca in the study area. Gas flaring could alter soil quality parameters including physio-chemicals and microbial characteristics as seen in table 2. it has been reported that temperature, bulk density decreases with distance from flaring sites while CEC, organic matter and moisture contents increases away from gas flare stations as seen in our reports in tables 2 and 3.

Table 5: Heavy metals in cocoa soils in gas flared areas in the Niger Delta

Soil S/n	Pb cmol/kg	Cr cmol/kg	Ni cmol/kg	Cd cmol/kg	Cu cmol/kg	Zn cmol/kg
1	54.25	-	-	22.45	15.75	33.45
2	42.25	-	-	17.25	43.00	20.25
3	39.50	-	-	15.25	18.00	36.45
4	30.25	-	-	11.50	26.50	27.75
5	18.50	-	-	7.25	38.00	23.25
6	9.25	-	-	10.25	35.75	18.25

CONCLUSION

Heavy metal pollution has been reported in cocoa soils but focus was on the use of agrochemical. The possible heavy metal contamination of cocoa soils due to (oil and gas) flaring is presented in table 5. Cadmium is a component of refined products of petroleum as an impurity (Buekers, 2007). The range of Pb, Cd, Cu and Zn contents around flaring sites in the study areas is presented in table 5. It can be observed that the values decreased away from the gas flaring points with exception of Zn at sample point 3. The cadmium values in cocoa farms around gas flare areas was higher in all samples far above the critical safety level for cadmium by various authorities (0.8mg/kg WHO, 1996, 0.76mg/kg, Commentuijn *et al.* (1997), 0.5mg/kg (Saadia *et al*., 2016). It is important to stress that excessive levels of cadmium in soil (>1 mg/kg) presently found in samples is due to closeness of such farms to some gas flaring and other petroleum contamination of the areas and may largely be as a result of emissions (Oversteyns.,1992). Cu and Zn values were lower in samples but the range suggest a build up above the permissible or critical levels and probably a clean up process going on the area. There is need to expand the study to other areas and monitor cocoa production closely in the Niger Delta since majority of cocoa beans comes from the Niger Delta region.

ABSTRACT
Coffee production has social and economic impact locally and internationally as about two (2) billion cups of coffee is consumed worldwide on a daily basis (British Coffee Association., 2021), coffee is second only to petroleum in the world trade (Famaye, 2019). Adequate soil nutrition is essential in modern coffee production to increase yield therefore, agricultural practices in coffee plantations should preserve the soil fertility, which is the wealth of the growers. Healthy soils are the foundation of agriculture and indeed civilization itself. There are strong indications of soil nutrient deficiency across coffee plantations irrespective of age. The soils reaction was slightly acidic to neutral, ranges from 5.20 to 7.15 and the soil pH across the plantations was within the critical levels of coffee cultivation which is 5.5 to 7.0 (Robusta) and 4.5 to 5.5 (Arabica) as reported by Daniel et al (2015). The N values are moderately adequate for coffee with few inadequacies but the P and K values are all inadequate across plantations thus limiting yield as well as income to farmers. Similar research across coffee plantations nationwide should be carried out with a view of developing data base for coffee cultivation. The use of organic (coffee waste) or inorganic fertilizers and rehabilitation of the coffee plantations used for this study is strongly recommended.
Key words*: Coffee, soil, nutrients, yield, critical.*

INTRODUCTION

Coffee production has social and economic impact locally and internationally as about two (2) billion cups of coffee is consumed worldwide on a daily basis (British Coffee Association., 2021), coffee is second only to petroleum in the world trade (Famaye, 2019). Adequate soil nutrition is essential in modern coffee production to increase yield therefore, agricultural practices in coffee plantations should preserve the soil fertility, which is the wealth of the growers. Healthy soils are the foundation of agriculture and indeed civilization itself (Joel *et al*., 2010). Plant roots grow and absorb water and nutrients according to the physical, chemical and biological properties of the soil which in turn affects yield of crops among other factors. It was based on the assumption that the plant itself is used as a soil nutrient extractor and, within certain limits, there is a relationship between the supplies of nutrients, either from the soil or the fertilizer, and leaf nutrient contents; increases in leaf nutrient content are related to higher yields, and decreases to lower yields (Bataglia *et al*., 2004). Leaf analysis is an efficient way to monitor the health and nutrient status of plants which play a vital role on the quality and yield of coffee berries (Joel *et al*., 2010).

Since most of the coffee plots in the Institute were established over two decades ago, the nutritional reservoir in the soil might be insufficient to completely meet the nutrients demand; it is therefore necessary to evaluate the nutrient status of the soils. Soil nutrient status is proportional to the yield and quality of plants and production can be drastically reduced in poor soils if limiting factors are not quickly detected and promptly corrected.

MATERIALS AND METHODS

The experiment was conducted at Cocoa Research Institute of Nigeria Ibadan, Nigeria (Lat 07°10¹ and Long 03°51¹E) and altitude 124m above sea level with average daily temperature of about 30°C. Ibadan is located in the forest ecological zone with a bimodal rainfall pattern and a mean annual rainfall of 1300mm. Soil samples was taken from two different soil depths (top at 0-20cm and subsoil 20-40cm) using soil auger. The composite soil sample was processed through 2mm sieve and analyzed using standard laboratory procedures. The soil pH was measured in 1:1 soil-water ratio, the particle size was determined by Bouyoucos hydrometer method (Bouyoucos,1951). Available P was by Bray P1(Bray and

Kurtz 1945) Leaf samples was collect from the 3rd and 4th leaf on the branches of coffee trees and was processed and analyzed following standard laboratory processes.

RESULTS AND DISCUSSION

Physical properties of soil under coffee plantations

Table1: presents the summary of the physical properties of the soil at the (0 – 20) cm and (20-40) cm soil depth under coffee plantations. Results showed that the physical properties of the soil under different coffee plantations varied. The soils of the plantation varied in their sand, silt and clay content, nevertheless, the textural class is generally sandy loam**.** The soils reaction was slightly acidic to neutral, ranges from 5.20 to 7.15 and the soil pH across the plantations was within the critical levels of coffee cultivation which is 5.5 to 7.0 (Robusta) and 4.5 to 5.5 (Arabica) as reported by Daniel et al (2015).

Chemical properties of the soil and leaf under coffee plantations at CRIN, Ibadan

Table.2 presents the summary of the chemical properties of the soil at the (0 – 20) cm and (20-40) cm soil depth under coffee plantation. Results showed that the chemical properties of the soil under different coffee plantations also vary. The N content in samples 1 and 2, CRIN demonstration plot top and subsoil was adequate and above 0.09%, similar results was obtained in zone 5 coffee germplasm plot and samples 7 and 8. But samples 3,4,9 and 10 were below the nitrogen level required for coffee production. This trend shows a continuous depletion of soil nutrients across the plantations. The K contents are grossly inadequate across coffee plantations both top and subsoil, it ranges from 0.154 cmol/kg to 0.352cmol/kg against the minimum critical value of 4.5cmol/kg (Daniel *et al.,* 2015). These inadequacies maybe related to the removal of nutrients due to harvesting over two decades. The P content was also very low across plantations, with the highest value of 11.76mg/kg and the least value of 1.46mg/kg against the recommended critical value of 30mg/kg for coffee production confirming the high levels of nutrient depletion across the coffee plots as a result of nutrient mining majorly through harvest of berries and this also confirm the non usage of fertilizers in the coffee research plots for over two decades which definitely affects yields.

Coffee leaf analysis

Table 3 presents the results of the coffee leaf analysis which shows varying degrees of deficiency. The % N contents in the leaves was lower in most samples except samples 5 and 6, others are below the critical range of 2.5-3% irrespective of the age of the plantation. The N values ranged from 2.013 to 2.835 % N showing similarity of low N with the soil samples. The K content was also inadequate except for samples 3and 4 with 2.443% K and 2.299% K values compared to the critical range of 2.1 o 2.6%K recommended by Abayneh *et al*., (2015, FAO undated). The Ca and Mg content of the leaf samples was found to be below the critical range of 0.75-1-5 and 0.25-0.40% for all leaves samples while Na values for all leaf samples was adequate for coffee as seen in table 4.

Table1: Soil physical properties under coffee plantation

	pH	Sand	Silt	Clay

Source: Abayneh *et al*., 2015

CONCLUSION AND RECOMMENDATIONS

The soil and plant nutrients analysis of coffee plantations across the institute headquarters is far revealing. There are strong indications of soil nutrient deficiency across coffee plantations irrespective of age. The soils reaction was slightly acidic to neutral, ranges from 5.20 to 7.15 and the soil pH across the plantations was within the critical levels of coffee cultivation which is 5.5 to 7.0 (Robusta) and 4.5 to 5.5 (Arabica) as reported by Daniel *et al* (2015). The N values are moderately adequate for coffee with few inadequacies but the P and K values are all inadequate across plantations. The leaf samples show similar deficiencies for N, K, Ca, Mg in the study areas. Similar research across coffee plantations should be carried out with a view of developing data base for coffee cultivation. The use of organic or inorganic fertilizers and rehabilitation of these coffee plantation is strongly recommended.

ABSTRACT
Tomato (Lycopersicon esculentum Mill.) is one of the most important vegetables worldwide. This experiment was conducted at National Horticultural Research Institute (NIHORT), fifteen cultivars of tomatoes were sown in planting trays in the nursery on February 14th, 2014. The seedlings were transplanted on the 24th of March 2014 onto a plot of 9m^2. Plant to plant distance was 50cm apart with RCBD experimental design replicated three times. Data collected were seed germination percentage, seedling survival, seedling height, number of leaves per seedling, height at maturity, stem girth, number of branches, day to first fruiting and number of fruits (yield) per plant and weight of fruit per plant, fruit pH. The result of the establishment count after two weeks of transplanting to the field showed that AVTO 1303 had 97.62 % while Star 9063, UC82 B(BB), UC 82 B(SA) and ROMA VF (BB) had 60% germination. STAR 9064 and RIO GRANDE (SA) had slow growth rate at 7WAP (Plant height 3.25 cm, 5.5cm; Stem diameter 0.12 cm, 0.13 cm; Number of Leaves 1.75, 1.75,). The cultivars Star 9064, Rio Grande (BB), Rio Grande (SA), and UC 82 B were late flowering.
Keywords: *Tomato, varieties, yield, pH, fruit quality*

INTRODUCTION

Tomato (*Lycopersicon esculentum Mill.*) is one of the most important vegetables worldwide. Tomato belongs to the Solanaceae family. World tomato production in 2001 was about 105 million tons of fresh fruit from an estimated 3.9 million ha. It is a relatively short duration crop and gives a high yield, it is economically attractive and the area under cultivation is increasing daily. It is an important source of vitamins and an important cash crop for small holders and medium scale commercial farmers (Krishna *et al.,* 2022). Tomatoes contribute to a healthy, well-balanced diet. They are rich in minerals, vitamins, essential amino acids, sugars, and dietary fibres. Tomato contains much vitamin B and C, iron, and phosphorus (Oladokun *et al.,* 2022) fruits are consumed fresh in salads or cooked in sauces, soup and meat or fish dishes. They can be processed into purées, juices, and ketchup. Canned and dried tomatoes are economically important processed products.

Three different types of tomato plants can be distinguished: tall or indeterminate type; semi-bush or semi-indeterminate type; bush or determinate type. The tall varieties are the best choice for a long harvest period. They keep growing after flowering. This feature is called indeterminate. However, under tropical conditions, diseases and insect attacks will stop growth. The plants generally have more foliage. This will keep the temperature lower within the crop and the fruits grow in the shade of the leaves. Because they are covered, the sun does not damage the fruits and they ripen more slowly. Slower ripening and a high leaf/fruit ratio improve the taste of the fruits and in particular the sweetness (Almansa *et. al* 2011). `The tall types must be staked, caged, or trellised. Short types usually support themselves and need no staking. Under severe weather conditions such as heavy rain however, staking may be advisable. Determinate types stop growing after flowering. They require less labour, so they are popular for commercial cultivation. They have a relatively concentrated fruit set which lasts only two or three weeks, and the fruits ripen much faster than those from indeterminate types.

Tomatoes are normally transplanted, because much better results are gained when seedlings are raised in a nursery (Chiomento *et al.,* 2020). Two methods of raising seedling in nurseries can be used: sowing in seedbed; sowing in seedling tray. Smaller quantities of seed are needed, the seedlings can be selected for growth and health before planting in the field, the plantlets can be well protected, and the planting distance is more regular than after sowing directly in the field. The objective of this research was to test the viability, yield, and adaptability of the tomato cultivars to different agro ecologies in Nigeria.

MATERIALS AND METHODS

Fifteen cultivars of tomatoes were sown in planting trays in the nursery on February 14th, 2014. The seedlings were transplanted on the 24th of March 2014, to the experimental field in NIHORT onto a plot of $9m^2$. Plant to plant distance was 50cm apart. Data collected were seed germination percentage, seedling survival, seedling height, number of leaves per seedling, height at maturity, stem girth, number of branches, day to first fruiting and number of fruits (yield) per plant and weight of fruit per plant. The pH of the fresh fruit samples was determined using One gram of sample homogenized in 1ml of distilled water and 1ml of de-ionized water of pH 7.0. The pH of the juice was recorded using an electronic pH meter. The pH meter was standardized using a buffer solution of pH, the method described by Rangana (1979).

RESULTS AND DISCUSSION

Germination in the nursery: 15 cultivars of tomatoes were planted, after 3 days all other cultivars except Bro Portinari, Brs Nagar, Brs Kiara, Brs Montese and Brs Couto germinated. However, after 5 days, Brs Couto, Brs Montese and Brs Kiara germinated. All the 13 cultivars that germinated were transplanted to the field on the 24th of March 2014. The establishment count after two weeks of transplanting to the field showed that AVTO 1303 had 97.62 % while Star 9063, UC82 B(BB), UC 82 B(SA) and ROMA VF (BB) had 60% respectively (Table 2). However, Brs Couto, Brs Montese and Brs Kiara did not survive. These can be due to some factor that was identified by Ma *et a*l., (2023)

Vegetative growth of cultivars: The vegetative growth for the different cultivars was highly significant (p=0.05%). However, STAR 9064 and RIO GRANDE (SA) had slow growth rate at 7WAP (Plant height 3.25 cm, 5.5cm; Stem diameter 0.12 cm, 0.13 cm; Number of Leaves 1.75, 1.75,) respectively (Table 1). Significantly higher plant height was observed with AVTO 1303.

Reproductive parameters of cultivars: The cultivars Star 9064, Rio Grande (BB), Rio Grande (SA), and UC 82 B were late flowering as shown in Table 2 indicating average number of flowers per plant. This affected the days to first fruiting and fruiting in the different cultivars. For average fruit weight per plant, UC82 B(BB) 61.46g, AVTO 1303 65.72g and Ibadan Local 60.67g is significant (Table 2). The fruit weight obtained in this study is higher than the fruit weight per plant reported by Nwosu *et al.,* (2018) who obtained as low as 2.72g fruit weight.

Fruit Quality: The pH of the fresh tomato fruits from ten varieties was in the range of 4.1 to 5.9 (Table 2). UC (SA) had the highest pH of 5.9 while Star 9063 had the lowest pH of 4.1. The pH of most varieties fall within suitable pH range for tomato processing. Tomato pH ranges from 4.3 to 4.9 according to Aboagye-Nuamah *et al*., (2018)

CONCLUSION

The study has shown that significant differences exist in the morphological properties of the ten tomato varieties The pH of the fresh fruit meet the recommended level of desirable traits for industrial tomato processing.

Table 1: Vegetative parameter for Tomato cultivars

	7WAP			9WAP			
Cultivar	Plant height (cm)	Stem diameter (cm)	No of Leaves	Plant height (cm)	Stem diameter (cm)	No of Leaves	No of branches

ABSTRACT
Telfairia occidentalis (Hooks F.) is king of leafy vegetable and an economically important cash crop. The variability among the accessions was studied by characterizing their agronomic and yield traits. The 38 accessions used were collected from different geopolitical zones in Nigeria. The experiment was performed in a randomized complete block design with three replications. Mean square values due to accessions were highly significant (p >0.01) for all the traits studied. Acession38 gave the highest female leaf area at 437.80cm2. AC39, AC14, AC1 and AC38 recorded early days to flowering at 80.33, 86.67, 91.33 and 92.33 respectively. Early days to pod set was observed in AC14, AC38 and AC1 at 106.31, 106.33, and 116.67 respectively. AC38 had maximum number for female percentage ratio at 96.67%. AC10 and AC38 had maximum pod lengths at 72.75cm and 64.65cm respectively. AC10 and AC38 had maximum pod widths at 84.50cm and 72.90cm respectively. Greater number of pod weight was observed in AC38 and AC14 at 63.80g and 45.13g. AC38, AC 14 and AC3 recorded higher number of pod yield per plot at 9.5, 8.67 and 7.0 respectively. Based on the evaluated traits, promising lines; AC38 AC14 and AC 10 can be deployed as progenitors to develop early maturing, high yielding Telfairia occidentalis varieties adaptable to south western Nigeria. This information is vital for conservation of different genetic materials and initiation of improvement programme for Telfairia occidentalis in western Nigeria
Keywords: *Telfairia occidentalis, accessions, characterization, leaf area, internode, pod length, pod width, pod weight*

INTRODUCTION

Fluted pumpkin (*Telfairia occidentalis* Hook. F.), named after the famous Irish naturalist, botanist and plant collector Charles Telfair is a member of the family cucurbitaceae and order Telfaireae. (Compleat botanica, 2004; Jeffrey, 1980). The two main species in the genus are Telfairia occidentalis (Hook (F) and Telfairia pedata (Smith ex sim World Agro Forestry Centre, 2004). Botanically, it has a creeping growth habit and its vines spreads across the ground to produce an efficient cover to the ground against erosion and produces large fruits with many large seeds ((Horsfall and Spiff, 2005; Ajayi et al., 2004; Purseqlove, 1997). It is a dioecious plant with male and female flowers borne on different plants (Boualem *et al*., 2015). Male plants start flowering earlier at means of 129 days compared with 150 days after planting for female plant and over a longer period of 59 days versus 17 days for females plant (Fayeum *et al.,* 2016a; Akoroda, 1990). There are more than 300 open male flowers to single opened female flowers and male flowers open in the evening. About 10 – 15% of given female population do not flower in the first year of planting and abortion of fruit is high (Fayeum et al., 2016a). Plant may set up to six fruits but usually one large and one or two medium sized fruits are eventually carried to maturity. (Ajayi *et al.,* 2016; Akoroda and Adejoro, 1990).

Telfairia is indigenous to Nigeria. It is commonly cultivated in the South Eastern part of Nigeria (Akoroda, 1990). Studies conducted by Schippers, 2002 show that its cultivation is gradually gaining prominence in the South Western part of the country. It serves as food for millions of people in the world and is widely grown in tropical wet coastal areas of West Africa, principally in Benin, Cameroon, Ghana, Nigeria and Sierra Leone (Odiaka *et al*., 2008; Okoli and Mgbeogwu, 1983; Akoroda, 1990). Also, it is grown in Florida as summer vegetable (Ajayi *et al.,* 2007; Uguru and Onovo, 2011). The leaf is used for preparing delicacy like “Edikang Ikong” and Ubo abak soups. The leaves of the plant are very much sought after by sheep and goats hence could be used as fodder (Boualem *et al*., 2015; Akoroda *et al*., 1990). Chukwudi and Agbo, 2014 reported that fluted pumpkin is an important vegetable supplement in the carbohydrate dominated staple food chain of West Africa. It is very rich in iron and protein and is used to cure anemia. A low dose of 400 mg/kg body weight fluted pumpkin seed oil improved sperm count and testicular histology in rat (Akang *et al.*, 2010). The seeds are enriched in amino acids (94.9%) which contains higher levels of essential amino acids than soya bean with 93.7%. (Odiaka *et al.,* 2008; Esuoso *et al.,* 1998).

Despite being a very important vegetable crop well known for its rich source of protein, vitamins, mineral, oil, medicinal value, economically cash crop and means of livelihood of many rural communities (Chukwudi and Agbo, 2014; Odiaka *et al.,* 2008; Ajayi *et al.*, 2007; Okafor, 1983), report from the regional stakeholder workshop for West Africa held in 2010, in Cotonou, Benin categorized fluted pumpkin among the neglected and underutilized plant species with the potential to play key role in supporting rural livelihoods and in alleviating food insecurity. However, research findings have revealed there are scanty data or information on phenotypic and genetic identification of existing accessions of this orphan crop which would be beneficial to increase food security. There is also a problem in differentiating existing accession from one another due to wide genetic variations among them which is essential for the long term success in breeding programme and maximizing the exploration of germplasm resources (Chukwurah and Uguru, 2010; Balaj *et al.,* 2002). There is insufficient knowledge of genetic relationship among these accessions which would aid in selecting promising and desirable progenitors for future breeding programme. The success of any crop breeding programme largely depends on studying the availability of huge genetic variability and possible genetic progress that might arise among accessions (Nwangburuka *et al.,* 2014). Therefore, it was on this basis that this study was conducted to identify, and differentiate existing accessions and to select promising and high yielding accessions for crop improvement programme.

MATERIALS AND METHODS

The study was conducted in 2022 wet growing season at the Research Farm of National Horticultural Research Institute, Ibadan (Latitude 7º24’26”N, and longitude 3º50’43”E; 191 meters above sea level) Ibadan has bimodal rainfall distribution, which peaks in June/July followed by a two weeks break in August. This distribution creates two cropping season generally categorized as early and late. The early rain occurs between late March/April and end of July while the late rain occurs from August/September to November (Olaniyan *et al* 2001). Total number of 38 accessions of Telfairia occidentalis were collected from different geopolitical zones of Nigeria. Seeds of each accessions were raised in trays containing sterilized sawdust for two weeks in the screen house and watered four times in a week. Two weeks old telfairia seedlings were transplanted to the field during early rainfall. The experiment was laid out in randomized complete block design with 3 replications. The plot size was 2m x 2m and plant spacing of; 1m inter spacing and 50cm intra spacing making a population of 20,000 plants per hectare. Weeding and all other agronomic practices and farm hygiene were carried out as at when due.

DATA COLLECTION

Data were collected on agronomic traits as follows: Internode length (cm), Petiole length (cm), Male leaf area (cm2), Female leaf area (cm2), Male days to flowering, Female days to flowering, Days to pod set, Pod length (cm), Pod width (cm), Fresh pod weight (grams) and Number of pod yield per plot based on the International Plant Genetic Resource Institute (IPGRI, 1995) descriptors for Telfairia. The data were subjected to statistical analysis, means were separated using the Least Significant Difference (LSD) (Ajayi *et al.,* 2007).

RESULTS

The primary aim of this study was to characterize the existing levels and patterns of phenotypic diversity among the accessions of Telfairia Occidentalis. The information about the existing diversity is an essential prerequisite for the success of any breeding program and provide a good opportunity for the selection of accessions with desirable quantitative traits, such as high leaf yield, pod size and shape, and acceptable to consumers. Table 1 shows the mean square value for all the traits studied. It revealed that mean square values due to accessions were highly significant ($p > 0.01$) for all the traits studied which includes internode length, petiole length, male leaf area, female leaf area, male days to flowering, female days to flowering, days to pod set, pod length, pod width, pod weight and number of pod yield per plot. The mean performance of the accessions of telfairia occidentalis indicates considerable variation was observed among the accessions studied. Maximum internode length was recorded for AC21 at 19.15cm while AC16 had minimum internode length at 7.95cm. For the petiole length, AC38 had the highest

petiole length at 18.36cm but AC1 had least petiole length at 6.65cm. The trait female leaf area was identified for AC38 at 437.80cm2 while a minimum of 68.55cm2 for AC26. AC38 recorded maximum mean value for male leaf area at 227.55cm2 but AC26 displayed minimum male leaf area at 37.50cm2.
In the determination of days to first flowering, for male days to flowering, it was observed that AC39, AC14 and AC38 had early number days to first lowering at 73.33, 79.00 and 81.31 respectively while AC21 had late number of days to first flowering at 127.50. For female days to flowering, AC39, AC14, AC1 and AC38 recorded early days to flowering at 80.33, 86.67, 91.33 and 92.33 respectively but AC21 had late days to flowering at 141.50. Days to pod set was moderately lower for AC14, AC 38 and AC1 at 106.31, 106.33, and 116.67 respectively while AC4 recorded maximum days to pod set at 129.00. For the percentage male to female ratio, AC38 had maximum number for female ratio and minimum number for male ratio while AC35 had maximum number for male ratio but minimum number for female ratio. AC10 and AC38 had high level of pod length at 72.75cm and 64.65cm respectively but AC23 had lower pod length at 23.12cm. Again, AC10 and AC38 had maximum pod width at 84.50cm and 72.90cm respectively while AC23 had minimum pod width at 16.97cm. Greater number of pod weight was observed in AC38 and AC14 at 63.80g and 45.13g but AC20 had lower pod weight at 4.0g. A greater number of pod yield per plot was witnessed in AC38, AC 14, and AC3 at 9.5, 8.67 and 7.0 respectively but AC20 and AC10 recorded lower number of pod yield per plot at 1.5 and 1.0 respectively.

DISCUSSION

All the morphological traits showed highly significant ($P \leq 0.01$) variations indicating the presence of sufficient amount of genetic variability among the Telfairia occidentalis accessions for all the studied traits. This was evident by the outcome of the ANOVA. (Chukwudi *et al.,* 2016; Ogar and Asiegbu, 2005; Ajayi *et al.,* 2007 reported sufficient genetic variation in Telfairia occidentalis which warrant selection and hybridization among this specie for development of superior genotypes. Similar variability was reported by Rego *et al.,* (2015b); Akoroda and Adejoro (1990) which showed that traits evaluated had highly significant differences for almost all the genotypes studied indicating a wide range of variability among the genotypes evaluated and that breeders should select such genotypes to develop superior varieties. All the traits studied which includes Internode length, petiole length, male leaf area, female leaf area, male days to flowering, female days to flowering, days to pod set, pod length, pod width, pod weight and number of pod yield per plot varied significantly at ($P \leq 0.01$. Maximum internode length was recorded for AC21 at 19.15cm. AC38 had the highest petiole length (These results confirmed the studies carried out by Odiaka and Akoroda (2009). Maximum average female leaf area of 437.80cm2 was identified for AC38 and a minimum of 68.55cm2 for AC26). AC38 recorded maximum male leaf area 227.55cm2. (Fayeum *et al.,* 2016b; Akoroda *et al*., 2006).
AC14 and AC38 had early number days to male first flowering at 73.33, 79.00 and 81.31 respectively. AC21 had late number of days to male first flowering at 127.50. AC39, AC14, AC1. AC38 recorded early days to female flowering at 80.33, 86.67, 91.33 and 92.33 respectively similar results were reported by (Ogwu *et al*., 2017; Fayeum *et al.*, 2016a ; Ajayi *et al.,* 2004). AC21 had late days to female flowering at 141.50 similar results were reported by (Chukwudi and Agbo, 2016; Aremu and Adewale, 2012). AC38 had maximum number for female ratio and minimum number for male ratio while AC35 had maximum number for male ratio but minimum number for female ratio (Ezenwata *et al.*, 2019; Adeyemo and Tijani, 2018; Grumet et al., 2011). AC14, AC 38 and AC1 had early days to pod set at 106.31, 106.33, and 116.67 respectively but AC4 had maximum days to pod set at 129.00 (Akoroda and Adejoro, 1990; Uchechukwu *et al.,* 2017). AC10 and AC38 had maximum pod length at 72.75cm and 64.65cm respectively but AC23 had lower pod length at 23.12cm. AC10 and AC38 had maximum pod width at 84.50cm and 72.90cm respectively while AC23 had minimum pod width at 16.97cm. Greater number of pod weight was observed for AC38 and AC14 at 63.80g and 45.13g. AC20 had lower pod weight at 4.0g (Odiaka *et al*. 2008). A greater number of pod yield per plot was witnessed for AC38, AC 14, and AC3 at 9.5, 8.67 and 7.0 respectively. AC20 and AC10 recorded lower pod yield per plot at 1.5 and 1.0 respectively (Fayeun *et al.*, 2016; Nyaka *et al.,* l 2005; Ajayi *et al*., 2004)

CONCLUSION AND RECOMMENDATION

1. The genetic variations that existed among the studied accessions were evident in the morphological traits measured and yield obtained
2. Accession AC38 and AC14 due to its distinguishing high leaf yielding in the is recommended for further genetic/crop improvement programme

3. Accession AC1 and AC38 with early days to pod sets are recommended to be included in hybrid breeding programme for crop improvement
4. The highest fruit yield/plot obtained for AC38 and AC14 are recommended for further genetic/crop improvement programme
5. AC38 and AC14 with highest average fruit weight are also recommended for further genetic/crop improvement programme

ABSTRACT
This study was carried out to determine the effect of groundnut oil in protecting stored cowpea (Vigna unguiculata L. Walps) from attack by Callosobruchus maculatus. The experiment was laid out in completely randomized design (CRD) replicated three times with five treatments admixed with 100g cowpea seed; 0 (T_1), 3.5 (T_2), 4.0 (T_3), 4.5 (T4) and 5.0 ml (T5). Data were collected on adult mortality, oviposition, progeny, seed damage and weight loss. The recorded data were analyzed using analysis of variance and the treatment means were compared by Fisher's least significant difference (F-LSD) at 5% probability level. The results showed that there were significant differences between the treatments ($P \leq 0.05$). Cowpea treated with 4.5 and 5.0 ml recorded 100% insects' mortality at 72 and 96h while 4ml exerted 100% mortality at 48h. oviposition was completely inhibited in cowpea treated with 4, 4.5 and 5ml oil. While progeny emergence was suppressed in 3.5, 4.0, 4.5 and 5.0ml dishes. The result shows that least weight loss and seed damage was observed in cowpea treated with groundnut oil compared to other control. Based on this study it was recommended that groundnut oil can be used to protect cowpea from damage caused by C. maculatus infestation as it has no documented health risk compared with the use of pesticide.

INTRODUCTION

Cowpea (*Vigna unguiculata* L. Walps) as a pulse is commonly stored as staple for man and animals due to its high protein content especially in tropical and subtropical regions where it complements the expensive animal protein source in human diet. It also as livestock feed to make silage and hay (Diouf, 2011). Enormous losses of between 20-50% have been reported on stored cowpea due to attack by cowpea weevil (*Callosobruchus maculatus*) and sometimes the loss could be 100% (Abulude *et al*., 2007). It is used as human food. According to Peace (2015) who reported that, more than 5.4 million of dried cowpeas are produced worldwide, with Africa producing nearly 5.2 million. Nigeria, the largest producer and consumer, accounts for 61% production in Africa and 58 % worldwide.

Cowpea production is affected by insect pests and disease infestations which lead to economic losses. Insect damage is the major constraint to cowpea grain production in most cowpea producing nations (Singh *et al*., 1978). The cowpea weevil, *Callosobruchus maculatus* (F.) (*Coleoptera: Bruchidae*), is a cosmopolitan field-to-store pest ranked as the principal post-harvest pest of cowpea in the tropics (Caswel, 1981). It causes substantial quantitative and qualitative losses manifested by seed perforation and reductions in weight, market value and germination ability of seeds (Oluwafemi, 2012). Apart from direct damage to grains, losses also occur as a result of contamination with insect faecal material, nitrogenous waste (frass) and exuviae (Udo, 2000) thus making it unfit for human consumption.

Concerted efforts have been made by farmers and governmental agencies to control and or reduce infestation and attack of stored cowpea by the bean weevil. Insect pest control in stored produce relies heavily on the use of fumigants and residual contact insecticides. The implications of these are serious problems of toxic residues, health and environment hazards, development of insect strains resistant to insecticides, increasing cost of application and erratic supply of safer chemicals in the developing countries due to foreign exchange constraints (Obeng-Ofori *et al*., 1997). The need to find materials that effectively protect stored produce, that are readily available, affordable, relatively less poisonous and less detrimental to the environment had stimulated interest in the development of alternative control strategies and re-evaluation of traditional botanical pest control agents (Talukder and Howse, 1995). Resource poor farmers in developing countries use different materials to protect stored grains against pest infestation by mixing grains with protectants made up of plant products. Plant derived pesticides are effective against many pests as antifeedants, repellents or toxicants and are less hazardous (Obeng-Ofori, 1997).

Groundnut extracts have been found to be effective against many economically important insect pests, groundnut products are broad spectrum in activity and are known to affect over 300 species of insects as well as mites, nematodes, fungi, bacteria and few viruses, and groundnut products are harmless to mammals and most beneficial arthropods, biodegradable and appear less likely to build up genetic resistance in target pests (Obeng-Ofori, 1997). In spite of the highly positive benefits derived from the use of the groundnut products, their utilization as pesticide is limited in Africa (Obeng-Ofori, 1997). In this study, laboratory bioassays were used to evaluate the efficacy of groundnut oil for the control of cowpea beetle *Callosobruchus maculatus* in stored cowpea.

MATERIALS AND METHODS

Experimental Site

The study was conducted between the month of December, 2019 and January, 2020 at the Department of Crop Production and Horticulture laboratory, Modibbo Adama University of Technology Yola, (Latitude 9^0 and 11^0N and longitude 12^0 and 20^1E)

Treatment and Experimental Design

The experiment consisted of five treatments; at 0 (No application), 3.5, 4.0 ml, 4.5 and 5.0 ml of groundnut oil / 100g cowpea seed laid out in a Completely Randomized Design (CRD), replicated three times. Each of the containers with the cowpea grains were treated with groundnut oil by mixing thoroughly to ensure adequate contact and twenty adult insects were introduced into each treatment. Each treatment was replicated three times while the control had no groundnut oil added to it.

Source of Materials

Insect culture

Collosobruchus maculatus was obtained from an infested stock of grains from the Jimeta grain market, Adamawa State, Nigeria and cultured in the Crop Production and Horticultural Laboratory, Modibbo Adama University of Technology Yola, Nigeria with culture conditions being 28 ± 2ºC temperature and 66% relative humidity respectively. After seven days of oviposition, the parent adults were discarded and the emerging progeny was used for the various bioassays.

Grain samples and groundnut oil

Grain and oil samples were obtained from Jimeta main market, Adamawa State, Nigeria. The grains were cleaned to remove impurities and any hidden infestation. Fifty grams of the grain samples were placed into 200 ml glass jar and covered with white muslin cloth held in place with rubber bands to which each of the treatment was added.

Twenty-five unsexed newly emerged adult *C. maculatus* were introduced into each jar containing 100g cowpea seed admixed with five different concentrations; 0 (T_1), 3.5 (T_2), 4.0 (T_3), 4.5 (T4) and 5.0 ml of the groundnut oil. A control experiment comprising untreated seeds was also set up. The experiment was arranged in the laboratory at room temperature, laid out in a Completely Randomized Design and replicated three times. The *C. maculatus* adult mortality was recorded for four days at every 24 hours Dead insects were removed, counted and recorded to calculate percentage adult mortality at each observation (Adesina et al, 2022). After 96 hour of *C. maculatus* infestation all living and dead insects were removed, number of eggs laid on treated and control seeds were counted using a hand lens and the jars with treated seeds and control were kept undisturbed in the laboratory for adult emergence (Adesina et al., 2022). The number of adults emerged from the treated cowpea was counted and recorded at 14, 21 and 28 days after treatment. Percentage seed damage was determined by counting damaged seeds with adult emergence holes on the surface of the stored seeds, 28 days after infestation (Adesina and Mobolade-Adesina 2020). While percentage weight loss was collected after sieving the treated and control dishes of insects and frass through a 3 mm sieve (Idoko and Adesina 2013) and the stored seeds reweighed.

Data Collection and Analysis

Data collected on adult mortality, number of eggs laid, adult emergence, seed damage and weight loss were subjected to one-way analysis of variance (ANOVA) and significant treatment means were compared by using Duncan New Multiple Range Test (DNMRT) at the 5% level of significance (P< 0.05).

RESULTS

Effect of Groundnut Oil on Mortality of *C. maculatus* at different Time (Hours) after Treatment

Table 1 shows the effect of groundnut oil on mortality of *C. maculatus* at different hours after treatment. From the result there were highly significant differences (P≤0.01) among the treatment all through the different time after treatment. At 24 hours, the result showed that 0 ml has no mortality with 0.00 while 4.5 ml recorded highest percentage mortality (19.33%). Similar trend was observed at 48 hwith 95% (20) mortality recorded as the highest number of insect mortality. At 72 and 96 h cowpea treated with 4.0, 4.5 and 5.0 ml have the highest insect mortality of 20.00 (95%). insect mortality.

Effect of Groundnut Oil on Oviposition of *C. maculatus* after Treatment to stored cowpea

Table 2 shows that groundnut oil has significant oviposition suppression on *C. maculatus*. Cowpea in the control dish (0 ml) recorded the highest number of eggs laid (24.67), distantly followed by 3.5 ml which produce 0.67 eggs laid compared to other treatments (4.0 4.5 and 5.0 ml) that completely inhibited oviposition.

Effect of Groundnut Oil on *C. maculatus* Progeny Emergence

Table 3 shows that the different dosage of groundnut oil significantly suppressed *C. maculatus* progeny emergence. Across the storage duration, highest number of progeny emergence was noticed from cowpea in the control dish. While, cowpea treated with 3.5, 4.0, 4.5 and 5.0ml of groundnut oil completely inhibited progeny emergence.

Effect of Groundnut Oil on Weight loss and Level Damage Caused by *C. maculatus* to Stored Cowpea

Result in Table 4 shows the effect of groundnut oil on weight loss level of damage caused by *C. maculatus* to stored cowpea 28 days after treatment. . The result revealed that, at 28 days of storage, cowpea treated with 4.5 ml recorded the lowest weight loss (0.97g) compared with untreated control that suffered the heaviest weight loss (4.07g). Similar trend was observed in terms of percentage seed damage, *C. maculatus* inflicted the highest percentage damage on cowpea in the untreated control dishes (48.29%) compared to the significant almost zero percentage damage recorded in the treated cowpea (0.09-0.55%).

CONCLUSION

The study shows that at 4.5 mls proved to be more effective in protecting stored cowpea as it significantly evoked higher percentage insect mortality, inhibited oviposition, adult emergence, percentage seed damage and weight loss compared to other treatments. and with less reduction in This is an indication that groundnut oil could reduce the infestation of stored cowpea grains against *C. maculatus* infestation. In light of the foregoing, adoption of groundnut oil as stored cowpea grains protectant as environmental friendly substitute to the use of chemical (pesticide) by resource poor farmrer

RESPONSE OF LEAF VEGETABLE (*Corchorus olitorius*) TO NITROGEN FERTILIZER IN OGBOMOSO

Adepoju P. F., *Olusakin S. G. and G. O. Kolawole
Department of Crop Production and Soil Science, PMB 4000, Ladoke Akintola University of Technology, Ogbomoso, Nigeria

*Corresponding author: Sundayolusakin6@gmail.com

ABSTRACT
Poor soil fertility, particularly inadequate N, may limit the cultivation of Corchorus olitorius. This study was conducted to determine the effects of N to maximize C. olitorius production in Ogbomoso between June and August 2023. The treatments were 0, 30, 60, 90, 120, 150 and 180 kg N/ha, laid out in a Randomized Complete Block Design replicated thrice at the Teaching and Research Farm, Ladoke Akintola University of Technology, Ogbomoso, Nigeria. Data on growth (plant height, number of leaves, stem diameter and number of branches) and yield (shoot biomass, leaf biomass and leaf/shoot ratio) were subjected to Analysis of Variance and treatment means differences were compared using $LSD_{0.05}$. Nitrogen applied at 90 kg N/ha had the highest number of leaves (268), branches (18), stem diameter (9.67 mm) and plant height (89.8 cm) while the control had the lowest number of leaves (110), branches (18) and diameter (6.17 mm), while180 kg N/ha had the lowest plant height (66 cm) at 7 weeks after transplanting. The 60 kg N/ha produced the highest quantity of shoot (8,833 kg/ha) and leaf biomass (2,506 kg/ha) while the control had the lowest shoot value (4,667 kg/ha) and leaf biomass (1,408.7 kg/ha). Regression analysis revealed that leaf yield increased linearly with nitrogen rate until diminishing return sets in. In conclusion, the application of N at 60 kg/ha was adequate for the growth and yield of corchorus in the study area.

INTRODUCTION

Corchorus olitorius known commonly as 'fruited jute', 'bush okra' or 'jute mallow' is a common tropical leafy vegetable found in Africa, Asia and some parts of the Middle East and Latin America (Odofin *et al.,* 2011). It has succulent leaves which soften rapidly with cooking, and thickens into a viscous mucilaginous soup which can be eaten with starchy foods (Adediran *et al.,* 2015). The edible portion of the plant, the leaf, is mucilaginous like okra. Corchorus is nutrient-rich and contains dietary fiber, protein, iron, calcium, thiamin, riboflavin, niacin, and folate. Vitamin C, E and β-carotene, Galactose, galacturonic acid, and rhamnose are also present (Fondio and Grubben, 2004; Ndiovu and Afolayan, 2008). The cultivation of *C. olitorius* faces various challenges, including inadequate nutrient supply from the soil. To meet the growing demand for this crop and improve its yield, farmers often rely on the application of fertilizers, with nitrogen being a key nutrient in plant growth and development.

Nitrogen is an essential nutrient for plant growth and development, influencing processes such as photosynthesis, protein synthesis, and overall plant vigor (Taiz and Zeiger, 2010). Several studies have been conducted to investigate the effects of nitrogenous fertilizers on the growth and yield of various crops, including vegetables (Pandey *et al*., 2019; Xu *et al*., 2018). Olaniyi, and Ajibola (2008) observed that, application of N, P and K significantly increased the plant height, number of leaves, fresh shoots, dry matter yield of *Corchorus olitorius* above the control (no fertilizer). However, the response of *C. olitorius* to nitrogen fertilization remains relatively underexplored. Understanding the location specific requirements and rates of this crop will help optimize fertilizer application and contribute to sustainable agricultural practices; therefore, the objective of this study was to determine the effects of varying rates of N-fertilizer on the growth and biomass production of *Corchorus olitorius*.

MATERIALS AND METHODS

The study was conducted at the Teaching and Research Farm, Ladoke Akintola University of Technology (LAUTECH), Ogbomoso, Oyo State, Nigeria, during the 2023 growing season. The land was cleared of bushes and beds measuring 1 × 1 m with 1 m spacing between beds were made. Two weeks old Corchorus seedlings were transplanted at two plants per hill at plant spacing of 0.5 × 0.5 m to make a population of 80,000 plants/ha. Manual weeding was carried as and when due. The experiment was laid out in a Randomized Complete Block Design (RCBD) replicated three times. Urea (45% N) was used to supply nitrogen at 30, 60, 90, 120, 150 and 180 kg N/ha. Beds without any soil amendments (Control treatment) were included for comparison. Fertilizer was applied a week after transplanting in split dosage with application of 60 kg N/ha and the balance for the treatments above 60 kg N/ha applied at two weeks after transplanting. Data on plant height, stem diameter, number of leaves, number of branches were collected on five randomly selected tagged plants from three weeks after transplanting (WAT). At seven weeks after transplanting, the plants were harvested and fresh shoot and leaf biomass were obtained using sensitive weighing balance. Data were subjected to analysis of variance (ANOVA) and treatment means compared and significant mean differences were separated with LSD at $p < 0.05$.

RESULTS

Application of 90 kg N/ha resulted to significantly more leaves than the control at 5 and 7 weeks after transplanting (WAT), it also had significantly more leaves than all the other treatments, while the control had significantly lowest number of leaves compared to other treatments (Table 1). It was observed that 150 kg N/ha rate resulted to the tallest plant at 5 WAT while it was 90 kg N/ha that gave the significantly tallest plant compared to the control at 7 WAT. The 180 kg N/ha rate resulted to significantly shortest plants at both periods of observation (Table 2). Application of 120 kg N/ha gave the highest stem diameter at 5 WAT (Table 3), while the 90 kg N/ha rate resulted to significantly highest stem diameter than the control at 7 WAT. However, treatments at 180 kg N/ha and Control had significantly lowest stem diameter at 5 and 7 WAT r. The 60 kg N/ha treatment had the highest number of plant branches at 5 WAT while 90 kg N/ha had significantly highest number of branches at 7 WAT (Table 4). The 180 kg N/ha and 0 kg N/ha treatments had significantly least plant branches at 5 WAT and 7 WAT.

It was observed that the 60 kg N/ha had significantly highest shoot biomass (8,833 kg/ha) while it was lowest for the control (4,667 kg/ha) (Table 5). There was no significant difference between the leaf/shoot ratios at all the fertilizer rates. The highest leaf biomass was observed at 60 kg N/ha (Fig 1) while it was lowest for the control. Leaf biomass declined at rates above 60 kg N/ha. The leaf biomass response curve indicated that the increase in leaf biomass was linear with increase in fertilizer rates until diminishing return sets in after 60 kg N/ha rate.

Table 1: Effects of nitrogen fertilizer rates on the number of leaves of *Corchorus olitorius*

Fertilizer rate (kgN/ha)	Weeks after transplanting	
	5	7

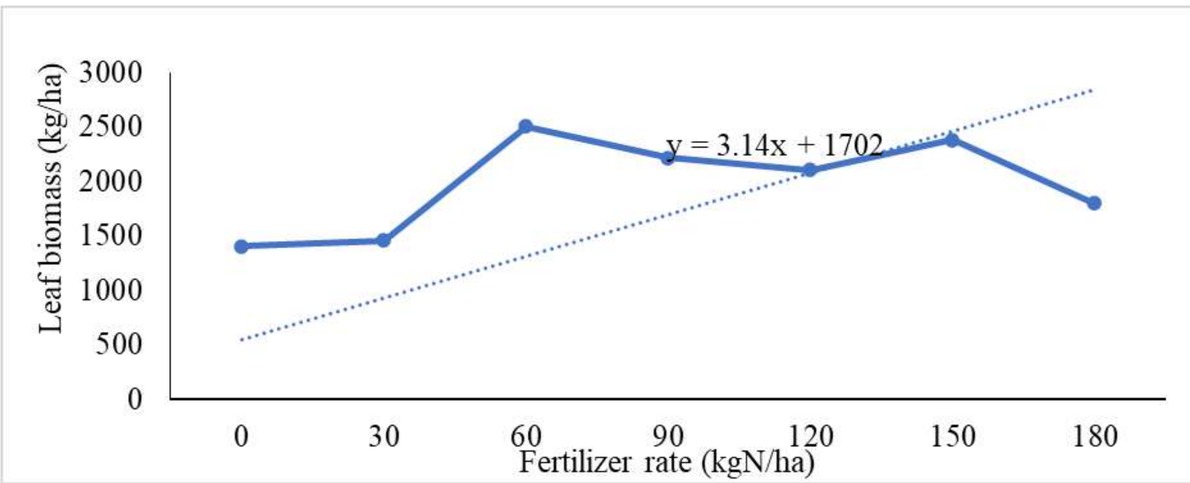

Figure 1: Effects of fertilizer rates on the leaf biomass of *Corchorus olitorius*

DISCUSSION

There were significant variations in the response of *C. olitorius* in growth parameters to varying rates of N application. Nitrogen rates higher than 90 kg N/ha reduced the growth parameters. It shows that excess nitrogen can interfere with the uptake of other essential nutrients, such as potassium and calcium, potentially leading to deficiencies in these elements which can further affect the overall health and quality of the crop (Albomoz, 2016). These findings were in agreement with observation of Tovihoudji *et al*. (2015) that the application of N at rate above 100 kg N/ha of urea, did not enhance the growth of *C. olitorius*.

Nitrogen rates had significant influence on the Cochorus fresh shoot and leaf biomass with 60 kg N/ha producing the highest shoot and leaf weights. Beyond this rate, there was decline in shoot and leaf biomass produced. This indicates that the optimum N rate for the economic yield of *C. olitorius* in the study area had been reached. Isah, *et al*. (2012) reported that N fertilizer application levels on leafy vegetables had a positive influence on the yield of leaf and shoot production. However, Olaleye *et al*. (2008), reported that nitrogen applied at a 50 kg N/ha rate to Corchorus cultivated under cocoa plantation soils rich in organic matter had the highest shoot and leaf biomass production. Also, Olaniyi and Ajibola (2008) reported that 45 kg N/ha rate had the highest shoot and leaf yield for oniyaya variety of *C. olitorius*. The differences in the N rates observed could be due to the varieties of Corchorus cultivated and the inherent soil fertility status.

The decline in performance of *C. olitorius* beyond 60 kg N/ha could be related to the plant's luxury consumption. This observation agreed with the report of Mbia *et al*. (2020), who noted that increasing application of N to Corchorus increases the yield until diminishing returns at over 90 kg N/ha. In conclusion, application of 60 kg N/ha was optimum for improved economic yield of Corchorus in the study area.

Correspondence author: aristan2009@yahoo.com

ABSTRACT
A cross sectional growth, fruit and extracted kernel yields parameters were taken on existing Ogbono trees in orchards of Mbato, out station of NIHORT Okigwe, Imo State, South east Nigeria. The study was done during the 2023 fruiting season of Ogbono tree. The main purpose was to compare the monthly and annual pension of level 6 -13 retired NIHORT staff to one tree kernel yield money value in a year. Result showed that a middle aged Ogbono tree kernel gave net profit range of #57,000 -66,000, about twice federal minimum wage and then three times (#17,000 monthly pension) or one quarter the #204,000, per annum minimum pension alert of a level-6 retired NIHORT staff. Recommendation was made for one to plant today (not tomorrow) stands of Ogbono trees as a backup benefit for retirement in these days of unbearable high cost of living.
***Keywords**: Age, Benefit, Kernel yields, Marketing, Ogbono, Retirement support*

INTRODUCTION

Ogbono seed kernel tree (*Irvingia gabonensis* var wombolu) has various local names that includes Dika bread tree,Oro-apon, Bush mango ,African mango and wild mango is included by UNESCO as a multipurpose fruit tree which by indebt research, traced its origin to humid low land rainforest of central African and West Africa characterized with Ultisols (Okafor,1983, Mbagwu,1992, Nzekwe,1995 ,Van Dyke,1997,Reguengo,*et al*,2023). Presently, it is called African wild Apple (Okpara *et al*, 2021). This may not be unconnected with recent findings that *I. gabonensis* fruits pulps or peels that lie waste on farms and homestead as a local bye products in the course of seed kernel extractions has found use in winery and food/diet supplement industries.Thus the arrays among other products by Amazon of African mango Bio-Lipo dietary liquid extract(Amazon Com.Inc.,2023). The seed of the fruit consists of a hard shell, an outer brown testa (hull) and inside, the kernel, composed of two white cotyledons (National Research Council, 2006). The kernels, rich in fat (myristic and lauric acids), protein (Linoleic) and carbohydrates are the main products of *I. gabonensis* and constitute an important part of West and Central Africa diet, providing income for all the actors along the market chain from the farmer,harvester to the final consumer even as it is traded across Europe and America(FAO,2015,ICRAF & FAO,2021).Income generation,especially among retired civil servants employed by the federating states of Nigeria is gravely difficult as many are owed over 12 months of salary arrears before retirement.

Many states in the South east, following the regime change in May 2023 inherited unpaid gratuity and backlog of months/years of salary and pension arrears with attendants warning strikes by labour unions (The Daily Sun,7th Sept,2023). The load will take months if not years to liquidate before attending to recent and about to retire civil servants. Retirement is the official disengagement from public or civil service (Pension, Act,2004). It could be by volition based on health grounds, fraud or public disaffection due to unpopular policies by a seating government or individual. The later is common in USA where a seating governor and in world bank where a Director resigned due to scandal. Retirement could also be statutory after one has put in useful time and energy at work and service for 35 years or attained 60 years of age. The ILO (revised ed.2018) maintained 40% (2 out of 5 portions) of civil servant last salary package as the monthly pension. In Nigeria, using Chilean model, one third (1 out of 3) that is about 33.3 % is by principle allowed (Pension Act, 2004, Odia &Okoye, 2012). Following monthly payment alerts via clients of many contributory Pension Fund Administrators within and among retired staffs of

NIHORT Okigwe, it ranged between 17,000 and 87,000 for level 6 – 13 staffs. Their state counterparts is quite lower than the afore mentioned Federal staff.

With the trend of worsening living standards and market prices, present civil servants should embrace the pre-retirement culture of planting Ogbono (*Irvingia gabonensis* var wombolu) tree in any available plot within and around their wild or homestead farms as a support to their retirement benefits. Ogbono, Garcia cola and Treculia africana produce are trending with high prices in both local and international markets with deficit in supply. This work is aimed at looking cross sectionally,the monitary value of kernel yields of Ogbono trees in NIHORT orchards and comparing same with the pensions of retired staffs.

MATERIALS AND METHODS

The survey was carried out from the of March to June 2023 that coincided with fruiting, picking and gathering of freely felled fruits of Ogbono trees (*Irvingia gabonensis* var wombolo) from various orchards in Mbato Okigwe out station, Imo State, Nigeria. The station lies on latitude 05^0 33^1N and longitude 07^0 23^1E and altitude of 130 meters above sea level. Okigwe is characterized by undulating dissected plains and soils derived from shale and sandstone, classified as ultisol. This cross-sectional view of Ogbono tree kernel yield was done to determine its proceeds dependability as a pre and post-retirement benefit support or venture in Okigwe geographical area. These trees were established by our staffs many of whom are of blessed memories in the years 1984 (about 20 stands),1994 (about 2 ha), 2001 (about 25 stands, scattered by bushfire) and 2005(extension of 1994 main orchard) and is found as documents in, Indigenous Fruit tree Establishment in: NHM/ADM/58/VOL_2 (1984-1997).

Samples of trees were chosen based on two (2) extremities of the highest and the lowest in terms of expressed growth parameters of heights, canopy spread diameters, stem diameters and number of branches of existing, grown and fruiting trees in the separate orchards. For Heights, trees were climbed with measuring tapes and one long, dry and slender (2-4cm girth) bamboo pole. Climbing was made to topmost apical branch that can support human weight and also has the highest twigs above the climber's head. With the tip of the measuring tape attached to the bamboo pole end, and the now improvised tool pushed and extended above the climber head to align (mere eye aid) with the tip of the topmost twig of the tree, height reaching is achieved. Having done this, the rest of the measuring tape with its rolling casen were released from above high under gravity to the base of the trees. The rolled out lengths of the measuring tapes is observed and recorded as tree heights.

Similarly, canopy spread diameters, were measured. For the stem diameters, it was done by taking the circumference measurements of trees at 100cm above ground and imputing same into circle formular for two times radius values. For the number of branches per tree stand, considerations for a branch to be counted was based on attainment to girth range of 7 – 12 cm girth using verniers caliper. Branches with their adjoining apical and side twigs recorded a range of 75 – 140 fruit per tree stand. A working mean of 100 fruits per tree stand was taken to estimate branches fruits number of per tree stand. In this part of Nigeria, our markets have standard container measures in cups and buckets. Tomato cup size(210ml) and custard starch bucket size(4200ml) are most popular, acceptable and routinely used as measure of standard scales for buying and selling in the open markets. Fruits and fruit kernel yield were in this trial measured using the fore mentioned scales. A range of 42 – 62 fresh fruits (pending fruits shape and size) makes a bucket full and the same range for a cup full of extracted cotyledon or kernel. A working mean of 55 fruit per paint of picked fresh fruit for the estimation of total fresh fruit yield per tree stand was adopted. The range of extracted kernel weights (g) in cups was 132 – 159g and their market price value in March - May 2023 was $1100 - $2000 per cup. It is worthy of note that twenty (20) tomato cup measure (210ml) makes a custard starch bucket(4200ml) and 30 custard bucket measure gives 100kg bag of extracted Ogbono kernel in the open market. The cost of mandays per 1000 fresh fruit picking and gathering ranged $1500 - $2000 while it cost $4000 to extract a bucket full of Ogbono kernel. Manual fresh fruit kernel extraction must involve very sharp knives; cutlasses etc to get cotyledons that are in-tight to attract market. It also goes with knife accidents that can disfigure or chop-off human fingers. Thus, costly labour/ mandays and yet less than 10% of the market value of a bucket of Ogbono kernel.

RESULTS AND DISCUSSIONS

Table 1, shows the varied tree spacing did not vary with kernel yields but every other parameter varied. Significant (P< 0.05) variations was observed across tree year of establishment, range for heights canopy, stem diameters, number of branches, number of fruits, and the per annum pension. The fruit proceeds from 1984 orchard was reportedly used in the establishment on 1994 orchard translating to 10 yr interval. Gestation period was at 7 – 10 years (Harris,1996). Height was highest at 19 – 22 metres on the 1984 orchard establishment. Vihotogbe, (2016) reported a range of 10 – 50 metres upon tree maturation. Chinaka and Obiefuna (1999) reported a gestation range of 15 – 20 years at about 30 meter high and stem diameter of 1.0 meters. The orchard established in 1984 measured 0.8 – 0.9 meters girths.

Table 2, shows the range of number of fruits in a custard starch bucket(4200ml), their corresponding number of cotyledons/kernels and also their corresponding weights in grammes in the market standard tomato cup(210ml) measure which did not show any significant (P< 0.05) difference. But there was for the total number of fruits per tree, their corresponding cups and bucket measures of kernels and market or monetary values as well as their mandays cost of picking and kernel extractions and the net profits. The oldest orchard of 1984 recorded the highest in fruit number at 4800 – 5700 fruit per tree with cups of kernel yields at 87- 103; translating to a range of 95,700 – 113,300 with 68,700 – 81,380 net profits. A 12-year old trees have yielded 1060 fruits, Tchoundjeu (1998). With improved agricultural technology, topping and budding can make a tree mature for economic yield at 5- 7 years (Chinaka and Obiefuna,1999). Just a tree stand from the middle year orchard of 1994, with 2900 – 3800 fruits and kernel sales net profit range of 57,000 – 66,000 is three times the monthly pension alert (17,000) of level-6 retired NIHORT staff and about twice the current minimum wage. The present minimum wage in Nigeria as approved by Civil Service Commission (2011) is thirty thousand (30000) naira. Yet, many private schools, circular and sacred organizations still pay lower killer wages to their numerous employees. Ten stands of such tree on a homestead or farm will give a net profit range,570,000 – 660,000. Which is more than 50% of the total annual pension alert of 1,044.000 for a level-13 retired NIHORT staff.

RECOMMENDATIONS

The take- away message of this work in this era of low Gross domestic product (GDPs) is that for the unsaturated (supply deficit) local and international market chains of kernels, there is now a clarion call on all private, public, circular and sacred employees to invest while in service on Ogbono tree as support for envisaged retirement benefits. Sometimes, these benefits due to analogue pension model still operational in the federating States do not come until a retiree dies. For the retired, please plant budded or progressively topped Ogbono seedling for early fruiting.

ABSTRACT
Blighia sapida K.D. Koenig is a tropical fruit crop belonging to the family Sapindaceae. It is commonly called ackee apple. Ackee is a crop of high economic importance which bear fruits that can be eaten raw when ripe or processed in brine. All parts of the tree has medicinal uses traditionally. Disease is among the major constraints to the production of all crops. Leaf necrosis was observed on some ackee trees within the indigenous fruits orchard of National Horticultural Research Institute, Ibadan. The disease incidence was between 40-60 % on the leaves. Infected leaf samples from B. sapida were surface sterilized using 70% ethanol, and cultured on sterilised Potato Dextrose Agar (PDA) for 3-4 days at 28±2^{0}C. The isolated fungus was identified based on its cultural and microscopic morphological characteristics as Fusarium species. The pathogenicity test showed that the fungal isolate was pathogenic on leaves of B. sapida.
Keywords: *Ackee, Blighia Sapida K. D. Koenig, Fusarium spp, Leaf necrosis.*

INTRODUCTION
Ackee, *Blighia Sapida* K.D. Koenig is a tropical fruit belonging to the family *Sapindaceae.* It is a polygamous, evergreen tree that originated in the forests of West Africa. It has been introduced to the America, Australia, some Asian countries and Caribbean. In Caribbean it is now grown wildly and also cultivated. It is called Ishin in South Western part of Nigeria. The genus name of ackee, *Blighia* is from the name of Captain William Bligh who in 1793 conveyed the fruit from Jamaica to England (Areces-Berazain, 2019). Ackee fruit was first known for its poisonous phytochemicals- hypoglycin A and hypoglycin B, The ripe fruit flesh (aril) contains only low quantities of hypoglycins, while unripe fruits has very higher quantities which is poisonous for human consumption (Wray *et al*., 2020). The fruits are naturally splitted open when ripe; four big glossy black seeds are embedded in spongy, cream-colored buttery arils which are edible. The fruit is consumed raw when ripe in Nigeria and other West African countries. The fruit arils can also be curried and used to prepare soups, stews, and other dishes in Caribbean countries. In Jamaica, it is an ingredient of the national dish ackee saltfish. Ackee fruit arils is a a good source of nutrients including lipids; linoleic, palmitic, and stearic acids as the major fatty acids, with 55% being linoleic acid an essential fatty acid (Emanuel and Benkeblia, 2012). Fruit arils contain a high total protein content, vitamin C, riboflavin, carotene, niacin, dietary fiber, calcium, potassium, zinc, and iron,

Ackee is a crop of high economic importance when processed and canned in brine in Jamaica, Haiti, and Belize. Jamaica is the largest producer and exporter. Between 2006 and 2009 export of canned ackee in brine earns Jamaica approximately $35.4 million (Gordon, 2015). Various plant parts of *Blighia sapida* is used traditionally for medicinal purposes. There are many health benefits attributed to the ackee tree and its fruit. Pulverised bark with some spices is used for treatment of various ailments in different part of West African. The fruit seed and capsule are used to produce soap (Wray *et al*., 2020). Hypoglycin A found in ackee is of interest in pharmacology, because it is believed that when the level of toxicity on ackee is reduced, there is a possibility that it could be used for the treatment of diabetes to reduce blood sugar to low levels, (Latif and Luthra, 2017).

Pest and disease is among constraints to production of all crops. Among reported fungal pathogen of ackee are *Collectotrichum* species, *Phomopsis* sp. *Verticillium* spp. (Subbarao, 2020). Necrosis was observed on leaves of some ackee trees within the Indigenous fruits orchard of National Horticultural

Research Institute (NIHORT), Ibadan. The disease incidence was between 40-60 % on the leaves. The occurrence of the leaf infection on ackee trees was noticed for the first time since the orchard was established about thirteen years ago. The objectives of this work are therefore to i) isolate the leaf necrosis causing pathogen (ii) identify the pathogen for proper management of the infection within the orchard.

MATERIALS AND METHODS

Collection of infected leaves

Infected leaf samples were randomly collected in bags from the indigenous fruits orchard of National Horticultural Research Institute (NIHORT), Jericho Area, Ibadan; and taken to the Pathology Laboratory of the Institute for pathogen isolation and identification

Isolation

The leaves were washed under running tap water to remove dirt and dust particles. The lesions on the infected leaves were cut into small sizes of between 2-3mm. The samples were surface sterilized using 70% ethanol for 30 seconds. The ethanol on the sample was rinsed thrice with sterilized distilled water and the samples were blotted dry between Whatman No 1 Filter papers. The surface sterilized samples were cultured on solidified chloramphenicol amended Potato Dextrose Agar (PDA) in petri dishes. Samples were cultured on many PDA plates and incubated at 28 ± 2^0C for 3-5 days. Mycelium from the edge of each colony was transferred to a new PDA plate till pure cultures were obtained.

Identification of fungal isolate

The isolate was identified based on cultural and microscopic features of the fungal isolate and by comparing with identification book available Barnnet and Hunter (1972)

Pathogenicity Test

This test was carried out to confirm that the isolated fungus was actually the disease- causing agent on *B. sapida.* The isolate was tested for pathogenicity using Koch's postulate (1893). Apparently healthy leaves of *B. sapida* were surface sterilised and inoculated with conidial suspension of the fungal isolate. The pure culture of the isolated fungus was sub-cultured on PDA plates and incubated at 28 ± 2^0C for 7 days. Each plate was rinsed with 15 mls of sterilized distilled water to collect conidia. The spore (conidia) concentration was adjusted to 1 x 10^6 conidia /ml by using haemocytometer. A 100µL of spore suspension was carefully dropped on each leaf previously surface sterilized; with a sterilized glass rod spreader, the suspension was spread on the leaf. Control experiment was leaves inoculated with 100 µL of sterilized distilled water. The leaves were incubated in desiccators which had their bases lined with pieces of moistened cotton wool to provide a humid environment for the germination and growth of the conidia. Incidence of the initial leaf disease noticed on the *B. Sapida* leaves in the orchard was daily looked out for and recorded. The experiment was repeated twice

The inoculated leaves became infected and the fungal pathogen was re- isolated and identified again as the initial fungal isolate.

RESULTS AND DISCUSSION

Leaf lesions were observed on leaves of *B. sapida* in late August, 2023 in the Indigenous fruits orchard of NIHORT. The incidence of the infection was between 40-60% on *B. sapida* trees (Fig. 1). This is the first time such infection was observed on the trees after thirteen years of establishment. The lesion expanded into irregular necrotic lesions and the infected leaf part turns brown/grayish white with yellow marginal (Fig. 3). Leaf infection on the horticultural crops impedes yield potential of crops. The leaf is the photosynthetic part of a plant. Any reduction in the leaf surface area results in a reduction of the amount of photosynthetic products by the plant Pathogens causing infections on leaf can produce toxins that interferes with normal metabolism in the plant (Okorski *et al*., 2008; Gortari *et al*., 2018; Farooq et al., 2019; Yang and Luo, 2021; Huang and Luo, 2021). Fungi identification was based on colony and microscopic morphological characteristics.The isolated fungus grew from every sterilized infected sample on PDA plate (Fig. 4). The colony growth was initially white cottony, aerial mycelia growth with pinkish pigmentation on the reverse side on plate (Fig. 5). At older age, the mycelium turns pinkish both front and reversed side.

The fungus isolate has septate and hyaline hyphae. It produced curved macroconidia (which are hyaline, multicellular) and clusters of microconidia which are hyaline, unicellular, and ovoid to cylindrical in shape) (Fig 6). These descriptions are in accordance with the *Fusarium* species identification illustrated by Nelson *et al*. (1983). *Fusarium* identification is based mainly on distinctive characters of the shape of sizes of macro- and microconidia, presence or absence of clamydospores and colour pigmentation and colony appearance (Leshie and Summrell, 2006). The isolated fungus from the infected leaves of *B. sapida* was identified as *Fusarium* species. The healthy leave inoculated with the fungus produced similar symptoms as infected leaves from the orchard and same fungus was re-isolated from the inoculated leaves. Leaves from the control experiment did not show the disease infection symptom. The pathogenicity test confirm that the isolated fungus *Fusarium* species was pathogenicon leaf of *B. sapida*.

Fusarium spp have been identified as pathogens of high economic importance in production of crops like tomato, lettuce, cucumber, eggplant, pepper, onion, banana, avocardo e.t.c. (Edel-Hermann *et al*., 2019). *Verticillium dahlia* was reported by McMillan *et al.* (2002 and 2003) to be a fungal wilt pathogen on *B. sapida* spreading from infected tree to health trees causing leaf necrosis and branch death. Other reported fungal pathogens of *B. sapida* are *Colletotrichum gloeosporioides, Phyllosticta* sp, *Cladosporium oxysporum*, *Rhizopus stolonifer*, *Phoma* sp. (Farr *et a*l., 2008)

CONCLUSION

There is a large variation within the genus *Fusarium,* therefore there is a need for further molecular identification of the pathogen for proper management of the disease.

VARIATION OF SOIL MOISTURE, HYDRAULIC CONDUCTIVITY, AND EFFICIENCIES OF SELECTED IRRIGATED FARMS IN OGUN STATE SOUTHWEST NIGERIA

Olatunde O. J. A., Dada P. O.O., Adewumi J. K and Ogunbosoye T. A.

ABSTRACT

This study examined the changes in soil moisture, hydraulic conductivity, and irrigation efficiencies in six selected irrigation farms in Ogun State, Southwest Nigeria. Water melon was planted and soil moisture content was measured regularly during irrigation, and soil samples were collected to determine physical properties and hydraulic conductivity. The irrigation efficiency, water-use, conveyance, application, and overall efficiency, were also determined. The findings showed variations in bulk density, porosity, moisture content, and hydraulic conductivity among the farms. The efficiencies of conveyance, application, water use, and irrigation varied ratiosacross the farms. There was (R=0.75) correlations between water-use efficiency and moisture content, as well as (R=0.32) between yield and bulk density. Mokoloki and Ogun-Osun farms, which had larger land areas and higher water application, showed better efficiencies, increased moisture content, and improved crop performance. This study highlights the influence of water application and soil management practices on soil moisture, hydraulic conductivity, and irrigation efficiencies.

Keywords: *- Irrigation efficiency - Irrigation management - Soil compaction - Soil hydraulic properties - Soil moisture content*

INTRODUCTION

Irrigation has long been practiced to sustain crop production, but it can significantly alter the state of the soil. Irrigation is critical for sustaining agricultural production in areas with uneven rainfall. In Nigeria, only about 1% of cultivated land is irrigated, despite irrigation's potential to improve yields and food security (Anyanwu *et al*., 2010). Continuous irrigation alters soil properties including moisture content, porosity, bulk density, and hydraulic conductivity, with implications for agricultural sustainability (Kami, 2017). Understanding how intensive irrigation influences these parameters over the long term provides insights into appropriate soil and water management practices. Previously fertile lands, suitable for agriculture and grazing, have become barren wastelands owing to poor management practices. Unless we take heed of our current practices, we risk repeating these mistakes and follow the same path of destruction (Lal, R., 2015). This study investigated variations in soil moisture content, hydraulic conductivity, and irrigation efficiencies on six irrigated farms in Ogun State, southwest Nigeria. The farms studied were Asero, Odeda, Osiele, Ogun-Osun, Mokoloki, and Oyan, all relying on pressurized sprinkler irrigation. Soil samples were collected to measure bulk density, porosity, gravimetric moisture content, and particle size distribution. Hydraulic conductivity was determined using a constant head permeameter. Irrigation efficiencies were calculated for each farm based on water volumes applied versus stored in the crop root zone. This empirical study revealed how intensive irrigation alters soil physical properties and water dynamics in Nigeria's irrigated areas. The findings have important implications for maintaining agricultural productivity and soil quality while promoting sustainable water management tailored to local conditions. As irrigation expands in Nigeria but research remains limited, this study provides needed evidence on irrigation's long-term impacts on soils to guide appropriate management practices.

METHODOLOGY

Study Area and Experimental Design

The study was conducted on six irrigated farms in Ogun State, southwest Nigeria: Asero, Odeda, Osiele, Ogun-Osun, Mokoloki, and Oyan. The farms relied on pressurized sprinkler irrigation and had areas ranging from 1.85 to 5.85 ha. Field experiments were conducted using a split-plot design with irrigation efficiencies as the main plot and other management techniques as the sub-plot with water melon as the crop.

Soil samples were collected from each farm at depths of 0-8 cm using a cylindrical metal core auger. Samples were analyzed in the laboratory to determine particle size distribution, moisture content, bulk density, and total porosity. Particle size analysis was conducted using the hydrometer method. Gravimetric moisture content was measured by oven drying samples at 105°C to a constant weight. Bulk density was determined using the core method and total porosity was calculated.

Saturated hydraulic conductivity (Ks) was determined for soil samples from each farm using a constant head permeameter. Darcy's Law was applied to calculate Ks based on steady-state flow rate through the soil, cross-sectional area, and hydraulic gradient.

The water conveyance, application, storage, and overall irrigation efficiencies were calculated for each farm based on water volumes. Conveyance efficiency was the fraction of water delivered to the farm inlet versus diverted from the source. Application efficiency was the fraction of water stored in the crop root zone versus delivered to the farm. Storage efficiency was the fraction of water stored in the root zone versus the zone's capacity at field capacity. Overall efficiency combined conveyance and application efficiencies. Some empirical expressions used to evaluate the irrigation efficiency: (Pereira *et.al*., 2002)

1. Application Efficiency (Ea) Ea = (Water stored in root zone / Water delivered to field) x 100
2. Storage Efficiency (Es) Es = (Water stored in root zone / Water precipitated by system) x 100
3. Consumptive Use Efficiency (Ec) Ec = (Crop evapotranspiration / Water delivered to field) x 100
4. Irrigation Sagacity (Is) Is = Crop yield per unit irrigation water applied

The data on soil properties and irrigation efficiencies were statistically analyzed using analysis of variance (ANOVA) and means separated using Duncan's Multiple Range Test at $p \leq 0.05$. Correlations between variables were evaluated using the Pearson coefficient.

RESULTS AND DISCUSSION

Results

Bulk density increased while total porosity decreased over the plant growing period at all farms, indicating soil compaction. For instance, bulk density ranged from 0.77 to 1.08 g/cm3 at Asero and 0.94 to 1.38 g/cm3 at Mokoloki. Significant variation in gravimetric moisture content was found between farms and over time, ranging from 3.74% (Oyan) to 32.51% (Odeda). Volumetric moisture content followed similar trends. Hydraulic conductivity also varied significantly, from 13.80 cm/hr (Oyan) to 70.20 cm/hr (Asero).

Irrigation efficiencies differed between farms based on water management. Conveyance efficiency ranged from 50.90% to 75.50%, application efficiency from 20% to 35%, and overall efficiency from 61% to 79%. Mokoloki and Ogun-Osun had the highest efficiencies and yields, which also had the largest land area and water application ratios.

Correlation analysis found that water-use efficiency increased with higher gravimetric moisture content after 2 weeks (R=0.33) and 4 weeks (R=0.52). Hydraulic conductivity was positively correlated with total porosity (R=0.58).

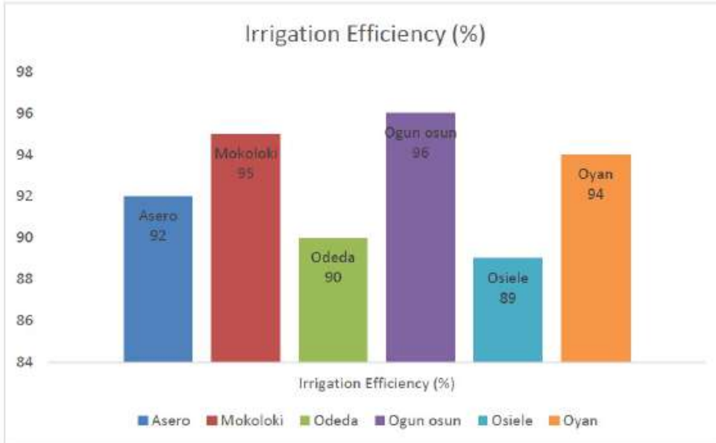

Figure 1: Irrigation Efficiency in Farm Locations

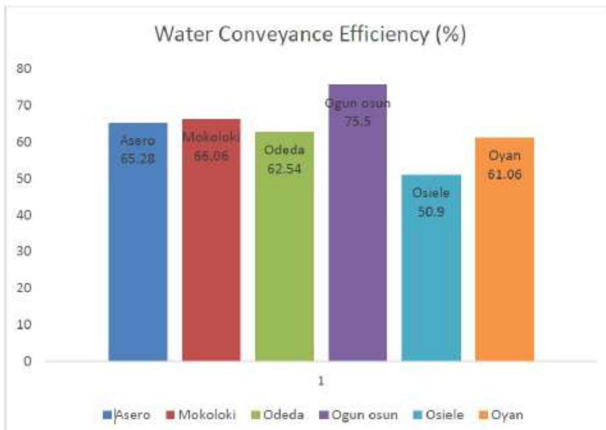

Figure 2: Water Conveyance Efficiency in Farm Locations

DISCUSSION

The reduction in porosity and increase in bulk density over time can be attributed to continuous wetting and mechanical compaction from irrigation. This likely impeded water flow and root growth. The differences in moisture content highlight spatial variability in water availability and plant uptake across farms. The wide range in saturated hydraulic conductivity indicates the soils had distinct transmission capacities shaped by texture, structure, and management. Mokoloki and Ogun-Osun's higher efficiencies and yields can be credited to sufficient water application enabled by larger water access. This maintained soil moisture at 32% and 31% for optimal plant growth. Correlations between moisture content, porosity, and yield further underscore the importance of available water and connected pore networks for crop productivity in irrigated systems.

This study reveals how intensive irrigation alters soil physical properties and water retention over successive cropping cycles. Managing irrigation to improve moisture uniformity and limit compaction is critical for sustainability in these systems. The findings provide practical evidence to guide irrigation decisions tailored to local soils and better leverage Nigeria's water resources.

CONCLUSION

This study investigated variations in soil physical properties and irrigation efficiencies on six farms water-melon was grown under intensive sprinkler irrigation in Ogun State, Nigeria. Key findings were:

- Bulk density increased while total porosity decreased over time on all farms, indicating progressive soil compaction.
- Gravimetric and volumetric moisture content varied significantly between locations and over the cropping cycle, highlighting spatial and temporal variability in soil water availability.
- Saturated hydraulic conductivity ranged widely from 13.80 to 70.20 cm/hr, reflecting differences in soil transmission capacities.
- Farms with larger irrigation water access and land area had higher efficiencies, stored moisture, and yields.
- Soil moisture content and porosity were positively correlated with crop yield and water use efficiency.

Continuous intensive irrigation was found to compact soil over successive cropping cycles, progressively reducing porosity and hydraulic conductivity. Managing irrigation to improve moisture uniformity and limit compaction is critical for sustainability. The results provide practical evidence to guide context-specific irrigation management in Nigeria tailored to local soils and cropping systems. We therefore recommend that irrigation practices should be careful carried out based on determined engineering accessmemts by a soil and water engineer.

ABSTRACT

Conservation of pepper seeds for utilization in its improved state is a major challenge. The objective of this study was to investigate the effects of two processing methods on the germination and seedling vigour of pepper seeds to know the best processing method. Ten accessions of freshly harvested pepper fruits were processed using two methods: (i) Extraction of seeds directly after harvesting and dried at 18±2^{0}C and 20±5% relative humidity and (ii) Extraction of seeds from sun-dried fruits. The experiment was arranged in 10 x 2 factorial in a completely randomized design (CRD) in three replications using one hundred seeds per sample. The samples were evaluated for standard germination and germination index test. Germination of pepper seeds dried under controlled environment was significantly higher (71.27%) compared with those extracted from sun-dried fruits (58.27%), which indicated that pepper seeds dried under sun may result in poor quality due to uncontrolled temperature and ultra violet radiations from the sun.

Keywords: *Pepper, processing, conservation, germination, emergence.*

INTRODUCTION

Pepper (*Capsicum annuum* L.) is an important fruit vegetable that belongs to the family Solanaceae. It forms a significant part of human diet in many parts of the world. Its' fruits are consumed fresh, cooked or in processed forms and fresh peppers are often used in salads. The fruits can also be processed into various fermented products, powders, sauces, and curry pastes. However, conservation of pepper seeds for utilization in its improved state is a major challenge. The germination and vigour of pepper seeds are two important physiological attributes of its quality. Germination capacity is a measure of maximum germination potential of a seed batch under optimum conditions. The standard germination test, also known as the "warm test", estimates germination under ideal growing conditions (Munamava *et al.,* 2004). The concept of seed vigour on the other hand, was developed on the basis of the observation that two seed batches or genotypes with similar viability would perform differently under stressful field conditions (Delouche and Baskin, 1973). Hence, vigour test have therefore been proven to be more useful as predictors of seed quality than the use of germination test.

Seed processing is an important aspect of gene-bank operations which involves cleaning seed samples, drying to optimum moisture levels, testing their germination and packaging in appropriate containers for conservation and distribution. Among these seed processing operations, seed drying is very crucial. The objective of this study was to investigate the effects of two processing methods on the germination and seedling vigour of different accessions of pepper seeds.

MATERIALS AND METHODS

The seeds of ten accessions of pepper were sourced from the seed gene bank of National Centre for Genetic Resources and Biotechnology (NACGRAB), Ibadan which were regenerated at the experimental field of the Centre during the late growing seasons of 2021. Fruits from the accessions were harvested at physiological maturity stage and processed using two methods as (i) Extraction of seeds directly after harvesting and dried in the drying room at 18±2^{0}C and 20±5% relative humidity and (ii) Extraction of seeds from harvested and sun-dried fruits. The materials were dried to about 10% moisture content and thereafter subjected to germination test. The germination test was conducted at the seed testing laboratory of NACGRAB in January, 2022. The experiment was arranged in 10 x 2 factorial using completely randomized design (CRD) in three replications. The two factors were ten accessions of pepper and two processing methods. The test was assayed by placing 100 seeds per sample in germination plastic containers lined with four layers of tissue paper and moistened with 15ml of distilled water. The containers were covered and placed in a germinating chamber at 25 ± 2°C. The seeds were kept moist every day for seven days. Germination percentages were calculated by expressing the number of seedlings in a replicate that emerged 7 days after planting as a percentage of the number of seeds planted. Germination Index (GI) was calculated by taking the germination counts at 5, 7 and 9 days after planting and the data were substituted into the formulae:

$$\text{Germination percent} = \frac{\text{Number of emerged seedling 7th day after planting}}{\text{Number of seeds planted}} \times 100$$

Germination Index (GI) was calculated by taking the germination counts at 5, 7 and 9 days after planting and the data were substituted into the formulae:

$$GI = \sum (Gt/Dt)$$

where Gt= number of germinated seeds on day t and Dt= time corresponding to Gt in days.

Data obtained were subjected to analysis of variance (ANOVA), using Generalized Linear Model Procedure (PROC GLM) of Statistical Analysis System (SAS, 1990) package. Treatment means were were separated by use of the least significant difference (LSD) at 0.05 level of probability.

RESULTS AND DISCUSSION

The results of analysis of variance (ANOVA) revealed that pepper accessions and processing methods interactive effects were significant ($P<0.01$) on germination percentage and germination index

Table 1: Mean squares, means, coefficient of determination (R^2) and coefficient of variation (CV) from the analysis of variance for germination (G%) and germination index (GI) of pepper seeds

Sources of Variation	DF	G%	GI
Replication	2	162.87ns	0.26ns

Mean		64.77	5.94

*, **, Significant at probability level of 0.05 and 0.01, respectively; ns = not significant

index of pepper seeds (Table 1). This suggests that genetic differences exist among pepper cultivars for seed quality depending on the processing method used after harvest. Accession NGB01848 had the highest germination (84.33%), with the lowest germination index of about 5 days.

Table 2: Germination and Germination index of pepper seeds across genotypes and processing methods

Factors	Germination (G%)	Germination Index (GI)
Accession		
NGB01848	80.33a	5.45edf
NGB02621	70.00b	6.95b
NGB01864	65.67bc	5.37ef
NGB01858	65.67bc	7.63a
NGB02641	64.33bc	5.97dc
NGB00564	64.00bc	5.12f
NGB00701	64.00bc	5.94edc
NGB00620	63.67bc	5.33f
NGB01852	59.33dc	5.09f
NGB00704	50.67d	6.49bc
LSD	**10.06**	**0.60**
Processing method		
Controlled-drying	71.27a	6.03a
	58.27b	5.84a
Sun-dried fruits		
LSD	**4.50**	**0.27**

Means with different letters within the column of the same factor are significantly different at P=0.05

Accession NGB 02621 also had significantly lower germination rate (70.00%). However, it was less vigorous compared to NGB01848 with germination index of about of about 7 days. Accession NGB00704 had significantly lowest germination of 50.67% with germination index of 6 days (Table 2). Seed processing method significantly influenced the germination rate of pepper seeds. Although, the FAO/IPGRI (1994) gene-bank standard recommends the use of 15±5% relative humidity and 15±5^{o} C temperature for drying seeds; seeds of pepper freshly extracted and dried under controlled environment (18±2^{0}C temperature and 20±5% relative humidity) had significantly higher germination rate (71.27%) compared with pepper seeds extracted from sun-dried fruits with germination rate of 58.27% (Table 2). This was in line with the findings of Ibrahim, *et. al.* (2017) who reported that air-drying pepper seeds had significantly higher germination percentage and germination index compared with pepper seeds dried under sun.

CONCLUSION

The study helps to show that processing methods of pepper seeds plays an integral role in maintaining its seed quality and it was therefore suggested that pepper seeds at physiological maturity should be carefully extracted during processing and dried in a controlled temperature and relative humidity as recommended by FAO/IPGRI (1994) gene-bank standards. The study further revealed that dried under the sun may result to poor quality seeds due to the hot temperature and ultra violet radiations from the sun.

ABSTRACT.
Establishment of orchard were done in NIHORT, each plant was given a space of 8m x 8m, they were prepared by hand slashing and tractor about 3 months prior to planting. At each planting site poultry manure are dug in to a depth of 300 mm over a one square meter area before planting the seedlings. Control of weed were used by herbicide (CD erases), also ring weeding before fertilizer application, were given a spaced of 50cm gap before applying NPK 20.20.20 fertilizer application were basal (45gram for each plant). The application dose and proportion of manures and fertilizers are generally based on the soil fertility, tree age, growth and yield. Commence feeding of young trees after one year of growth, using a balanced fertilizer, four times yearly. Older trees benefit from feeding with nitrogenous fertilizer applied in late winter and early summer.

INTRODUCTION

Avocado (*Persea americana* L.) belongs to the family Lauraceae which is composed of 50 species. It is an evergreen tree found in tropical and subtropical areas. Cultivated species of avocado are native to Mexico, Central America and South America. There are three horticultural races of avocado that reflect the centre of origin i.e. the West Indian race native to West Indies (Central America and Northern part of South America); Guatemelan race; and the Mexican race. It is an ancient fruit and constitutes part of the diet in the countries of origin. The fruit spread to North America in the 18th century and the old world in the late 19th century. Avocado commonly referred to as the African Pear (*Dacryodes edulis*) is a well-known plant in West Africa. The fruits are edible, and the bark, leaves, stem and roots are used for local medicine against diseases (Neuwinger, 2000; Ji rovetz *et al.* 2003; Annabelle *et al.* 2004). In Nigeria the fruits are gathered for household use or for sale in local markets. Despite its increasing popularity as one of the most nutritious plants in the fruits family due to the rich presence of essential vitamins A, B and E in the fruits and are high demand in Europe, the plant species has remained largely underdeveloped in the country. As a matter of fact, the nation has continued to witness reduction on its non-timber forest products availability and utilisation. According to World Wildlife Foundation, the rate of deforestation in Nigeria has been put at 350,000 ha per annum (NEST, 1991). This has left in its wake the loss of endemic forest resources in different ecological zones as a result of destructive land use patterns and conversion of forest lands to other uses. The Federal Environmental Protection Agency reported that a total of 5,981 higher plants were identified in Nigeria. Out of these, 0.14% are threatened and 0.22% are endangered. Between 1980 –1992, a total of 43 – 48% of the nation's forest ecosystem are lost through human activities and natural ecological disasters such as erosion, flooding and desertification (FAO, 2000).

METHODOLOGY

Orchard establishment were are located to National Horticultural Research Institute field latitude and longitude N 07º 24′ 41.6″ , E 003º 57′ 35.7″ and the avocado fruits were gotten from three locations which is southeast, southwest and southsouth potted in nursery garden with different pot accessions at Institute , after 3 to 4 weeks or more of germinations depending on the fruit seed, emergence data was collected for the germination period and were transplanted at the field which were mapped 40 x 56, and extended to second field were also mapped out 16 x 64 which the seedlings were transplanted. Establishment of orchard each plant was given a space of 8m x 8m, they were prepared by hand slashing and tractor about 3 months prior to planting. At each planting site poultry manure are dug in to a depth of 300 mm over a one square meter area before planting the seedlings. Control of weed were used by herbicide (CD erases),also ring weeding before fertilizer application, were given a spaced of 50cm gap before applying NPK 20.20.20 fertilizer application were basal (45gram for each plant) for each.

Site selection

The selection of a suitable site is of the utmost importance. Avocados are extremely susceptible to the root rot fungus *Phytophthora cinnamomi*. No avocado rootstock is completely resistant to this disease. Surface and subsoil drainage must be excellent. Sloping ground with a porous top soil structure may be unsuitable if clay bands or hard pans prevent the free flow of water through the soil. Checking the profile with soil pits to a depth of about 2 metres is a pre-requisite. Natural vegetation can indicate localized soak ages and high water tables.

Pest management

Pest management practices, there are different and more varieties of pests found in Nigeria avocado orchards. Some common types of pests include loopers, moths, thrips, persea mites, gophers, and ground squirrels. In Nigeria, avocado orchards are under good biological control due to beneficial insects that prey on parasitize harmful pests like the omnivorous loopers and amorbia moth. Thrips and persea mite control methods include application of insecticides such as Abamectin (Agri-Mek) mixed with 1% narrow range 415 oil (NR415) once per year in April beginning in establishment year 3 when trees reach bearing age.

Weed Management

The weed management practice commonly used in the area for conventional avocado. Weeds can harbor insects and pests, making it difficult for rodent control. Also, too much weed interferes with efficient application of irrigation water to the avocado trees. The two typical weed management practices include herbicide applications and weed whipping. Herbicide is sprayed three times per year during February, May, and August. Each herbicide application consists of about 10 ounces of generic glyphosate and water mixture per acre.

CONCLUSION

The application dose and proportion of manures and fertilizers are generally based on the soil fertility, tree age, growth and yield. Commence feeding of young trees after one year of growth, using a balanced fertilizer, four times yearly. Older trees benefit from feeding with nitrogenous fertilizer applied in late winter and early summer. However, farmers should generally avoid establishing an avocado orchard in fields with poor drainage and high salinity. Additionally, avocados should be planted in fields with a maximum slope of 15% and areas protected from strong winds. It is generally recommended in colder areas to plant the young trees at the start of fall, while in warmer regions, the mid-end of spring is the most suitable period. This way, the plants will have time to establish and adjust before the extreme temperatures.

ABSTRACT
Obafemi Owode and Sagamu Local Government Areas were purposively selected to asses the status of coffee consumption among farmers in Ogun state from 2019-2021. Simple random sampling technique was used to obtain data, from 138 farmers, using structured questionnaire. Data were analysed using descriptive statistics, composite score analysis and linear regression. Majority of the farmers (77 %) were between 31 and 60 years in age with mean of 48±11 years, 88% were males, mean household and farm sizes were 7±4 persons and 1.4±1.3 ha respectively. Fortnightly, 42 % farmers consumed coffee; order of consumption in 2019 and 2020 was low level > intermediate > high levels while it was low level > high > intermediate in 2021. Determinants of coffee consumption include: price, taste, household acceptability and monthly expenditure. This study showed that coffee consumption in Ogun state is low. Companies producing coffee could improve on the taste by adding flavours in order to enhance consumption.
***Keywords**: Coffee, consumption, low level, Ogun state, taste*

INTRODUCTION

Coffee is mainly an agricultural export produce that is vital to the economies of the nations that produce it. About fifty nations in Africa, Latin America, and Asia depend heavily on the coffee industry for their economic prosperity (Dinesh *et al*. 2015); it provides job for sizable section of the populace (Krishnan, 2017); it is the second-most popular drink after water (Iscaro, 2014) that is consumed because of its great taste, aroma and nutritional value (Gebeyehu and Bilika, 2015). Coffee plant is categorized among medicinal plants (Eva *et al*. 2016). Poor farming techniques, lack of mechanization, climate change, poor funding and resources inhibit coffee productivity in Nigeria (PwC, 2017; Mohammed *et al*. 2013, and Ayoola *et al*. 2012). There is the need to assess the current status of coffee consumption among farmers in Ogun state and to sensitize them on the need to improve on the consumption of coffee, hence the justification for this study.

Objectives of the study

i) To profile socio economic characteristics of coffee consumers in the study area;
ii) To determine the level of consumption;
iii) To assess the factors influencing the level of coffee consumption in the study area.

METHODOLOGY

The project was carried out among coffee farmers in Ogun state. Obafemi Owode and Sagamu Local Government Areas (LGAs) were purposively selected in the state because of the high concentration of coffee farmers in these areas. Simple random sampling technique was used to collect data from a total of 138 farmers with the aid of structured questionnaire and the data obtained were analysed using descriptive statistics, composite score analysis, budgetary analysis and linear regression.

Composite score analysis

This was used to measure the level of coffee consumption categorised into 3 namely:

(i) High category = between highest coffee consumption (kg) to (mean + S.D) points
(ii) Medium (intermediate) category = between upper and lower categories
(iii) Low category = between (mean – S.D) points to 0 point.

RESULTS AND DISCUSSION

Demographic characteristics of coffee farmers in Ogun state

The farmers interviewed were 51 % and 49 % from Obafemi Owode and Sagamu Local Government Area (LGAs) respectively (Table 1). Majority (77 %) of the farmers were between 31 and 60 years in age with mean of 48 years which implies that most of the coffee farmers were in their active age to be agriculturally productive; majority (88 %) of them were male. This is in line with the findings of Kangile *et al.,* (2022) who reported gender disparity in farmers in Tanzania. The mean household size, as shown in Table 1, was 7 persons with 46 % of the households having 6-10 membership. Majority of the farmers in the study areas were small scale holders with a mean of 1.4 ha; most (94.2 %) of them were married and 30 % had secondary level of education. Majority (90 %) had farming as their main occupation and most (87 %) of them resided in rural areas, a situation that could make regular farm visits possible

In table 2, majority (90%) of the farmers did not process coffee. Coffee was consumed fortnightly by 42% of the respondents (Table 2). Coffee processors (85.7%) operated on a small scale. The high category of coffee consumption in 2019 was 5760 to 1341, intermediate 1340 to 579 and low 578 to 0. The values were 4250 to 1093, 1092 to 468 and 467 to 0 for high, intermediate and low levels of consumption respectively in 2020.

In 2021, the high category was 3500 to 827, intermediate 826 to 340 and low 339 to 0 (Table 3). In 2019 there were more farmers in the low level of consumption compared to intermediate and high levels. Similar pattern was observed in 2020. However, in 2021, consumption was in the order of low category > high > intermediate as shown in Table 3.

Table 3: Levels of Coffee consumption by farmers in Ogun state from 2019 – 2021

Year	Low	Intermediate	High
2019	54 (78.3)	3 (4.4%)	12 (17.4%)
2020	54 (78.3)	12 (17.4%)	3 (4.4%)
2021	55 (79.7)	3 (4.4%)	11 (15.9%)

Factors influencing consumption of coffee in Ogun state

Table 4 presented the result of the linear regression model used to determine the factors influencing the consumption of coffee in Ogun state. The dependent variable is the amount of coffee consumed in kg and

9 explanatory variables were considered in the model. Five variables were statistically significant at various levels. These were price of coffee, taste, no budget on coffee, household acceptability and coffee monthly expenditure. The coefficient for the cost of coffee sachet is negative and significant at 1% as shown in Table 4. This means that as the price of coffee increases the amount consumed will reduce. This could be due to the fact that the respondents were not sufficiently aware of the health benefits of coffee, such that an increase in the price would make respondents to opt out for other substitutes like lipton tea, milo, bournvita (Batat, 2020). The coefficient for taste is positive and significant at 1%. This implies that the taste of coffee plays a great role in its consumption. In Table 4, the coefficient for no budget on coffee is positive and is significant at 10 %, which implies that although farmers do not budget for coffee yet they consume it. The coefficient for household acceptability is negative and significant at 5% among the respondents in the study areas. This is majorly dependent on mothers who prepare the meal for their household. When women don't like coffee the probability that their household will not like it is high. Thus, the quantity of coffee purchased and consumed would be low. The coefficient for coffee monthly expenditure is positive and significant at 1% such that an increase in monthly expenditure for coffee increases consumption.

Table 4: Factors influencing consumption of coffee in Ogun state from 2019 - 2021

Variable	Coefficient	Std.Error	T	P>|t|
Age of farmer	-2.8533	8.1688	-0.35	0.729

Source: Field Survey, 2022

CONCLUSION

This study has shown a reduction in the consumption of coffee in Ogun state. Price of sachet of coffee, its taste, no budget for coffee, household acceptability and coffee monthly expenditure were determinant factors for coffee consumption among respondents in the study areas. Sensitization of farmers on the health benefits of coffee, improving on its taste and reduction in price could enhance its consumption in the study area.

ABSTRACT
The study examined the perceived constraints affecting coffee production in Nigeria, a case study of Edo State. Specifically, the study describes the socio-economic characteristics of the respondents; ascertained some coffee production technologies engaged in by the respondents, identified some constraining factors affecting coffee production, and determine coffee farmers' perception towards constraining factors affecting coffee production. Multistage random sampling techniques was used to select ninety (90) respondents for the study. Data was collected using a comprehensive questionnaire and analysis was done using means, frequencies percentages and Chi square. The result revealed that the average age of the respondents was 41.6years, male 61.1%, married 88.9%, no primary education 40%, farming as primary occupation 86.7%, family size (1-5) 86.7% and 91.1% got labour source from both personal and hired. The finding also revealed that 44% of the respondents' prune regularly, 70%, 64%, 73%, and 68%occationally practiced gapping up and use of improved varieties seedlings, control of pest and diseases, Timely harvesting and recommended spacing respectively. The constraining factors affecting coffee production are; Land tenure system (mean=1.58) ranked 1st, farmers'/herders clash and lack of technical know-how on coffee wet processing method(mean=1.57) ranked 2nd, price fluctuation and inadequate credit facilities (mean= 1.56) ranked 3rd pest and diseases (mean=1.55) ranked 4th. The chi-square analysis revealed a significant relationship between level of education(X=42.252), sources of labour (X=20.422), sources of capital(X=15.262) and constraining factors affecting coffee production. Farmers need training on some coffee production technologies like coffee rehabilitation technique.
Keywords*: Farmers, Constraints, Coffee, Production.*

INTRODUCTION

The origin of coffee farming has been traced to Ethiopia in Africa before its spread to other countries of the world (Williams, 2008, Ngussie and Dererse, 2007). Coffee belongs to the botanical family Rubiaceae, which has some 500 genera and over 6,000 species (Davis 2001). Most are tropical trees and shrubs that grow in the lower storey of forests. Other members of the family include gardenias and plants that yield quinine and other useful substances, but Coffee is by far the most important member of the family economically (Payel G *et al* 2014) Brazil is by far the largest grower and exporter of green coffee beans in the world followed by Vietnam, Colombia, Indonesia, Ethiopia and India – producing nearly 2.5 million tonnes of green coffee beans per year (Franca *et al* 2009). Although Coffee is grown and exported by more than 50 developing countries, it's mainly consumed in the industrialized countries namely United States of America, Finland, Sweden, Belgium and Japan among others (Agbongiarhuoyi *et al*., 2006; and Daviron and Ponte, 2005). The two most important species of cultivated coffees in Nigeria are Arabica coffee (highland coffee) and Robusta coffee (lowland coffee). In the international market, Arabica coffee is of the greatest economic importance but in Nigeria, Robusta coffee account for 94% while Arabica coffee accounts for only 4% of coffee export.

The increasing use of Robusta coffee in the preparation of instant (soluble) coffee is making it to gain ground on Arabica coffee in the international market (Williams, 1998). In the world market, Coffee plays a vital role in the balance of trade between developed and developing countries; being an important foreign exchange earner, contributing in varying degrees to the national income of the producing countries (Cambrony, 1992 as cited by Ayoola *et al* 2012.). Despite the importance of coffee products to nations economy, its production is faced with so many challenges Several factors and challenges have been attributed to the country's dwindling production level, majority of which have forced farmers to abandon coffee for other crops to make ends meet. Major factors contributing to the abandonment of coffee farms, include poor pricing and marketing channel, lack of training on good coffee farming practices and value chain for coffee, lack of government support in terms of funding, provision of inputs and land acquisition.

According to Gbenga Akinfenwa (2019), explained that most of the coffee plots are old and farmers have suspended major cultural practices on their farms. Other noticeable factors constraining coffee production are Transport problem, Land tenure system, Prolonged draught, Climate change, Soil erosion, Pests and diseases, Farmers/herders clash and Lack of technical know-how on wet processing method. All the aforementioned production constrains are being considered with the aim of determining ways of bringing coffee farming back to its lost glory Specifically, the objectives were to describe the socio-economic characteristics of coffee farmers; ascertained some coffee production technologies engaged in by farmers, identify some constraining factors affecting coffee production, and determine coffee farmers' perception towards constraining factors affecting coffee production. The hypothesis of the study was stated in null form; there is no significant relationship between socioeconomic characteristics of the respondents and the constraints to cashew production.

METHODOLOGY

The research work was carried in Edo State. Multi stage sampling procedure was used in selecting respondents for the study. The first stage involved purposive selection of three Local Governments Areas noted for coffee production. These are Owan East, Owan West and Uhunmwonde. The second stage involved purposive selection of one community per LGA where coffee is produced in large quantity. Lastly, thirty respondents were randomly selected in each community to make a total number of ninety respondents. A structured interview schedule was used for field data collection from coffee farmers in the study areas. Descriptive statistics and chi-square were used in data analysis. The variables were measured at 0.05 Level of probability. The variables of the study were measured as follows

Perceived Constraints to Coffee Production

The respondents were presented with a list of fourteen perceived constraints to coffee production. A three-point scale of 'Not a constraints', 'Minor constraints' and 'Major constraints with scores of 0,1 and 2 assigned respectively. The mean score for each perceived constraint was obtained and used to rank them in order of severity

RESULT AND DISCUSSION

The socioeconomic characteristics of the respondents

The result of socioeconomic characteristics shown in Table 1 revealed that 67.7 percent of the respondents are between 31to 50 years of age with mean age of 41 years. This indicates that the respondents are still in their productive age. The result of age distribution of farmers contradicted the findings of Ayoola *et al* (2012) that the majority of sampled coffee farmers was above 50 years old The result also revealed that 61.1 percent of the respondents were male while 38.9 percent are female. The male dominance in coffee production may be as a result of having access to land through inheritance which their female counterpart did not. Also, greater percentage (88.9%) of the respondents are married, this may be because coffee production needs more hands during maintenance and processing. Sixty percent of the respondents had primary school certificate and above. It indicates that most of coffee farmers in the study areas are literate. The table also indicates that majority (91.1%) used both family and hired labour in their farm. This could be as result of tedious nature of coffee work that required more hands

Table1: Distribution of the respondents based on Socioeconomic characteristics n=90

Variables	Frequency	Percentage	Mean
Age			
Less than or equal to 30	11	12.2	
31- 40	27	30.0	41.6 yrs
41-50	33	36.7	
51-60	12	13.7	
61 and above	7	7.8	
Sex			
Male	55	61.1	
Female	35	38.9	
Marital status			
Single	5	5.6	
Married	80	88.9	
Divorced	4	4.4	
Widowed	1	1.1	
Religion

Distribution of the respondents based on coffee production technologies utilization

The distribution of respondents based on coffee production technologies utilization is shown in Table2. The result revealed that 18.9% of the respondents never prune their coffee plantation while 36. 7% and 44.4% occasionally and regularly prune their coffee plantation with mean score of 0.75. coffee farmers need to be encouraged to regularly prune their plantation to enhance high productivity. Also, 13.3% of the respondents never gap up the death stands while 70% and 16.7% occasionally and regularly gapping up dead coffee stands in their plantation. Furthermore, 63.3% of the respondents never practiced coffee rehabilitation. This technique is very important in order to increase the economic life span of unproductive coffee plantation and coffee farmers must be trained on rehabilitation technique. The table also revealed that 64.4%, 73.3% and 70% of the respondents occasionally practiced control of pest and diseases, timely harvesting of coffee berries and use of improved coffee seedlings respectively while only 7.8% of the respondents never practiced recommended planting spacing

Table 2: Distribution of the respondents based on coffee production technologies utilization

Coffee production Tech.	Never	Occasionally	Regularly	Mean
Regular pruning	18.9	36.7	44.4	0.75
Gapping up	13.3	70	16.7	1.02
Coffee Rehabilitation	63.3	23.3	12.4	1.11
Control of pest and diseases	13.3	64.4	22.2	1.07
Timely Harvesting	6.7	73.3	20.0	1.13
Use of improved coffee seedlings	12.2	70	17.8	1.06
Recommended planting spacing	7.8	68.8	23.3	1.14

Distribution of respondents based on constraining factors affecting coffee production

The various production constraints encountered by coffee farmers and their rank order of severity was presented in table 3. Constraints like land tenure system farmers-herder clashes and Lack of technical know-how on wet processing method ranked 1st and 2nd. respectively. The issue of farmers-herder clashes is a serious problem in coffee farming in fact, some farmers are almost given up as a result of incessant attacks by herdsmen. Also, coffee wet processing method is the best method to get good quality coffee products but unfortunately, farmers lack needed training and equipment to carry it out. Price fluctuation and inadequate credit facilities ranked 3rd in order of severity in constraints faced by coffee farmers. Coffee farming is a capital intensive project, farmers need to purchase agrochemicals, pay wages to labourer and purchase some farm implements. It is difficult to get loan from the bank to finance coffee farming Akinbode SO (2013) explained that the requirement from commercial banks make it difficult for farmers to access credit to finance farming work Also, pests and diseases, inadequate information and climate change with mean 1.55 ranked 4th while soil erosion and unavailability of labour with mean score 1.48 ranked least.

Table 3: Distribution of respondents based on constraining factors affecting coffee production

Constraints	Not a constraints	Minor constraints	Major constraints	Mean	
Inadequate credit facilities	24.4	31.1	61.1	1.19	3rd
Unavailability of labour labour	5.6	41.1	53.3	1.48	8th
Transport problem	3.3	41.1	55.5	1.51	6th
Poor extension visit	4.4	41.1	54.4	1.49	7th
Prolonged draught	5.6	38.9	55.5	1.49	7th
Soil erosion	6.7	37.8	55.5	1.48	8th
Climate change	6.7	31.1	62.2	1.55	4th
Unstable government policies	6.7	34.4	58.9	1.53	5th
Land tenure system	5.6	31.1	63.3	1.58	1st
Price fluctuation	4.4	34.1	61.1	1.56	3rd
Pests and diseases	5.6	34.1	60.0	1.55	4th
Inadequate information	5.6	33.3	61.1	1.55	4th
Farmers/herders clash	8.9	31.1	60.0	1.57	2nd
Lack of technical know-how on wet processing method	10.0	30.9	59.1	1.57	2nd

Source: Field survey, 2022.

Respondents perception to coffee production constraints

The table revealed that greater percent (93.3%, and 85.6%) of the respondents agreed that credit facilities is not readily available and unstable government policies affect coffee production while 70% of the respondents strongly disagreed that farm labour is cheap and affordable. The table also revealed that 60%, 51.1%, 52.2% and 56.7% of the respondents agreed that pilfering is common practice in coffee farm, information about GAP is not readily available, farmers-herders' clashes is a problem and pest and diseases respectively are serious constraints affecting coffee production while 54.4% and57.4% of the respondents strongly disagreed that climate change is not a serious problem and it is cheap to transport coffee

Table 4: Coffee farmers' perception about constraining factors affecting coffee production

Statements	SA	A	U	D	SD
Credit facilities are not readily available	5.5	93.3	1.2	/	/
Unstable government policies	4.4	85.6	6.7	3.3	/
Farm labour is cheap and affordable	8.9	/	1.1	20.0	70
Pilfering is common practice in coffee farm	22.2	60	18	26.7	3.3
Information about GAP is not readily available	18.9	51.1	25.6	1.1	3.3
Farmers/herders clashes	44.4	52.2	/	3.3	/
Pests and diseases is a problem in coffee production	17.8	56.7	20.0	2.2	3.3
Middlemen make more gain	16.7	57.8	20.0	2.2	3.3
Climate change is not a serious problem	21.1	1.1	3.3	20.0	54.4
It is cheap to transport coffee	13.3	24.4	1.1	3.3	57.4

Source: Field survey, 2022.

Test of hypotheses

The result of chi-square showing relationship between respondents selected socioeconomic characteristics and constraints to coffee production. The table revealed a significant relationship between level of education (X=42. 252; p<0.000), Sources of labour (X=20.422; p<0.000), Sources of capital (X=15.262; p<0.000) and constraints to coffee production. The implication of significant relationship between education and constraints is that the more educated a farmer is the less constraints he/she may likely face because of the high level of exposure. Also, the significant relationship between sources of labour, sources of capital and constraints implies that labour and capital are key factors in coffee production. A farmer that has good sources of finance is likely to overcome some of the constraints to coffee production. It may likely assist farmer to hire labour instead of depending on family labour only.

Table 5: Chi- square analysis between respondents' socioeconomic characteristics and constraining factors affecting coffee production.

Variable	X^2	DF	p-valve	Decision
Marital status	30.293	3	0.532	NS
Level of Education	42.252	3	0.000	S
Sources of labour	20.422	2	0.000	S
Sources of capital	15.262	2	0.000	S

Source: Field survey, 2022.

CONCLUSION AND RECOMMENDATION

The study concludes that coffee farmers are still in their productive stage. Farmers frequently utilized most coffee production technologies. The study had revealed array of constraints facing coffee farmers which might affect coffee production in commercial purposes these include; lack of access to credit, price fluctuation, farmers-herders' clashes, sharp practices of middlemen, price fluctuation etc. As a result of the importance of coffee production and its products to Nigerian populace, government should intervene in the present crisis rocking the coffee sector by creating appropriate marketing channel and put in place price control system. Farmers need to be encouraged by making available to them credit facilities as most of them depend on personal savings and money gotten from family and friends to finance their farming operation. Inputs should be subsidized by government and made available to farmers in large quantity. Lastly, farmers need training on some coffee production technologies like coffee rehabilitation technique

ABSTRACT
A field experiment was conducted at the student demonstration field in Samaru College of Agriculture, Division of Agricultural College, Ahmadu Bello University, Zaria in the Northern Guinea savannah ecological zone of Nigeria (11° 11 N, 07°38 E and 686mm above the sea level) during 2021 dry season to determine the growth and yield of irrigated Garden cress (Lepidium sativumL) varieties as influenced by sowing methods at Samaru. The treatments consist of three sowing methods (Broadcasting, Drilling and Dibbling) and two varieties (Ex Jaba and Halim). The treatments were factorially combined and laid out in randomized complete block design (RCBD) and replicated three times. The result shows that taller plants with more number of leaves and branches as well as earlier flowering, fresh and dry yield were recorded when Ex Jaba variety and broadcasting methods were used compared to the other variety and sowing methods. In conclusion, Ex Jaba variety and broadcasting method of sowing could be used for optimum growth and higher vegetable yield of garden cress during dry under irrigation at Samaru.

INTRODUCTION

Garden cress *(Lepidium sativum)* known as garden or common cressis an annual herb belonging to the family *Brassicaceae* and the centres of origin of the crop is the high lands region of Ethiopia and Eritrea (Stchenkova, 2009). The genus *Lepidium* comprises of several species growing mostly in warm climate. Species in this family have a worldwide distribution and have the highest diversity in the Mediterranean region, West and Central Asia and parts of Northern America (Jubrin 2012 and Vipul D. *et al*, 2014). The crop can grow on wide range of environmental and soil conditions as it tolerant slight acidity and insects attack, therefore its cultivations becomes easier and widely distributed across the globe (H. Falana *et al.* 2014). In Nigeria the crop is grown in the Sudan and guinea savannah ecological zones, throughout the during wet and dry seasons. Garden cress is a short live, easily perishable leafy vegetable, cultivated for its nutritional and medicinal values and serve as source of income for part time vegetable producers (Jibrin *et al.* 2016). However, the cultivation of the crop is greatly affected by inadequate quality seed and choice of suitable variety and sowing methods by the poor resource vegetable farmers. Therefore, appropriate sowing method has to be employed in order to avoid seed wastage, poor germination and establishment of the crop in the field which will affect the yield.

Garden cress has varieties and the performance of the varieties depends on variation in geographical location as influences by environmental conditions and soil type. Mostly farmers in Samaru cultivate only the local Ex Jaba variety and do not cultivate of improved exotics varieties which may attain maturity at very much earlier period, resist pest and diseases compare with local variety (s). Based on the foregoing, this study was conceived with the following objectives

- To determine the suitable garden cress variety (s) for higher growth and yield of garden cress in Samaru and environs.
- To determine the proper sowing method proper growth and higher of garden cress.

MATERIALS AND METHODS

The experiment was conducted at student demonstration field of Samaru College of Agriculture, Ahmadu Bello University Zaria in the Northern Guinea Savanna Agroecological zone of Nigeria (11° 11 N, 07°38 E and 686mm above the sea level) during 2021 dry season. It comprises of six (6) treatment combinations consisting of two varieties (Ex Jaba and Halim) and three sowing methods (Drilling, Dibbling and Broadcasting). The treatments were factorially combined and laid out in a randomized complete block design (RCBD) replicated four times. The field was harrowed twice and made into a sunken bed. The gross plot size was 1m × 1m (1 m^2) and 0.5m^2 net plot .A spacing of 0.5m between the plots and 1m between the replicates were made. The seeds (Ex Jaba and Halim) were sown according to the layout using drilling, dibbling and broadcasting methods on 1st May, 2021. Seeds were covered with a thin layer of soil immediately after sowing. NPK 15:15:15 was applied to the field at sowing to supply N, P and K for the crop at the rate of 40 Kg per hectare immediately after sowing. Weeds were controlled during land preparation using 360g/l of Grammazone and by hand picking and hoe weeding at 2 and 3 weeks after sowing (WAS). The crop was harvested by uprooting the whole plant at 4 WAS. Data on plant height, number of leaves, days to 50% flowering, fresh and dry yield were recorded.

RESULTS

The effect of sowing method on plant height of garden cress varieties was presented on Table 1. At week 2, 3, and 4 there was significant difference between the varieties. Ex Jaba variety produced significantly the tallest plants while Halim produced the shortest plants. No significant response was noted throughout the sampling periods due to varietal differences and varied sowing methods used. In addition, the interaction between varieties and sowing methods was not significant on plant height at all the sampling weeks. Table 2 shows the effect of sowing method on number of leaves of garden cress varieties. No significant response was recorded for both varieties and sowing methods with regards to number of leaves at week 2, 3, and 4. The interaction of the varieties and sowing methods on the same parameter was also not significant in all the sampling period.

The effect of sowing method on days to 50% flowering of garden cress varieties was presented on Table 3. There was a significant difference between the days, took by the varieties to attain 50% flowering. Ex Jaba has attained 50% flowering earlier than Halim. The significant effect due to varied sowing methods showed that dibbled garden cress took more days to attain 50% flowering compared to broadcast and drilled plants which were statistically at par and attained 50% flowerings much earlier. There was no significant response on the days to 50% flowering due to differences in varieties and sowing methods. The effect of sowing method on the fresh and dry yields of garden cress varieties was presented on Table 4. Varietal differences and dry yields where higher yields were recorded in in ex Jaba compared to Halim variety. When sowing methods were compared, significant differences was recorded in which broadcast and drilled garden cress had higher and similar fresh yield, whereas higher dry yield was noted using broadcasting methods. However, lower yield was observed in dibbled garden cress which was at par with drilled plants. There was no significant response on the fresh and dry yields between the two varieties under varied sowing methods.

DISCUSSION

Both plant height and number of leaves have produced no significant difference with regards to sowing method. However, sowing method was observed to significantly affect other parameters like days to 50% flowering, fresh yield and dry yield**.** This could be due to high temperature when the experiment was carried out as against the temperature requirements of the crop. The earlier flowering of the broadcasted plants could be due to the number of plants per stand in broadcasting. For drilling, the earlier flowering was because it has closer inter row spacing compared to dibbling. The broadcasting and drilling methods resulted in the higher fresh yield, while the dibbling method had the lower yield. This could be due to earlier flowering coupled with the number of plants per stand which allow the plants to utilize more sunlight which is an ingredient for photosynthesis. For the dry yield on the other hand, broadcasting produces the highest value while dibbling produced the least value but the two methods are all at par with drilling. This could be attributed to the non significant response of plant height and number of leaves to the different sowing methods.

This is in agreement with the experiment of Azizur Rahman *e.t al* (2019) on Mustard which shows sowing method having effect on parameters like seed weight and yield of seed per hectare and biological yield per hectare with broadcasting producing highest values than drilling. Ex Jaba has produced higher plants with more leaves, while Halim has highest value for canopy spread. This different might be due to the variation in their genetic makeup and adaptability. Abey *et al.* (2002) also reported that different crop varieties possess varying genotypic and phenotypic traits.

CONCLUSION

In conclusion, it was observed that efficient growth and higher yield of garden cress under irrigation at Samaru was obtained when Ex Jaba variety was sown using broadcasting method.

ABSTRACT
Vegetables are considered essential for well-balanced diets as they are sources of phytonutrients, vitamins, minerals and dietary fibre. Daily intake of vegetables has strong connection with overall good health, reduced risk of some forms of cancers, anaemia and other non-communicable diseases. The industrial standard of counting calories as metric for food security does not lead to improved nutrition, rather to persistent malnutrition, ill health and hunger. To meet the nutritional needs and reduce the over dependence on few vegetable crops, attention should be given to the impact of Neglected and underutilized species of vegetables on their nutritional requirements to the general public. One of such local vegetables with excellent nutrition and medicinal potentials is African nightshade, Solanum scabrum. This review explored the nutritional and medicinal attributes of Solanum scabrum in improving food and nutritional security with the view of bringing the attention of the public to its importance in human well-being. The review also x-rayed the enormous medicinal uses of the vegetable with the view of improving the health and economy of rural communities in Nigeria and the world in general.
Keywords: *African nightshade, Medicinal, Nutrition security, Solanum scabrum, Vegetable*

INTRODUCTION

Vegetables constitute an important portion of human diet in various parts of the world and play a vital role in human nutrition, particularly as providers of phytonutrients, vitamins, minerals as well as dietary fibre. Some of these phytochemicals in vegetables have strong antioxidant and antibacterial properties that are believed to aid in the reduction of the risk of chronic diseases by protecting human bodies against free-radical damage, through the modification of metabolic activities and detoxification of carcinogens or even influencing the processes that alter the course of tumor cells (Herrera *et al*., 2009). A daily intake of vegetable have been strongly linked with overall good health, improved gastrointestinal health and vision, reduced risk of some forms of cancer, heart disease, stroke, diabetes, aneamia, arthritis and other chronic diseases (Keatinge *et al*., 2010). In the year 2017 alone, about 3.9 million deaths worldwide were attributed to non-eating of enough vegetables (WHO, 2019). Inadequate vegetable intake in an unbalance diets have been projected to cause approximately 14% of deaths from gastro-intestinal cancer, 11% of those due to ischemic heart disease and about 9% of those caused by stroke globally (Afshin *et al*., 2019).
The year 2021 was declared by the United Nations (UN) General Assembly as the International Year of Vegetable to raise awareness of the nutritional and health benefits as well as Food and Nutrition Security of vegetables and their contribution to a balanced and healthy diets and lifestyle. Nutrition Security refers to sustainable access to available and affordable foods and beverages that promote human well-being and prevent and possibly treat disease. Therefore, in this context, Food Security does not exist without Nutrition Security (Aliyu *et al*., 2022). On the contrary, many food policies rather focus on quantity than quality. It is the difference between eating bread every day or a diverse diet incorporating all the food groups every day. One satisfies our hunger while the other enriches our body to reach its full potential (FAO, 2020). Although the World Health Organization (WHO) recommends a daily consumption of at least 400g of vegetables to reap their nutritional and health benefits, the Food and Agriculture

Organization on the other hand, opined that the industrial standard of counting calories as the metric for food security is not leading to improved nutrition outcomes. Persistence of malnutrition, ill health, hunger and nutrition-related non-communicable diseases are still on the rise globally (Baldermann *et al*., 2016), indicating that the world is not on track to reaching any of the targets set by the United Nations Sustainable Development Goal 2 of zero hunger by 2030 (FAO, 2020). Recent reports by the United Nations on micronutrient malnutrition showed that in 2020, about 12% of the world population were severely food insecure and that 22% of children below age five (5) suffered from stunting (UN, 2021). To correct the misdirected focus on only delivering calories, there is a global paradigm shift to focusing on Nutrition Security through dietary diversity and utilization of locally available vegetables. This forms the basis of the concept Food Security as outlined by Aliyu, *et al*. (2022).

To meet the nutritional needs of the ever growing population and to reduce over dependence on few vegetable crops, research and development scope should be broadened to include a much wider range of vegetable species. Most vegetables we have today were collected form the wild by crop-gatherers and brought under cultivation in different parts of the world. Plants that are useful to humans and grown by them are called crops. However, certain crop plants that are either not useful to their full potential or strongly linked to their cultural heritage or adapted to a specific agro-ecological niche are referred to as Neglected and Underutilized Species (NUS). In Nigeria and many other countries of the world appreciable attention has not been given to the impact of these underutilized vegetables on the nutritional requirements of the people. This is evidence in the global production of vegetables in 2021, by type where no record is mentioned about underutilized vegetables (Shahbandeh, 2023). Many of these underutilized or minor vegetables are nutritionally rich and complement significantly to the diet based on few staple crops by providing important vitamins and minerals. Similarly, some of these neglected vegetables and herbs have multiple uses (i.e. food and medicinal) and the key to unlocking their true potential lies in our ability to harness their uses beyond the traditional single-use approach (GFAR, 1999). One of such vegetables with tremendous potentials to enhancing food and nutrition security cheaply in Nigeria is the African nightshade, *Solanum scabrum*. Though of an uncertain geographical origin, Linnaeus attributed it to Africa where it is cultivated as edible leafy vegetable or pot herb (Mwai *et al*., 2007). Therefore, the objective of this review is to examine the nutritional and health benefits of African nightshade, *Solanum scabrum* in enhancing food and nutrition security.

The African nightshade, *Solanum scabrum*

African nightshade also known as garden huckleberry is an annual or short-lived perennial plant that belongs to the family solanaceae. Its growth habit varies from herb to tree and grows up to 1m in height. The stem is hairless or sparsely hairy. The leaves are ovate in shape, 7-12cm in length and 5-8cm in width, together with fresh shoots are widely used as cooked vegetable and served with corn flour or *tuwo masara*. Inflorescence is simple or sometimes branched. The flowers are 4-5 parted with the petals fused into a tube-like structure that contains the stamens (Garjila, 2016). The fruits which are initially green in colour but turns dark-blue or black when mature are not edible berries, 10-17mm in diameter developed from ovaries and contain more than one seed. The vegetable is commonly cultivated in Sardauna Local Government Area in Taraba State of Nigeria and the areas bordering the hilly highlands of the Republic of Cameroon. Studies have shown that African nightshade production extends from the coast of West Africa to East Africa, and south to Mozambique and South Africa where it is extensively cultivated as leafy vegetable (Abukusta-Onyango *et al*., 2013). The wide range of diversity of African nightshade particularly in Nigeria and Cameroon suggests that its origin is likely to be in the warm humid forest belt of West and Central Africa (Muthomi and Musyimi, 2009) with different names among the locals such as *mange* and *nzhi* in Mambilla and Kaka languages, respectively. However, in Taraba State and other neighboring States of Adamawa and Gombe in Northeastern Nigeria, it is locally referred to as *kumbi*.

Nutritional benefits of African nightshade

African nightshade is principally cultivated for its leaves that are cooked and eaten as pot herb served with different types of such as corn flour, semovita, rice, pounded yam or even pounded coco yam. The leaves are rich in micronutrients, especially vitamins A, C, and E, ascorbic acid, riboflavin, minerals (iron, calcium, and zinc) and dietary fibre (Neugart *et al*., 2017), making it an important source of nutrients for the resource-poor. A variety of health promoting bioactive phytochemicals such as phenolic compounds, carotenoids and chlorophylls have also been not quite long identified in *Solanum scabrum* (Jimenez-Aguilar and Grusak, 2015), which could be the reason for its popularity in its area of origin and by extension its long use in traditional medicine. The nutrient composition of the leaf is likely comparable to other green leafy vegetables. As it has bitter taste, some people especially the elderly appreciate the taste and prefer not to use salt. The bitter taste is associated with high content of alkaloid and solanine which is found throughout the plant but with more concentration in the unripe fruits and in older leaves. That might be the reason why the fruits are not consumed because of high content of anti-nutrient substances such as solanaceous glycoalkaloids (Yuan *et al*., 2018). However, the bitterness is reduced by discarding the very dark-green cooking water and replacing it with fresh water. Vitamin A plays an important role in cell growth, vision, and the immune system. It helps skin develop and stay healthy and promotes the growth of bones and teeth. Ascorbic Acid or Vitamin C, a food substance needed by humans to prevent scurvy, a disease of the gums, bones, and blood vessels, and to increase the body's resistance to infection. Ascorbic acid acts as an *antioxidant,* a nutrient that chemically binds and neutralizes the tissue-damaging effects of substances in the environment known as free radicals. As a result, ascorbic acid is vital for the growth and maintenance of healthy bones, teeth, gums, ligaments, and blood vessels (Markell and Siddiqi, 2022). Because of its role in the formation of *collagen,* the body's major building protein, ascorbic acid is a central component of all body organs (Keller, 2004).

Riboflavin, also called vitamin B_2 is a substance essential for the breakdown and utilization of carbohydrates, fats, and proteins in the body, and in the production of energy. Riboflavin plays a vital role in the health of the skin and is needed for production of certain hormones by the adrenal glands, the pair of hormone-secreting organs that sit on top of each kidney. Because it is a water-soluble vitamin—that is, it is not stored in the body, but is excreted in sweat or urine—riboflavin needs to be constantly replaced in the body. Hemoglobin is contained entirely in the red blood cells, amounting to perhaps 35 percent of their weight. To combine properly with oxygen, red blood cells must contain adequate hemoglobin. Hemoglobin, in turn, is dependent on iron for its formation (Litwack, 2022). A deficiency of hemoglobin caused by a lack of iron in the body lead to anaemia. There are different types of anaemia but the most common type is iron-deficiency anemia. When the body's need for iron increases—such as during periods of rapid growth in childhood, during pregnancy, or when there is chronic bleeding—an iron deficiency may develop. Low iron levels impair the body's ability to produce hemoglobin, a primary component of red blood cells. All these nutrients are provided by Solanum scabrum. Even though the cultivation and utilization of African nightshade is restricted to few communities in Taraba Sate, its nutritional importance in food security cannot be overestimated especially in the north-east sub-region of Nigeria.

Medicinal benefits of African nightshade

Generally, over the past few years, plants have become an indispensable source of food and medicine to mankind globally (Sodipo *et al.*, 2000). In most parts of rural Africa, traditional healers prescribing medicinal plants are the most easily accessible and affordable health resource available to the local community and at times the only therapy that subsists (Mahomoodally, 2013). These medicinal plants play an important role in the lives of the rural people who produce and consume them, especially those in the remote parts of the developing countries where adequate health facilities are limited (Safwan and Mohammed, 2016). The nightshade family has about 90 genera and 2600 species including African nightshade, *Solanum scabrum* or garden huckleberry. The garden huckleberry though mainly cultivated for its leaf that is eaten as pot herb, there is strong indication that it has some medical attributes that remains hidden in indigenous knowledge systems, thus justifying its continuous cultivation and consumption as leafy vegetable (Chivenge *et al*., 2015). Odongo *et al.* (2018) reported that African nightshade extracts showed strong health promoting potential, especially when fermented.

Therefore, the consumption of *Solanum scabrum* leaves should be encouraged, preferably after cooking or fermentation of the plant against eating it raw as practiced by some Mambilla natives. For instance, the use of African nightshade as a remedy for ailment has a long-standing history in Africa where extracts prepared from leaves and fruits are used in the treatment of jaundice and diarrhea in children (Roy *et al*., 2014). It is believed among the locals especially in East Africa that African nightshade is an excellent preventive medicine for jaundice by helping in strengthening the liver muscles thereby limiting the chances of coming down with the disease when included in daily diet. It is also recommended as an ideal treatment for stomach ulcer and other related painful sores (Malaika, 2006) and because of its antibacterial properties, regular consumption of the leaves as part of diet helps in healing stomach ulcer. However, being viewed as part of folk medicine among the natives of Mambilla plateau in Taraba State, it is believed that African nightshade can help to calm sore throats by crushing some fresh leaves and squeezing the extract directly into the throat of the victim and therefore it is recommended as an ideal pot herb for local singers. As a traditional medicinal plant, Nyeem *et al*. (2017) reported that the rich fibre content in African nightshade can act as a natural laxative agent by inhibiting constipation.

This assertion is validated by Mrs. Rose W. Okan (personal communication) who confirmed that daily consumption of the vegetable contributes in regular bowel movements and overall digestive system improvement. Similarly, Mrs. Rose W. Okan explained that in Mambilla ethnomedicine, juice extracts from fresh leaves of *Solanum scabrum* can be used in treating convulsion in children. Herbal medicine, also known as phytomedicine or botanical medicine, have been using parts of plant such as the leaves, fruits, bark or roots for over 5,000 years (Jabeen-Begum, 2021). *Solanum scabrum* might have anti-diabetic properties as reported by Mrs. Nellis Gimba (personal communication), a diabetes patient who said on regular consumption of the plant, her blood sugar level dropped drastically to an extend that she has not use any diabetes drugs for the past two years. She said whenever she eats the vegetable, she kept passing urine indicating that *Solanum scabrun* might have some diuretic properties that enhances the flow of urine and thus eliminates accumulation of water in the cells, tissues, blood and organs.

On the diuretic nature of the plant, Odongo *et al*. (2018) reported that the potassium content in *Solanum nigrum*, another species of the nightshade family is a natural diuretic that can help to reduce the risk of heart disease. Mrs. Nellis' testimony seems to be a common believe among the natives who prefer eating the diet in the morning hours rather than late in evening to enable them urinate throughout the day than disrupting their sleep at night. All these show that African nightshade holds the ability to assist in regulating blood sugar levels and flushing out of urinary tract infections and can be of advantage to people with diabetes and those suffering from urinary tract infections. Other medicinal uses of the nightshade family in parts of Asia include treatment of atopic dermatitis (AD) of various skin infections such as allergies, heat boils, eczematous skin and skin irritation as reported by Hong *et al*. (2020). Similarly, Mrs. Rose W. Okan (personal communication) confirmed that in Mambilla folk medicine, African nightshade fruits are used for the treatment of eczema and ring warm infections especially in infancy and childhood and sometimes even in adults where paste from the fruit is externally applied directly to the affected areas of the body.

These findings and reports clearly indicates that African nightshade, *Solanum scabrum* has some medicinal potentials that if judiciously harnessed, can positively impact on the well-being and economy of local communities in Nigeria in particular and the world in general.

ABSTARCT
One of the limitations of pineapple production is erratic natural inflorescence and fruit production. This could be ameliorated by using different induction chemicals. Field experiments were carried out at Teaching and Research farm, Ladoke Akintola University of Technology; Ogbomoso to assess the effects of different induction substances on post induction growth, fruits yield and quality of pineapple plants. The treatments tested included Calcium carbide, ethephon, Urea, ethephon + Urea, compost extract, and iced block. The treatments were applied on 14 month old pineapple plants plots previously laid out in a Randomized Complete Block Design replicated 3 times. Data were collected on growth parameters, fruit and fruit yield attributes as well as fruit proximate, elemental and phytochemical compositions. Data collected were subjected to analysis of variance and significant means were separated using Duncan Multiple range Test at 0.05 level of significance. There were significant difference in performance of pineapple plants treated with various induction chemicals. The use of calcium carbide resulted in the highest mean number of flowers, (105.21) which was significantly higher than the number of flowers produced by the other treatments, while plants treated with iced block produced the lowest number of flowers (45.84) at 2 months after application. The use of calcium carbide and ethephon did not negatively affected the proximate, elemental and phytonutrient components of pineapple fruits. The results obtained with the use of these substances compared favourably with what was obtained with plants treated with compost extracts. Therefore, any of the ethephon, calcium carbide or compost extracts is therefore recommended for use by farmers for pineapple floral induction in the study area.

INTRODUCTION

Pineapple (*Ananas comosus* (L.) Merr.), is an herbaceous monocotyledonous perennial tropical plant of the family *Bromeliaceae*. It is cultivated in more than 60 countries, where its present great demand and economic importance. In Brazil, it is the fifth more cultivated tropical fruit and represents a great option for cultivation in non-traditional areas such as the semi-arid region. Pineapple is a well appreciated fruit all over the world. It plays an important role in human diets and a good source of fiber and micronutrients especially vitamins and minerals. The pineapple is a tropical plant with an edible fruit and the most economically significant plant. It is indigenous to South America, where it has been cultivated for many centuries. The crop is the third most important tropical fruit in world production. In the 20th century, Hawaii was a dominant producer of pineapples, especially for the US; however, by 2016, Costa Rica, Brazil and Philippines accounted for nearly one-third of the world's production of pineapples (Bartholomew et al; 2002). The rich nutritional content of pineapple is highly beneficial for strengthening bones and connective tissue, thus preventing fractures and osteoporosis. Pineapple have been shown to regulate glucose metabolism, which makes it ideal for diabetics and people with high blood sugar.

Pineapple fruit is low in calories as 100 grams of this tropical fruit provide 20% of the suggested limit for sugar intake (up to 50 grams per day). This is due to its high levels of dietary fiber, which improve glucose metabolism, making it ideal for diabetics and people with hyperglycemia (Dass, et al; 1975). A significant problem of pineapple farmers is the low predictability of fruit yield and harvest date. In order to circumvent this problems, pineapple plants are induced at certain age with different chemicals. Calcium carbide, ethephon, and or urea have been reported to the efficient in stimulating flowering and fruiting in pineapple plants. However, the phyto toxicity, health hazard, and cost associated with the use of some of these chemical substances call for concern, and thus necessitated research into alternate safe and cheaper methods (Cunha, 1998; Cunha, 2005). The objective of the present work is to access efficacy of different induction chemicals on the flowering and fruiting of pineapple plants.

MATERIALS AND METHOD

Experimental Site

The field experiment was carried out at the Teaching and Research Farm, Ladoke Akintola University of Technology, Ogbomoso Oyo state. Ogbomosho falls on latitude 41^0E and longitude 81^0N which is located in the guinea savanna zone.

Experimental Materials

The smooth cayenne pineapple suckers were obtained from Ladoke Akintola University of Technology, Ogbomoso**.**

The induction substances used are:
T1: No application of any material
T2: Ice Block applied at the rate of 10g/stand
T3: Compost Extract (5kg of compost in 10 litres of water) applied at 40ml/stand
T4: Ethephon (Mix 30ml of ethephon in a 6 litres of water) applied at 40ml/stand
T5: 50% Compost Extract + Ethephon. The mixture applied at the rate of 40ml/stand
T6: Calcium Carbide (22.8g of calcium carbide in 6 litres of water) applied at 40ml /stand.
The treatment was laid out in Randomized Complete Block Design with 4 replicates.

Crop Management

i. **Weeding:** Weeding was done twice per month depending on how rapid the weed grows.
ii. **Application of Fertilizer (Urea):** A uniform application of urea at the rate of 120kg N/ha was supplement the soil nutrients

Data Collection: Data were collected on days to 50% flowering and fruiting, mean fruit weight, and fruit yield. The fruit proximate, elemental, and Vitamins A and C contents were also assessed.

Data analysis: The data collected were subjected to analysis of variance (ANOVA). Means were compared using Duncan Multiple Range Test (DMRT) at 5% level of significant.

RESULTS AND DISCUSSION

The effect of induction chemical types on the number of pineapple flowers at 2 months after application is presented in Fig. 1. Application of calcium carbide resulted in the highest number of flowers (105) which was significantly higher than the number of flowers produced by the other treatments with the least from plants treated with iced block. All physicochemical properties of the pineapple fruits measured were significantly affected (with the exception of pH) by types of induction chemicals. Nonetheless T4, T5 and T6 were highest in titratable acid and sucrose. The T1, T2 and T3 were highest in total sugar and lactose whereas only T4 was highest in fructose.

Effect of induction chemical types on proximate analysis of pineapple is presented in Table 2. The T4 and T6 produced the highest crude protein which were not significantly different from the other treatments. Plants treated with T4, T5, and T6 produced the highest fat content, crude fiber and total ash but were not significantly different from the values obtained from the other treatments. The moisture content was comparable among the six treatments however, T4 had the highest moisture content. The effect of induction chemical types on chemical composition of pineapple fruit is presented in Table 3. Pineapple plant treated with T4, T5 and T6 produced fruits with the highest calcium content which were not significantly different from other treatments. The T4 produced the highest sodium and iron content while T6 produced the highest potassium. T4 and T6 produced the highest phosphorus content and were not significantly different from the other treatments. T5 and T6 both produced the highest magnesium contents but were not significantly different from the other treatments. T4, T5 and T6 produced the highest zinc content and was similarly not significantly different from the results of the other treatments.

Effect of induction chemical types on mineral analysis of pineapple is presented in Table 4. T5 produced the highest vitamin C and vitamin A and were not significantly different. The effect of induction chemical types on pineapple fruit yield is presented in Table 5. T1 resulted in the highest weight in whole fruit, fruit and crown but were not significantly different.

Chemically induced fruits have higher sugar contents than non-induced fruits, as a result of low moisture content and high sucrose. The pH value also shows that the induced fruits are more acidic than non-induced fruits. This confirms that the report of Chang (2000), which asserts that treatment of pineapples with chemicals for floral induction affect the acidity of the fruits. However, the pH values of both induced and non-induced fruits fall within the range of 3.8-4.5. This implies that the use of calcium carbide, ethephon, compost extract and iced block does not seriously affect the acidity of the pineapple fruit beyond the acceptable limit. Pineapple fruits with no induction chemicals produced a higher weight of the whole fruit, fruit and the crown than the induced fruits but the induced fruits ripened faster than the non-induced fruits. The non-induced fruit had lower vitamin content in them than the induced fruits which ranges from 9.12-9.74 in vitamin C and 2.70-3.50 in vitamin A, which makes the chemically induced fruit more accessible to boost the immune system in the body. In the elemental composition, the chemically induced fruit has higher contents than the non-induced fruits. Fruits treated with ethephon and calcium carbide especially had the highest content in calcium, sodium, iron, magnesium and zinc. This four elements are essential and important in human health and also help builds the body system.

CONCLUSION AND RECOMMENDATION

The study concluded that the use of calcium carbide and Ethephon for floral induction influenced positively the quality of pineapple fruits. Fruits from chemically induced pineapples were preferred due to high accumulated sugar content. Thus, Ethephon and Calcium carbide are therefore recommended for use by farmers in this study area.

ECONOMIC ANALYSIS OF COST- RETURN STRUCTURE OF COFFEE PRODUCTION IN KOGI STATE, NIGERIA

Orisasona,T.M, Agulanna,F, T; Oladokun,Y.O.M. and Agboola, L.O
Economics and Extension Division, Cocoa Research Institute of Nigeria, Ibadan.

Corresponding author: taiwosona1976@gmail.com

ABSTRACT
The study examined the profitability of coffee production in Kogi state, Nigeria. There have been a lot of studies on cost return structure of annual crops with little attention given to perennial crops such as coffee. Therefore, this study examined the profitability of coffee production. Multi stage sampling technique was used to select the respondent for the study. The first stage was the purposive selection of three Local Government Areas (LGAs) from the State. Second stage was the random selection of 15 coffee producing communities from the three selected LGAs (the selection was proportionate to size), while the third stage was the random selection proportionate to size of 400 coffee farming households from the selected communities. Data were collected with the use of structured questionnaire for the literate respondents and an interview schedule for the illiterate respondents. The data collected were analyzed using descriptive statistics, Gross Margin (GM) and Net Revenue (NR) to analyze the profitability of the coffee farmers. The result showed that production of coffee as a venture is profitable because for every ₦1 invested in the business, it yielded ₦1.39. The study also recommended that government should support expanded production of coffee to other potential areas by taking further research on cost and benefit analysis of increasing coffee production, government and other lending agencies should also do more in assisting the farmers with soft loans in order to reduce the problem of inadequate capital among the farmers. These will enhance connectivity in research and extension for an improved coffee productivity and quality.
Keywords; *Coffee, Production, Productivity and Profitability*

INTRODUCTION

Agriculture is the mainstay of the Nigerian economy from the standpoint of its various contributions to the economy. During the 1960s, agriculture contributed about 85.5% of the total export and hence became the vital source of foreign exchange earnings. However, by 1984, Its contribution to export dropped to 2.6 percent while in 2004 the contribution to as low as 0.81 percent (Central Bank of Nigeria, 2010). Coffee belongs to family member of the Rubiaceae. lt has two major species in Nigeria, *Coffea arabica and Coffea canephora (robusta).* Coffee plant is native of Africa. The origin of Coffee arabica has been traced to Ethiopia in the 9th century while Coffee robusta is believed to have come from Central Africa. In 1859 specifically coffee was introduced to Nigeria and is mostly cultivated in the lowland areas (*Coffea canephora*) and Highland areas (*Coffea arabica*). Coffee growing and drinking started in Ethiopia. Today, it is an important commodity and a popular beverage in the world. Coffee is one of the important export crops commodities in Africa and Latin America countries (Opeke, 2005).

Costs-Return Structures and Gross Margin Analysis

Gittinger (1994) defined the cost ascribed to any good or service as the amount in monetary value of the good or service and what it requires to acquire the good or service. Total cost represents the totality of all cost incurred by a farm in a production process. It is simply the summation of the variable cost and fixed inputs used in a production process, that is,

$$TC = FC + V$$

Fixed cost is the cost incurred in the period during which some factors of production (particularly capital equipment) are fixed.

This cost does not vary with the output. The following are described as component of fixed cost: machinery cost, farm buildings and structures, salaries of administrative staff among others, variables cost, on the other hand are which vary positively with output, rising as more is produced and falling as less is produced. Examples include, cost of seeds, fertilizer, herbicides, labour wages etc.

Revenue is the total income accruing from the sales of product or service. The revenue to be accrued is dependent on the total quantity of produce (i.e. quantity consumed and quantity of produce yet to be sold) and the price/unit of this produce. Thus, Revenue refers to the product of the unit Price and output Quantity; Gross margin, is defined as benefit accruing when the fixed cost of the process of production has not been charged or rather when only cost of variable input have been charged (deducted) in the revenue. It is the return made when depreciation on fixed assets, administrative charges, and other explicit cost have not been charged in the total revenue. That is, Gross margin is the Total Revenue less the Total Variable Cos**t.**

Objectives of the Study

(a). describe the socio-economic characteristics of the respondent (coffee farmers) in the study area and

(b). determine the profitability of production of coffee in the study area.

RESEARCH METHODOLOGY

The study was specifically carried out in Kogi State, Nigeria, It's capital is Lokoja, located in north central of Nigeria, confluence of the two largest rivers in West Africa - Rivers Niger and Benue. First administrative headquarters of Nigeria is Lokoja. Kogi state is located in central States of Nigeria, created on the 27th August, 1991.The state has a total population of about 3.278 million (NPC, 2006). Kogi State occupies a total land area of 29,833 square kilometres. The annual temperature varies between 27°C and 37°C with relative humidity between 30 and 40% in January and rising between 70 and 80% in July to August. the annual rainfall is between 1000mm and 1500mm. The research design adopted for the study was the surveying method in which sample was drawn from the population which is considered to be the representative of the population. The study made use of primary and secondary data. A multi-stage sampling technique was used for the study. First stage involved the use of purposive sampling technique to select 3 out of 4 Agricultural zones in the state. ln the second stage of sampling, 3 out of the 15 Local Government Areas in the selected zones were selected using simple random sampling in order to guarantee that each of the 15 Local Government Areas had equal and independent possibility of being selected since they are all producers of coffee. In the final stage of sampling, simple random sampling proportionate to size was again used to choose the respondents that were administered structured questionnaire. Descriptive statistics were used to analyse socio economics characteristics of the respondent and Gross Margin (GM) and Net Revenue (NR) were used to analyze the profitability of the farmers in the study area; Gross Margin (G.M) = TR-TVC

Where:

TR = Total Revenue

TVC = Total Variable Cost (operating expenses which include; cost of agrochemical, transportation, labour wage, cost of seed/cuttings).

RESULTS AND DISCUSSION

Sex of the Respondents

Sex determines the ability to perform some physical work. It is generally believed that men are more efficient in activities than woman. This perhaps, is because they are more energetic and can handle more tedious work than their female counterparts. This is in fact, the basis for comparing the sex of the Farmers. Table 4.1 showed that majority of the respondents, (77.8%) were male while 22.2% were females. This tends to show that any likely increase in efficiency of coffee production would be as a result of the predominant involvement of male farmers who are most likely to be more agile than their female counterparts. This implies that activities of coffee production in the study area are gender sensitive.

Table 1: Distribution of Respondents by Sex

Sex	Frequency	Percentage
Male	311	77.8
Female	89	22.2
Total	**400**	**100.0**

Source: Field Survey, 2022.

Primary Occupation of Respondents

The primary occupation distribution was analyzed to show the different primary occupation of the respondents was involved apart from farming. Table 2 show the main occupation of the respondents. The result showed that 69.8% of the farmers were farming by occupation. However, respondents engaged in other income generating activities such as marketing (13.0%) This implies that majority of the farmers engaged in farming which might have provided employment and means of livelihood for them, Also, the emphasis given to agriculture by the successive administrations in the country might be a reason for many people going into farming.

Table 2: Distribution of Respondents by Primary Occupation

Primary occupation	Frequency	Percentage
Farming	279	69.8
Marketing	52	13.0
Agricultural labour	31	7.8
Craftsmanship	8	2.0
Civil servant	27	6.8
Others	3	0.8
Total	**400**	**100.0**

Source: Field Survey, 2022.

Result of Cost - Return Structure and Profitability of Coffee Production

The average gross total revenue was ₦673,530.00 and the average gross total variable costs excluding the cost of seed purchased was ₦36304.27, whereas the average gross profit margin was ₦637225.73 and average net profit margin of ₦492347.60 and return on investment was ₦1.39. The result showed that production of coffee as a venture is profitable because for every ₦1 invested in the business, it yielded ₦1.39 (Table 16). This result is closely similar to that of Haruna, *et al.,* (2012), who reported ₦1.20 as returns per naira invested on fresh tomato marketing in Bauchi State, Nigeria. The benefit/cost ratio for goat in Oyo State according to Oladejo (2014) was ₦1.17, and for Ado-Ekiti Metropolis in Ekiti State according to Bamgboye *et al*., (2019) was ₦1.45, suggesting the enterprise is profitable in the study area. Mafimisebi *et al*., (2013). Profitability Index for the study showed a value of 0.14, whereas the efficiency index of 0.4 was obtained. According to Mafimisebi *et al*., (2013), if the value for profitability ratio is greater than 0, marketing is said to be money-making to the group of market intermediaries in question while if the value obtained is less than 0, the group of market intermediaries being studied are operating at a loss.

Therefore, when the value of the efficiency ratio is greater than 1, it is concluded that the market is operationally efficient while a value of less than 1 is interpreted to mean operational inefficiency. Thus, the findings from the coffee markets in the study area can be adjudged to be relatively profitable but operationally price inefficient. The findings are similar to what Mafimisebi *et al*., (2013) reported for cattle markets in Ondo and Oyo States. Bila and Bulama (2007) however observed a low marketing margin (47-84 percent) for cattle markets in Maiduguri, Borno State while the marketing efficiency was significant (42.6 percent) with inefficient pricing (-333.54 percent) and net income per head was ₦1,698.76. the authors concluded that the market is fairly efficient with inefficient pricing system. Price inefficiency could have arisen from non standardisation in product nature and the existence of market associations that brought a lot of distortions to the pricing system in cattle. This is consistent with the position of Adekanye (1982): Akanni (2013) who posited that the aim of overall marketing efficiency is to provide goods to the consumers in the required from, time and place at the lowest possible costs as desired by the producers. This is however achieved by passing the costs to producer and or consumer under the force competition.

Result of Cost- Return Structure and Profitability of Coffee Production

Table 3: Distribution of the Respondents by Cost -Return Structure of Coffee Production

Variable	Mean value (₦)	Standard Deviation
Hired labour cost	16809.50	14641.95
Family labour cost	13129.50	15828.67
Seed cost	5441.50	6043.47
Fertilizer cost	9190.50	139.44
Chemical cost	2136.25	1342.22
Total Variable Cost	**36304.27**	**31530.95**
Cutlass cost	1162.00	686.72
Hoes cost	198.63	111.09

Price Inefficiency	0.12	
Return on one Naira Invested	1.39	

Source: Field Survey, 2022

CONCLUSION AND RECOMMENDATION

The result shows that larger percentages (69.8%) of the respondents were farmers by occupation. The average gross total revenue was ₦673, 530.00 and the average gross total variable costs excluding the cost of seed purchased was ₦36304.27, whereas the mean gross profit margin was ₦ 637225.73 and average net profit margin of ₦492347.60 and return on investment was ₦1.39. The result showed that production of coffee as a venture is profitable because for every ₦1 invested in the business, it yielded ₦1.39. With regards to farmer's specific factors, especially education, there is need for policy to promote formal education as a mean of enhancing the production of coffee over a long-term period. As this would enable the farmers to make better technical decision and help in allocating their production input effectively. More coffee farmers should be encouraged to form and join viable cooperative societies in order to access financial assistance at concessional rates, obtain goods and services at low prices, thereby importing their standard of living.

Lastly. Farmer should make sure that the farm environments are kept clean especially during the dry season to prevent fire outbreak which may cause havoc to coffee farm and drastically reduce efficiency of coffee production.

ABSTRACT
*Hevea brasiliensis of the Euphorbiaceae family supplies 99 per cent of the world's natural rubber. The seeds have useful chemical composition and are utilized mainly for the production of root stocks. This study was initiated to assess early emergence and growth vigour of Hevea brasiliensis as influenced by seed orientation in Rubber Research Institute Substation Akwete, Abia State. The seeds were sown in three seed orientations; horizontal with hilum side wards (HHS), vertical with hilum downwards (VHD) and vertical with hilum upwards (VHU). The experiment was laid out in a completely randomized design replicated three times. The study revealed non- significant effect ($P > 0.05$) of seed orientation on days to seedling emergence initiation (DEI), percentage emergence at 3 weeks after sowing (% E), stem girth growth rate (SGR), seedling shoot length rate (SLR), seedling root length rate (RLR), total seedling length rate (TLR), vigour index rate (VIR). However, Leaf area growth rate (LAR), number of leaves per seedling rate (NLR), and total dry weight growth rate (TWR) were significantly ($P < 0.05$) influenced by seed orientation. Positive and significant correlations were found between TWR and LAR (r=0.831**), NLR (r=0. 677 *), RLR (0.741*) and TLR (0.705*). VIR and % E (r=0.899**), SLR (r=0.893**), RLR (0.764*) and TLR (r=0.946**). Generally, vertical seed orientation with hilum downwards (VHD) gave early days to seedling emergence initiation (5 days), higher % E (100 %), larger LAR (2.97 cm^2), longest SLR (5.36 cm) and highest VIR (860) of rubber root stocks.*
Keywords: *Emergence, seed orientation, rootstock, vegetative growth.*

INTRODUCTION

Rubber tree (*Hevea brasiliensis* Muell. Arg.) is a multipurpose plant grown primarily for latex production with numerous useful by-products such as rubber seed, woods and oil. The seeds are dispersed by explosive mechanism which occurs from the period of August break to early October. The seeds are regularly collected during this time to avoid mouldiness which can affect viability of seeds (Uraih and Omokhafe, 2001). The mode of germination is hypogeal which occurs within six to seven days after sowing and about 75 percent germination is considered good. Fresh and heavy seeds show early germination (Saraswathyamma and Nair, 1976) and viability can be maintained for about seven days when kept under shade (Marattukalam and Mercykutty, 2000). Each rubber tree yields about 800 seeds (1.3 kg) and 500 999kg/ha/yr. The tree growth has limitation at the seed production level. Seeds collection, maintenance of seeds quality and low seeds germination make it necessary to use large quantity of seeds for plant establishment (Moreno *et al*., 2006). There is a great demand for certified rubber planting materials. In order to raise large scale rubber plantation, quality seeds and proper seed orientation are considered in the root stock pre nursery establishment.

Germination is a life cycle that produces new generation. Seeds have a physiological ability to germinate and correctly orient themselves according to gravity, a process known as gravi -tropism (Takakura *et al*., 1996). Seed orientations during sowing and in a suitable environment greatly affect the germination rate, seedling emergence, high plant population, seedling physiology and seedling morphology (Kevin *et al*., 2015; Lee *et al*., 2016). According to Jha *et al*. (2012) when radicle points upwards, the embryonic root and stem emerge in the wrong direction and have to change orientation, which requires energy and subsequently reduces plant growth. Several studies have been carried out on seed orientation effect on plant germination, growth vigour and its interactive effect (Rama Bhat, 2011; Ahn 2017). This study investigated the effects of seed sowing orientation on emergence and vegetative growth of rubber for root stock production.

MATERIALS AND METHODS

Study Area

The study was conducted in screen house of Rubber Research Institute of Nigeria, Sub-Station Akwete Abia State between August and November, 2022. Akwete is located at a latitude of 4^o 50′ and 4^o 65′ N and Longitude 7^o 00′ and 7^o 19′ E at an elevation of 122 meters above sea level in the tropical rainforest zone of south east Nigeria (Kamalu *et al*., 2014). The area is characterized by annual rainfall of about 2352.23 mm, mean air temperature range of (23 to 34 ^oC) and relative humidity range of (50 to 86.4 %). The soil was classified in USDA soil taxonomy as Fluvaquentic Dystrudept (Ugwa *et al*., 2017).

Planting Material

The seeds of Nigeria 811 (NIG 811) obtained from rubber clonal garden in the Substation were laid in a complete randomized design replicated three times in the screen house. The nursery bags filled with top soil were sown with one seed per bag and arranged according to three seed orientations (horizontal with hilum side wards (HHS); vertical with hilum downwards (VHD) and vertical with hilum upwards (VHU)). However, there was no fertilizer application and the pots were maintained accordingly.

Traits Assessments

Vegetative traits measured included: days to seedling emergence initiation – recorded as number of days between sowing and emergence, percentage emergence- done by counting the number of seedlings that emerged per treatment divided by the total number of seeds sown for each treatment multiplied by 100 , seedling height- measured with a meter rule from ground level to the apical region of the stem, root length- measured from soil base to the longest root, number of leaves per plant- counted and recorded of fully formed leaves, leaf area per plant - obtained by multiplying the leaf Length x Breadth with a correction factor of 0.654 (Tim and Narayana, 1972). Stem girth was also measured using a vernier caliper at 10 cm from the seedling base and biomass accumulation was obtained by cutting the shoot biomass (stems and leaves) and oven dried until a constant weight was obtained. Vigour index (VI) was computed as percentage emergence x total seedling length (root + shoot) (Abdul-Baki and Anderson, 1973) and expressed as a whole number. These activities were performed on monthly basis. However, for this study, instead of comparing the measured traits from different ages, the seedling growth rate was obtained by dividing9999 vegetative traits by the seedling age at the end of the study (4 months). The seedling growth rates evaluated included; seedling shoot length rate (SLR), seedling root length rate (RLR), total seedling length rate (TLR), number of leaves rate (NLR), stem girth rate (SGR), leaf area rate (LAR), vigour index rate (VIR) and total dry weight rate (TWR).

Data Analysis

The data obtained were subjected to one-way analysis of variance and the means separated using the least significant difference at 5 % level of probability (LSD) Genstat (2009).

RESULTS

The days to seedling emergence initiation was within two weeks and varied from 5.7 to 8.7 with no significant difference ($P > 0.05$) among the treatments. Similarly, percentage emergence was not significant (Table 1). Seed orientation; vertical with hilum downwards (VHD) with lower days to seedling emergence initiation (5 days) recorded the highest percentage emergence of 100 %. While seed orientation; vertical with hilum upwards (VHU) and horizontal with hilum side wards (HHS) with days to emergence initiation of 5.7 days and 8.7 days recorded percentage emergence count of 83.3 % and 66.7 % respectively. Seed orientation had no significant ($P > 0.05$) effect on all measured seedling growth rate except LAR, NLR and TDWR (Table 2). Seed orientation- VHD produced larger LAR which was 52.2 %

and 7.74% higher than HHS and VHU respectively; longer SLR and better VIR. While seed orientation - VHU recorded the highest and smallest NLR (1.90), RLR (3.39), TLR (8.48) and TWR (0.41) respectively. Also, SGR values were higher when seeds were sown with HHS followed with VHD orientation. The results also revealed that the higher the percentage emergence with corresponding earlier days to seedling emergence initiation, the greater the leaf area, number of leaf and seedling height growth rates.

The Pearson's correlation coefficients (Table 3) showed that TWR had a significant correlation with leaf area rate (LAR) with correlation coefficients (r) = 0.831**, NLR (r = 0. 677 *), RLR (0.741*), TLR (0.705*). The relationship with % E (r = 0.447), SLR (0.517) and VIR (r = 0.15) were not significant. Similarly, VIR had a positive and highly significant relationship with % E (r = 0.899**) and SLR (r = 0.893**), TLR (r=0.946**) and RLR (0.764*). The association of TLR with % E (r = 0.727*), SLR (0.911**), SLR (0.842) were also positive. % E and RLR were positively correlated with the studied parameters except with DEI (- 0.289) and SGR (r = - 0.262) respectively. TLR and NLR were also positively correlated with LAR (r = 0.484), NLR (r = 0.438) and LAR (r = 0.438) and LAR (0.586) respectively.

DISCUSSION

Seed orientation did not show any significant influence on emergence traits suggesting that acceptable rubber rootstock seedlings could be raised irrespective of seed orientation. However, Bowers and Hayen (1972), Masilamani *et al*. (1999), Ahn *et al.* (2017) reported significant effect of seed orientation on germination and seedling growth in bean, canjan and peanut, respectively indicating a close relationship between seed orientation and germination.

Table 1: Effect of seed orientation on germination characters

Treatments	Days to seedling emergence initiation	% seedling emergence at 3 weeks after sowing
HHS	8.7	66.7
VHD	5	100.0
VHU	5.7	83.3
$LSD_{(5\ \%)}$	12.72ns	47.09ns

LSD = Least significant difference, ns = not significant. Seed orientations; (HHS) = Horizontal with hilum side wards, (VHD) = vertical with hilum downwards and (VHU) = vertical with hilum upwards.

Table 2: Effect of seed orientation on seedling growth rate traits

Treatments	LAR (cm^2)	NLR	SGR(mm)	SLR(cm)	RLR(cm)	TLR(cm)	VIR	TWR (g)
				Month $^{-1}$				
HHS	1.42	1.06	0.56	3.77	1.98	5.75	439.0	0.24
VHD	2.97	1.50	0.43	5.36	3.24	8.4	860.0	0.39
VHU	2.74	1.90	0.44	5.09	3.39	8.48	706.38	0.41
LSD (5 %)	0.701**	0.59*	0.42ns	2.384ns	2.131ns	3.603ns	549.9ns	0.1051*

LSD = Least significant difference, ns = not significant, **, * Correlation is significant at the 0.01 and 0.05 level (2-tailed) respectively. Seed orientations; (HHS) = Horizontal with hilum side wards, (VHD) = vertical with hilum downwards and (VHU) = vertical with hilum upwards. Leaf area rate **(LAR),** number of leaves rate (**NLR**), stem girth growth rate (**SGR**), Seedling shoot length growth rate (**SLR**), Seedling root length growth rate (**RLR**), total seedling length growth rate (**TLR**), vigour index growth rate (**VIR**), total dry weight growth rate (**TWR**).

Table 3: Correlation matrix of the studied parameters of the evaluated rubber seed orientation

	LAR	SGR	NLR	DEI	% E	SLR	RLR	TLR	VIR	TWR
LAR	1									
SGR	-.343	1								
NLR	.586	-.530	1							
DEI	-.316	-.187	-.246	1						
% E	.399	.287	.015	-.289	1					
SLR	.473	.063	.233	.226	.756*	1				
RLR	.360	-.262	.555	.030	.508	.548	1			
TLR	.484	-.097	.438	.160	.727*	.911**	.842**	1

TWR	.831**	-.266	.677*	-.218	.447	.517	.741*	.705*	.615	1

**, * Correlation is significant at the 0.01 and 0.05 level (2-tailed) respectively. leaf area growth rate (LAR), stem growth rate (SGR), number of leaves rate (NLR), days to seedling emergence initiation (DEI), percentage seedling emergence (% E), seedling shoot length rate (SLR), seedling root length rate (RLR), total seedling length rate (TLR), vigour index rate (VIR), total dry weight rate (TWR).

The earliness to days of emergence initiation and high percentage emergence recorded was in line with the works of Wongvarodom *et al*. (2014) and Atminingsih and Andriyanto (2020) who reported between 54 to 85.50 percent germination of rubber seeds within two weeks after sowing. In this study, VHD largely had earlier time to emergence initiation and greater percentage emergence followed by VHU. Similar results were obtained by Rama Bhat (2011) in *Calamus prasinus* and Srimathi *et al*. (2014) in *Jatropha curcas* L. According to Ma and Hasenstein (2006), Finch-Savage *et al*. (2010) and Jha *et al*. (2012), this was attributed to proper radicle direction leading to a rapid emergence, germination and initial downward growth of the seedlings little energy. In contrast to our result, Gunasekaran (1997) observed that horizontal orientation with micropylar end facing sideways proved superior to vertical and inverted position in Clove (*Syzgium aromaticum*), Nutmeg (*Myristica fragrans*) and Rubber (*Hevea brasiliensis*). While Krishnasamy (1992) in cucurbitaceous vegetables and Rama Bhat (2011) in *Calamus stoloniferus* and *C. thwaitesii* reported early and higher percentage emergence as well as seedling vigour when seeds were in sown vertical orientation. This really indicated that selection of seed orientation expressed in the emergence traits is genetic identity of each species. Though the plants from seed orientation; VHD and VHU generally exhibited better growth rate traits, the difference was statistically significant ($P < 0.05$) for LAR, TWR**.**

The non –significant effect of the growth rates; SGR, SLR, RLR, TLR and VIR of the seedlings among treatments exhibited similar pattern; indicating that rootstock seedlings and traits are not affected by seed orientation. According to Atminingsih and Andriyanto (2020), Marattukalam and Mercykutty (2000) budding is dependent on rootstock age and type of budding thus, not necessarily on seed orientation. The maximum SLR, VIR and RLR recorded at seed inverted and up orientation were similar to the earlier reports of Rama Bhat (2011) in *C. prasinus* and *C. thwaitesii*. The observable higher seedling emergence with corresponding higher seedling growth rate is similar with the results of Atminingsih and Andriyanto (2020). The positive and significant correlations between TWR and most parameters suggested that an increase in performance of one implies an increase in performance of the others. According to Prawiranata and Tjonodronegoro (1995), TWR of seedlings expresses an indicator to determine whether or not plant reflects the plant nutrient status, the rate of photosynthesis and plant respiration. The positive correlation between RLR and SLR according to Budiman *et al*. (2015) reflects the capacity of the root to support the above ground biomass not only for anchorage but also in absorbing water and nutrients from the soil especially in limited soil water area (Takoutsing *et al*., 2014). Similar reports were also made by Budiman *et al*. (2015).

CONCLUSION

The results of this present study inferred that vertical seed orientation with hilum downwards (VHD) resulted to a better seedling emergence and general growth vigour. Thus, could be utilized in pre-nursery for raising of rubber root stock materials. To confirm this result, further work is expected to be done using more rubber seed genotypes.

ABSTRACT
The study investigated perceived effect of adoption of Export Standard Practices (ESP) on Coffee farmers' productivity in Kogi State, Nigeria. Specifically, the study described the personal characteristics of the respondents, assessed the extent of adoption of ESP and examined the effect of the adoption of ESP on coffee productivity. Multistage random sampling was used to select two hundred and twenty seven (227) coffee farmers. Data was collected using validated interview schedule while frequency count and percentages, weighted mean score and binary logistic regression were used for data analysis. The results revealed that 43.74 is the mean age of the respondents, majority of the respondent were male (84.1%), married (86.8%) with mean household size of 8.52 persons and mean farm size 5.8ha. The farmers did not deliberately adopt this practice with the continuous usage of only 5.7% based on the findings of this study. The extent of adoption of ESP among the coffee farmers' is very low indicated by the result analysis. The effect of awareness of export standard practices (Mean = 2.59) did not contribute to farmers' productivity. This means that awareness may not lead to adoption and utilization but it is just the first stage in the adoption process. However, if awareness is well managed, it can determine adoption provided inputs information and monitoring are incorporated at the awareness stage.
Keywords: *Adoption, awareness, practice, coffee, farmer, effect, export standard practices.*

INTRODUCTION

Coffee used to be one of the major cash crops of Nigerian economy before the discovery of petroleum. People rely on coffee for their livelihood and major means of survival, thus it recognition falls due to poor management practices, inadequate post-harvest handling, poor pricing. Coffee production ranged from 18,000 bags in 1961 to 50,000 bags in 2008. The highest annual production (95,000 bags) was obtained in 1964, 1988 and 1990 respectively (Williams 2008). Coffee is produced in more than 70 countries in the world and 97% of these countries are exporting members of International Coffee Organization. Most of these countries coffee export is not only vital contributor of foreign exchange but also accounts for a significant proportion of tax income and Gross Domestic Product (ICO, 2013). During the year 2010, it was estimated that about 26 million people in 52 producing countries were employed by the sector. The importance of the crop is diminishing as it was only in seven producing counties between 2000 – 2010 where average share of total export earnings exceeded 10% compared to 15% in the same category in the period 1996-2000.

Globally consumption of coffee is seen to grow at low rate but steady from 1980 to date (ICO, 2013), which is a good gesture towards sustainable coffee market. Over 600,000- 700,000 smallholder farmers are engaged in coffee production commanding a 48% share of the market. Over 80% of coffee from developing countries particularly Nigeria, is produced by small scale farmers who have inadequate technical education and are faced with low market prices leading to poor management, poor productivity and abandon farms (Agbongiarhuoyi *et al*., 2006). There has been a decline in coffee production in recent years mainly due to decline in prices and non-compliance with adoption of ESP in coffee production that could guarantee improves sales. Consequently, farmers are faced with poor price, low income, low profits and increased poverty. Idrisu, *et al.* (2012), reported that some problems arising from several factors related to the quantity and quality of the product, these factors include poor information on appropriate husbandry practices, good agricultural/management practices, quality of the product, processing, pricing, marketing problem.

Kogi State is known as the major producers of Coffee robusta in Nigeria. Income generated from production and marketing of coffee in the State has contributed immensely to sustenance of livelihoods and development of communities. It is unfortunate that marketing of coffee is no longer lucrative in the State. A lot of factors have been suggested to cause crisis in coffee trade; however, the issue in marketing chain and low price were considered paramount (Idrisu *et al*, 2012). According to Laven and Boosma (2012), the adoption of improved export standard practices is a platform for increased price of coffee, farmers' profits, through higher yields, good quality and internationally accepted coffee for export.

The specific objectives of the study were to;

1. describe the personal characteristics of coffee farmers in the study area,
2. assess the extent of adoption of ESP,
3. examine the perceived effect of adoption of ESP on coffee productivity in the study area

MATERIALS AND METHODS

Kogi state is purposively selected for this study because the state is the highest producer of coffee in Nigeria (Akinpelu and Oluyole, 2020; Idrisu*et al.* 2012). A three stage sampling procedure was used to select coffee farmers. The first stage is purposive selection of Kogi State for their higher coffee production in the country. The second stage was random selection of four Local Government Areas (LGAs) among the 16 LGAs in the State with the highest production of coffee. The third stage is random selection of 227 respondents coffee farmers from the list obtain from coffee association in Kogi State. The primary data collected through field survey. Respondents' was interviewed through the use of structured questionnaire and it was supplemented by information through focus group discussion with the coffee farmers' group leaders. The questionnaire was designed to obtain information relevant to the objectives of the study. The questionnaire was designed and presented for modification before experts in Agricultural Extension Services to ensure its validity.

Effect of adoption of ESP on farmers' productivity on coffee production was measured by asking the respondents to indicate their extent of agreement with the statement on productivity which will be ranked using a 5-point likert-type scale such as Strongly agree (SA-5), Agree (A-4), Undecided (U-3), Disagree (D-2), Strongly disagree (SD-1). This will be added to obtain 15 and will be divided by 5 to obtain the mean point of 3; any statement of productivity below 3 points will be regarded as statement not true with productivity. This study considered two paramount sets of variables which are independent and dependent variables. The dependents variable of this study is perceived effect of adoption of export standard practices (ESP) while independent variable includes: socio-economic characteristics of the respondents, profitability of ESP to adopters and non-adopters,

Coffee is an important crop globally. It contributes to National GDP, tax generations, job creation food security and inequality reduction. Globally, 25 million people in coffee growing countries are employed in the sector. Low coffee production resulting from world coffee prices of 1990s saw the production dwindling resulting to increase in poverty especially of small scale farmers due to low finances to support it's production. In Kenya for example 80% of coffee is produced by 700,000 small scale farmers currently the production dropped from 130,000 MT tones in 1987/88 to current 55,000 MT and contribution to national GDP dropped from 40% to currently 3.2% and hundreds of jobs were also lost(Karanja and Nyoro, 2002). Irrespective of poor coffee prices due to global crisis and inefficiencies throughout the coffee production value chain, farmers are still producing coffee which is of low quality despite of country's potential of producing specialty coffee due it's ecological positioning and unlikely to uplift them from poverty mainly because of lack of better paying alternatives, over regulation and high sunk cost associated with uprooting the crop (Kegonde, 2005).

RESULTS AND DISSCUSSION

Socioeconomics Characteristics of Coffee Farmers

Results in Table 1 show that the mean age of the respondents was approximately 44 years, hence, the farmers are still in their economically productive age and can therefore withstand the rigour associated with plantation farming. This implies that farmers are still young to know the significance of export standard practices of coffee on the quality of produce and pricing. This is because research has confirmed that learning reduces with an increase in age (Kelemen, 2014) and adoption of farming related practices has been documented to be influenced by age (Serebrennikov, Thorne, Kallas and McCarthy, 2020; Wauters and Mathijs, 2014 and Liu; Bruins; Heberling, 2018). Evidence in Table 1 also shows that majority (84.1%) of the respondents were male while women constituted less than one-quarter (25%) of the coffee farmers in the study area. The reason for this may not be farfetched as women and youth are less likely to be allocated farmland for tree crops in many parts of Nigeria due to cultural implications of land ownership (Chigbu, 2020). Culturally and traditionally, women access to farmland is limited as they are not mostly allowed to access farmland for plantation farming. This is because this type of farming is assumed to be synonymous to permanent ownership of farmland. Also, Kidido and Lengoiboni (2019) asserted that the fear of selling farmland by the youth and the impatience of the youth for the gestation period of most tree crops were responsible for the limited access given to youth with respect to farmland. However, both women and youth may be encouraged through mixed farming and communal land ownership as this would curtail the traditional fear of transferring ownership of farmland to women and the fear of youth selling the farmland if they are given the full ownership. It was also observed those majorities (86.8%) were married and widowed (1.8%). Marital status is said to be a measure of commitment as opined by Aderolu *et al*., 2014.

This finding is in line with Akinpelu and Oluyole (2020) who reported marital status of coffee farmers in Kogi State as a significant variable in their involvement in coffee production. The high marital status may be useful in the area of family labour and commitment to coffee production. Results in Table 1 further shows that about 18.1% and 23.3% of the respondents had no formal education and primary education, respectively while 45.8% had secondary education and only 12.8% had tertiary education. The findings show that most of the coffee farmers had between primary and secondary education while few had tertiary education. The level of education is adequate to promote awareness and adoption of practices that may enhance their mean of livelihood such as coffee farming. This is because education has been researched as a significant determinant of adoption of farming practices by extant literature such as Akinpelu and Oluyole (2020), Adinoyi and Attanda (2016) and Mohammed, Ayanlere and Ekenta (2013) in their various studies on adoption. This implies that with this moderate level of education in which majority had between primary and secondary education, the level of awareness and adoption may be high if other various are assumed to be constant. Based on the results of analysis of the findings, it was revealed that 39.2% and 43.6% of the farmers who produced Coffee in Kogi State were either Muslims or Christians while relatively high proportions believe in the traditional way of worship. The findings show that Islam and Christianity are the dominant religion practice by the respondents, although few of them were still found in the traditional religious belief system.

The finding is in consonant with the findings of Agwu,Ndakotsu and Ifeonu (2019) that reported that the ratio between Christians and Muslims farmers in Kogi State was about 50:40 as the findings specifically stated that about 54.2% and 45.8% of the farmers were Christians and Muslims, respectively. However, the findings further stated that religious affiliation has not influence whatsoever on the cultivation of tree crops and no religious restriction was found on the cultivation of major tree crops among farmers in the State. Meanwhile, religious affiliation may be advantageous to farmers as they could represent a viable and sustainable information sources on members means of livelihood. The numbers of members of a household are those that eat from the same pot and sleep under the same roof at a particular period of time. In this study, it was found that on average, about 9 persons were found as members of the Coffee farmers household and about 45.4% had between 5 and 10 household members while 28.6% had between 11 persons and above as their household size. The findings show that Coffee farmers in the study area had moderately high household members and the implication of this is that they may have enough members of their family being used as family labour provided their interest in farming is aroused through better yield, the use of technology and better profit. The finding is in-line with the findings of Agwu *et al*. (2019) that reported that about 50% of farmers in Kogi State had between 5 and 10 household size and Akinpelu and Oluyole (2020) reported that in the same state, about 52.0% and 24.0% of Coffee farmers had between 5-10 and 11 and above as members of their household, respectively.

Results in Table 1 show that farmers had huge experience in Coffee production as the mean years of experience was found as approximately 22 years and about 38.3% and 41.4%, respectively had between 20 and 29 years and 30 years and above as their years of experience in the production of Coffee. This means that the experience of the farmers may come to play in the awareness and adoption of practices that will ensure that the crops, being an export crops are internationally recognized and accepted, provided the information of the export standard practices are sought for by the farmers. The finding conforms with the findings from the various authors such as Agwu *et al*. (2019) that reported that in Kogi State the average farming experinec recorded by the Coffee farmers was 19 years, while Akinpelu and Oluyole (2020) asserted that Coffee farmers in the State had approximately, on average, 29 years of farming experience and Mohammad *et al*. (2013) affirmed that about 78% of the Coffee farmers in the state had over 30 years of farming experience.

Farm size was measured in hectares as the standard of measurement and report from the study shows that the average farm size by the farmers was about 5.76 hectares while only 4.0% of the farmers had less than 2.5 hectares of farmland, 35.7% had between 2.5 and 5 hectares and 60.4% had 5 hectares and above as the size of the farms dedicated for Coffee production. The findings show that Coffee farmers in the study area operate medium scale farming as most of them operate on a farm land that is more than 5 hectares. In Africa, due to land tenure system, farm land ranging from 1 – 5 hectares are classified as small scale while between 5 hectares and above are classified as medium scale according to Lowder and Raney (2016). This implies that most of the farmers in this study operate at medium scale farming with 5.76 hectares as the average farm size. The finding conforms to the previous findings by Akinpelu and Oluyole (2020) whose results showed that farmers cultivated about 5 hectares of farmland for Coffee production while Aderolu*et al.* (2014) posited that the average farm size dedicated for Coffee production in Kogi State was approximately 6.1 hectares.

Source: Computed from Field Survey, 2021.

Results in Table 2 show that almost 90% (89.9%) of the Coffee farmers in Kogi State cultivated Robusta species of the tree crop while only 10.1% cultivated Arabica type. The findings show that the most common type of Coffee cultivated in the study area is the Robusta type. This is in line with the previous findings by authors like Aderolu *et al*. (2014) that reported that 100% of farmers in Kabba Local Government Ares of Kogi State cultivated Coffea Robusta, Ali, Adesanya, Agboola-Adedoja, Adelusi, Ogunwolu, Ugwu and Akinpelu (2021) revealed that although two types of Coffee are cultivated in Nigeria but Coffea Robusta was the common cultivate species suitable for the soil and other climatic conditions in Nigeria. On the mode of farmland acquisition, report shows that most of the respondents, a little below average (48.0%) acquired their farmland by inheritance, 34.8% acquired farmland by outright purchase while 9.7% rented and 7.5% were gifted their farmland used for Coffee farming. This shows that most of the respondents used family land inherited from their family members for the Coffee plantation. Usually, land is a critical factor in the production of economic tree crops in Nigeria due to the undue pressure on land as a result of land tenure system.

Therefore, the easiest way of securing a land for such permanent crops is through inheritance because land ownership is in the hands of individual and community as an entity, hence, individual and community control the ownership of land. In situation where a farmer has enough money to purchase, it is always difficult to acquire large expanse of farmland due to the communal and family influence that usually generate into crisis for the buyers. This finding is in tandem with the studies of Aderolu *et al*. (2014) and Mohammed *et al*. (2013) that reported that 90.0% and 87.0% of the coffee farmers in Kogi State acquired their farmland by inheritance while only 10.0% and 8.0% were respectively reported by the authors as those that purchase their farmland. This simply means that land by inheritance is the viable mode of land acquisition for plantation farming like Coffee.

Evidence in Table 2 shows that most of the Coffee farmers used hired labour as slightly above 80% (82.2%) reported the use of hired labour for Coffee production while only 10.6% indicated that they used family labour. Similarly, about 38.8% of the farmers used both family and hired labour. This means that hired labour is the common form of labour used. The use of family labour for farming has been affected by rapid migration of youth out of rural areas to urban areas due to lack of basic amenities that could make them to stay (Ajaero and Onokala, 2013). This has been a major set-back to farming in Nigeria as farming primarily takes place in rural areas due to less pressure on land for building construction and other industrial uses (Yusuf, 2018).

Results in Table 2 show that on average farmers earned about ₦795, 500.14 from the sales of Coffee annually. This means that on a monthly basis, a farmer earns about ₦66, 291.00 as an income from the sales of Coffee. This shows that Coffee farmers in Nigeria earn far more above the monthly minimum income of ₦30, 000.00 per month and ₦360, 000.00 per annum. This implies that Coffee production may be profitable just like every other tree crops in Nigeria. Though, cost of inputs and other factors of production may grossly affect the farmers' income under adequate cost and returns analysis of Coffee production. Even with this, it could be observed from the above analysis that Coffee farming enterprise is profitable. This is in conformity with the finding of Mohammad *et al*. (2013) that stated that the profitability index of Coffee farmer was 0.29; an indication that Coffee farmers earn 0.29 on every naira invested into production and this low level of profit was attributed to the high cost of labour. This is because the study submitted that the cost of labour takes about 95.16% share of the total variable cost. This may be attributed to the scarcity of family labour in rural areas where farming takes place; hence, farmers have no choice than to depend on hired labour.

Findings show that Coffee farmers did not just depend on Coffee production as the only mean of livelihood but engage in other forms of enterprises such as crop and animal rearing, artisanship, trading and civil and public services to complement the income from Coffee. Specifically, the findings show that 85.9% of the farmers engaged in other forms of faring activities, 29.5% engaged in artisanship, 31.3% were found to have indicated their involvement in trading while about 25.6% were involved in public service. The findings show that Coffee farmers have high degree of income diversification. This may be of great benefit as income from other occupation may be useful in keeping the family going before the maturation of Coffee trees. This is based on the assertion of Feintrenie, Ollivier and Enjalric (2010) on the significance of agro-forestry as a strategy to alleviate poverty. This is because tree crops take a longer period to attain gestation and farmers on solely depend on them for survival may suffer before this period. The concept of agro forestry is a strategy to support the establishment and maintenance of tree crops. Also, establishment of tree crops require huge investment and getting income from other sources may be of great help in securing such an investment in tree crop farming.

Evidence further shows that reasonable amount of income is obtained by farmers from other sources. It was revealed that on average, farmers earned approximately about ₦507, 590.44 from other sources. This will serve as a great source of investment for the maintenance of Coffee plant which takes approximately 3 – 4 years for the newly established plantation. Specifically, about 33.5% earned less than ₦500, 000 as their annual income from other income sources apart from Coffee production while only about 5.7% earned ₦900, 000 and above. Just like every other tree crop farming in Nigeria, farmers involve in other economic enterprises that sustain them during the growing period and off season. This may also be the case among Coffee farmers in the study area as this finding found that they involved and earned substantially from other occupation apart from Coffee production.

The finding reveals that contact with extension agents was very poor as just about a quarter (26.9%) of the farmers indicated that they had contact with extension agents. This shows that extension visit to coffee farmers was poor and the implication of this is that coffee farmers may be poorly updated with respect to technologies that would be used for optimal production and information that could enhance the quality of coffee beans, most especially information on the export standard practices that may promote and encourage the production of high quality coffee beans that would be internationally recognized and accepted by the international communities, hence, better earnings. The finding support the study of Aderolu *et al*. (2014) that submitted that only 15.0% of Coffee farmers received information from extension agents in the Kogi State. The significance of extension contact was emphasized by the study of Ntshangase, Muroyiwa and Sibanda (2018) where extension contacts made huge contributions to the adoption of zero tillage among farmers in Zashuke, KwaZulu-Natal Province in South Africa**.**

Access to credit is also another critical factor of production in farming. Based on the findings of this study, it was observed that less than the average (42.3%) of the farmers had access to credit in form of either loan or grants. This shows that farmers may be unable to manage large hectares of farmland if they are to depend on their own finance without assistance from external sources such as the government, NGOs, and other stakeholders in agriculture. Similarly, Ntshangase *et al* (2018) indicated that only about 10% of farmers in South Africa could access credit for farming while Ajah (2017) posited that farmers in Nigeria only access credit within their self-built effort such as cooperative society and other forms of self-help mechanism as government pays less attention toward improving agricultural productivity in terms of credit and grants to farmers.

Results in Table 1 show that very few (5.3%) of the respondents indicated their awareness of Export Standard Practices in Coffee production. The findings show that awareness of ESP among Coffee farmers was low despite the introduction of these practices by CRIN with a view to increasing farmers' profitability in cocoa production in line with the guideline of International Coffee Organization (ICO, 2018) Coffee Exporter's Guide for coffee processing. The implication of this finding is that Coffee farmers may still be using old technique for Coffee production. The low awareness of the export practices in Coffee production and processing may be attributed to the poor extension contact earlier recorded. This may have negative significant implication on the quality of Coffee beans and farmers' profit in the study area.

**Multiple responses given

The extent of Adoption of Export Standard Practices

Results in Table 3 show that only about 8.4% of the respondents were aware of the regular harvesting of ripe berries fortnightly and weekly at peak period as one of the export standard practices that must be adopted to improve the quality of Coffee bean while the remaining 91.6% indicated that they were not aware of this practice. The findings further show that the few farmers that indicated awareness also interested evaluated and tried this practice while only 5.7% were still using it as at the time of this research. However, 2.6% used but later rejected it. This shows that most of the farmers did not deliberately adopted this practice with the continuous usage of only 5.7% based on the findings of this study. The low number that adopted the ESP must have seen the positive implication of carrying out this practice as a way of improving the quality of the produce for international market and they must have made deliberate effort or unconsciously adopting such practice without knowing the implications on the quality of Coffee beans. Meanwhile, only 7.9% of the farmers aware of the sorting out of berries after harvest while majority 92.1% indicated their not aware of this practice as one of the practices to improve the acceptability of the produce as foreign earner. Interestingly, all the 7.9% who indicate their awareness developed interest, evaluated, tried and used but never rejected.

Similarly, all the respondents (100.0%) were aware that fermentation must be covered and protected from rain with continuous usage but none of the respondents indicate their awareness of the turning of beans once daily during fermentation. This shows that fermentation is taken very seriously by the respondents as an important practice in improving the quality of the Coffee beans but they failed to recognize the importance of turning daily for even dryness and quality of the Coffee beans. This may be responsible for the poor Coffee beans quality usually recorded in Nigeria by the international markets (Aderolu *et al.*, 2014). The level of adoption is recorded to be low as a result of the low knowledge they have about the significance of fermentation to the quality of agricultural produce. This is in line with the assertion of Nutley *et al.* (2002) that identified knowledge as the first and critical stage in the innovation decision making process. In addition, 87.7% never aware of drying of beans on a raised slab but only 12.3% continued the usage of this practice. The significance of this practice may need to be re-integrated into agricultural extension programme for better adoption as this seems to encourage fast and better drying of Coffee bean for quality assurance purpose. The poor adoption and continuous usage is an indication that respondents had poor knowledge of the importance of this practice as part of the export standard practices that could enhance the quality of Coffee beans.

Furthermore, thickness of the drying materials that must be between 3 and 5 cm was not aware by all the respondents (100.0) and none of them was found to be using it as at the time of data collection for this study. This shows that respondents never consider this practice as a measure to improve on the quality of Coffee beans. On the storage in a well-ventilated house, respondents never aware of this practice while the practice of avoiding strong odour like smoke where Coffee beans are being stored recorded 6.6% awareness and continuous usage. This shows that Coffee farmers had poor adoption level on the various practices on the export standard practices that would promote the recognition and acceptability of high quality Coffee beans in the study area.

Table 3: The extent of Adoption of Export Standard Practices

	NA	A	I	E	T	UR	SU
ESP Practices	**F(%)**	**F(%)**	**F(%)**	**F(%)**	**F(%)**	**F(%)**	**F(%)**

Effect of adoption of ESP on farmers' productivity

Results in Table 4 show that adoption of ESP has effects on Coffee farmers' productivityscale-type. Specifically, it was observed that selection of fertile soil (Mean = 3.91), planting of viable seeds (Mean = 3.53), adequate maintenance of farms (Mean = 4.15), adequate training (Mean = 3.61), good processing techniques after harvest (Mean = 4.27), adoption of ESP (Mean = 4.11), planting of improved varieties (Mean = 3.55), up-date on new technologies (Mean = 3.57) and length of adoption (Mean = 3.12) were the variables that had high effects on farmers' productivity in Coffee production.

The findings imply that many of the variables had significant effects on the Coffee farmers' productivity. However, awareness of export standard practices (Mean = 2.59) did not contribute to farmers' productivity. This means that awareness may not lead to adoption and utilization but it is just the first stage in the adoption process but if awareness is well managed, it can determine adoption provided inputs, information and monitoring are incorporated at this awareness stage based on the findings of Mignouna*et al*. (2011), Lavison (2013) and Rogers (2003) that regarded awareness as a critical stage in the adoption process.

Table 4: Effect of the adoption of ESP on farmers' productivity

	Mean	**Std. Dev**
Selection of good fertile soil for coffee production enhances good productivity	3.91*	0.11
Planting of viable seeds/seedling boost coffee productivity	3.53*	0.52
The bigger the size of coffee farm land the more the productivity	1.43	0.17
Adequate maintenance of coffee farm land determine the productivity	4.15*	0.21
Awareness of ESP increases the productivity	2.59	0.42
Adequate training on ESP on post harvesting handling discourage loss of coffee productivity	3.61*	0.61
Good processing of coffee after harvesting increases acceptable productivity internationally	4.27*	0.13
Adoption of ESP increases productivity	2.65	0.28
Adoption of ESP enhances the price of coffee	4.11*	0.09
Planting of improve varieties always improve productivity	3.55*	0.19
Productivity will increase while planting old varieties	2.21	0.25
Updates on new technology, innovation and adoption often enhance productivity on ESP	3.57*	0.12
Length of adoption (in years) usually enhance increase in productivity	3.12*	0.32
Adoption of ESP increases connection and relationship with other coffee farmer across the world which facilitates to higher productivity	2.55	0.27

Source: Field Survey, 2021
*Mean > 3.0 = High effect

CONCLUSION AND RECOMMENDATION

The study concludes that farmers are still in their economically productive age and can therefore withstand the rigour associated with coffee farming. It was also discovered that the extent of adoption on each practices is low while some were higher this indicate that respondents need serious enlightenment on ESP. The adoption of ESP has effects on Coffee farmers' productivity with the numerous variables that had their means greater than 3.0 benchmark for a 5 - point likert scale-type. Specifically, it was observed that selection of fertile soil, planting of viable seeds, adequate maintenance of farms, adequate training on good processing techniques after harvest (Post-harvest training), planting of improved varieties, adoption of ESP, up-date on new technologies and length of adoption were the variables that had high effects on farmers' productivity in Coffee production. If the farmers' adhere to ESP practices strictly, it will have positive effect on their production, quality and quantity of the produce, marketing and price of the produce, livelihood, revenue to the government and more people will develop interest on coffee production. Therefore, the youths should be encouraged and motivated by providing financial assistance to coffee farmers because those that were producing coffee now were aged farmers. Efforts should be geared by government and relevant agencies towards encouraging coffee farmers to practice export standard practices because it produces good quality green coffee which attracts high premium in the international market.

ABSTRACT
Sustainable horticultural production requires measures for improving the soil and conserving water. Soil and water conservation are crucial to lowering production expenses and has a positive influence on the environment. Sustainable agriculture and the preservation of the natural ecosystem depend on the integrated management of soil and water resources. The necessity of the hour is to safeguard soil and water from deterioration through efficient management. Some of the commonly employed methods towards the conservation of soil and water include mulching, zero or minimal tillage, composting, mulching, cover cropping, crop rotation, contour farming, afforestation and grassing among others. This article reviews the extent to which the aforementioned conservation practices are used in Nigeria. It aims to raise knowledge of the different institutional and procedural frameworks, both governmental and non-governmental, that have been built in Nigeria to carry out effective soil and water conservation projects.
Keywords: *Horticulture, Soil Conservation, Water Management*

INTRODUCTION

Soil generally needs to be protected since it provides the physical environment in which plants develop. These soils are necessary for agriculture and other primary production activities. It is composed of both organic and mineral components. While it takes nature hundreds or even thousands of years to develop a 2.5 cm layer of soil, tons of earth can be swept away during a strong rain event. Soil resources are now a key concern in the country's effort to conserve its natural resources (Abbas *et al*., 2013). For effective and profitable crop production, it is crucial to provide soil conditions that can retain enough soil nutrients and moisture for sustained seed development and growth. Sustainable horticulture production requires measures for improving the soil and conserving water. Organic matter is abundant in healthy soil, which serves to increase water infiltration and retention, lessen erosion, and supply nutrients to plants. Water conservation is crucial since it lowers expenses and has a positive influence on the environment. (FAO, 2019)

However, soil is also a fragile resource that can be easily eroded by wind and water (Lal, R. 2015). This is especially true in agricultural areas, where the soil is often disturbed by ploughing and other farming practices. Numerous issues might result from soil being eroded, including: Increased risk of flooding reduced crop yields, siltation of waterways, loss of biodiversity, increased water pollution. The Nigerian government persisted in promoting soil protection measures after independence. Government officials created the National Soil Conservation Program (NSCP) in 1972. The NSCP was created to assist farmers in putting soil conservation techniques into place and enhancing soil fertility. The Nigerian government has also started a number of additional programs recently to encourage soil conservation, such as:

- The Great Green Wall Project: The Great Green Wall Project is a massive tree-planting project that aims to plant 25 million trees by 2030. The project is designed to help reduce soil erosion, improve soil fertility, and combat climate change.
- The National Agricultural Land Development Authority (NALDA): NALDA is a government agency that works with farmers to implement soil conservation practices and improve agricultural productivity.

- The Federal Ministry of Agriculture and Rural Development: The Federal Ministry of Agriculture and Rural Development provides a variety of resources and support to farmers to help them implement soil conservation practices. (FAO, 2019)

The study was aimed at reviewing the progress that researchers have made in the area of soil improvement and water conservation strategies in horticultural production system in Nigeria. For this study, related literature was downloaded in January 2022 (only studies published within a space of one decade, i.e., 2013–2023, were downloaded) from search engines such as Google Scholar, Scopus, and Researchgate.

Soil improvement and water conservation strategies

The history of soil conservation practices in Nigeria can be traced back to the pre-colonial era. Indigenous farmers used a variety of techniques to protect their soil from erosion, below are some but not limited to the techniques in soil and water preservation in Nigeria

Composting: Breaking down organic debris to produce a nutrient-rich soil amendment is known as composting. Compost can be put to the soil to enhance the soil's structure, increase its ability to retain water, and supply nutrients. In addition, compost can aid in the control of diseases and weeds.

Mulching: This is the process of adding an organic layer of material to the soil, such as compost, straw, or wood chips. Mulch aids in stopping soil erosion, holding onto moisture, and controlling weeds. Mulch can aid by enhancing soil structure by incorporating organic matter.

Minimal or zero tillage: Reduced soil disturbance is achieved through minimal tillage, a type of tillage. This lessens soil erosion and helps to improve soil structure. Reduced runoff and improved water infiltration can both be achieved with minimal tillage.

Cover cropping: In Nigeria, where soil erosion is a significant issue, cover cropping is a particularly crucial method of soil conservation. Numerous issues, such as decreased agriculture yields, increased water pollution, and biodiversity loss, can be brought about by soil erosion. In many ways, cover crops can aid in preventing soil erosion. In the beginning, cover crops aid in reducing runoff. Second, cover crops aid in shielding the soil from the damaging effects of rain. Also, cover crops contribute to the soil's organic matter content, which strengthens the soil's structure and reduces the likelihood of erosion. A simple and reasonably priced method of conserving soil is to plant cover crops. On a variety of soils and in a range of climates, cover crops can be produced. Additionally, a number of crops may be cultivated with cover crops. Some examples of cover crops that can be grown in Nigeria are: Beans, cowpea, Mucuna, pigeon pea, Sesbania, e.t.c

Crop rotation: Growing several crops in the same field over time is known as crop rotation, which helps save soil. Crop rotation can assist to control pests and diseases, improve soil fertility, and prevent soil erosion. In Nigeria, where soil erosion is a significant issue, crop rotation is a particularly significant soil conservation method. Numerous issues, such as decreased agriculture yields, increased water pollution, and biodiversity loss, can be brought about by soil erosion. Crop rotation can aid in preventing soil erosion in a number of different ways. First, crop rotation shortens the period of time the land is bare. Second, crop rotation aids in enhancing soil structure, making the ground less prone to erosion. Thirdly, crop rotation aids in the management of weeds, which can rob crops of water and nutrients and worsen soil erosion. Crop rotation can help to increase soil fertility in addition to preventing soil erosion. Crop rotation aids in increasing the amount of organic matter in the soil, which enhances soil structure, boosts water retention, and provides nutrients. Crop rotation can also aid in the management of diseases and pests. Different crops require various nutrients and are vulnerable to various pests and illnesses. Farmers can lessen the risk of pests and diseases as well as the loss of soil nutrients by rotating their crops. A simple and reasonably priced method of conserving soil is crop rotation.

Examples of possible crop rotation patterns for Nigeria include: Maize - cowpea – cowpea, Maize - bean – bean, Maize - cassava – cassava, Yam - cowpea - cowpea

Contour farming: Crops are planted along the contours of the land as part of the practice of contour farming, which conserves soil. Runoff is slowed, and erosion is decreased as a result. In Nigeria, where soil erosion is a significant issue, contour farming is a particularly significant method of soil conservation.

Numerous issues, such as decreased agriculture yields, increased water pollution, and biodiversity loss, can be brought about by soil erosion. Numerous contour farming techniques can aid in preventing soil erosion. In the beginning, contour farming slows runoff. Contoured farming also aids in retaining water and sediment on the ground.

Afforestation: Planting plants and creating forests in previously arid places is known as afforestation. In Nigeria, where soil erosion is a significant issue, it is a crucial method of soil conservation. Numerous issues, such as decreased agriculture yields, increased water pollution, and biodiversity loss, can be brought about by soil erosion.

In many ways, reforestation can aid in preventing soil being eroded. First, trees help in reducing runoffs. Furthermore, trees aid in capturing sediment on the ground. Also, trees contribute to the development of organic matter in the soil, which strengthens the soil's structure and reduces the likelihood of erosion.

Afforestation can also be practiced in conjunction with a variety of other soil conservation practices, such as cover cropping and conservation tillage.

Examples of afforestation practices that can be used in Nigeria include:

- Planting trees in areas that have been cleared for agriculture or other development.
- Planting trees in areas that have been degraded by erosion or other factors.
- Planting trees in areas that are at risk of flooding or landslides.

Grassing: often referred to as vegetative cover, is the process of putting down and keeping up a layer of grass or other vegetation on top of the soil. In Nigeria, where soil erosion is a significant issue, this method of soil conservation is crucial. Numerous issues, such as decreased agriculture yields, increased water pollution, and biodiversity loss, can be brought about by soil erosion. Grassing has several advantages for preventing soil erosion. First, vegetation such as grass and trees slows runoff. Second, vegetation such as grass and trees aids in the sedimentation of the land. Third, grass and other vegetation help to increase the organic content in the soil, which strengthens the soil's structure and reduces the likelihood of erosion. The Government encouraged farmers to plant grass on their land to help reduce soil erosion and improve soil fertility.

Examples of grassing practices that can be used in Nigeria include:

- Planting grass on bare land.
- Overseeding existing grasslands.
- Interseeding grass into crops.
- Establishing grass strips along waterways.
- Planting grass on terraces and bunds.

Also, some practices for water conservation in horticultural production systems:

- **Drip irrigation**: Drip irrigation is a method of irrigation that delivers water directly to the roots of plants. This helps to reduce water evaporation and runoff.
- **Rainwater harvesting**: Rainwater harvesting is the collection and storage of rainwater for later use. Rainwater can be used to irrigate crops, water livestock, and for other purposes.
- **Water mulching**: Water mulching is the practice of covering the soil with a layer of water. This helps to reduce water evaporation and suppress weeds. Water mulching can also help to improve soil structure by increasing water infiltration.
- **Drought-tolerant crops**: Drought-tolerant crops are crops that can withstand periods of drought. Growing drought-tolerant crops can help to reduce water use in horticultural production systems.

Some benefits of practices used in soil improvement and water conservation in horticultural production systems: Improved soil health, reduced soil erosion, increased water holding capacity, Improved soil structure, reduced water use, reduced runoff, Suppressed weeds and diseases, increased crop yields

CONCLUSION

Sustainable horticulture production strategies depend on improving the soil and preserving water. Cover crops, crop rotation, composting, mulching, minimal tillage, drip irrigation, rainwater harvesting, water mulching, and drought-tolerant plants are just a few methods that can be utilized to promote soil health and preserve water. The particular horticultural production system, the environment, and the available resources will all influence the choice of soil improvement and water conservation measures. However, many of the techniques covered in this essay can be applied to horticultural production systems to enhance soil health and save water. Improved soil structure, enhanced water holding capacity, less soil erosion, decreased water consumption, decreased runoff, suppressed weeds and diseases, and higher crop yields are all advantages of utilizing soil improvement and water conservation measures in horticultural production systems.

Overall, sustainable horticulture production strategies depend on improving the soil and conserving water. A more sustainable and fruitful horticultural sector may result from the application of soil enhancement and water conservation techniques. In order to equip farmers with the skills and technical know-how, they need to conserve their soil and water resources, stakeholders in soil and water conservation should participate in rigorous planning for the utilization and management of soil and water resources. Regular research, education and extension (training) of soil and water conservation technologies for stakeholder should be prioritized. Soil and water conservation practices should be site-specific considering the variations in soil types, crops and climatic conditions across the various ecological zones in the country.

ABSTRACT
The result of this study concludes that there are strong and varying differences in their mineral content. Phosphorous and potassium were the highest minerals present. There were no significant differences in their presence when tested across different substrates. Phytochemical compositions were relatively low. Saponin content was the highest (1.11±0.02 for Palm bunch and 0.18±0.01 for Saw dust). Interestingly, antioxidant activities of Pleurotus pulmonarius exhibited high DPPH free-radical-scavenging ability and TEAC. Pleurotus pulmonarius grown on Saw dust exhibited higher DPPH free radical scavenging ability while Pleurotus pulmonarius grown on Palm bunch exhibited higher ABTS scavenging ability and reducing power in Saw dust. This proved that Pleurotus pulmonarius could be more effective in managing oxidative stress condition and its various complications.*

INTRODUCTION
Oyster mushroom belong to the class Basidiomycetes and family Pleutaceae and this specie of mushroom is known to grow naturally in temperate and tropic regions (Sánchez, 2010). Apart from mushrooms being known to grow abundantly in the wild, they are capable of converting agro-waste into protein rich palatable food through enzymatic reactions (Waquas *et al*., 2011). The cultivation of Oyster mushroom is not only commercially purposed but also as a therapeutic agent (Waquas *et al*., 2011). Mushroom are repositories for important phytochemicals such as phenol, saponin, alkaloid and flavonoid. Not only that these mushrooms have bioactive components, they have also shown important antioxidant activities (Ivanova *et al*., 2014). In vivo and in vitro studies on edible mushroom have shown antioxidant, antitumor, antihypertensive and antiaging potentials (Iwalokun *et al*., 2007). These bioactive compounds in mushroom mediate biological activities including the stimulation of interleukin-12, nitric oxide synthase activation, free radical scavenging and iron chelating properties (Kinge *et al.*, 2016). This research aim to determine the phytochemical, antioxidant and mineral contents of Pleurotus pulmonarius grown on palm bunches and sawdust subtrates.

MATERIALS AND METHODS
Study area and sample collection
The various samples used for this research were collected from Okigwe town in Imo State, Nigeria. The samples collected include; Saw dust, Palm bunch and spawn for inoculation. Sawdust of Gmelina aboreawas collected from the timber shops at Okigwe town in Okigwe L.G.A, Imo State, Nigeria. The Palm bunches was sourced at Umuowa-Ibu village and National Horticultural Research Institute (NIHORT), Mbato premises, both located in Okigwe L.G.A, Imo State. The spawn of Pleurotus pulmonarius was obtained from the mushroom unit, NIHORT, Ibadan.
Composting
The method of Adebola *et al*., (2016) was used with slight modifications. Saw dust was moistened sufficiently. One kilogram each of the substrate was weighed and packed tightly in polythene bags. The neck of the bag was made with heat resistant PVC tubes and covered with a cotton plug. The bags

containing each substrate was then sterilized by tyndalization and then allowed to cool to room temperature.

Spawn inoculation and incubation

After cooling, 10% w/w ratio of the spawn to the substrate was introduced into the bags through the neck aseptically and incubated for 28 days. Thereafter the bags were transferred into a dark room. After primordial initiation, the substrates were then transferred to a cropping house (Kinge *et al*., 2016; Adebola *et al*., 2016).

Preparation of sample for phytochemical analysis

The mushroom will be air dried, grinded into powder using a blender with stainless steel, blade and body and processed for phytochemical analysis (Adebola *et al*., 2016). The phytochemical and antioxidant activity of Pleurotus pulmonarius in this study was conducted at IITA, Ibadan, Nigeria following standard laboratory procedure.

RESULTS

The bioactive components of mushroom such as its antioxidant and phytochemical composition are mainly contributed by the active compounds present in them (Iwalokun *et al*., 2007). These important phyto-components may contribute to improving the quality of life by inhibiting the onset of degenerative diseases which are usually associated with ageing (Ibe *et al*., 2014). There were significant differences in Palm bunch than sawdust substrate. Though this work aims at determining the effect of two substrates (Palm bunch and Saw dust) on the mineral contents, and bioactive component of *P. pulmonarius*. The result indicated that, there are no significant differences ($p \leq 0.05$) in their phosphorous, calcium, magnesium and potassium content, overall, saw dust possessed the highest mineral content (Table 1). Phytochemical analysis of *P. pulmonarius* was shown in Table 2. There are significant differences ($p \leq 0.05$) in the phenolic, tannin, saponin, flavonoid and alkaloid content. Table 3 shows the antioxidant activity of. pulmonarius. Free-radical-scavenging ability of the extract against 1, 1-diphenyl-2-picrylhydrazyl (DPPH) was relatively higher in Saw dust compared to palm bunch substrate. ABTS scavenging ability and the reducing power of the extracts were higher in Palm bunch than in Saw dust.

DISCUSSION

The mineral content of P. pulmonarius includes phosphorous, calcium, magnesium, sodium, potassium, manganese, iron, copper and zinc. Potassium content (3.93%) is higher in percentage compared to other minerals for P. pulmonarius grown on palm bunch and 3.9% for Pleurotus pulmonarius grown on Saw dust substrate. Calcium content was relatively low in mushroom harvested from both substrates (about 0.18%) and there was no significant difference. Phytochemical content was relatively low in P. pulmonarius. The total saponin, alkaloid and other phytochemicals were significantly different. The review of the biological activities of saponins showed that they exhibit antioxidant activities. Saponins have haemolytic and hypolipidaemic activities as well as the ability to lower cancer risks and inhibit microscopic life forms. Pure alkaloids were also present, though no report of the antioxidant activity as yet and their derivatives have basic medicinal value due to the analgesic, antispasmodic and antibacterial properties they posses.

DPPH radicals have been extensively used by many workers to investigate the scavenging activity of some natural components. This is due to its high sensitivity. This was employed to investigate the free-radical-scavenging ability of the mushroom. As antioxidants donate protons to this radical, the absorption decreases. The extent of the decrease in absorption is taken as a measure of the extent of radical scavenging (Ibe et al., 2014). The SC50 value for P. pulmonarius grown on saw dust substrate caused the inhibition of DPPH absorbance (73.57 ± 0.27) presented in Table 3. Since SC50 is a measure of inhibitory concentration, a lower SC50 is a reflection of greater antioxidant activity of the sample. Pleurotus pulmonarius grown on saw dust has the highest inhibition potential (73.57) for saw dust compared to 28.22 recorded for alm bunch). The amazing high antioxidant activity of P.s pulmonarius grown on saw dust could still be attributed to the crude composition of the substrate.

ABTS* scavenging ability which was reported as the trilox equivalent antioxidant activity (TEAC). The results showed that there was significant difference ($p \leq 0.05$) in the order of palm bunch (38.45) > saw dust (14.71) respectively. Interestingly, DPPH was significantly higher in P. pulmonarius grown on aw dust. This shows that substrate plays a major role in the composition of mushroom. It could therefore be inferred that P. pulmonarius grown on palm bunch exhibited a better ABTS* scavenging ability. The reason for varying antioxidant activity of P. pulmonarius grown on different substrates may be due to difference in methods even though P. pulmonarius grown on both substrates exhibited antioxidant capabilities.

ABTS assay is based on the inhibition of the absorbance of the radical cation. ABTS* which has a characteristic long wavelength adsorption spectrum. ABTS* radicals are more reactive than DPPH radicals and unlike the reactions with DPPH radical which involves H atom transfer; the reactions with ABTS* radicals involve electron transfer process (Boutaoui et al, 2018). The extensive use of DPPH for screening antioxidant activity assay may have been because it can accommodate many samples in a short period and it is sensitive enough to detect active ingredients at low concentration (Ezeonu and Ejikeme, 2016).

CONCLUSION

The result conducted proved that Pleurotus pulmonarius could be more effective in managing oxidative stress condition and its various complications. Pleurotus pulmonarius could therefore be recommended as important food due to its high its medicinal value.

ABSTRACT
Field trials were conducted in 2020 and 2021 at the Teaching and Research Farm of the Federal University of Agriculture Abeokuta, Ogun State, Nigeria to evaluate the effect of biochar application under different weeding regimes on growth and yield of okra. Treatments were laid out in split- plot in a randomized complete block design with three replications. Main plot treatments were three levels of biochar while sub-plots treatments consisted of four weeding regimes. Results showed that biochar applied at 20 t/ha increased okra yield by 47.5% compared to the control. Weeding at 3, 6 and 9 WAS gave the highest okra yield. Uncontrolled weed infestation throughout crop growth resulted in 87.3% yield reduction in okra. It is concluded that weed suppression, growth and yield of okra can be enhanced by the application of biochar at 20t/ha and weeding at 3, 6 and 9 WAS hence recommended.
Keywords: *Biochar; Okra; weeding; weed competition*

INTRODUCTION

Okra (*Abelmoschus esculentus* L.) is one of the most widely known and utilized species of the family Malvaceae (Naveed *et al.,* 2009) and an economically important vegetable crop grown in tropical and sub-tropical parts of the world (Oyelade *et al.,* 2003; Andras *et al*., 2005). Okra is known by many local names in different parts of the world. It is called lady's finger in England, gumbo in the United States of America, guino-gombo in Spanish, guibeiro in Portuguese and bhindiin India (Ndunguru and Rajabu 2004). Okra is a multipurpose crop due to its various uses of the fresh leaves, buds, flowers, pods, stems and seeds (Mihretu *et al*., 2014). Crop growth and yield are generally reduced by poor fertility. Glaser *et al.* (2002) reported that to overcome the problems of poor soil fertility and low crop yield, it is important to adapt to new technologies such as using biochar as a soil amendment. Biochar is defined as charcoal obtained when organic materials (biomass and manures) are burned under low pressure and high temperature condition through prolysis process (under low or absence of oxygen) (Lehmann, 2007; Laird, 2008). Biochar improves soil fertility, crop yield and also sustains the environment for future use while mitigating climate change.

Weed infestation is a major problem in the production of okra (Rao, 1983). Uncontrolled weed growth throughout the life of okra could reduce pod yield by 39 to 84% (Adeyemi *et al*., 2015a). The extent of weed competition depends on the type of weed species, the severity of weed infestation, the duration of infestation and climatic conditions (Rao, 1983). One of the major factors that enhance weed infestation is the inability of the okra plants to compete with weeds at the early stage of growth due to poor canopy formation. Addition of soil amendements (biochar) has the benefits of harnessing the soil nutrient resources to boost crop growth and thus enhance the competitive bility of the crop against weeds. However, there are scanty research information on the integration of biochar with timely weed removal in okra.The study was therefore conducted to determine the effect of application of biochar under different weeding regimes on growth and yield of okra

MATERIALS AND METHODS

Description of experimental site

The field trials were conducted in 2020 (September to December) and 2021 (June to October) on the Teaching and Research Farm Directorate of the Federal University of Agriculture, Abeokuta, Nigeria in the forest savannah transition agroecological zone (7^0, 20'N, 3^0, 23'E). The details of physico-chemical properties of the soil before the commencement of the trials are contained in Table 1. The result of the analysis showed that the soil was sandy loam in texture in both years with soil pH of 6.54 and 6.71 in 2020 and 2021, respectively (Table 1).

Table 1: Soil physico-chemical properties of the experimental sites

Soil Composition	2020	2021
pH	6.54	6.71
Particle size analysis		
Sand (g/kg)	768.1	756.5
Silt (g/kg)	190.4	167.2
Clay (g/kg)	41.5	76.3
Textural class	sandy-loam	sandy-loam
Chemical composition		
Organic carbon (%)	1.74	2.21
Available P (mg/kg)	3.26	3.01
Total N (%)	0.12	0.2

Treatments and experimental design

The trial in both years were laid out in split-plot in a randomized complete block design in three replicates. In both years, the main plot treatments were three rates of biochar application at 0 t/ha, 10 t/ha and 20 t/ha. Four weeding regimes assigned to the subplots were; weeding at 3, 6 and 9 WAS, weeding at 3 and 6 WAS, weeding at 3 WAS and weedy check as control.

Cultural practices

The experimental site in each cropping season was ploughed and harrowed at two-week interval to destroy established vegetation, destroy weed seedlings and produced a level, smooth and weed-free fields. Before planting, application of 0 t/ha, 10 t/ha 20 t/ha of biochar (made from bamboo) were applied into appropriate plots, according to the treatments and incorporated into the soil. Okra seeds were sown at 0.6 m by 0.3 m at two seeds per hole and later thinned to one plant per stand at 2 weeks after sowing to give a total plant population of 55,555 plants/ha. Hoe weeding was carried out using West African hand hoe.

Data Collection

Weed cover score was done using a visual rating scale of 10 – 100; total weed dry matter production and weed count was also done.

Data analysis

Data on number of pods, pod yield, seed weight, weed cover score, weed density and weed dry matter production for the two years were pooled and analyzed using the GENSTAT procedures. Least significant difference (LSD) was used to separate significant means at a 5% level of probability.

RESULTS AND DISCUSION

Weed Parameters

Application of biochar generally caused reduction in weed cover score, weed density and cumulative weed dry matter. The lowest values of weed cover (29.3) and cumulative weed dry matter (3027 kg/ha) were recorded from the plots treated with application of biochar at 20 t/ha (Table 3). The reduction in weed growth parameters as a result of the application of high rates of biochar could be attributed to the fertilizing effect of biochar on okra which was able to boost its growth give it higher competitive advantage over the weeds. In addition Okra being a C4 plant having efficient photosynthesis (Mucube and Banda, 2017) could have developed enough canopy to suppress the growth of the weeds and reduce the weed ground coverage and biomass. This result is similar to those of Osunleti et al., 2021c who reported reduction in total weed count with application of organo mineral fertilizer.

Weeding twice at 3 and 6 and thrice at 3, 6 and 9 WAS resulted in lower weed cover score than weeding once at 3 WAS and no weeding (Table 3). No weeding and weeding thrice at 3, 6 and 9 WAS resulted in the highest and lowest weed count (5,793,200/ha and 379,600/ha) and cumuative weed dry matter (7487kg and 369 kg/ha), respectively (Table 3). The lowest weed cover score, weed density and dry matter production on the plots weeded at 3, 6 and 9 WAS could be as a results of regular weed removal which did not give room for weed accumulation as seen on plots left weed infested throughout and those weeded for only 3 weeks. This results coroborates earlier findings of Adeyemi *et al.,* 2015b who reported lower total weed weight when okra was weeded three times. Osunleti *et al*., 2021b also reported lower total weed biomass with timely weed removal

Table 3: Effects of biochar rates and weeding regime on weed cover score, weed count and weed dry matter

Treatments	Weed Cover Score at 9 WAS	Weed Count (x 000/ha) at 12 WAS	Cumulative Weed Dry matter (kg/ha)
Biochar Rates (B)			
0 t/ha	34.7	2703.7	4141
10 t/ha	31.2	1958.3	3339
20 t/ha	29.3	1979.1	3027

p value	<.001	<.001	<.001
Interaction			
B × W	5.189	361.406	346.5

Yield and yield components

Okra yield and yield components increased with increasing in biochar rates. The highest number of pods, fresh pod yield and seed weight were recorded on plots treated with biochar at the rate of 20 t/ha (460,000 pods/ha, 3562 kg/ha and 564 kg/ha) respectively while the lowest was obtained from the control plots (250,000 pods/ha, 1870 kg/ha and 239 kg/ha) (Table 2). Weeding thrice at 3, 6 and 9 WAS resulted in the highest number of okra pods (530,000 pods/ha), okra yield (4,484 kg/ha) and okra seed weight (680 kg/ha) (Table 6). Also, weeding twice at 3 and 6 WAS resulted in higher yield and yield components than weeding once at 3 WAS and no weeding (Table 2).

The result from this study demonstrated the importance of biochar application for soil ammendments in okra production, as it showed a great influence on okra yield. Application of at least 10 t/ha of biochar resulted in 37.5% increment in okra yield compared to the control, with a further increase of 10.5% when 20 t/ha of biochar was applied. This shows that okra responded well to application biochar as it increased the yield of okra. Adamu and Junaidu (2021) had earlier reported that biochar addition to the soil increased the soil N, P, K, Ca, Mg and soil pH. It also played a major role in lowering exchange capacity (E.C) which enhances soil nutrient availability as well as serving as a liming agent by increasing the pH from 6.26 to 6.72 which is ideal for okra production. Regular weed removal on the plots at 3, 6 and 9 WAS reduced weed-crop competition to the bearest minimum and allowed the crop to make good use of both the soil and envoronmental resources thereby resulting in the maximum yield. Subsequent weed infestation beyond the first three weeks caused marked reduction in okra yield resulting in 87.3% pod yield reduction. Weeding beyond the first 3 weeks is therefore a necessity for optimum yield in okra production. This result agrees with earlier report of Oyewole and Obaweda (2020), who reported increase in okra yield with increase in weeding frequency.

Table 2: Effects of biochar rates and weeding regime on yield and yield components of okra

Treatment	Number of Pod (no./ha)	Fresh Pod yield (kg/ha)	Seed Weight (kg/ha)
Biochar Rates (B)			
0 t/ha	250000	1869	239
10 t/ha	380000	2993	456
20 t/ha	460000	3562	563
LSD (0.05)	104942.6	552.7	85.1
p value	0.005	<.001	<.001
Weeding Regime (W)			
No weeding	100000	571	77
Weeding at 3 WAS	350000	2420	341
Weeding at 3 and 6 WAS	470000	3758	581
Weeding at 3, 6 and 9 WAS	530000	4484	680
LSD (0.05)	70644.7	430.0	73.1
p value	<.001	<.001	<.001
Interaction			
B × W	141314.1	807.6	132.4

CONCLUSION

This study showed that okra yield can be increased by 45.5% by the application of 20 t/ha of biochar compared to the control. Weeding at 3, 6 and 9 WAS gave the highest okra yield. Uncontrolled weed infestation throughout crop growth resulted in 87.3% yield reduction in okra. It can therefore be concluded that weed suppression, growth and yield of okra can be enhanced by the application of biochar and timely weed removal.

ABSTRACT
Many food spice crops are being endangered into extinction in Nigeria because of climate change as well as deforestation occasioned by population pressure and urbanization. This review was aimed at identifying the nutritional, health benefits and agronomic research gaps of these endangered aromatic food spice crops. Nine endangered food spice crops identified are: Guinea pepper (Piper guineensis), Utazi (Gongronema latifolium), Hoary or Thai lemon basil (Ocimum africanum), Mint basil (Ocimum gratissimum), whole country onions (Afrostyrax lepidophyllus), Jansa (Cussonia bateri), Negro pepper (Xylopia aethiopica), Ataiko or Orima (Afromomium danielli), Aidan (Tetrapleura tetraptera). This review discovered that these species are capable of improving the nutrition and health of the rural dwellers but yet, are minimally cultivated. The paper therefore recommends that agronomic packages be evolved in order to initiate and increase the cultivation and productivity of the selected endangered food spice crops.
***Keywords**: Review, Endangered, food spice crops, South Eastern Nigeria.*

INTRODUCTION

Endangered food spices are food flavouring crop species that are likely to go into extinction in the near future (https://en.wikipedia.org>wiki.endanderedspecies and https://www.fs.fed.usd/wildflowers>ethnobotany>food). Many food spice crops are being endangered into extinction in Nigeria. Some of the causes of biodiversity loss or extinction of species are human activities such as deforestation, damages to the habitats of many crop species occasioned by population increase, infrastructure development, urbanization, road construction, harvesting of wood from tree species, extraction of mature trees from timber species and bush fire (Barau *et al*., 2015; Oyetunji, Ibitoye, Akinyemi, Fadele and Oyediji, 2020). Forest degradation and habitat destruction are the major causes of global biodiversity loss. Plant species destruction are on the increase. All these exert pressure on the population of the wild species of crops such that the resultant effect is the extinction of useful plants. Yet, these crops have suffered neglect in terms of research and agronomic attention. The environment of the whole world is changing due to endless production of greenhouse gases. As the environment changes, some organisms like plant species can no longer thrive, thus causing crop losses worldwide, and reducing yields of crops by more than 50% (Chikezie *et al.*, 2015).

Presently, these food spice crops are made available in the markets in South eastern Nigeria through collections from the forests. If conscious efforts are not made to initiate the cultivation of these crops and to improve the productivity of these crops through increased research attention into their environmental and agronomic requirements, with time, losses of species from the wild will begin to occur. Efforts should be made therefore to preserve these crops bearing in mind their usefulness. Paucity of relevant literature materials necessitates that these useful plants harvested from the wild be given adequate research attention in order to evolve agronomic and cultural packages that can be utilized to sustain their productivity. It is against this background that this paper is written.

The objective of this paper was to:

1. Describe the selected endangered food spice crops widely consumed in Southeastern Nigeria

2. Identify the current status of the cultivation of the selected endangered food spice crops in Southeastern Nigeria
3. Identify the nutritional and health benefits of these selected endangered food spice crops in South eastern Nigeria. Make recommendations based on findings

Identification of selected endangered aromatic food crop spices in South Eastern Nigeria

In Nigeria, many plants used as spices have a lot of medicinal values (Edeoga *et al*., 2005). Medicinal plants, according to WHO, are plants that have substances that are capable of being used for treating ailments or plants that have parts are used for the production of drugs. Certain spice crops have been selected in this review that are crops that are commonly utilized in various ways in a variety of dishes and as medicinal plants in South eastern Nigeria.

Nine food spice crop species identified to be facing the danger of extinction in South eastern Nigeria include: Guinea pepper (*Piper guineensis*), Utazi (*Gongronema latifolium), Hoary or Thai lemon basil (Ocimum africanum)*, Mint basil (*Ocimum gratissimum*), Whole country onions (*Afrostyrax lepidophyllus*), Jansa (*Cussonia bateri*), Negro pepper (*Xylopia aethiopica*), Ataiko or Orima (*Afromomium danielli*), Aidan (*Tetrapleura tetraptera*) .

The following endangered food crop spices that are commonly consumed in South eastern Nigeria have been identified (Table 1). Many of these species (Guinea pepper/Ashanti pepper (uziza), Utazi, Thai lemon basil and Mint basil are commonly grown in home gardens but their agronomic requirements are yet to be investigated. The other species included in this review are: whole country onions, Jansa, negro pepper, ataiko and aidan are supplied from collections made from the forest.

Table 1: Identification of selected endangered aromatic food spice crops

S/N	Common name	Botanical Name / Family	Parts being utilized	Local name in South Eastern Nigeria
1	Guinea pepper	*Piper guineense* / Piperaceae	Leaves and fruits	Uziza
2	Utazi	*Gongronema latifolium* / Asclepiadaceae	Leaves	Utazi
3	Thai Lemon basil	*Ocimum africanum* / Lamiaceae	Leaves	Curry
4	Mint basil	*Ocimum gratissimum* / Lamiaceae	Leaves	Nchuanwu
5	Whole country onions	*Afrostyrax lepidophyllus* / Huaceae	Fruits	Control onions
6	Jansa	*Cussonia barteri* / Araliaceae	Fruits	Jansa
7	Negro pepper	*Xylopia aethiopica* / Annonaceae	Bark and Fruits	Uda
8	Ataiko/Orima	*Afromomum danielli* Zingiberaceae	Fruits	Orima
9	Aidan	*Tetrapleura tetraptera* / Fabaceae	Fruits	Uhiokirihio

Proximate composition of the selected endangered food spice crops in South Eastern Nigeria

Many of the aromatic spice plants contain nutritional substances that can boost human health. The proximate composition of some of these selected endangered food spice crops have been reported (Table 2), by Nwankwo *et al*., 2014, Imo *et al*., 2018a, Imo *et al*., 2018b, Besong *et al*, 2016, Adeyeye and Olaleye, 2020, Udousoro and Ekanem, 2013, Adewole, 2014.

Table 2: Proximate composition of selected endangered food spice crops in Southeastern Nigeria.

S/N	Plants	Moisture content %	Crude protein%	Crude fibre%	Fat%	Total ash%	Carbohydrate%
1	Guinea pepper	11.70	16.67	20.99	2.24	7.73	48.21

	leaves

The current status of the production of the identified endangered food crop spices in South Eastern Nigeria

The current status of the production of identified endangered food spice crops and their economic importance were reviewed and findings are presented below:

1. Guinea pepper (Ashanti or Benin pepper) (*Piper guineense* Schumach*)*

Piper guineense, popularly known as (uziza) in Igbo, "Odusa" in Efik/Ibibio, is a West African culinary spice widely used in traditional medicine and has a lot of pharmacological properties. It is used locally to manage cough, bronchitis, and stomach ache. The plant is known as Guinea pepper or Ashanti pepper. It has anti-inflammatory, antioxidant and anti- sickle cell crisis properties (Dzoyeme *et al*, 2017). In South eastern Nigeria, it is known as *uziza*. It is used as a flavouring for stews and soups. It contains 5–8% of the chemical called Piperine which gives it the peppery taste. Research shows that Guinea pepper has preservative properties and it is effective in the preservation of smoke-dried cat fish (Kabari *et al*., 2011). Essential oils from the plant has been documented to have ovicidal properties against insect pests such as *Tribolium castaneum* and *Callosobruchus maculatus* (Arvind *et al*., 2020). Researches have shown that seeds are used traditionally as postpartum tonic (Echo *et al*., 2012).

Currently, there are no agronomic recommendations for the cultivation of Guinea pepper. It is minimally cultivated by a minute fragment of the inhabitants of South eastern Nigeria in home gardens. It deserves improved research attention in the areas of improved production since it has the potential to boost human health and it is underutilized (Alagbe *et al*., 2021; Ojimelukwe, 2021). The fruits of Piper guineense are shown in figs 1, 2 and 3.

Fig1

Fig 2

Fig 3

Figs 1, 2, 3 – Fruits of Piper guineense (Source- Google)

2. Negro pepper (*Xylopia aethiopica)*

Fruits of *Xylopia aethiopica* are widely used to spice soups especially for postpartum mothers. There are claims that almost all parts of *Xylopia aethiopica* possess medicinal values (Fetse *et.al*., 2016) and that infusions of the plant's bark can be used to treat bronchitis, dysenteric conditions and febrile pain. The cultural and agronomic requirements of the plant have not been reported. The fruits of Negro pepper (Xylopia aethiopica) are shown in Figs 4, 5, and 6.

Fig 4

Fig 5

Fig 6

Fruits of *Xylopia aethiopica* (Figs 4,5,6) . Source – Google

3. Utazi (*Gongronema latifolium*)

Utazi is a climbing shrub with bitter leaves. There are claims that Utazi promotes the flow of bile, stimulates appetite for food, increases the activities of the pancreas, enhances the functions of the liver, reduces blood sugar and hypertension, although these health benefits have not been proved through research analysis. There are no available documented reports on the cultural and agronomic requirements of Utazi in Nigeria.

Fig 7- Utazi leaves (Source- Google)

4. Thai Lemon Basil (*Ocimum africanum*)

Internet postings revealed that Thai lemon basil is a hybrid between sweet basil (*Ocimum basilicum*) and American basil (*Ocimum americanum*)(Wikipedia). The crop is widely cultivated in home gardens in the South eastern Nigeria. The plant produces natural sweet aroma which adorns the environment. The leaves are relished as a spice in stews and sauces. Medicinally, there are claims that the plants contain substances capable of lowering blood sugar although there is no research analysis that can provide the evidence. There are no available documented reports on the cultural and agronomic requirements of Thai lemon basil in Nigeria. A picture of the plant showing the leaves and flowers is shown in Fig 8.

Fig 8- Leaves and flowers of Thai Lemon Basil (Source- Google)

5. Mint Basil (*Ocimum gratissimum*)

Mint Basil or Scent leaf is a popular spice crop in South eastern Nigeria where it is used to prepare a variety of dishes. Scent leaf, botanically known as *Ocimum gratissimum*, is an aromatic, perennial, homegrown shrub, although it can be found in the wild, and is used mainly as a spice for cooking delicacies due to its aromatic taste. There are many claims on the health benefits of Mint Basil such as treatment of diarrhea, and has anti-fungal, anti-bacterial properties. There are no documented evidence of research attention on the agronomy of this mint basil. A picture of mint basil showing the shoot is presented in Fig 9.

Fig 9 – Mint basil shoot (Source-Google)

6. Whole Country Onions *(Afrostyrax lepidophyllus)*
   Whole country onions is a widely consumed spice crop which is harvested harvested from the wild. It is popularly called "Control onions "in South eastern Nigeria where is constitutes the major ingredient in preparing mixed spices for cooking stews and sauces. Medically, it has been reported useful in the treatment of appetite loss, frontal headache, management of mumps, asthma and spleen disorders (Egbe *et al*., 2012) There are no available documented reports on the cultural and agronomic requirements of whole country onions in Nigeria. Fruits of country onions is shown in Fig 10.

Fig 10. Fruits of country onions (Source- Google).

7. Jansa- *Cussonia barteri*
   Jansa is a deciduous tree which grows in Africa. Seeds are widely used to spice up stews, sauces and soup because of its pleasant aroma and sweet taste. It has been reported to have analgesic, anti-malarial, anti-inflammatory, anti - anemic, anti-diarrhea, anti-poison, anti -psychotic and anti-epileptic properties (Igbe *et al.,* 2018). There is no documented evidence of research attention on the agronomy of the crop and how to optimize production. A collection of Jansa seeds is shown in Fig 11.

Fig 11 – Fruits of Jansa (Source- Google).

8. Ataiko or Orima (*Afromomum danielli*)
   Seeds of Ataiko or Orima are small, spindle shaped. They are widely used as the main spice for cooking "Banga soup". It can be combined with other spices to make African cuisines. There are no documented reports on its medicinal values as well as its cultural and agronomic requirements. Pictures of seeds are shown in Figs 12 and 13.

Fig 12

Fig 13
Figs 12 and 13- Fruits of ataiko. (Source- Google)

9. Aidan (*Tetrapleura tetraptera*)

Aidan is a deciduous tree which produces sweet fragrance. Fruits are used to spice dishes. Internet postings reveal that fruits also serve for medicinal purposes such as cleansing the digestive system, has anti inflammatory, analgesic and hypoglycemic properties. (www.abs-biotrade info>value-chain>aidan-tree). There is no documented evidence of research attention on the agronomy of the crop and how to optimize production. The fruits of Aidan is shown in Fig 14.

Fig 14 – Fruits of aidan. (Source- Google)

CONCLUSION AND RECOMMENDATION

Attempts have been made in this paper to review the agronomy of these identified threatened food spice crops in the semi-urban South eastern Nigeria environment and findings showed that there is little research attention on them. Findings also revealed that these species are capable of improving the nutrition and health of the rural dwellers but yet, are minimally cultivated. Availability of these food spice crop species come from collections made from nearby bushes and forests. This paper therefore recommends that agronomic packages such as pre-planting, planting and post - planting requirements be investigated through researches and recommendations should be made based on the results of the researches in order to initiate and increase their cultivation as well as their productivity.

ABSTRACT
The study examined kolanut production and the use of farm power among Kola farmers in Cross river state, Nigeria. A sample size of 50 respondents were selected using a proportionate sampling technique. The study revealed that socioeconomic characteristics of kola nut farmers also had a significant influence on kola nut production (F-statistics=10.52; P<0.01); Farm power had significant effect on kola nut production (F-statistics=10.52; P<0.01) while human power was mostly used on the field. The study also found out that human power use on the farm has significant influence on the output of kola nut (t-statistics=4.22; P<0.01). Cost of ownership and maintenance of farm power was a constraint towards using farm power machinery on kola nut farm. It was concluded that there was a great dearth of information on use of appropriate farm power on kolanut supply-side. It was recommended that Kola nut farmers should adopt the use of efficient farm power that guarantee high yield and maximum profit; Youths who inherited kola nut farms from their parents should be encouraged to devote time to invest in kola nut production, Kolanut farmers should adopt the use of simple but efficient labour-saving devices as farm power that guarantee reduced drudgery and increase the land planted to Kola in the area to enhance the productivity and provide a basis for the development of the kola nut industry.
Keywords: *farm power, kolanut, Nigeria*

INTRODUCTION

Kola (a member of the family Sterculiaceae) is a tropical tree crop with over 140 species of which 50 species have been described in West Africa by Adebola, (2003) cited in Dadzie *et al*., (2013). C. acuminate Schott and Eudl. and C. nitida Schott and Eudl. are the most common species, but the later which originated from Ghana and Sierra Leone has gained much preference and become the more important of the two kola species Squire *et al.,* (2000) and Asogwa *et al*., 2012). Over 90% of the world's kola nut is produced in West Africa of which Nigeria contributes 50%, Cameroon 27%, Ivory Coast 16%, and Ghana 8% FAO (2013). Kolanut is of enormous medicinal benefits and great socio-cultural importance in many West African cultures. Nigeria is currently the world's fourth largest producer of Kola nut, after Ivory Coast, Indonesia, Ghana, and the third largest exporter, after Ivory Coast and Ghana (Oseni, 2011).

Farm power is an essential input in agriculture for timely field operations for operating different types of farm equipment and for stationary jobs like operating irrigation equipment, threshers/shellers/cleaners/graders and other postharvest equipment (Verma, 2016). During last 50 years, the average farm power availability has increased from about 0.25kw/ha in 1951 to about 1.35kW/ha in 2010 (FAO, 2015). Over the years, the shift has been towards the use of mechanical and electrical sources of power, while 1951 about 97.4% farm power was coming from animate sources where bulls, oxen, horses were used in tillage operations, planting, processing and transportation of goods to the market (Nwankwo *et al*., 2010). But in early 20th century the contribution of animal sources of power increased from 2.6% to about 82% (FAO, 2015). Tractors are invented to carryout farm operations like clearing and stumping, tillage, planting and others (CTA, 2012). These generations of farm power has made less utilization of other sources of farm power and has made work interesting reducing drudgery on the farm thereby increasing production opportunities (Hemen *et al*., 2016). This present study seeks to analyse the effect of farm power use on the production of kola nut in Boki Local Government Area of Cross River State. Farm power is used on the farm daily to carryout simple farm operations to complex ones. Human/Manpower is the most used on the farm to drive other farm powers. Field operations such as site selection, land clearing, planting and maintenance of kola nut are carried out with effective farm power (Dauda *et al*., 2012). Farm power is very important as it reduces drudgery and increase working time which avails the precision of work done on the farm and off farm that involves transportation and processing (CTA, 2012). Kola nut farmers are poor and have low investment in kola nut farm. Some of these kola nut farms have kola nut varieties that have been planted during the ancient days with little or no improved varieties of kola nut.

Many farmers hardly obtain high yield from kola nut due to lack of capita/money to invest in the farm properly. They need to get equipment for pruning dead branches, detecting pest and diseases attack on crops, employ more labour. This is not possible since the poor varieties of kola nut yield little and the yield does not quantify expenses to employ more hands and explore other production capabilities. One of the challenges is that not all farm power is used on the farm due to the non-availability or low purchasing power thus man power which is readily available but prone to drudgery is usually used. The use of manpower alone on the kola nut farm has made other farmers do better than others. Several studies have been carried out concerning the effect of farm power on crop production such as Akande (2016) on Effects of Agricultural mechanization on Environmental Management in Nigeria; Takeshima *et al*., (2020) on the effect of Agricultural Mechanization on economics of scope in crop production in Nigeria; and Abubakar (2011) Farm power utilization in Agriculture. But little or nothing is done concerning effect of farm power on kola nut production in Boki Local Government of Cross River State. The outcome of the study will be of significance to kola nut farmers, policy makers, agricultural engineers and researchers.

The following null hypotheses were tested in the study

Ho_1: Socioeconomic characteristics of kola nut farmers has not significant influence on kola nut production

Ho_2: Farm power has no significant effect on kola nut production

METHODOLOGY

Data collection was through the interview method through the use of structured questionnaire. This study was conducted in Boki Local Government Area of Cross River State, Nigeria. Boki Local Government Area in Cross River State of Nigeria. It has a population of about 300,000 (NPC, 2015) and a contiguous territories border with the Republic of Cameroon. Boki bears a national and international reputation for being a major commercial centre where forest and internationally quoted agricultural commodities such as kola nut, cocoa coffee, timber, palm products, etc. are sourced and supplied for international consumption. Boki Local Government Area is bounded in the west by Ogoja, north by Obudu, south by Ikom Local Government Areas while in the west, it is bounded by the Republic of Cameroun. With Boje its headquarters, Boki has about fourteen major communities including Bateriko, Bumaji, and Wula. The population of this study consisted of 200 registered kola nut farmers in Boki Local Government Area of Cross River State, Nigeria. A sample size of 50 respondents was selected using a proportionate sampling technique. A total of 146 registered kola nut farmers were found to be involved in kola nut production in the six (6) selected villages (Cross River Ministry of Agriculture, 2022). The distribution was proportionately done based on the number of farmers in the selected villages. The distribution of sample in the six (6) selected villages is presented in Table 1 below.

Table 1: Distribution of Sample in the 6 Selected Villages in the Study Area

s/no.	Wards	Villages	No. of Farmers	No. of Sample
1	Bateriko	Bateriko 1	47	16
		Bateriko 2	35	12
2	Wula	Angbaiso	23	8
		Ekumpo	18	6
3	Bumaji	Baggo	14	5
		Bunu	9	3
		Total	**146**	**50**

Model Specification
Ordinary Least square
Y=f(x)
Y= kola nut output in yield/kg/year
X= farm power
$Y= B_O + B_1X_1+B_2X_2 +B_3X_3 + B_4X_4 + B_5X_5 + e_I$
B_O-B_5= Regression Coefficients
X_1= animal power was measured as number of animals used
X_2 = human power was measured as the time of sun light per day in hours
X_3 = Mechanical power is measured as the time of mechanical traction on the farm in hours
X_4 = Electrical power was measured in the watts/ohms
X_5= human power
e_i= error term

RESULTS AND DISCUSSIONS
Effect of Farm Power on Kola Nut Production
The result of the multiple regression analysis is presented in Table 2. The result gave the coefficient of determination (R^2) of 50.14 which implies that 50.14% of the variation in Kola nut output is explained by the explanatory variable farm power. F-statistics of 10.52 was statistically significant at 1% level which implies that farm power affects the output of kola nut. Electrical power, Human power and animal power are significant at 1% level at their respective coefficient. Electrical power coefficient is positive (325351.3) and significant at 1% level which implies that 1-unit increase in the use of electrical power will reduce kola nut output by 325351.3. This is true because use of electrical power a priori expectation is to increase efficiency and thus output level. The largest use of electric power in the rural areas is for irrigation and domestic water supply. Its operation and maintenance needs less attention and care. It is clean, quiet and smooth running (Abubakar, 2011). Electrical power is used for water pumping for irrigation, storage, farm product processing. Nowadays electricity has become a very important source of power on farms in various states of the country; Electrical power is used mostly for running electrical motors and for pumping water among others. Human power coefficient is positive (1662531) and significant at 1% level which implies that 1-unit increase in the area of human power will increase the output of kola nut by (1662531). This is expected. Human power is an important source for operating small implements and tools stationary work like chaff cutting, lifting water, threshing, winnowing and many other such works are done using manual labour. Animal power is negative (-1469507) and significant at 1% level which implies that an increase in 1 animals power will decrease kola nut output by (-1469507).
Balogun and Ogheneruemu (2012) opined that there was disequilibrium in resource use, as the number of family members engaged in farming, land area cultivated on kola nut, cost of durable inputs, cost of non-durable inputs, amount of money spent on labour were used efficiently as against hired labour that was inefficiently used. Lamidi and Akande (2013) carried out a research review on challenges and prospects of agricultural mechanization in Osun State of Nigeria. Results identified shortage of capital, land tenure,

small farm holding and fragmented land, poor infrastructural facilities, poor attitudes toward adoption of new innovation and non- availability of storage means as problems. Infrastructural problem was identified by 60 percent of the respondents. The deprivation in abundance amongst farmers in the state and in their produce is partly due to inability to mechanize agriculture to improve its efficiency, cost effectiveness, diversity and competitiveness. Omoare *et al.* (2006) in their study to compared kola nut farmers' knowledge and attitude to trainings on good cultural management practices in Ogun and Ondo States, Nigeria identified major constraints to kola nut production and CMP in the study areas as poor feeder roads (100%), irregular supply of agro-inputs (90.0%), and instability in government policy (88.4%). The study concludes that majority of the kola nut farmers carried out Cultural Management Practices to obtain good yield, and has positive attitude towards CMP trainings as it is highly beneficial to their kola nut farming.

Amos (2017) carried out a study on analysis of productivity and technical efficiency involved in kola nut production in Nigeria and relied upon primary data generated during the 2003/2004 production season. The study observed that there was an opportunity for increase in farmers' efficiency and concluded that policies that would directly affect these identified variables should be pursued vigorously. David (2011) presented a report on Nigerian Kola nut Production Increases and reported average kola nut yield in Nigeria does not exceed 500 kilograms per hectare. Popoola *et al*., (2015) investigated the profitability of kola nut enterprise, the technical efficiency, and drivers of efficiency among kola nut farmers, in southwest Nigeria. The study revealed that yield of kola nut per year in the southwestern states were: Ondo- (1337.53kg/year), Osun (078.27kg/yr) and Ekiti (2217.07kg/yr). The majority of kola nut farmers were relatively technically efficient in their use of resources, with a mean technical efficiency of 0.8126. Farmers in Ekiti state are most technically efficient with a mean of 0.8922 followed by Ondo state with a mean of 0.8132 while Osun state has the least mean of 0.7323. Education was positively and significantly associated with efficiency, while area of land and age of kola nut trees negatively affects technical efficiency. This indicates that public investments in education have complementary and synergistic effects on improved kola nut technical efficiency, and younger kola nut trees should be planted by farmers in southwest Nigeria.

Adewale *et al*., (2016) in their report on Kola nut Seed Garden: a means to disseminating improved planting materials for enhanced national productivity reported that the country is currently experiencing low and declining yields due to inconsistent production patterns, disease and pest attack. Low levels of mechanization with dependence on cutlass and hoe agriculture and ageing of kola nut fields play a role in decreased productivity, especially in southwest states that contribute nearly 80% of national kola nut yields. Although reports are conflicting, annual kola nut yields for Nigeria are generally estimated at an average of between 300 to 350,000 tons. Reports also set production per hectare at 0.38 tonnes but these are reported to have declined to less than 0.3tonnes per hectares mostly due to reduced rainfall.

Table 2: Multiple regression analysis of Effect of Farm Power on Kola nut Production

Yield	Coefficient	Std. Error	p-value

Null hypothesis 1 which states that: "Socioeconomic characteristics of kola nut farmers has no significant influence on kola nut production" was rejected with F-statistics of 10.52 significant at 1% level and the alternative hypothesis accepted that socioeconomic characteristics of kola nut farmers has significant influence on kola nut production**.** Null hypothesis 2 which states that "Farm power has no significant effect on kola nut production" was rejected with F-statistics of 10.52 significant at 1% level and the alternative hypothesis accepted that socioeconomic characteristics of kola nut farmers has significant influence on kola nut production.

Challenges of Using Farm Power

Result on challenges of using farm power is presented in Table 3. Multiple responses on the challenges faced in using farm power are presented in Table3. The challenges were ranked in order of importance from the first to last. The result showed that cost of owing farm power (78.0%) is high. This is true because to manage a source of power on the farm is capital intensive. Other challenges include: technical know-how 62.0%, irregular supply of agro-inputs (60.0%), instability of government policy (52.0%), poor feeder roads (44.0%) and lack of spare parts (68.0%). This is in line with Oluyole and Sanusi (2019) who reported that technical know-how prevents farmers from using efficient method of production. Ebi (2019) reported lack of spare parts to repair the machinery during break down. FAO (2017) reported that lack of feeder roads prevents innovation in rural arrears.

Table 3: Challenges of Using Farm Power

s/no	Items	Multiple Response (%)
a.	Costs of ownership of farm power	78
b.	Technical know how	62
c.	Poor feeder roads	44
d.	Irregular supply of agro-inputs	60
e.	Instability in government policy	52
f.	Lack of spare parts	68
g.	Abundance of small scale kola nut farmers	40

Source: Field survey, 2022

CONCLUSION

Based on the findings of the study, the study also found out that human power, wind power and mechanical power are mostly used on the field; mechanical power, human power are mostly used in the processing system while human power, wind power are mostly used in the storage. The study also found out that farm power use on the farm has significant influence on the output of kola nut. The study concludes that cost of ownership/maintenance of farm power is a constraint towards using farm power machinery on kola nut farm. Nonetheless, there is a great dearth of information on kola nut supply-side practices and constraints that can provide a basis for the development of the industry. Based on the findings of the study, the following recommendations are made: Youths who inherited kola nut farms from their parents should be encouraged to devote time to invest in kola nut production, Kolanut farmers should adopt the use of simple but efficient labour-saving devices as farm power that guarantee reduced drudgery and increase the land planted to Kola in the area. Agricultural Extension workers should introduce kola nut technologies to farmers and train them on how to use machinery innovations effectively so as to enhance. To the kola nut farmers, the outcome of the study has revealed the different kinds of farm power used in kola nut production and helped other farmers to choose from many options unknown to them. To the policy makers, the outcome of the study was to make them formulate the exact policy that will favour the use of farm power in kola nut production in other to provide credits and incentives thereby reducing cost of production. Also, to the agricultural engineers, the outcomes of the study have exposed them to the right farm power needed in kola nut production and in turn employ many engineers to go into production of farm power machineries to enhance production.

ABSTRACT
Globally, increasing lack of access to safe, nutritious and affordable food has been part of the greatest challenge of the world economies. Solution to this global challenge has been part of main focus of the United Nations Sustainable Development Goals (SDGs). In order to achieve SDG-2, which is to "end hunger, achieve sustainable food security, improved nutrition and promote agriculture by 2030", there has been global call for climate smart and innovative agriculture. Hence, this study examined food security impact of smart agriculture and innovation on food security in Africa using evidence from Nigeria. The study utilized time series data from 1960 – 2019, sourced from World Development Indicators – WDI (2019) and Food and Agricultural Organization of the United Nations (2020) data set and applied econometric approach based on OLS technique. It was found by the study that with respect to smart agriculture, it was found that fertilizer intensity (fertintern) has negative significant impact on food security (foodsec) by about 1.378546% on the average, while that of tractor intensity (tractintern) revealed that it has positive significant impact on food security (foodsec) by about 0.0050153%. On innovation, the results on number of internet subscribers (internetsub) revealed that it has positive but insignificant impact on food security (foodsec) by about 0.074778% on the average. The study therefore recommended among others that government and its agencies on food security should encourage people more to use natural manure or organic fertilizer instead of inorganic fertilizer. This can be done by boosting crop yields through numerous practices and technologies such as nutrient management practices and technologies geared towards organic fertilizer.
Keywords: *Food, Security, Smart Agriculture, Innovation, Africa, Nigeria, Econometric Approach*

INTRODUCTION
Globally, increasing lack of access to safe, nutritious and affordable food has been part of the greatest challenge of the world economies (FAO, IFAD and WFP, 2015). Solution to this global challenge has been part of main focus of the United Nations Sustainable Development Goals (SDGs). In order to achieve SDG-2, which is to "end hunger, achieve sustainable food security, improved nutrition and promote agriculture by 2030", there has been global call for climate-smart and innovative agriculture. Due to poor agricultural productivity occasioned by lack of smart agriculture and innovation, Africa has been the epic center of this global menace of food insecurity and malnutrition, with about 26% of 153 million adult populations suffering severe food insecurity (FAO report, 2016). Furthermore, the United States Department of Agriculture (USDA) prediction suggests that Sub-Sahara Africa (SSA) would remain the region with the highest level of food insecurity up to the year 2025 (Tandon *et al*., 2017). In African region, Nigeria is feared to be one of the countries said to be most at risk, due to her heavy food import-dependent, with an estimated value of food importation worth of 22billion US dollar (Ogundiran, 2019). This has been linked to lack of agricultural technology adoption and heavy subsistence farm participation of greater populace in Nigeria.
More so, World Bank's records revealed that 90% of agricultural production in Nigeria is made up of inefficient output of small scale farmers (Matemilola, 2017). Hence, farmers only succeed to produce enough food to sustain their household members. Consequently, high level of food insecurity prevalence

resulted to frequent high food prices and exposure to global commodity market shocks. The precarious state of food insecurity in Nigeria is also evident in the Global Hunger Index (GHI). Nigeria is ranked 98th out of the 107 countries with a score 29.2, which falls in the serious category (Global Hunger Index report, 2020). This reveal also that Nigeria is far from track in attaining the SDG-2 target. More so, Global Food Security Index (GFSI) score and rank as shown in figure 1 below indicates that Nigeria's ranking has continued to worsen since 2013 with a rank of 86 among 107 countries with 33/100 score and a rank of 94 among 113 countries with a score 48.4/100 in 2019, behind her African counterparts like Ethiopia, Niger and Cameroon (Economist Intelligence Unit [EIU], 2019).

Source: EIU (2019)

However, evidence has shown that existing, new and emerging agro technologies can go a long way to address different dimensions of food security in Nigeria and Africa in general (Adeagbo, 2012). These technologies, such as irrigation technology could assist in food availability, while post-harvest and agro-processing innovation can promote food accessibility. Tapping into these existing and emerging smart agricultural technologies for food security requires investments in physical and human capital. Sadly, most farmers in Nigeria are smallholder participants with low agro-tech knowledge and also lack access to affordable cultivating and harvest equipments (Mapfumo *et al*., 2015). Thus, most farmers depend on manual labour for farm activities (Matemilola *et al*., 2017).

Despite the high rate of tele-density witnessed in couple of decades in Nigeria, with over 203.5 million active telecommunications subscribers, Nigeria have not effectively harness the full potential of e-agriculture (Agrobusiness times report, 2021). Unlike countries such as India (Reuters Market Light), Ghana (mFarms), Kenya (MPesa, iCow), that have utilized ICT innovations to increase their agricultural outputs. Reuters Market Light (RML) in India for instance has improved farmers' productivity by 14-16 % with farmers trading even more profitably (IFPRI, 2002). The adoption of the emerging innovation by smallholder farmers in Nigeria has been slow and low (Jack, 2013).

Though concerted efforts have been made by private investors as well as the government to promote innovation and give a new face to agriculture in Nigeria. Like the adoption of 130 farmers in Jigawa state into the National Adopted Village for Smart Agriculture program by the Nigeria's Federal Ministry of Communications and Digital Economy. The program was targeted at providing farmers a means to showcase their farm produce to digital world market. Other efforts by successive governments to promote agricultural production include establishment of agencies and several policy intervention initiatives like Operation Feed the Nation, Lower River Basin Development Authorities, National Seed Policy and Seed Development Plan, Green Revolution and regulatory bodies such as the Directorate of Foods, Roads and Rural Infrastructure (DFRRI), Agricultural Transformation Agenda and National Agricultural and Land Development Authority (NALDA) among others. Yet these concerns and efforts by the Nigerian government have not translated into effective policy interventions and implementation. Nigeria still depends on massive importation of food and could not solve the long term food insecurity challenges.

Hence, this study seeks to investigate the effects of smart agriculture and innovation on food security in Nigeria. The rest of this paper is structured as follows; section 2 discussions on literature review, section 3 captures the methodology and data sources, while section 4 and 5 is the result discussion and policy recommendations.

LITERATURE REVIEW

Smart Agriculture is referred to as the application of modern technological techniques/skills into agriculture in order to increase productivity (Spandana & Pabboju, 2019). Smart Agriculture can furnish the farmers with daily/weekly updates with respect to the soil quality, crop health and energy consumption level within the farm (Spandana & Pabboju, 2019). Also it can assist farmers in the following farm activities; smart irrigation, crop monitoring, crop disease detection, green house management, plant growth monitoring and energy management among others (Iorliam, Iorlian & Blum, 2021). According to Jack (2013) agriculture innovations could enhance yields in Africa. This view is also corroborated by Senz *et al*. (2017) that indicated that smallholder farmers can feed Africa if the regions' small-scale producers adopt intensified agro practices with seeds and fertilizers.

In line with these views, factors that aid adoption of agricultural technologies have remained rather inconclusive. At both micro and macro level a number of studies have found different determinants as important in making adoption decisions by farmers (Arslan *et al*., 2014; Kabunga *et al*., 2012; Mariano, Villano, & Fleming, 2012; Pannell *et al*., 2014). Past literature indicates that there are several barriers to technology adoption, ranging from lack of insurance and limited access to credit to price risk, and majorly focuses on the effect of production risk on overall output (Kassie *et al*., 2008; Di Falco *et al*., 2011; Di Falco *et al*., 2014).

While some other empirical studies have focused on the implications of climate-smart agriculture on food security using micro data obtained from use of questionnaires (Hassan *et al*., 2018; Amadu, 2018; Wekesa *et al*., 2018; Jelagat, 2019). Their findings revealed that climate-smart agriculture practices significantly influenced food security. Amadu (2018) noted also that available knowledge on agricultural innovations was not available to small-scale farmers and therefore farmers continued practicing unsustainable farming in Southern Malawi.

Furthermore, literature expanded on the impact of ICT on crop production. Some of the studies in this area used macro data (Vanek *et al*, 2010; Aker, 2011; Armstrong. & Gandhi, 2012; Asenso-Okyere & Mekonnen, 2012; Chavula, 2013; Salampasis & Theodoridis, 2013; Adamides & Stylianou, 2013); Vosough *et al,* 2015; Zhang, *et al*, 2016), while others utilized micro data (Hassan *et al*, 2011; Chukwunonso, Abubakhar & Obidi, 2012; Ramli *et al.*, 2013). Most of these empirical studies revealed that ICT adoption and internet utilization have positive impact on agricultural output. Though these studies also indicate that most of the framers are not acquainted with these ICT tools and they are easily accessed by farmers in the communities studied (Ejemyovwi *et al*., 2017; Ugboh & Tibi, 2008). Therefore, recommended that ICT facilities be made accessible in most rural areas in various localities (Ugboh & Tibi, 2008).

In addition to ICT and internet utilization implications on agricultural output, quality of labour has also been identified in the literature as a key factor that affects agricultural output. A study in West Africa on the role of ICT on agriculture; labour and capital were elastic, which implies that any change in labour and capital would proportionately increase agricultural output (Akimuda, 2014).

Empirical literature on the impact of smart agriculture and innovation on food security abound in developed and developing countries. Most scholarly works have found a positive relationship between food security and smart agriculture, while other studies found inverse relationship. However, this current study would build on the existing knowledge by further assessing how smart agriculture and innovation impact on food security in Nigeria. Thus, this current study would utilize time series data from FAO and WDI, unlike most previous studies in Nigeria that used primary data.

METHODOLOGY

In order to investigate the effects of smart agriculture and innovation on food security in Nigeria, this study adopted econometric approach based on Ordinary Least Squares (OLS) technique. The functional form of the econometric model states that food security is a function of smart agriculture and innovation. This can be seen in equation one specified below:

$$foodsec = f(smtagric, innov) \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (3.1)$$

where;

foodsec = food security (proxied by food production index)

smtagric = smart agriculture (proxied by fertilizer intensity, and tractor intensity)

innov = innovation (proxied by number of internet subscribers/number of individuals using the internet (% of population)).

f = functional notation

However, there are other variables that could influence food security other than smart agriculture and innovation, such as employment in agriculture % of total employment), and foreign direct investment (FDI) inflows. For example, foreign direct investment (FDI) inflows have been shown to exhibit some impact on food security in Nigeria since Nigeria is an import dependent country. Therefore, modifying the functional form of the econometric model to capture each variable, and capturing the effects of employment in agriculture and that of FDI as control variables in the model, the study specifies the mathematical form of the model as given below:

$$foodsec = \alpha_0 + \alpha_1 fertintern + \alpha_2 tractintern + \alpha_3 internetsub + \alpha_4 empagric + \alpha_5 fdi \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (3.2)$$

where;

foodsec = food security (proxied by food production index)

fertintern = fertilizer intensity,

tractintern = tractor intensity,

internetsub = number of internet subscribers/number of individuals using the internet (% of population) (proxy for innovation)

empagric = employment in agriculture % of total employment

fdi = foreign direct investment inflows

α_0= the constant term

$\alpha_{i's}$ = the parameters of the model, for i = 1, 2, …, n.

Hence, in line with the mathematical specification of the model, the econometric specification of the model is given as:

$$foodsec = \alpha_0 + \alpha_1 fertintern + \alpha_2 tractintern + \alpha_3 internetsub + \alpha_4 empagric + \alpha_5 fdi + \mu_t \ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots\ldots (3.3)$$

where; the variables remained as defined above. μ_t = stochastic error term.

Data and Data Sources

The study data for the study is a time series data from 1960 – 2019, sourced from World Development Indicators – WDI (2019) and Food and Agricultural Organization of the United Nations (2020) data set. While food production index (proxy for food security), , number of internet subscribers/number of individuals using the internet (% of population) (proxy for innovation), employment in agriculture % of total employment, and foreign direct investment (FDI) were sourced from WDI (2019) data set, fertilizer intensity, and tractor intensity (proxies for smart agriculture) were sourced from FAO (2019) data set. The study performed some pre-estimation tests such as the descriptive statistics, unit root test and cointegration test.

RESULTS AND DISCUSSIONS

Before analyzing the model, the study looked at pre-estimation tests like the summary statistics, unit root test and the cointegration test, in order to inspect the nature and time series characteristics of the variables of the model. These are examined in the sub-sections that follows as given below:

Summary Statistics

The summary statistics results presented in the table 4.1 shows the raw data level forms of the model variables. It also reveals the nature and characteristics of the model variables inspected in a bid to observe whether the variables vary sufficiently in their mean, standard deviation, and minimum and maximum values. Consequently, the study presents the summary statistics of the variables applied in the model as given below in table 4.1:

Table 4.1: Summary Statistics Results of the Model Variables

Variable	Obs	Mean	Std. Dev.	Min	Max
foodsec	60	61.40779	35.63483	22.91	125.77
fertintern	60	3.42925	2.846379	.01	11.27
tractintern	60	9875.917	7009.825	500	24800
internetsub	60	5.548633	12.85764	.008833	57.9175
empagric	60	47.11308	4.624483	36.384	50.172
fdi	60	1.728601	1.136197	-1.150856	5.790847

Source: Author's computation from available data

The summary statistics results indicate that all the variables of the model revealed sufficient variations in their mean, standard deviations, and their minimum and maximum values respectively. The results show that there 60 observations corresponding to data generated from 1960 – 2019 for all the model variable.

Unit Root Test

The study applied the Augmented Dickey-Fuller (ADF) test for unit root in order to examine the level of integration or level of stationarity of the variables. Hence, the ADF test for unit root can be seen summarily as presented in table 4.2 given below:

Table 4.2: The Summary Results of Unit Root Test

	Level		First Difference		Oder of Integration
Variable	ADF t-Statistics	5% Critical Values	ADF t-Statistics	5% Critical Values	
foodsec	0.780	-2.923	-11.634	-2.924	Oder one (i.e.I(1))
fertintern	-0.919	-2.923	-8.984	-2.924	Oder one (i.e.I(1))
tractintern	5.243	-2.923	-7.467	-2.924	Oder one (i.e.I(1))
internetsub	3.741	-2.923	-8.183	-2.924	Oder one (i.e.I(1))
empagric	3.245	-2.923	-5.070	-2.924	Oder one (i.e.I(1))
fdi	-3.900	-2.923			Oder zero (i.e.I(0))

Source: Author's computation from available data

The results of the unit root test presented in table 4.2 indicate that all the variables of the model food security (foodsec), fertilizer intensity (fertintern), tractor intensity (tractintern), number of internet subscribers/number of individuals using the internet (% of population) (internetsub), and employment in agriculture % of total employment (empagric), are all integrated of order one (i.e.I(1)), except for foreign direct investment (fdi) which was found to be integrated of order zero (i.e.I(0)).

Cointegration Test

The study applied the two-step Engel cointegration test in order inspect if there exist long run relationship among the variables of the model. If there is evidence of cointegration among the variables of the model, the study would implement the error correction model (which is also known as the short run model), otherwise, the study would utilize the long run econometric model based on OLS for its analysis. The cointegration test results can be seen in table 4.2.1 as follows:

Table 4.2.1: The Cointegration Test Results

	Test Statistic	1% Critical Value	5% Critical Value	10% Critical Value
Z(t)	0.613	-3.567	-2.923	-2.596

MacKinnon approximate p-value for Z(t) = 0.9879

Source: Author's computation from available data

The cointegration test results show that there is no cointegration among the variables of the model since the absolute value of the ADF t-statistic, 0.613, is less than its 5% critical value, -2.923 in absolute terms (that is; /0.613/</-2.923/). Therefore, there is no need for constructing error correction model or short run model. This implies that the long run econometric model based on OLS would suffice for the study's analysis and interpretations of results.

The Empirical Results of the OLS Econometric Model

In line with the findings of the pre-estimation test and cointegration test, the study adopts the long run econometric model based on OLS for the study's analysis and interpretations of results as presented in table 4.3 below:

Table 4.3: The Summary Results of the Econometric OLS Model

foodsec	Coef.	Std. Err.	t	P>|t|
fertintern	-1.378546	0.5467624	-2.52	0.015
tractintern	0.0050153	0.0003763	13.33	0.000
internetsub	0.074778	0.1619835	0.46	0.646
empagric	0.8534069	0.6684604	1.28	0.207
fdi	3.016793	0.7615282	3.96	0.000
_cons	52.0109	34.25205	1.52	0.135

Source: Author's computation from available data

Table 4.3 indicates that from the econometric regression model, fertilizer intensity (fertintern) has negative significant impact on food security (foodsec). This implies that a unit increase in fertilizer intensity significantly reduces food security by about 1.378546%. This result is surprising since it is expected that a rise in fertilizer intensity would significantly increase food production and as such, contribute significantly to food security in Nigeria. The implication of this result is that in Nigeria, fertilizer intensity reduces food security significantly due largely to the use of inorganic fertilizers which may contain some chemicals that are very harmful to the land used in the food production, microorganisms, and some crops/plants. This therefore shows that natural manure or organic fertilizer should be applied instead of inorganic fertilizer. Again, the problem of land tenure system could also militate against smart agriculture emanating from fertilizer intensity in Nigeria and as such, makes food security to fall. This finding is in consonance with the finding by Stewart & Roberts (2012), and Yousaf, Li, Lu, Ren, Cong, Fahad, & Li (2017) who found that in order to boost crop yields, numerous practices and technologies such as nutrient management practices and technologies geared towards organic fertilizer, among others, should be adopted instead of using inorganic fertilizers.

Results on tractor intensity (tractintern) revealed that it has positive significant impact on food security (foodsec). This implies that a unit increase in tractor intensity would significantly encourage food security by about 0.0050153%. This result is not surprising since it is expected that a rise in tractor intensity (tractintern) would significantly increase food production and as such, contribute significantly to food security in Nigeria. The implication of this result is that in Nigeria, the more intensive tractors are used for food production, the more food production would increase and hence, bring about significant rise in food security.

On innovation, the results on number of internet subscribers (internetsub) revealed that it has positive but insignificant impact on food security (foodsec). This implies that an improvement in innovation (internetsub) would positively but insignificantly influence food security by about 0.074778% on the average. The implication of this result is that with a continuous innovation, food security will improve in economy although, insignificantly. This study's finding is in line with the finding by Ejemeyovwi *et al*. (2017) who found that internet utilization is positively but insignificantly related to food security.

It was also found by the study that a percentage increase in employment in agriculture as a percentage of total employment (empagric) has positive and insignificant impact on food security (foodsec). This implies that a percentage increase in employment in agriculture (empagric) would positively but insignificantly impact food security by about 0.8534069% on the average. The implication of this result is that whenever employment in agriculture rises, food security would improve, although insignificantly.

Foreign direct investment (fdi) results also indicate that a unit increase in foreign direct investment would significantly increase food security (foodsec) by about 3.016793% on the average. This result is not surprising since it is expected that a rise in investment inflows would significantly increase food production, food inputs, and as such, contribute significantly to food security in Nigeria. The implication of this result is that in Nigeria, the inflows of foreign investments would on the average increase food security significantly in Nigeria.

Controlling for other factors that could affect food security in Nigeria (_cons), it was found by the study that the constant term positively but insignificantly affect food security.

CONCLUSION AND RECOMMENDATION

This study examined food security impact of smart agriculture and innovation in Africa using evidence from Nigeria. The study utilized time series data from 1960 – 2019, sourced from World Development Indicators – WDI (2019) and Food and Agricultural Organization of the United Nations (2020) data set and applied econometric approach based on OLS technique. With respect to smart agriculture, it was found that fertilizer intensity (fertintern) has negative significant impact on food security (foodsec) by about 1.378546% on the average, while that of tractor intensity (tractintern) revealed that it has positive significant impact on food security (foodsec) by about 0.0050153%. On innovation, the results on number of internet subscribers (internetsub) revealed that it has positive but insignificant impact on food security (foodsec) by about 0.074778% on the average. On the control variables, it was found that employment in agriculture has a positive and insignificant impact on food security (foodsec) by about 0.8534069% on the average, while foreign direct investment (fdi) results also indicate that a unit increase in foreign direct investment would significantly increase food security (foodsec) by about 3.016793%.

Based on the findings of the study, the study recommends that:

1. Government and its agencies on food security should encourage people more to use natural manure or organic fertilizer instead of inorganic fertilizer. This can be done by boosting crop yields through numerous practices and technologies such as nutrient management practices and technologies geared towards organic fertilizer.

2. Again, government should try to solve the problem of land tenure system in a bid not to militate against smart agriculture, especially, that which emanates from fertilizer intensity in Nigeria which makes food security to fall.
3. Innovation was found to have positive but insignificant impact on food security, hence, government and all agencies responsible for food security should strive more to innovate the more in a bid to have a significant contribution from innovation on food security. This would held in increased production and a significant rise in food security.
4. Employment in agriculture was found to have positive and insignificant impact on food security, thus, there is need to mechanize agriculture, adopt improve seedling, crops that can withstand harsh climatic conditions. This would help to improve the positive effects of employment in agriculture and possibly, make it significant in affecting food security in Nigeria.
5. Foreign direct investment was found to significantly encourage food security in Nigeria, consequently, government and its agencies responsible for food security should try harder to create more conducive environment that would attract more foreign investments in the sector. However, there should be some form of controls in order to avoid some risks of unintended consequences of FDI inflows in the country.

ABSTRACT
Field experiment was carried out during the wet season of 2021/2022 and 2022/2023 at the experimental farm site of Federal College of Forestry Mechanization, Afaka, Kaduna. To determine the most suitable weeding regime and the optimum phosphorus fertilizer rates on growth and yield of sunflower production. The experiment was laid out in a Randomized Complete Block Design (RCBD) replicated three times. From the result, plant height for the first year and second year were significantly influenced by weeding regime and phosphorus fertilizer rates. For the first year and second year, weed dry weight, number of leaves per plant and seed yield of sunflower were significantly influenced by weeding regime only. The plots with hoe weeding every three weeks, the weed free treated plots and the plots with 50kgha^{-1} phosphorus fertilizer rates could be suggested for farmers planting sunflower in the study area for better production of sunflower in the study area.
***Keywords**: Sunflower, weeding regime, phosphorus fertilizer rates.*

INTRODUCTION

Sunflower (*Helianthus annus* L.) is an oil seed crop that belongs to the family *compositae.* It can be easily distinguished from other crops by it's prominent head that bears the seeds. Sunflower is grown principally for it's seeds that contain oil (36 to 52%) and protein (28 to 32%) as reported by Rosa *et al*., 2009). The crop originated in North America (Anonynmous, 2016). Sunflower is a crop that is cultivated throughout the world (Groove et al., 2005). FAO (2010) reported that the current world area under sunflower cultivation was 22.3 million hectares, while seed production and average yield stood at 27.7 million tons per hectare respectively (Sani *et al*., 2014). The major growing countries in the world are Russia, Ukraine, Argentina, China, USA, India and Turkey. Today it has become naturalized in many locations of the Tropics and it's widely cultivated in Africa. Although statistic level hectares in Nigeria are not available (Adebayo et al., 2010). It can be used as an edible oil in form of margarine, salad dressing oil, and cooking oil (Qahar *et al*., 2010). Sunflower can be used as silage for animal feed, which is richer in nutrients than corn (Qahar *et al*.,2020).

Weed significantly affect sunflower yield and reduce the quantity and quality of karnel during harvest. According to report, loss due to weeds, may be reached up to 44 – 96% at the global level (Mohammed, 1994). Monaco (2002) reported that 41 – 100% yield reduction due to weed competition in sunflower if the first weeding is delayed. Weeds drastically reduce sunflower yield from 70 – 80 percent lost (Anonymous 1998). Fertilizer application either organic or inorganic therefore becomes a major condition towards yield increase. Phosphorus (p) is a majoy requirement for the growth of sunflower. It's deficiency results in stunted growth, purplish discolouration of leaves. It also affects flowering, fruit production and seed production (Aduayi *et al*., 2002). Flower size is reduced to half it's normal size, head Is decrease to one – third. Uptake of major nutrients elements by sunflower has also been reported to be facilited when phosphorus was applied at the rate of 40 – 60kgha^{-1} in the forest zone (Fagbayide and Adeoye, 1999). Based on the above views, this study was initiated with the objective of determining the performance of sunflower as influenced by weeding regime and phosphorus fertilizer rates.

MATERIALS AND METHODS

Field experiment was carried out at the experimental farm site of Federal College of Forestry Mechanization, Afaka, Kaduna (latitude 10^037N and longitude 7^017E). The physical and chemical properties of the soil at the experimental site was taken for analysis prior to land preparation. The treatments consisted of weeding regime (hoe weeding every 3 weeks, hoe weeding every 4 weeks, hoe weeding every 6 weeks, weed free and weedy check) and three rates of phosphorus fertilizer at 0, 40 and 60kgha^{-1}. The treatments were arranged in a Randomized Complete Block Design (RCBD) replicated three times. The gross and net plot sizes were 3.375m^2 (1.5m × 2.25m) and 1.125m^2 (1.5m × 0.75m). The sunflower seeds were planted in situ, with 2 to 4 seeds per hole and thinned to one plant seedlings per stand after establishment. Harvesting of sunflower was done when the sunflower head turned yellowish brown. The sunflower heads were cut from their stems and sun dried and a small stick was used to stick the back of the sunflower head to remove the sunflower seeds. Data collected include weed dry weight, plant height, number of leaves per plant and seed yield. All the data collected were subjected to analysis of variance (ANOVA) as described by Snedecor and Cochran, 1967. The significant differences between the means were compared using Duncan Multiple Range Test (DMRT) (Duncan, 1955).

Weed dry weight

Weeding regime significantly influenced weed dry weight. From table x, for both years the weedy check plots recorded significantly higher weed dry weight than the other weed control treatments. The weed free treated plots gave the least significant weed dry weight compared to the other weed control treatments. This result is so, as it goes in line with the work of Jabran *et al*., 2008, who reported that weeds left unmanaged causes massive yield losses in sunflower field crop. For the first year phosphorus fertilizer rate significantly influenced weed dry weight. The 40 and 50kgha^{-1} phosphorus fertilizer rates recorded significantly higher weed dry weight than the 0kgha^{-1} phosphorus fertilizer rates.

Plant height

Weeding regime and phosphorus fertilizer rates significantly influenced plant height of sunflower for both years. For both years the weed free treated plots gave significantly taller plants than the other weed control treatments, this was followed by the plots with hoe weeding every 3 weeks. The weedy check plots recorded the shortest significant plant height compared to the other weed control treatments. This result could be as a result of phosphorus not being deficient for both years, as reported by Aduayi *et al*., 2002.

Number of leaves per plant

For both years weeding regime did not have any significant effect on number of leaves per plant. Phosphorus fertilizer rates significantly influenced number of leaves per plant. For both years the 50kgha^{-1} phosphorus fertilizer rate produced significantly higher number of leaves per plant than the other phosphorus fertilizer rates. This result could be as a result of phosphorus been applied at the right rate, as reported by Fagbayide and Adeoye, 1999. The least phosphorus fertilizer rates was recorded by the 0kgha^{-1}.

Seed yield

For both years weeding regime significantly influenced seed yield of sunflower; and the weed free treated plots recorded significantly higher seed yield of sunflower than the other weed control treatments. Weed check plots gave significantly lower seed yield. This result could be as a result of weeds being controlled effectively, irrespective of the presence of phosphorus.

Table 1: Effect of weeding regime and phosphorus fertilizer rates on weed dry weight and plant height of sunflower (*Helianthus annus* L.) during 2021/2022 and 2022/2023 rainy season at Afaka.

Treatments	Rate (kgha^{-1})	Weed dry weight 2021/2022	2022/2023	Plant height 2021/2022	2022/2023
Weeding regime

ABSTRACT
This study evaluated the performance of green beans (Phaseolus vulgaris L.) as affected by fruit setting hormones and time of application in Minna, Suthern guinea savanna Nigeria. The treatments were three levels of fruit setting hormones (Control, Cytokinin and Beta Naphth Oxy-acetic Acid (BNOA)) and four periods of application (seed priming for 8 hours + application at vegetative and flowering stage, application at vegetative and flowering stage only, application at flowering stage only and application at two weeks interval throughout the experiment). These were factorially H combined to give twelve treatments combinations which were arranged in a randomized complete block design with three replicates. Data were collected on growth, flowering and yield parameters. Data collected were subjected to analysis of variance using General Linear Model procedure of Minitab software. Differences between the means were separated using least significant difference (LSD) at 5% level of probability. The results revealed that seeds primed with cytokinin were the fastest to emerge while those primed with BNOA did not emerge. Plants that received BNOA at 2 weeks interval and plants that received Cytokinin both at vegetative + flowering stage had the longest vine, fattest stem and largest leaf area. Plants that received BNOA were the earliest to approach 50% flowering (33 days) compared to other treatments (34-40 days). Plants that received Cytokinin at two weeks interval throughout the experiment had the longest pod, fattest pod, heaviest fresh and dry pod weights as well as the highest number of pods per plant. Application of cytokinin at 2 weeks interval throughout the growth stages of green beans can therefore be recommended to improve the productivity of the crop.
Keywords: *Fruit setting hormone, time of application, Cytokinin, Beta Naphth Oxy-Acetic Acid, green beans*

INTRODUCTION

Green Bean (*Phaseolus vulgaris* L.) is an annual vegetable of the legume family (Fabaceae). Fabaceae ranks second in economic importance after the Poaceae family (Husham and Ali, 2020). They serve as major source of protein, minerals and vitamins for many households in Nigeria. *Phaseolus*is a large genus of annual plants that can be grown in many different climates (Savita, 2020). China is the world largest producer of green beans (14 million metric tons), followed by Indonesia (1.4 million metric tons) and Turkey (0.6 million metric tons) (FAOSTAT, 2021b). It is an important vegetable crop in Nigeria, providing a significant source of nutrition and income for farmers. Nigeria produced apparently 178,550 metric tons of green beans in 2020 (FAOSTAT, 2021a). It is predominantly grown in Jos, plateau state and in Kaduna states (Rashida *et al.,* 2022).

Fruit setting hormones (FSHs) are synthetic hormones that are applied to enhance fruit setting and yield in crops. They are also known as plant growth regulators (PGRs). They play an essential role in the development and ripening of fruit. There are several types of hormones involved in fruit setting, including auxins, cytokinins, gibberellins, abscisic acid and ethylene. Auxins play a crucial role in the early stages of fruit development by controlling cell division and differentiation in the ovary (Huang *et al.,* 2020). Beta Naphth Oxy-Acetic Acid (BNOA) stimulates the growth of reproductive organs and promotes fruit development. Gibberellins are involved in the regulation of fruit size, shape, and quality (Pan *et al.,* 2020). Cytokinins are involved in the regulation of cell division and enlargement, and they play a critical role in determining fruit size and shape (Osorio *et al.,* 2020) .

Many crops experience sub-optimal yields and low fruit quality due to inadequate pollination, low fruit set and poor crop nutrition (De Silva *et al.,* 2022). Fruit yields can be constrained by the percentage of flowers that are pollinated and fertilized, the percentage of fruit that develop to maturity, and the mass of the fruit components that contribute to yield (Alcaraz & Hormaza, 2021). The final size of the remaining fruit that reach maturity can be affected by environmental conditions, crop nutrition and fruit paternity (De Silva *et al.,* 2022). Despite the potential of green beans, the average yield obtained by African farmers (1.48 tons/ha) is much lower than the potential yield (2.5-3 tons/ha) (Melkamu *et al.,* 2023). Low fruit setting have been identified as one of the major factor responsible for the poor yield in green beans (FAOSTAT, 2021a).

One approach to increase crop yield is the use of plant growth regulators such as fruit setting hormones (FSHs). Oloyede *et al.* (2021) investigated the effect of FSHs and planting dates on yield and yield components of two cowpea cultivars in southwest Nigeria. The author reported that application of FSHs at flowering stage significantly increased yield and yield components of the bean cultivars. Previous studies have suggested that fruit setting hormones such as gibberellins, auxins and cytokinins can enhance fruit set and yield in various crops like oil palm (Edison *et al.,* 2021), tomatoes (Satoshi, 2012; Yoshihito *et al.,* 2020), pear (Caixi *et al.,* 2008) etc. However, the effectiveness of these hormones may depend on the timing of their application. This study therefore aimed to evaluate the effect of FSHs at different time of application on the performance of green beans.

MATERIALS AND METHODS

The experiment was conducted at the Horticultural Nursery, Federal University of Technology, (9.^{0}46.8' N, 6^{0}57.9' E) Minna, Niger State in the southern Guinea savanna of Nigeria under rain fed condition. The climate of Minna is sub humid with mean annual rainfall of about 1284 mm and a dry season of about 5 months duration occurring from November to March. The mean maximum temperature (about 33.5 ^{o}C) remains high throughout the year (Adediran *et al.,* 2019)

The treatmentsconsisted of three levels of fruit setting hormones (control, Cytokinin (100ppm) and Beta Naphth Oxy-Acetic Acid (200ppm)) and four periods of application (seed priming for 8 hours + application at vegetative and flowering stage, application at vegetative and flowering stage only, application at flowering stage only and application at two weeks interval throughout the experiment). These were factorially combined to give twelve treatmentscombinations which were arranged in a randomized complete block design replicated three times.Net plot size was consisting2m x 2m (4m^{2}) consisting of three ridges, with 75 cm between rows. Inter and intra row spacing of 75cm x 40 cm was maintained by three seeds per hole which was later thinned to two plants per stand. Data were collected from five randomly tagged plants at six weeks after planting on vine length, stem diameter, leaf area, number of leaves, pod length, pod weight, pod diameter and number of pods/plant. Data collected were subjected to analysis of variance using General Linear Model procedure of Minitab software. Where significant interaction exists between hormone and time of application, tables of main effects are not presented. Differences between the means were separated using Duncan Multiple Range Test (DMRT) at 5% level of probability.

RESULTS

Vine length

The vine length was significantly affected ($P<0.01$) by hormone, time of application and interaction between the two (Table 1). Plants that received Cytokinin at vegetative + flowering stage had the longest vine (31.77 cm) and were at par with plants that received BNOA every two weeks throughout the experiment (32.26 cm) and plants that received cytokinin every two weeks throughout the experiment (29.87 cm). The shortest vine was recorded from plants that received Cytokinin at priming + vegetative + flowering stages (23.56 cm) similar to the control plants (24.35 cm) (Table 2)

Table 1: Mean square values for response of green beans to fruit setting hormone and time of application

Source of variation	Vine Length (cm)	Stem Diameter (mm)	Leaf Area (cm^2)	Number of Leaves	Number of Branches
Hormone (H)	120.37**	0.08**	92.87*	46.06**	31.74**

Means followed by similar alphabets are not significantly different at P = 0.05 using DMRT

Stem diameter

The stem diameter was significantly (P<0.01) affected by hormone, time of application and interaction between the two (Table 1). The fattest stem was obtained in plants that received cytokinin at vegetative + flowering stages (0.59 mm). The least value (0.50 mm) was obtained in plants the received BNOA only at flowering similar to the control plants (0.51 mm). (Table 3)

Table 3: Stem diameter (mm) of Green beans as affected by fruit setting hormone and time of application

Hormone	Priming+ Vegetative + Flowering	Vegetative + Flowering	Flowering	Every two weeks
Control (no hormone)	0.51cd	0.51cd	0.51cd	0.51cd
Cytokinin	0.54b	0.59a	0.54b	0.50cd
BNOA	0.00e	0.54b	0.50d	0.54b
SE±	0.009			

Means followed by similar alphabets are not significantly different at P = 0.05 using DMRT

Leaf area

The leaf area was significantly affected (P ≤ 0.01) by the hormone, time of application and interaction between the two (Table 1). The highest leaf area was recorded in plants that received Cytokinin at vegetative + flowering stages (84.57 cm^2) which was at par with values obtained in plants that received BNOA every two weeks throughout the experiment (84.09 cm^2), and those that received BNOA at vegetative + flowering stages (76.53 cm^2). The least leaf area value was obtained in plants that received BNOA at flowering alone similar to the control plants (Table 4).

Table 4: Leaf area (cm^2) of green beans as affected by fruit setting hormone and time of application

Hormone	Priming + Vegetative + Flowering	Vegetative + Flowering	Flowering	Every two weeks
Control (no hormone)	49.57de	49.57de	49.57de	49.57de
Cytokinin	59.86bc	84.57a	46.47e	50.23de
BNOA	0.00f	76.53a	58.28bcd	84.09a
SE±	2.99			

Means followed by similar alphabets are not significantly different at P = 0.05 using DMRT

Number of leaves

The number of leaves was significantly affected ($P \leq 0.01$) by the hormone, time of application and interaction between the two (Table 1). The interaction between hormone and time of application in respect of number of leaves is shown in Table 5. The highest number of leaves was recorded in plants that received BNOA at flowering stage only (20.87 leaves). This was statistically similar to the other treatments except those primed in the hormones and control plants which produced the least number of leaves (16.87) (Table 5).

Table 5: Number of leaves of green beans as affected by fruit setting hormone and time of application

Hormone	Priming + Vegetative + Flowering	Vegetative + Flowering	Flowering	Every two weeks
Control (no hormone)	16.87c	16.87c	16.87c	16.87c
Cytokinin	17.73bc	18.53abc	18.67abc	20.07ab

SME ±	0.42	0.002	60.69	4.28	3.40

*,**- significant at 5 and 1 percent respectively

Pod length

Highly significant difference ($P \leq 0.01$) exists between the hormone, time of application and interaction between the two in respect of pod length (Table 6). The longest pod was recorded in plants that received cytokinin at two weeks intervals throughout the experiment similar to other treatment combination except those primmed in the hormone which had the shortest pod similar to control plants (Table 7).

Table 7: Pod length (cm) of green beans as affected by fruit setting hormone and time of application

Hormone	Priming + Vegetative + Flowering	Vegetative + Flowering	Flowering	Every two weeks
Control (no hormone)	11.05bc	11.05bc	11.05bc	11.05bc
Cytokinin	10.91c	12.01ab	11.96abc	12.67a
BNOA	0.00d	12.07ab	12.13ab	12.21a
SE±	0.372			

Means followed by similar alphabets are not significantly different at P = 0.05 using DMRT

Pod diameter

The pod diameter was significantly (P<0.01) affected by response to hormone, time of application and interaction between the two (Table 6). Table 8 shows the interaction effect of hormone type and time of application on pod diameter. Plants whose seeds were primed in the hormone prior to sowing produced significantly slimmer pods than plants which received the hormones at vegetative, flowering and those who received at two weeks interval throughout the growth period (Table 8).

Table 8: Pod diameter (mm) of green beans as affected by fruit setting hormone and time of application

Hormone	Priming + vegetative + flowering	Vegetative + flowering	Flowering	Every two weeks
Control (no hormone)	0.77ab	0.77ab	0.77ab	0.77ab
Cytokinin	0.70b	0.82a	0.81a	0.83a
BNOA	0.00c	0.79a	0.84a	0.78a
SE±	0.027			

Means followed by similar alphabets are not significantly different at P = 0.05 using DMRT

Fresh pod weight

Highly significant difference (P ≤ 0.01) exists between the hormone, time of application and interaction between the two in respect of fresh pod weight (Table 6). The interaction effect of hormone and time of application on fresh pod weight is presented in Table 9. The result shows that plant that received Cytokinin at two weeks interval throughout the experiment had the heaviest pod (33.33 g). This was similar to the values obtained in plants that received cytokinin at vegetative + flowering stage (25.24 g), at flowering stage alone (21.76 g), and plants that received BNOA at two weeks interval throughout the growth period (20.30 g). The least pod weight was recorded in plants that received BNOA at flowering only (11.27 g) similar to the control plant (15.67 g) (Table 9).

Table 9: Fresh pod weight (g) of green beans as affected by fruit setting hormone and time of application

Hormone	Priming + vegetative + flowering	Vegetative + flowering	Flowering	Every two weeks
Control (no hormone)	15.67bcd	15.67bcd	15.67bcd	15.67bcd
Cytokinin	11.46de	25.24abc	21.76abcd	33.33a

Number of pods/plant

Highly significant difference (P ≤ 0.01) exists between the hormone, time of application and interaction between the two in respect of number of pod/plant (Table 6). The interaction between hormone and time of application in respect of number of pod per plant is presented in Table 10. The highest pods were recorded in plants that received Cytokinin at every two weeks throughout the experiment (8 pods/plant). This was at par with the number of pods recorded in other cytokinin treated plants except those whose seeds were primmed in the hormone prior to planting (3.40 pods/plant) and also similar to plants that received BNOA at two weeks interval throughout the experiment (5.83 pods/plant). The least pods/plant was recorded in plants that received BNOA at flowering stage only (2.87 pods/plant).

DISCUSSION

This study found that FSHs significantly affected the growth and yield of green beans. This is in agreement with the findings of Oloyede *et al.* (2021) who investigated the effect of FSHs and planting dates on yield and yield components of two cowpea cultivars in southwest Nigeria. The authors reported that the application of FSHs significantly increased the growth, number of pods and seeds per plant as well as the total seed yield of cowpea. The growth components (vine length, stem diameter, leaf area and number of leaves) were highest in plants that received Cytokinin at vegetative and flowering stages. This was followed by plants that received BNOA at vegetative and flowering stages had a higher growth component than the control (no hormone). Cytokinin increases cell division and enlargement. Osorio *et al.* (2020) similarly reported that cytokinins improved the development of tomato fruits resulting in larger fruits. Oloyede *et al.* (2021) reported that application of FSHs at flowering stage significantly increased yield and yield components of cowpea cultivars. Investigation on the effect of BNOA on the growth and yield of two cowpea cultivars in Nigeria by Adekiya *et al.,* (2020) Shows that the application of BNOA significantly increased the plant height, number of branches, number of pods and seeds yield of the cowpea cultivars. These studies suggest that the application of fruit setting hormone at the appropriate time can significantly improve the performance of bean production in Nigeria. BNOA stimulates the growth of reproductive organs and promotes fruit development. Furthermore, Debi (2022) reported that foliar application of growth regulators and chemicals at the flowering stage may improve the physiological efficiency and may play a significant role in raising the productivity of crop. Wamiq *et al*., (2020) studied the effect of GA3 and NAA on yield of bottle gourd (*Lagenaria siceraria*) (MGH-4) and reported that application of 40 ppm gibberellin at 2, 4 leaf stage was found most effective in terms of number of female flowers per vine, fruit per plant, fruit yield per plant, fruit yield per hectare.

The yield components were higher in plants that received Cytokinin at every two weeks throughout the experiment. Zhang *et al.* (2021) reported that the application of cytokinin increased fruit set and yield in cowpea, while also improving the quality of the fruit. This was followed by plants that received BNOA at every two weeks throughout the experiment which had a higher yield component than the control (no hormone). This was in line with the study of Manish *et al*., (2020) who concluded that foliar application of Ethrel at 300 ppm sprayed at different stages of growth i.e., at two true leaf stage, four true leaf stage and flower initiation stage was beneficial for higher seed yield and better growth of bottle gourd.

CONCLUSIONS AND RECOMMENDATION

The study revealed that hormones and time of application significantly influenced green beans growth and yield. Plants that received cytokinin at vegetative + flowering stages had the longest vine, fattest stem and largest leaf. Plants that received BNOA at flowering stage only had the highest number of leaves. Plants that received cytokinin at two weeks interval throughout the growth stageshad the longest pod, fattest pod, highest number of pods/plant as well as highest pod yield. Based on the result of this study, it is recommended that farmers should apply cytokinin at two weeks intervals for maximum pod yield.

ABSTRACT
School garden could be explored to develop attitude of students in horticulture to enhance diversification of the Nigerian economy. The study assessed the attitude of 100 senior secondary school students from two NIHORT adopted secondary schools within 5km radius of the Institute's headquarter office in Ibadan to school gardening activities. Data were collected using well-structured questionnaire and analyzed with descriptive statistics. Results revealed that most of the students were males (51.0%), aged 16-18 years (55.0%), 74.0% participated in home gardening activities with 55.0% having between 1-3 years of gardening experience. Fifty-five percent strongly agreed that school gardening activities should be made compulsory in secondary school curriculum while 49 percent strongly agreed that these activities help increase students' sense of ownership and responsibility. Forty-four percent strongly disagreed that getting involved in school gardening activities will have negative influence on their academic performance. Most of the students reported seasonality in agriculture (51.0%) and lack of organized regular tours to agricultural institutes (50.0%) as severe constraints to participating in school gardening activities. Thus, it is imperative that school gardening activities be made part of secondary school curriculum to initiate students' interest in horticulture and by extension agriculture as a career.

INTRODUCTION

A school garden is a powerful environmental education tool. School garden is an innovative teaching tool and strategy that lets students incorporate hands-on activities in a diversity of multidisciplinary, standards-based lessons. School gardens is an interesting and effective way to create engaging learning environment (Passy, 2012). Through gardening, students become responsible caretakers as they have an opportunity to engage in agricultural practices on a small scale, learning about the responsibilities and impacts of land cultivation. They explore the web of interactions among living and nonliving components of life. By doing so, they develop a greater understanding of the natural world. Students also learn the importance of caring for natural resources. The garden engages students by providing a dynamic environment in which to observe, discover, experiment, nurture, and learn. School gardens not only improve students' health but also add to the attractiveness of the educational spaces and encourage experimental learning (Utter et al., 2016).

NIHORT adopted secondary schools (Agricultural Research Outreach Centers) are an avenue through which the Institute reaches out to students by increasing their awareness of horticultural practices. These schools are meant to showcase horticultural technologies developed in NIHORT. This is in a bid to initiating their interest in horticulture as a career and means of livelihood. With this background the present study was conducted to assess the attitudes of secondary school students towards school gardening activities.

Objectives of the study

1. Describe the personal characteristics of the students in the study area
2. Ascertain the attitude of students on school gardening activities in the adopted schools

3. Identify the constraints faced by students participating in school gardening activities in the study area.

METHODOLOGY

The study area was NIHORT Adopted schools (Oba Abass Grammar School, Eleyele, and Anwar -Ul-Islam Grammar School, Eleyele), both within 5km radius of the headquarter office of the National Horticultural Research Institute, lbadan, Oyo state. Two-stage sampling technique was used to select respondents to arrive at the population of the students used for the study respondents for the study; the first stage involving a purposive selection of the two school from the adopted schools because the Institute through her extension programme had trained the students on school gardening activities. At the last stage, 50% of the students from Senior Secondary School 2 and 3 were randomly selected given a total of 100 students involved in the study. A well-structured questionnaire was used to elicit information from the students. Descriptive statistics such as frequencies and percentages were used to analyze the data collected.

RESULTS AND DISSCUSSION

Personal Characteristics of Students

The result in Table 1 shows that 51.0% of the students sampled were male. This could be associated with the prominent roles male children play in the society as they were powerful young teens full of strength and vigor. Hence, they will be able to carry out school gardening activities more. More than half (55.0%) of the students were within 16-18 years old, 90.0% of the students have home garden while 74.0% were participating in home gardening activities. More than half (55.0%) of the students have 1-3years gardening experience while 62.0% were involve in planting vegetables. Gardening offers students opportunities for outdoor exercise while teaching them useful life skills such as handling of tools, planting and post-planting care (Cairns, 2017). Eighty percent of the students got their knowledge from Agricultural teachers on school gardening activities while (97.0%) needs more training on school gardening activities.

Attitude of students on school gardening activities

As regard the attitude of students in school gardening activities, Table 2 shows that half of the students strongly agreed that school gardening activities should be made a compulsory part of secondary school curriculum, 49% also strongly agreed that the school gardening activities help increase their sense of ownership and responsibility while 48% reported that engaging in school gardening activities improve their social behaviour. Moreover, 53% agreed that school gardening activities help achieve group cohesion and improved interpersonal relationships among students and teachers. Studies have shown that students who are allowed to learn in an outdoor environment such as a garden have improved in environmental attitudes, positive work ethics, increased students' self-esteem, among others (Kallhoff and Schörgenhumer, 2017). On the other hand, 44% strongly disagreed that getting involved in school gardening activities will have negative influence on their academic performance. This implies that school garden is a perfect tool to provide hands-on learning experiences for any academic subject (Williams, 2018). Moreover, 39 percent of the students respectively strongly disagreed to the statements that say "I do not like gardening activities because it is a hard work" and "I do not like gardening activities because it is a dirty job".

Constraint faced by students participating in school gardening activities

The result in table 3 shows that most of the students opined that seasonality in agriculture (51.0%), regular tours to agricultural institute not organized (50.0%), and non-availability of nursery tools (47.0%), were severe constraints to their participation in school gardening activities. This implies that seasonality in agriculture could hinder students' participation in gardening activities due to the timing of the school calendar. Lack of regular tours to agricultural institutes and non-availability of nursery tools could be as a result of lack of planning on the part of the school administration.

CONCLUSION AND RECOMMENDATIONS

The secondary school students surveyed expressed overwhelmingly positive attitudes about school gardening activities, seeing benefits like increased responsibility, social skills, and group cohesion. The majority of respondents were male students in their late teens who had some previous gardening experience at home, indicating an engaged demographic eager to learn through hands-on gardening. However, several constraints were identified including seasonality of gardening, lack of agricultural institute tours, and insufficient tools, pointing to logistical limitations in implementing school gardening programs. Hence, the results highlight students' motivation and interest in gardening alongside barriers of resources and planning. Targeted support from school administrations, such as securing adequate gardening supplies and incorporating tours, could help optimize the impact of school gardening initiatives. With enthusiastic students ready to learn, addressing key logistical constraints can help school gardening activities flourish.

ABSTRACT
The use of residues from human consumption, farming and municipal waste will improve the physical and chemical properties of the soil, as well as add fertility to the soil and development. Due to their fertile soils, urban dump sites are frequently employed for agriculture, despite the dangers posed by poisonous heavy metals. Without considering the potential health risks that the heavy metal levels of such soil type may present, farmers use soil from dumpsites. To determine their fate, the concentrations of these heavy metals must be determined. The build-up of heavy metals in agricultural soils is a growing source of worry due to issues with food safety, potential health risks, and negative effects on the environment of the soil. This development required investigation into the relationship between the quality of the dumpsite-soil metal and the rate of plant bioaccumulation, as well as the impact of municipal and rural dumpsites on the levels of underlying soil metals. Using data collected, collation, and analysis, this study intends to investigate the ability of sweet corn to accumulate heavy metals and evaluate the bioaccumulation factor (BAF). The study was carried out in Delta State, Nigeria. The municipal solid waste dumpsite selected are the area with heavy domestic and industrial waste which were over-populated. With the aid of a soil Augar, soil samples were taken from the vicinity of the selected municipal solid waste dumpsites and farms in Delta State, Nigeria, at a depth of 0–60 cm. The statistical analysis of variance software SPSS 17 for Windows (SPSS Inc., USA) was used to evaluate the data gathered (ANOVA). The results of the soil samples' physicochemical analysis showed that the soils from municipal solid waste dumpsites were moderately acidic, had sizable amounts of organic matter, and contained some ionisable inorganic compounds. The study's findings also showed that plants grown on plots with amended dumpsite soils bio-accumulated had more metals than those grown on plots with typical agricultural soils. It was also noted that different plant parts of the same plant differed in their capacity to bio-accumulate these metals. However, the plant accumulated elevated concentrations of heavy metals in their shoot, when compared with other part of the plant. The findings of this study will be very helpful to academics and environmental regulators in developing nations.

INTRODUCTION
Urban areas with a high concentration of industrial activity produce more pollutants and are consequently at risk from the indiscriminate dumping of both domestic and industrial waste. Due to the high volume of waste produced as the population grows without adequate facilities in urban areas of Delta State, which is located in the center of Nigeria's oil-rich Niger Delta, open waste disposal practices have continued to be the only option for managing waste in our towns and cities. Almost all human activities produce garbage, and how this waste is handled, stored, collected, and disposed of can have negative effects on the environment and the general public's health (Zhu *et a*l., 2008). Earth is quite good at recycling waste, but when there are more wastes produced than the earth can handle, pollution results, posing a serious threat

to life. Recycling organic waste and nutrients that remain on farmland is a practical and desired idea. Because compost's organic matter content can offset the natural decline in intensively farmed soils, compost application to soil is utilized to preserve and enhance soil structure (Lillenberg *et al.,* 2010). The decomposition of these solid wastes releases chemicals that can alter the soil's natural balance of nutrients available for plant growth and development, increasing the concentration of heavy metals in the soil and reducing species diversity and agricultural outputs. Some waste products may contain non-essential elements, persistent organic compounds, and microbes that may be hazardous to plants in addition to the potentially useful nutrients found in waste materials (Chukwujindu *et al.,* 2005). According to Ayari et al. (2008), the presence of harmful heavy metals in municipal solid waste composts (MSWC) raises severe concerns about the unfavorable environmental impact of their excessive application to land used for agriculture. Both organic substances and geological sources, as well as human activities and anthropogenic sources, contribute heavy metals to soils.
Agricultural activities (fertilizers, sewage sludges, pesticides, and irrigation water; energy and fuel production), Mining and Smelting (tailing, smelting, refining, and transportation), Automobiles (combustion of petroleum fuels), Urban/industrial Complexes (incineration of wastes and waste products), and Natural Sources (soil parent material, volcanic eruptions, marine aerosols, and forest fires) are just a few of the According to Chukwujindu *et al.* (2005), high and excessive buildup of heavy metals in soil and other media may eventually poison the food chain for both humans and animals. Those metals with a specific gravity more than or equal to 5 g/cm are referred to be heavy metals. Copper, nickel, chromium, lead, cadmium, mercury, and iron are the most prevalent heavy metals. If present in low concentrations, certain heavy metals like iron and nickel are necessary for the survival of all forms of life (Leah et al., 2004). According to Awokunmi *et al.* (2010), exposure to heavy metals can result in neurological damage, lower mental capacity, renal damage, blood, bone, and bone diseases. Lowered energy levels, altered blood chemistry, harm to the liver, kidneys, lungs, and other crucial organs are all possible effects of heavy metal toxicity. Plants may absorb heavy metals from mobile ions in the soil solution through their roots or through foliar absorption when they are cultivated on soil that has been contaminated with home, industrial, or municipal trash. Plants' roots, stems, fruits, grains, and leaves bio-accumulate these absorbed metals (Fatoki, 2000). The capacity of plants to absorb metals and possibly other contaminants varies depending on the type of plant species and the type of metal contamination. Strong contaminant accumulates include cereals like Zea mays L (maize).

Sweetcorn (*Zea mays saccharata L.*) is becoming a popular horticultural product in Nigeria and it is highly demanded due to its sweeter taste when consumed. Sweet corn is a horticulture crop with the potential to help Nigeria achieve food security. In contrast to other corn varieties, sweet corn has a sweet flavor and a delicate, syrupy texture that makes it ideal for fresh consumption. The cultivation of sweet corn is commonplace worldwide. Sweet corn will have a maximum degree of market maturity when it has 5-6% sugar, 10-11% starch, 3% water soluble polysaccharides, 70% water, and reasonable quantities of protein, vitamin A, and potassium (Oktem & Oktem, 2005). Ajibola et al. (2020) argue that the production of sweet corn is extremely low because of the poor fertility of the soil and the inadequate application of an amendment at the required rate. Supplementing the soil with organic and inorganic fertilizer is one method of enhancing soil fertility and the quality and quantity of agricultural production (Pangaribuan & Hendarto, 2018). According to Nascimento and Xing (2006), sweetcorn has the capacity to continuously phytoextract metals from polluted soils by moving the metals from the roots to the shoots. The deposition of some heavy metals by the sweetcorn plant has even been demonstrated to exceed the thresholds for metal hyperaccumulation. Máthé-Gáspár and Anton (2005) categorized sweetcorn as an accumulator and a metal tolerant plant based on its capacity to absorb heavy metals and sensitivity to excessive metal pollution. The percentage of heavy metals that are easily mobilized in the soil environment and absorbed by plant roots is referred to as the bioavailable fraction. In general, absorption is higher in plants cultivated in places with more contaminated soil. Heavy metals' bioavailability to plants is influenced by a variety of physical and chemical substances in the soil. According to Peijnenburg and Jager (2003), these include soil characteristics such as pH, organic matter content, redox potential, cation exchange capacity (CEC), sulphate, carbonate, and hydroxide, soil texture, and clay concentration. The bioaccumulation factor (BAF) is used to assess the effectiveness of plants in accumulating and transporting metals, as well as to estimate the bioaccumulation influence of plants on the soil absorption of heavy metals. As a result, research on the transmission and accumulation of heavy metals from urban solid fluids in soil-plant systems has become crucial. The purpose of this study was to analyze the capacity of sweet corn to accumulate heavy metals and to determine the bioaccumulation factor (BAF) by gathering, compiling and analyzing data on the concentration of heavy metals in sweet corn.

MATERIALS AND METHODS

Study Area

The study was conducted at the Federal College of Education (Technical)'s demonstration farm in Asaba, Delta State, Nigeria. With a population of 4,098,291 (male: 2,674,306; female: 2,024,085), Delta State is one of Nigeria's oils and agriculturally productive states. It is situated in the South-South geopolitical area of the Niger Delta region. Asaba, the state's capital, is located at the northern end of the state and has a roughly 762 square kilometer (294 square mi) area. Ogwashi-Uku, the state's economic hub and most populous city, is located at the southern end of the state. Due to its tropical location, Delta State experiences a changing climate that ranges from tropical humid in the south to sub-humid in the northeast. An increasingly noticeable dry season follows the northward drop in humidity. The average annual rainfall in coastal regions is about 266.5mm, while in the far north, it is 1905mm. Three (3) senatorial districts—Delta central, Delta south, and Delta north—make up the state's legislative structure. Twenty-five local governments make up Delta State at the moment. The state's economy is mostly based on agriculture, with yams, cassava (manioc), rice produced by oil palm trees, and corn (maize) planted for consumption locally.

Soil Sample Collection

For this study, soil was randomly chosen from two (2) municipal solid waste dump sites spread over the Asaba Metapolitician Area of Delta state. Umuagu and cable point quarters in Asaba (Delta North Senatorial District) are the locations of the dumpsites. The dumpsites were selected taking into account the quantity and type of trash, the closeness to agricultural areas, and their age. Twenty (20) soil samples were obtained from the chosen dumpsites after the covering waste had been removed, with ten (10) samples from each dumpsite being necessary to adequately represent the area. at the Federal College of Education (Technical) Demonstration Farm in Asaba, Delta State (where there was no dumpsite or other human activity that could produce wastes) to serve as the control samples. With the help of a soil auger, soil samples were taken from each location at the soil profile (depths) of 0-15, 15-30, and 30-45 cm at a radius of 5 cm. Rocks and pebbles were removed before using a mortar and pestle to pulverize the surface soil samples, which had been air-dried. The crushed soil samples were run through a 2mm filter sieve to achieve uniform particle size. The sampling bags were stored within sanitized plastic containers to prevent contamination. The soil samples were scooped into air tight containers labelled according to the name of the area from which the samples were collected as well as the sampling point depth.

Laboratory Analysis

Twenty-five (25) different soil samples were taken to the lab for analysis. The locations, towns, and notations used to identify the soil samples are listed in table 1. Cd, Cu, Fe and Pb are the heavy metals that were examined in the soil and plants. Plant samples were collected from the field, rinsed under running water, and then split into parts including roots, stems, leaves, fruits, and shoots in order to remove clinging soils. The samples were dried in an oven for 48 hours (hr) at 80 degrees Celsius. The dried samples were crushed, sieved to 2 mm, and put into polyethylene bags for storage until further analysis using an agate mortar and pestle. The soil samples were mechanically ground and sieved to a size of 2 mm in diameter after being air-dried for two weeks at room temperature. Atomic absorption spectrophotometers (AAs VGB 210 System) were used to examine the soil and plant samples.

Table 1: Soil Sample Identification

Sample	Location	Town	Notation
1-10	Umuagu	Asaba	UAS1 – UAS10
11-20	Cable Point	Asaba	CAS11– CAS20
21-30	Control	Farm	CLF21-CLF30

*UAS – Umuagu Area in Asaba, CAS – Cable Point in Asaba, CLF – Control in the Farm

Experimental Design

The field experiment was carried out at the Federal College of Education (Technical) Demonstration Farm, Asaba, Delta State, Nigeria, where a 1296sqm (36m x 72m) land area (Uncultivated) was first disc-ploughed and then harrowed after a week of plowing. Using a plot size of 2.57 m x 5.14 m, growth patterns were arranged in an area of 1296 sq m for the various treatments in the experiment using a 5 x 2 factorial, randomized complete block design (RCRD), where five treatments were reproduced twice (2). Each plot was separated from the others by 1.0m to make it simple to identify them. At least 15 cm of topsoil from the experimental field was removed, and the soil from the municipal solid waste dumpsite was physically mixed in thoroughly at regular intervals. The soil was plowed deeper than the typical high soil depth in order to cover the complete rooting depth of sweet maize in the field while maintaining the soil's strength from the waste dumpsite (Nigussie et al., 2012). Three sweet corn seeds were inserted into each hole at a depth of 3 to 4 cm. Due to the seed's rate of germination, the sweet corn was trimmed to one plant per hole after it had grown for 15 days.

Determination of Bioaccumulation Factor of Heavy Metals

The Bioaccumulation factor (BAF) is the ratio of heavy metal concentrations in plants and soils. It's a measure of a plant's ability to absorb heavy metals (Borga, 2008). The BAF was calculated (Wang *et al*., 2017):

$$BAF_I = \frac{P_I}{S_I}$$

where, Pi is the concentration of a heavy metal in plants (mg/kg−1);
Si is the concentration of the same heavy metal in the soil where the plant grows (mg/kg−1).

Statistical Analysis

All statistical analyses were carried out using SPSS 17 for Windows (SPSS Inc., USA). One- way (ANOVA) was used to compare the difference of means from various sampling. Pearson's correlation coefficients of heavy metal elements in dumpsite soil and sweet corn. Comparison of sweet corn yield and heavy metal contents in sweet corn between the dumpsites were subjected to analysis of variance (ANOVA) using the SPSS version 10 with randomized complete block analysis. Correlation/regression analyses were carried using SPSS to determine the relationship between soil chemical properties, sweet corn yield and heavy metal contents in sweetcorn grain. The level of significance was set at $P > 0.05$ (two-tailed). In order to quantify the relative differences in bioavailability of metals to plants or to identify the efficiency of a plant species to accumulate a given heavy metal.

RESULTS AND DISCUSSION

Accumulation of Heavy Metals in the Soil

This study has attempted to identify the concentrations of heavy metals in the various soil samples since it is crucial for healthy crop development to assess the concentration levels of harmful components in dumpsite soils. The study takes into account both essential/non-essential heavy metals that are hazardous to plants when present in soil at concentrations beyond the tolerance limit, such cadmium and lead, as well as micronutrient metals like copper and iron as shown in table 1. The results indicated that the mean copper (Cu) concentrations in the dumpsite and farm soil samples ranged from 0.91 mg/kg to 4.98 mg/kg, with the lowest values at the CLF and the highest values at the CAS. The fact that Cu does not travel very far after being released, its speciation, and other geochemical properties in soil may be responsible for the high concentration of Cu in soils (Ezeh & Chukwu, 2011). This is because organic matter, in particular, binds copper so tightly that its availability in organic soils can be very low (Osakwe *et al.,* 2012). The low amount of Cu found in CLF soil, however, may be a result of its mobility in weathering environments and capacity to adsorb onto the surfaces of soil elements through ion exchange processes (Wuana & Okieiman, 2011). The concentration of copper exceeded the allowable limit in every dumpsite. This could be caused by the careless disposal of waste containing copper at the dump sites. According to Awokunmi et al. (2010), a biodegradable waste released metallic copper into soil at a level just a little beyond the levels found naturally in soils. Regardless of depth, it was discovered that the mean Pb concentration in the dumpsite was higher than that in the farmlands. The CLF had the lowest lead levels while the UAS dumpsite had the highest. This concentration was greater than the permitted level of 1 mg/kg established by SPCR (2001). The presence of hospital wastes, non-biodegradable metallic, and automobile and other non-food wastes throughout the dumpsites may be the cause of the elevated levels of Pb discovered in samples taken from the area. In comparison to other studies, lead levels were also high in this study (Akintan *et al.,* 2019). This shows a potential for the environmental metal (Pb) to bio accumulate in plant roots, stems, fruits, and leaves, rendering them unfit for consumption because doing so would expose people to the associated health risks if they ate them (Opaluwa *et al.,* 2012). There was significant difference between the concentrations of lead in soil in all locations on each dumpsite ($p < 0.05$).

Table 2: Mean Concentration of Heavy Metals in the Soil Samples at Different Depth

Sampl	Depth	Cu(mg/k	Pb(mg/k	Fe(mg/kg)	Cd(mg/k
UAS	0 – 15	2.89	12.75	9.92	4.80
	15 –30	2.31	11.75	8.93	3.30
	30 -45	1.87	11.35	8.19	2.90
CAS	0 – 15	4.98	10.67	8.68	5.00
	15 –30	4.18	10.20	8.46	4.50
	30 -45	2.78	7.60	7.32	4.40
CLF	0 – 15	1.11	3.60	6.00	3.15
	15 –30	0.98	2.31	4.31	2.10
	30 -45	0.91	0.81	3.21	1.08

The mean iron (Fe) concentration at the dumpsites under investigation in this study ranges from 7.32 to 9.92 mg/kg, while it is 3.60 mg/kg at the control site. Fe levels are greater in the waste dumpsite soil than in the control soil. The type of garbage put there may have contributed to the waste dump's high Fe concentration. The soil surrounding such waste dumpsites will unquestionably contain more Fe than control soil if the waste dump contains more metal scraps from mechanic workshops and welder's workshops than household wastes, which will have more spoilt food, wood from broken furniture, ashes, broken glasses, and plastics, etc. The UAS dumpsite has the greatest iron concentrations. This quantity of Fe, which was obtained from soil samples for this investigation, is still within the range of the 150 mg/kg criteria established by the WHO and FAO (2016). It's possible that the elevated iron levels found in all soil samples are not due to waste. According to reports, natural soils include significant concentrations of iron, indicating that other natural sources of iron must also be taken into account for the ecosystem to be fully protected from iron contamination that comes from waste items (Osakwe & Okolie, 2015). In addition, it has previously been claimed that iron is the element that is most prevalent in Nigerian soil (Amusan et al, 2005).

There was no significant difference between the concentration of iron at all the dumpsites ($p < 0.05$) but concentration of iron varies significantly at $p < 0.05$ in the control site. the average cadmium (Cd) content in the dumpsites ranged from 2.90 to 5.0 mg/kg, which was greater than the concentration in the control site (farmland). The CAS dumpsite soil contains a mean concentration of Cd of 5.0 mg/kg, whereas the control site's mean concentration is 1.08 mg/kg, demonstrating a greater concentration of Cd in the dumpsite. This investigation agrees with the findings of Akintan *et al.* (2019), who found higher levels of cadmium in the study area and explain possible routes of this metal into soil, including batteries, plating, pigments, and plastics from household wastes as well as the application of phosphates in agricultural areas. This finding of a higher Cd concentration is in agreement with works of Ndana *et al*. (2010), who looked at the presence of heavy metals in the soils of auto repair shops and waste disposal sites in different areas of Makurdi, Central Nigeria. The amounts of heavy metals in the soils taken from the dumpsite compared to the control site in this study varied significantly ($P < 0.05$). This is consistent with Adelekan and Alawode (2011) findings that the levels of metals in dumpsites were higher than the levels at the control site (farm land), which showed that the solid waste deposited at the site contained a high number of substances containing heavy metals.

Heavy Metals Concentration in Plant tissue from Amended Plots

This study was limited to the concentration of heavy metals in the tissues of sweet corn, such as the roots, stems, and leaves, fruit, and shoots, to make it easier to evaluate the metal transfer ratio from the soil to the plants as described in fig. 1. Crops' growth media, which the roots absorb from, are the principal suppliers of heavy metals for the crops. When compared to other parts of the plant, the results showed that heavy metals were predominantly accumulated in the plant's shoot. Pb concentrations ranged from 0.58 to 4.67 mg/kg while Fe concentrations ranged from 1.01 to 3.88 mg/kg in the plants shoot. In addition to essential nutrients, harmful metals are predominantly absorbed by plants through their root systems.

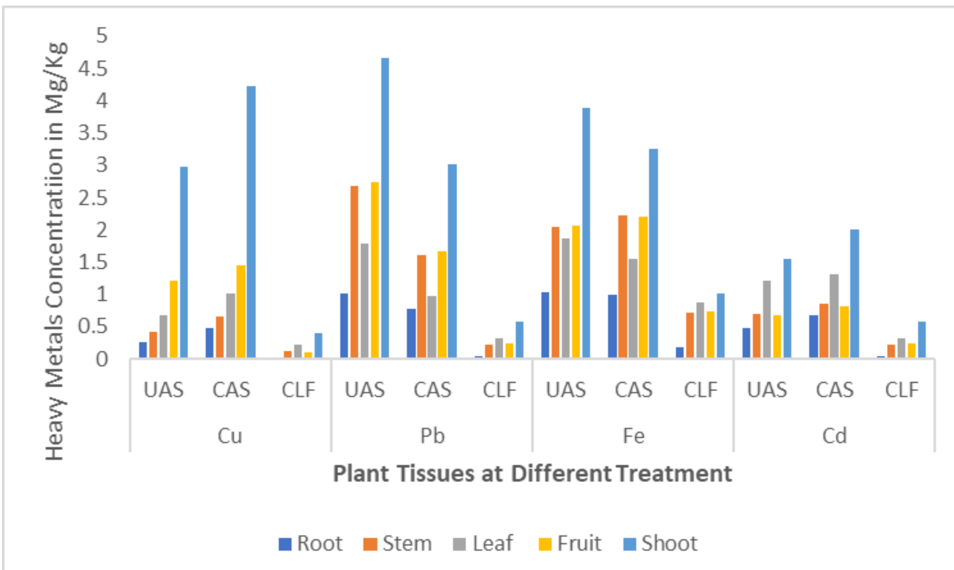

Figure 1: Mean Concentration of Heavy Metals (mg/kg) in the Tissue of Sweet Corn

When compared to other dumpsites, the plant from the plot treated with soil from the UAS dumpsite has the highest concentration of heavy metals; this could be because the garbage at the dumpsite has a relatively higher organic matter content. The findings of Awokunmi *et al.* (2015), who show high heavy metals accumulating ability for maize planted on the dumpsite soils in south western Nigeria, are compatible with the findings of this study. The findings revealed a significant difference ($P < 0.05$) in the content of heavy metals in plant tissues grown on plots treated with soil from dumpsites. Compared to plant tissues from the control site, plant tissues collected from plots treated with soil from dumpsites had greater quantities of heavy metals (Amusan *et al.,* 2005). This might be explained by the high levels of heavy metals in dumpsite soil that eventually get accumulated by the plants that grow there. The heavy metal concentrations in plants depend on the concentrations of the same metals in the soil where they normally occur, according to research by Udosen *et al.* (2006). The results are also consistent with those of Awokunmi *et al.* (2012) and Sun *et al.* (2009), who found that while maize's accumulating traits or efficacy have recently been used in environmental restoration, peasant farmers are discouraged from growing the plant on dump sites for consumption because heavy metals may eventually enter the food chain. Due to the effectiveness of their detoxification mechanisms, plants may become tolerant to naturally occurring heavy metals. It is well known that grains like maize and sweet corn are effective contaminant accumulators (Afolayan, 2018). Metal content and chemical forms in soil affect how much heavy metal is absorbed and accumulated in plant tissue (Shen *et al.,* 2000). Organic matter, soil pH, plant roots, and other soil conditions are factors in the bioaccumulation of metals.

Uptake of Heavy Metals by Sweet Corn Cultivated with Different Treatment

The results of the heavy metal content in sweet corn grown under different conditions are shown in Fig. 2. It was found that the plant bio-accumulated the metals in the following order: Pb > Fe > Cd > Cu, which may be an indication of the metal concentrations in the soil. The FAO/WHO (2001) recommended limit and measured quantities of heavy metals in sweet corn were compared to determine the extent of food contamination. The sweet corn grown on a plot with UAS dumpsite soil had the highest concentration of Pb (9.27 mg/kg), followed by the UAS dumpsite soil with highest concentration of Fe (7.09 mg/kg) and the CLF treatment (with the lowest concentration of Cu (0.67mg/kg). Mining, pesticides, production, the chemical industry, and metal pipes in the dumpsite soil that was utilized to grow the sweet corn could be the main causes of Cu contamination in the maize. However, CAS has a high Cu content since it is a region that is extremely close to industrialization. Its overdose in the human body could harm the kidneys and irritate the stomach and intestines if it is ingested or breathed (Malomo *et al.,* 2013). Malomo *et al.* (2013) found that although Cu is not poisonous to people, it is toxic to plants. As a result, some nations have placed limits on the amount of copper that can be found in soil. This is especially important since a larger concentration of these substances prevents the growth of plants, lowers land productivity, and restricts access to food. Comparing the Pb accumulation of sweet corn in this study to similar research by Malomo *et al*. (2012) and it was high. Lead is a well-known metal that harms a man's liver, kidneys, brain, central nervous system, and reproductive system and has no known necessary human function. Paint, pesticides, smoking, vehicular emissions, mining, and coal combustion are the main contributors of lead pollution. In general, Fe concentrations was high in all the treatment plots, which may be related to its capacity to transport oxygen for the synthesis of protein and the creation of chlorophyll (Kashif *et al.,* 2009). Except for the sweet corn produced on CLF treatment, the heavy metal accumulation by the plot treated with dumpsite soil in this study is significantly higher than the advised limit. According to Amusan *et al.* (2005), sweet corn cultivated in heavy metals-contaminated soils had higher amounts of heavy metals than sweet corn grown in soils without contamination.

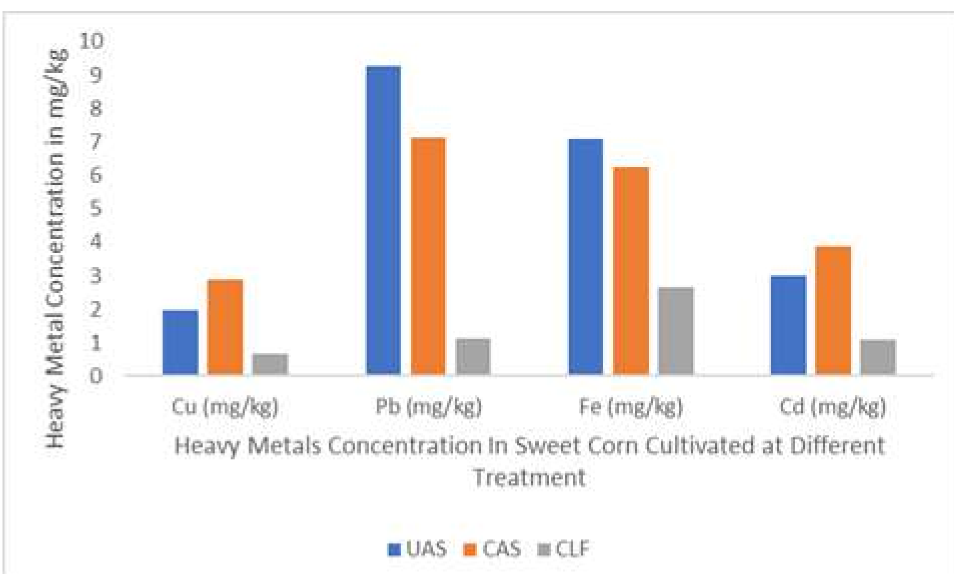

Figure 2: Mean Concentration of Heavy Metals in the Sweet Corn at Different Treatment

Plant species, particular metal concentrations, chemical forms, soil chemistry, and pH all show how hazardous metals are to plants (Malamo *et al.,* 2013). The findings of this study were consistent with those of Singh and Bhati (2005) and Aghabarati *et al.* (2004), who found that plants at the plot treated with dumpsite soils had much higher concentrations of these heavy metals than plants at the control site. Furthermore, in this study, a variety of soil variables, including pH and organic matter, combined to affect how well plants absorbed heavy metals. Heavy metals are known to be more easily mobilized in soil that is more acidic, which increases their absorption.

Bioaccumulation Factor of Heavy Metals into Sweetcorn

The ratio of the overall metal concentration in the soil environment to the level of metal in the plant parts is known as the bioaccumulation factor (BAF). Pb> Cu> Cd> Fe > were the reported trends for BAF in sweet corn as illustrated in fig. 3. This soil-to-plant factor is one of the most important elements of how humans are exposed to metals through the food chain. The values show the amounts of metals in the edible sections of the sweet corn as a percentage of the total metal concentration in the soil. These findings suggest that sweet corn has a higher potential for Pb accumulation than Zn accumulation. Despite the possibility that environmental parameters including pH, ECEC and binding capabilities contributed to the slow transfer rates between the soil and the sweet corn (Udosen *et al.,* 2006). High BAF values have been described as indicators or symptoms of soil heavy metal levels that are relatively high in reactivity, liability, and biological availability. In accordance with the findings of Oluyemi *et al*. (2008), the difference in the variation in values obtained for these heavy metals in the soil and crop plant samples at the plot treated with dumpsite compost as compared to the values obtained in the control site is an indication of their mobility from the dumpsites to the farmlands.

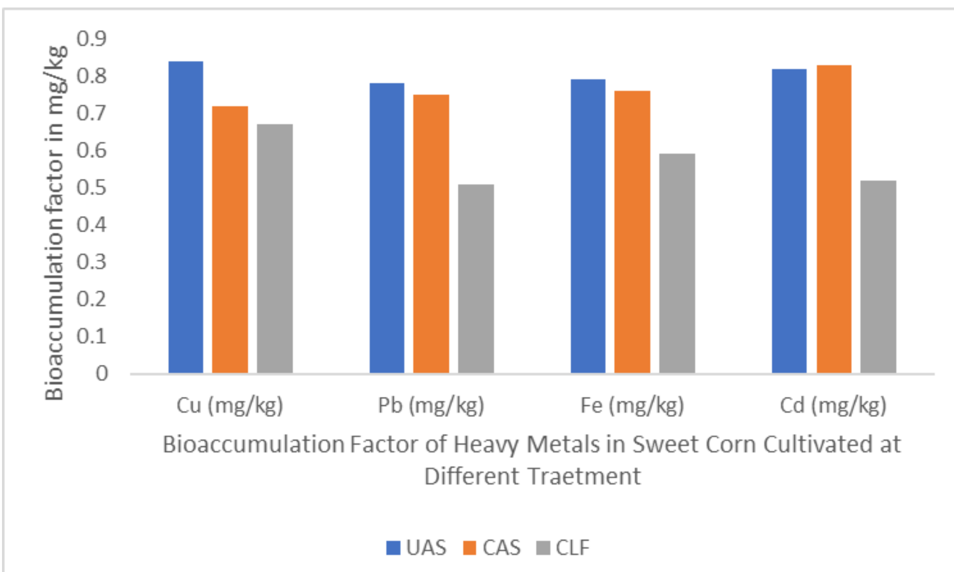

Figure 3: Bioaccumulation factor of Heavy Metals in the Sweet Corn at Different Treatment

The control site (CLF) had the lowest BAF values, ranging from 0.67 mg/kg for copper, 0.51 mg/kg for lead, 0.59 mg/kg for iron, and 0.52 mg/kg for cadmium. It was initiated that the bioaccumulation factors for the heavy metal in the plot treated with dumpsites were considerably different from those for control sites. The BAF found in this study gives an indicator of the likelihood that heavy metal present in the dumpsite soil may enter the food chain if an animal or a human consumes an edible plant of the sweet corn. Varied heavy metal concentrations in the soil and different plant absorption of different elements may be the cause of variation in the bio concentration factor among different roots and leaves of plants (Zheng et al., 2007). The discovery of trace metals in plant tissues and samples were not unexpected as plants are known to absorb and store trace metals from contaminated soil. Consuming plants with high levels of heavy metals on a regular basis could result in accumulation and have negative health effects, especially for Pb and Cd (Opabunmi, & Umar, 2003).

CONCLUSION

The study utilized sweet corn (Zea mays L. saccharum) cultivated on soil from a municipal solid waste dumpsite and a control site in Delta State, Nigeria. The study found that the soils from the dumpsites and control site contained heavy metals (Cu, Pb, Cd and Fe). Additionally, it was also found that some dumpsites had larger concentrations of these metals than others; this may be influenced by the geological formation of the locations and the presence of waste containing more of these heavy metals. The sequence of the heavy metal concentrations in the study's soil was Pb > Fe > Cd > Cu. The mobility of heavy metals (Cu, Pb, Cd, and Fe) from soil to plant tissues suggests that all of these elements were mobile from soil to plant components. It was discovered that sweet corn plant's shoots in all farm sites accumulated heavy metals the most. It was also discovered that the plant bio-accumulated the metals in the following order: Pb > Fe >Cd > Cu, which may be an indication of the metal concentrations in the soil. Lead (Pb) had the highest concentration in the plant sample, while copper (Cu) had a lesser concentration. They were all found in sweet corn grown on soils taken from dump sites. The bioaccumulation factor (BAF) of the metals revealed considerable Cd, Cu, and Pb accumulation in the sweet corn grown in soil from dumpsites. High soil heavy metal levels with high levels of reactivity, lability, and biological availability have been associated with high BAF values as indications or symptoms. On the basis of this, it was believed that eating sweet corn produced on soil derived from such dumpsites would be harmful to human health. Results of this study showed that plants cultivated on dumpsite soils acquire more toxic metals than plants grown on typical agricultural soils.

ABSTRACT

No plant is useless, it is just that their uses are not yet known. Knowledge on the use of medicinal plants is under threat in our society. Only few people value the plant species around them due to inadequate knowledge of their usefulness. So many tropical plants are grossly underutilized medicinally due to lack of adequate medicinal information on their uses. Indigenous knowledge is an understanding, skill and philosophy developed by societies with long histories of interaction with the natural and cultural environment within local level of decision making. For the nation to exploit and maximize the huge therapeutic, wealth and economic potentials of the rich biodiversity, its uses must be known and sustained. Hence, there is need for sustaining the indigenous knowledge through conservative efforts for the endangered species and proper documentation of their potentials to salvage the natural heritage "Medicinal Plants" from going into extinction.

Keywords: *Indigenous Knowledge, Medicinal Plants, Documentation, Sustainability*

INTRODUCTION

Herbal remedy otherwise known as ethno-medicine is a vital form of traditional medicine. Dependence on herbal medicine among the teaming populace is especially predominant in areas where orthodox medicine is often unavailable or simply too expensive in modern time (Odugbemi, 2008). In many areas, knowledge of the plant species used and method of preparing and administering the medication resides mostly with traditional healers and other knowledgeable members of the society (Odugbemi, 2008 and Sofowora, 2006). This knowledge is generally transmitted or passed from one generation to another orally through community, family and individual until implemented. It does not require formal education or specialized training in a field of study before it could be transmitted. During the early years of human existence, many plants by instinct, intuitions or trials by error were used to combat ailments. As ideas of difference tribes, communities, and culture developed, the use of various plants became wide spread in accordance with their belief (Odugbemi, 2008 and Sofowora, 2006). Unfortunately, there is decreasing number of herbalists or knowledgeable members of the society on the use of herbs for treatment of aliments with transfer of indigenous knowledge. This review paper is therefore necessitated by the need to sustain the indigenous knowledge on the use of medicinal plants with their potencies for the curing of diseases or sicknesses in the south-western region of Nigeria.

Meaning of Medicinal Plant and Herbal Medicine

A medicinal plant is any plant in which one or more of its tissues contain substances that can be used for therapeutic purposes or which are precursors for the synthesis of useful drugs (Oyebola 2010). Herbal medicines generally include all botanical medicines in form of decoction, infusion, maceration and tinctures (Falade, 2021). Herbal medicine is the most ancient method of curing disease and it has been said that botanical medicines are the very first and only true natural medicines ever used (Soladoye *et al,* 2010). The use of medicinal plants as remedies of certain illnesses is not only common practice but fundamental to health care regime of millions of people all over the world. In Asia and Africa, over 80% of the populace relied on traditional medicine for primary healthcare needs (Samuel *et al.,* 2018).

However, people used different combinations of plants to treat different types of ailments which vary from one community to another and in different ecosystems (Etukudo, 2000). Consequently, virtually all plant species found in natural ecosystems are of great values to man for medicine. According to Oyebola (2010), all plants are medicinal and for every health disorder, there is always a plant.

Origin and Evolution of Medicinal Plants

The origin of medicinal plants is supported by the Holy Books. For instance, the Holy Bible offers description of approximately 30 healing plants. In Ezekiel 47:12 "*And by the river upon the bank thereof, on this side and on that side shall grow all trees meal, whose leaf shall not fade, neither shall the fruits therefore be consumed: it shall bring forth new fruits according to his months, because their water they issued out of the sanctuary: and the fruits therefore shall be for meal and the leaves for medicines"* From the text quoted from the Holy Bible, it could be seen that God ordained the use of plants for medicine (Odugbemi, 2008). It is estimated that there are 1.5 million species of plants on earth (Cowan, 1999), a greater percentage of which are used for medicinal purposes as only 1-10% is used as foods by animals. This was established by Osai (1998) that medicinal plants used in the treatment and curing of sickness and diseases have been in existence for well over fifty centuries which until the last two and a half centuries was the main source of treatment to man and his domestic animals.

History of Medicinal Plants in South-Western Nigeria

According to legend, the first man to practice the art of healing through the use of herbal medicine in Yoruba speaking part of Nigeria was Orumila who was endowed with the knowledge from God (Oladumoye, 2018). Orumila had a younger brother Osanyin who gained the knowledge of medicinal herbal practice by assisting his brother to compound the medicines. The intertribal wars caused the separation of the two brothers which led to the rapid spreading of this knowledge among the Yoruba people and beyond (Oladumoye, 2018). A record of medicinal plant practices in earliest period in Nigeria was virtually not available because there was no record for their isolation, selection and preparation (Sofowora, 2006 and Oladumoye, 2018). Knowledge about potent herbs was passed orally from generation to generation. Early men could have gained some knowledge by washing the effect produced by various plants when consumed by domestic animals. In Nigeria, hunters have been reported as the original custodian of some effective traditional herbal recipes. Traditional practitioners also claimed that when in trance, it is possible to be taught the properties and futures of plants by the spirit of an ancestor who practices herbalism (Sofowora, 2006 and Oladumoye, 2018).

It was also believed that incantation enhances the efficacy of herbal medicines. Incantations are expressions of words delivered orally in poetic form apparently to conjure up forces into medicinal plants either during collection or usage. For instance: *Ohun ti a ba wi fun ogbo logbo ngbo, eyi ti aba wi fun ogba logbangba. Eyi timo ba wi fun iwo ewe yiloni ni ki o se o.* Meaning that the herb should do exactly what is requested to do. Some traditional preparatives can only be effective when an incantation is recited due to its evocative power (Oladumoye, 2018).

Values of Medicinal plants

The values of medicinal plants are the reasons for its uses. According to Oluwalana *et al,* (2008 and Falade, 2021), the use of medicinal plants has always been part of human action as some plant poses therapeutic properties which can and have been utilized in the treatment of human and some animal diseases. Our fore-fathers depended on plants for treatment of various diseases before the introduction of orthodox medicine. The increasing interest in herbal medicine using for the treatment of various diseases steered people to collection of medicinal plant materials from the forest (Oluwalana *et al,* 2008). Man can hardly do without medicinal plants for survival. Medicinal plants species are useful for curing human disease because of the presence of phytochemical compounds (Wadood *et al,* 2013). They are cheap and available especially in the rural area. Hence, herbal collectors have gainfully employed in the rural areas. WHO (2001) stated that, 80% of the world population or roughly two thirds of the world's population rely almost exclusively on herbal medicines mostly derived from wild plants for the treatment of diseases. However, according to Falade (2021) many of these medicinal plants are eaten as fruits, nuts and vegetable leaves in the course of treating or preventing sicknesses as shown in Table 1.

Table 1: The Table Showing some Medicinal Plants and the Ailments Cured in South-West, Nigeria.

Local Name	Common Name	Scientific Name	Family Name	Flora Type	Part collected	Mode of Preparation	Ailment/Disease cured
Ahon Ekun	Leopard's tongue	*Acanthus montanus*	Acanthaceae	Herb	Leave	Paste, Pounded, grinded	Poultices on boil, Fever, Rheumatism
Peregun	Peregun	*Dracaena arborea*	Agavaceae	Tree	Root	Decoction	Abdominal pain, Blood glucose
Iyeye	Hog plum	*Spondia mombin*	Anacardiaceae	Tree	Leave, Bark,fruits	Decoction	Ghonorrhea, cough, toothache
Ajekobale	Hushveld	*Croton gratissimus*	Euphorbiaceae	Shrub	Leave, Bark	Leave decoction	Anti-hypertension, Fever,Convulsion
Orogbo	Bitter Cola	*Garcinia kola*	Apiaceae	Tree	Seed, Bark	Chewing	Liver disorder, Diarrhoea, Chest cold, cough
Ahun	Stool wood	*Alstonia boonei*	Apocynaceae	Tree	Bark, Leaves	Bark decoction	Malaria, Asthma, dysentery, ulcer
Asofeyeje	African snakeroot	*Rauwolfia vomitoria*	Apocynaceae	Shrub	Leave and Root	Powdered root, leave decoction	Diarrhea, Snakebite, skin diseases,
Ogbo	Ogbo	*Parquetina nigrescens*	Periplocaceae	Climber	Leave	Infusion, Decoction	anaemia, wounds, burns hypotension
Ewe atura	Black benniseed	*Sesamum radiatum*	Pedaliaceae	Herb	Leave	Infusion, Decoction	Catarrh, Facilitatechildbirth

Source: Falade, 2021.

Plant materials such as barks, roots and leaves contain different active ingredients, which are extracted for medicinal purposes. Some of the methods of extraction include decoction, infusion, maceration and tinctures (Adebisi, 1999 and Falade, 2021). Most conventional drugs have their origins from plants or modeled compounds derived from plants with some modifications (Etukudo, 2000). Chemical compounds of plants like alkaloids, tanins, saponins, glycosides, anthraquinones etc are the basis for their therapeutic (Oladumoye, 2018 and Samuel *et al.,* 2018).

Need for Sustaining Indigenous Knowledge on the Use of Medicinal Plants

Indigenous knowledge on the use of medicinal plants is under threat. Though, medicinal plants have been observed to be very effective in the treatment of ailments in both rural and urban areas in developing countries, but only few people value the plant species around them due to inadequate knowledge of their usefulness (Etukudo, 2000 and Falade, 2021). Some tropical plants are grossly underutilized medicinally due to lack of adequate medicinal information on their various uses (Borokini *et al,*. 2013). Therefore, there is need to carry out research on the use of medicinal plants with a view to do proper documentations of the their various medicinal uses so as to prevent the loss of the indigenous knowledge with succeeding generations and also create awareness and enhance appropriate utilization.

Ways of Sustaining Indigenous Knowledge on the Use of Medicinal Plants

In other to improve health care of both the rural and urban people, there is need to discover and document plants of high medicinal value that could serve as alternative to modern medicines. To sustain the indigenous knowledge of ethno-medicines in south-western Nigeria, it is suggested that government should put in place policy frame work that will promote ethno-therapy among the general populace as alternative to orthodox medicine in Nigeria despite the availability of orthodox medicine. Concerted efforts should be made by botanists and other plant scientists to appropriately identify the medicinal plant species. This includes their local names, scientific names, medicinal uses, parts used, mode of preparation and chemical properties for proper record and documentation. The document will form part of the comprehensive inventory for medicinal plants in Nigeria towards promotion of traditional medicine for national economic growth and sustainable developments.

CONCLUSION AND RECOMMENDATION

According to the adage that says "Any festival not celebrated before children will soon go into extinction"; the extinction and genetic loss of some medicinal plants in this region is due to the lack of detailed information in this regard. Furthermore, cultivation of identified commonly used but endangered medicinal plant species is recommended. It can be done through on-farming system or the establishment of botanical gardens by both individual and group of people including government to save our precious medicinal plants and its indigenous knowledge from going into extinction.

ABSTRACT

Fresh market tomato is a very important horticultural cash crop in Nigeria. Production has increased over the past few years based on land area under cultivation with minimal improvement in fruit yield and other associated yield related traits. In this study, eight advanced (F_6) tomato breeding lines were evaluated with three check varieties under open field rainfed conditions at NIHORT, Ibadan Nigeria for yield and yield associated traits. The study identified promising high yielding tomato entries suitable for high humid (rainy season) tomato production in Nigeria. Tomato accession NHTO10-2 had the highest fruit yield (6119.52g), while NHTO105-1 was the earliest (57 days). The high significant positive association between yield and number of fruits shows the feasibility of indirect selection in favour of tomato lines with high yield potential.

Keywords: *Agronomic, Breeding lines, Tomato, Variability, Yield.*

INTRODUCTION

Tomatoes (*Solanum lycopersicum* L.) is one of the most important vegetables commercially produced in Nigeria and also harvested in home gardens (unpublished data). It is mostly produced during the late seasons in the northern states of Nigeria with minimal production from the southern states. Tomato contains minerals, vitamins, polyphenol, and lycopene which have health benefits for humans (Islam *et al*., 2022). Tomato yield in Nigeria is below world averages resulting from use of unimproved local cultivars with poor fruit quality (Agele *et al*., 2002; Oladitan and Akinseye, 2014). Ironically, most of the improved imported tomato varieties with desired fruit qualities exhibit poor adaptation to the diverse tomato growing environments in the country. Furthermore, these imported tomato varieties (mostly hybrids) are not only exorbitant but are not readily available and accessible to the poor resourced tomato farmers that are mostly domicile in the rural communities.

To mitigate these challenges and ensure increased productivity and availability of tomato varieties with desired fruit quality and adaptation, it is paramount to develop high yield, adapted superior varieties mainly for open filed rainfed production that is prevalent among farmers in Nigeria. Planning and execution of a breeding program for improvement of quantitative attributes such as yield depends to a great extent upon the magnitude of genetic variability and the extent to which desirable characters are associated in a breeding population (Islam *et al*., 2022). Limited access to the best-adapted tomato varieties to the local conditions, pests and diseases are the major limiting factors for improving productivity. This study presents the preliminary yield evaluation of new promising advanced tomato breeding lines under open field rainfed cultivation in south west Nigeria.

MATERIALS AND METHODS

The trial was carried out at the National Horticultural Research Institute (NIHORT), Ibadan, Nigeria, located in the humid forest savannah transition zone (210 masl, 7°30′N, 3°54′E). Experimental materials comprised of eight (8) new tomato breeding lines (F_6) developed by crossing selected parents comprising of popular tomato landraces/cultivars in Nigeria and exotic advanced breeding lines from AVRDC. These landraces (parents) were collections from farmers' field across different tomato growing regions in Nigeria and had undergone over 4 generations of selfing and selections. They are maintained in the Institute's tomato genetic improvement programme.

For the field experiment, seeds were sown in perforated plastic trays containing sterilized loamy soil in the screen house (soil was sterilized by steaming). Developing plants were watered using 75 cl of water for each tray 3 times a week to 30 days after sowing. The field was arranged in a Randomized Complete Block Design (20 stands per plot) with plant spacing of 0.5 m within row and 0.6 m between rows with 3 replications. Fertilizer was applied 3 weeks after planting at 140 $kg \cdot ha^{-1}$ of N and 25 $kg \cdot ha^{-1}$ of P. Manual weeding was carried out at 3 and 8 weeks after transplanting, while staking and trellising of plants was done at one week prior to the onset of flowering. Data were obtained on Total fruit weight, Total number of fruits per plot, DTF= Days to 50% flowering and average number of fruits per cluster. Analysis was with PB Tools (ver. 1.1.0, http://bbi.irri.org/products) and STAR statistical software.

RESULTS

The descriptive statistics (mean and range) of traits are presented in Table 1. High significant differences was observed for all the traits ($P \leq 0.01$). The highest mean and maximum range was recorded for total fruit weight while minimum range was observed for average number of fruits per cluster. The mean of the 9 new tomato breeding lines (F_6) tomato breeding lines for fruit yield, total number of fruits, days to flowering and number of fruits per cluster are presented in Table 1. Breeding line NHTO10-2 was the top performing genotypes for yield (6119.52g) while NHTO105-1 produced the highest number of fruits per plot (177 fruits) and was the earliest to reach 50% flowering (57 days). Advanced breeding line NHTO15-3 recorded the highest number of fruits per cluster (Table 1).

High significant positive association was recorded for yield and average number of fruits per plot while number of fruit per cluster associated positively with average number of fruits per plot (Table 2). Days to flowering had moderate negative significant association with average number of fruits per plot.

DISCUSSION

Tomato is an important cash crop in Nigeria and other west Africa regions where it can be produced during the rainy and dry seasons. However, tomato production and availability in the market is more successful and costs less during the dry season from November to December (Kelly *et al*, 2005). Due to different biotic and abiotic production constraints, farmers usually abandon tomato production during the unfavourable conditions (high rainfall months), thus, fresh market tomatoes are costlier and less available during the peak of rainy seasons (May to October) in Nigeria. In the current study, eight (8) new breeding tomato lines and three checks Roma VF+ (open pollinated), Cobra 26 and Platinum F1 (hybrid varieties) were evaluated for yield and yield contributing traits under open field rainfed conditions at the peak of the rains. The results showed varying yield potentials for each of the tomato genotypes.

Significant differences were observed in yield and other yield related traits among the tomato genotypes. The high significant variation observed for all the traits in this populations shows the feasibility of their improvement through selection. This supports the work of Bationo-Kando *et al.* 2015 and Bihon *et al.*, 2022 that reported high significant variation among traits considered in tomato. Maximum yield of 6119g was recorded by one of the new advanced tomato breeding lines NHTO10-2 indicating higher yield potential over the three checks Platinum F1 (5610.91g), cobra 26 (3845.12g) and the OP check Roma VF+ (1999.76g). The differences between the tomato genotypes in this trial might be attributed mostly to their varying inherent genetic makeups. Earliness is an important trait that controls returns to investment in tomato production since it determines how soon the farmer can take his produce to the market compared to his colleagues. The use of short duration genotypes is desirable as it allows a shorter stay in the field reducing exposure to biotic and abiotic constraints such as diseases and drought stress respectively (GatutWahyu *et al*., 2014).

New tomato breeding line NHTO105-1 despite been the earliest also exhibited yield potential comparable to the top performing hybrid check (Platinum F1). The top performing breeding lines for earliness

(NHTO105-1) and yield (NHTO10-2) are promising candidates that could be nominated for release to farmers or used as parents for creating new gene combinations for early maturing high yielding tomato varieties for tomato farmers in Nigeria. Selection for most complex traits such as yield and its component traits are influenced by interaction of genotype and environment and its selection efficiency can be improved through indirect selection of correlated traits based on correlation coefficient in a breeding programme (Hassan *et al*., 2021). The significant positive association observed between yield and total number of fruits in this populations shows that selection in favour of breeding lines with high number of fruits will favour genotypes with high yield potential. This is in accordance with Ghosh *et al.* (2010) who reported positive significant association between total fruit weight and number of fruits in tomato. Selecting very early maturing tomato genotypes will favour tomato breeding lines with reduced number of fruits while selecting genotypes with increased number of fruits per cluster will favour indirect selection of breeding lines with increased number of fruits in this population.

CONCLUSION

This study identified tomato entries and varieties, which provided better yield and earliness during the peak of rainy season in south western Nigeria. Top performing breeding lines for earliness (NHTO105-1) and yield (NHTO10-2) were identified as promising candidates that could be advanced for further evaluation towards nomination for release to farmers in Nigeria.

ABSTRACT
This experiment was conducted at Teaching and Research Farm, Ladoke Akintola University of Technology, Ogbomoso, Nigeria in 2018 to determine the effects of organic fertilizer rates and growth media on the early growth and nutrient uptake of oil palm (Elaeis guinneensis) seedlings. The treatments involved five rates of organic fertilizer (0, 50,75,100, 125kg/ha) and three growth media (soil, soil + sawdust, soil + manure). These were arranged in a factorial experiment and fitted into a complete randomized design with three replicates. Data were collected on the early vegetative growth, nutrient uptake, leaf area and dried plant weight. These were subjected to Analysis of Variance (ANOVA) at 5% probability level. The results showed that growth media and fertilizer rates significantly (P ≤ 0.05) influenced plant height, number of leaves, nutrient uptake, leaf area and dried plant weight assessed. The interaction effect between growth media and fertilizer rates had significant influence on the nutrient uptake of oil palm seedlings. The highest values were produced at 125kg/ha, closely followed by 100 kg/ha fertilizer application rate with the use of soil + manure as growth media while the lowest value was produced at 0kg/ha application rate with the use of soil only. In conclusion, the results obtained showed that for early growth and nutrient uptake of oil palm seedlings, the use of soil + poultry manure as growth media with organic fertilizer applied at 100kg/ha could be recommended in Ogbomoso, Southwestern Nigeria.

INTRODUCTION

Oil palm (*Elaeis guineensis*) is one of the important economic crop in the tropics. (Ayanwu; Anyanwu and Anyanwu, 1982). It belongs to the family *palmae* (having 225 genera with over 2600 species), and the subfamily *cocoideae* of which it is the most important member (Opeke, 1987). It is a versatile tree crop with almost all parts of the tree being useful and of economic value. Oil palm is one of the tree crops of the nation that has contributed to the growth of Nigeria before the advent of the civil war in 1966 it is one of the most rapidly expanding crops in the tropics National Institute for Oil Palm Research (NIFOR, 2003). Oil palm requires acidic soils with a pH of 5.5-5.7, cultivated oil palm seedlings begins bearing of fruits at the 3rd and 4th years after planting and attains peak fruits bearing at 12-15 years. Its continue bearing fruits for 40-50 years yielding 35-50kg oil plant per year (4.5 tonnes of oil per years) it is allogamous and propagated via seeds.

The principal product of oil palm is the palm fruit, which is processed to obtain three commercial products. These include palm oil, kernel oil and palm kernel cake. The uses of palm oil are many and varied (Adegbola *et al.,* 1979). Locally, it is used for cooking, soap making, metal plating and lamp oil. The palm kernel oil however, is used for soap making, as a source of glycerine, for manufacturing margarine, cooking fats and for making lubricants. The residue obtained after extraction of oil is called kernel cake, which is useful in livestock feed production. The midribs and rachis of oil palm are used for making brooms and roofing materials. The thicker leaf stalk is used for making the walls of village huts.

The bark of the frond is peeled and woven into baskets while the trunk (main stem) can be split and used as supporting frames in buildings.
Soilless medium helps to prevent root infecting pathogen related problem. This is due to its superior physicochemical characteristic coupled with lower infestation rate of pathogenic pests at the initial stage. Strangle weathered and sedimentary soils which are classified as ferralsols, nitosols, and acrosols, (oxisols and ultisols are mostly used for planting perennial crops including oil palm in Malaysia (Sabri, 2009). Thus, better performance of many plantation crops is achieved in Malaysia when it is planted in ultisols and oxisols soils which possess some of those qualities and could be found in most oil palm planting areas in the country (Salisu *et al.,* 2013*)* however these soils still heavily depend on fertilization and planting of cover crops for better plant yield (Rantala, 2006). This could be attributed to its low cation exchange capacity (CEC) and high aluminum content Yaacob *et al.,* (1992).

The objectives of this study were to:

i. Determine the appropriate Organic fertilizer rate required for the optimum growth and nutrient uptake of oil palm seedlings.
ii. Determine the best growth media for the growth and nutrient uptake of oil palm seedlings.

MATERIALS AND METHODS

The experiment was conducted at the Teaching and Research Farm, Ladoke Akintola University of Technology, Ogbomoso in the year 2018. Ogbomoso is on the latitude 8^0 10N and longitude 4^0 10 E (Olaniyi, *et al.,* 2000). The seedlings were obtained from NIFOR (Nigerian Institute for Oil Palm Research) Benin City, Edo state, Nigeria. Oil palm seedlings, polythene bags, topsoil, poultry manure, sawdust and organic fertilizer. The Organic fertilizer was applied at the rate of 0g, 50g, 75g, 100g and 125g and 3 growth media (soil, soil +manure and soil + sawdust) were used. Data collection commenced 4weeks after planting, and continues at four weeks interval. Parameters assessed include plant height, number of leaves, leaf area (multiplying length and breadth by correction factor of 0.55) and nutrient uptake i.e. leaves were been collected from various plant in each of the treatment, then sundried before they were taken to the laboratory to test for Nitrogen, Phosphorus, Potassium, Magnesium, and calcium concentrations. Nutrient uptake was calculated using formula: plant nutrient uptake x plant dried weight (g/plant). Data collected were subjected to Analysis of Variance (ANOVA) and significant mean were separated using least significant difference (LSD) at 5% level of probability.

RESULTS

Plant height

The effects of growth media and fertilizer rates on the plant height of oil palm seedlings are presented in (Table 1). Growth media significantly influenced ($P \leq 0.05$) plant heights at all the sampling period while fertilizer rates had no significant effect ($P > 0.05$) on the height of oil palm seedlings between 2 and 12 WAP. The tallest plants (18.94 cm) at 2 WAP was produced by soil at 125 kgN/ha of fertilizer while the shortest plants (11.72 cm) was produced by soil only at control fertilizer application. At 4 WAP, soil + manure produced the tallest plants (17.8 cm) at 125 kg/ha but at 6, 8 and 10 WAP, soil alone recorded the tallest plants of 21.44, 21.27 and 26.28 cm, respectively while the shortest plants between 4 and 10 WAP (12.58, 13.16, 12.72 and 16.70 cm, respectively) was consistently produced by soil only at control fertilizer application At 12 WAP, soil + manure produced the tallest plants (30.71 cm) while the shortest plant (18.39 cm) was produced from soil only at control fertilizer application. The interaction between the growth media and the fertilizer rates was not significant ($P > 0.05$) at all the sampling periods (Table 1).

Table 1: Effects of growth media and fertilizer rates on the mean plant height (cm) of oil palm seedlings

		PLANT HEIGHT(CM)

Number of leaves

Growth media had significant effect ($P \leq 0.05$) on the number of leaves of oil palm seedlings all through the sampling period except at 2 weeks after planting (WAP), while fertilizer rates significantly influenced ($P \leq 0.05$) number of leaves of oil palm seedlings at 2, 4, 6 and 12 WAP (Table 2). The highest number of leaves at 2 WAP (3.11) was produced by soil as a growth medium at 100 kgN/ha of organic fertilizer while the lowest number of leaves (2.11) was produced by soil + manure as the growth medium at 100kg and 125 kgN/ha of organic fertilizer rate.

Soil steadily produced the highest number of leaves at 4, 6, 8 and 10 WAP (3.78, 4.22, 4.22 and 5.87, respectively) at organic fertilizer rate 125 kgN/ha while soil + sawdust produced the lowest number of leaves at 4 and 6 WAP (2.11 and 2.22, respectively) between control and 50 kg/ha of fertilizer, soil + manure produced the lowest number of leaves at 8 and 10 WAP (2.44 and 4.58, respectively) at 0 kg/ha of fertilizer. At 12 WAP however, soil + manure produced the highest number of leaves (7.40) at 125 kg/ha of fertilizer while the lowest (5.32) was produced by soil only at control of fertilizer. The interaction effect between the growth media and fertilizer rate was not significant at all the sampling occasions (Table 2).

Table 2: Effects of growth media and fertilizer rates on the mean number of leaves of oil palm seedlings

		NUMBER OF LEAVES

The leaf area and dried plant weight

The leaf area of oil palm seedlings was significantly influenced ($P \leq 0.05$) by both the growth media and the fertilizer rates (Table 3). The highest leaf area (225.87cm^2) was produced by soil + manure at 125 kgN/ha of fertilizer while the lowest leaf area (71.86cm^2) was produced by soil only at control fertilizer application. The interaction between growth media and fertilizer rates did not significantly ($P > 0.05$) influence the leaf area of the oil palm seedlings. Similarly, the dried plant weight of the oil palm seedlings was significantly ($P \leq 0.05$) influenced by the growth media however the fertilizer rates did not have a significant effect ($P > 0.05$) on the dried plant weight of the seedling (Table 3). The highest dried plant weight (4.0 g) was recorded from the three growth media at 100kgN/ha and 125kgN/ha of fertilizer while the lowest dried plant weight (2.0 g) was produced by all the growth media at no fertilizer application. The interaction between the growth media and the fertilizer rates had no significant effect on the dried plant weight of the seedlings.

Table 3: Effects of growth media and fertilizer rates on the leaf area and dried plant weight of oil palm seedlings.

Growth Media	F rates (kg/ha)	Leaf area (cm^2)	Dried plant weight (g)
Soil	0	71.86	2.00
Soil	50	122.1	3.00
Soil	75	130.53	3.00
Soil	100	153.63	4.00
Soil	125	168.12	4.00
Soil + sawdust	0	159.13	2.00
Soil + sawdust	50	155.83	3.00
Soil + sawdust	75	201.12	3.00
Soil + sawdust	100	224.77	4.00

Soil + manure	0	79.2	2.00
Soil + manure	50	94.6	3.00
Soil + manure	75	127.6	3.00
Soil + manure	100	160.97	4.00
Soil + manure	125	225.87	4.00
LSD media		98.28	0
LSD FERTILIZER		76.12	Ns
LSD MEDIA x FERTILIZER		Ns	Ns

Nutrient uptake

The effects of growth media and fertilizer rates on the nutrient uptake of oil palm seedlings were presented in (Table 4). The uptake of all the evaluated nutrient element was significantly affected ($P \leq$

0.05) by growth media, fertilizer rates and their interactions. The highest value of nitrogen in the tissue of the seedlings (5.40) g/mg was produced by soil + sawdust at 100 kgN/ha of Fertilizer application rates while the lowest nitrogen content in the tissue (1.38) g/mg was produced by soil + sawdust and soil + manure at control fertilizer application. The highest phosphorus absorbed (5.08) g/mg occurred on plants on soil + sawdust at 125 kg/ha of fertilizer while the least phosphorus absorbed (0.60) g/mg occurred on soil + sawdust at control fertilizer application rates (Table 4). In terms of Potassium uptake, soil + sawdust produced the highest (1.44) g/mg potassium uptake at 75 kg/ha of fertilizer whereas soil + manure resulted in the lowest (0.31) g/mg of potassium at no fertilizer application. Soil + sawdust still resulted in the highest calcium uptake (5.04) g/mg at 100 kg/ha of fertilizer while soil + sawdust and soil + manure produced the lowest calcium uptake (1.26) g/mg at no applied fertilizer and for magnesium uptake, soil + sawdust resulted in the highest uptake (1.84) g/mg at 75 kg/ha of fertilizer while soil + sawdust and soil + manure produced the lowest magnesium uptake (0.32) g/mg at no applied fertilizer.

Table 4: Effects of growth media and fertilizer rates on the Nutrient uptake of oil palm seedlings.

Growth Media	Frates (kg/ha)	N	P	K (g/mg)	Ca	Mg
Soil	0	2.13	0.96	0.48	1.94	0.56
Soil	50	2.46	1.51	1.04	2.22	1.35
Soil	75	2.97	2.24	1.12	2.64	1.56
Soil	100	4.28	3.84	0.78	3.52	0.96

DISCUSSION

Increasing fertilizer rates also resulted in better growth of the seedlings across the evaluation period. This reveals that fertilizer application is essential for early growth of oil palm seedlings. The highest values of the growth parameters was obtained between 100kg/ha and 125 kgN/ha of fertilizer application rates, this indicates that ample nutrient supply will guarantee good performance among oil palm seedlings. With regards to the nutrient uptake of the seedlings as determined by growth media, sawdust consistently gave the highest N, P, K, Ca and Mg uptake by the seedlings. This may be as a result of the fable state of the media that enhance ready root penetration to access the nutrients available; also being an organic material t will also decompose to release its inherent nutrient for the use of the growing seedling. The release of nutrients from organic materials has been reported to be gradual and could meet the demands of the plants (Adamtey, 2011). Similarly, fertilizer rates 100 kg/ha and 125 kg/ha still had the highest nutrient uptake that can be attributed to early growth of the seedlings that may have resulted in early root development that aided more nutrient uptake. Kumah (2011) have reported that nutrient supply aids early growth that eventually enhances early root development by plant in similar research conducted on substrates in Ghana.

CONCLUSION

In conclusion, the results obtained from the experiment shows that for early growth and nutrient uptake of oil palm seedling, the use of soil + poultry manure growth media with fertilizer applied at 100 kg/ha could be recommended in Ogbomoso, Southwestern, Nigeria.

ABSTRACT
Tomato farming serves as a good source of income for farmers. In southeastern Nigeria, high relative humidity, pests, diseases, low soil fertility and absence of resistant varieties have limited the success farmers achieved in the business. An experiment was conducted in Awka, Anambra state to determine the effects of neem leaf as mulch material on the growth and yield of Padma 108 variety of tomato. Awka is in a rainforest agro-ecological zone with a bimodal rainfall pattern, characterized by high relative humidity which creates enabling environment for pests and disease pathogens of many crop diseases. The experiment had five (5) levels of neem leaf mulch which were 0kg/Ha, 2775kg/Ha, 5550kg/Ha and 8338kg/ha and three (3) replications. Treatment 5550kg/ha had the highest number of fruits while 8338kg/ha recorded significantly high fruit size and weight. Therefore, 8338kg/ha is recommended for farmers in Awka and areas with similar climatic and edaphic conditions.

INTRODUCTION

Tomato (*Lycopersicon esculentum* Mill.) is a staple fruit vegetable, one of the most important vegetables worldwide (Saeed-Awan *et al.,* 2012) considered as an important cash and industrial crop in many parts of the world (Ajagbe *et al.*, 2014) that has become popular over the last century. Tomato is a tender and compression-sensitive fruit (Babarinsa and Ige, 2014) it is a member of the Solanaceae family botanically known as berry (Abdullah *et al.*, 2014). It is the second most important vegetable crop next to potato (Abdullah et al., 2010). Despite the overwhelming importance of tomato, the production has suffered huge setback in southeastern Nigeria due largely to high rainfall, high relative humidity, inherent pest and diseases and edaphic factors such as soil pH, poor soil nutrient status, etc.

MATERIALS AND METHOD

The experimental site was located at the Teaching and Research Farm of the Department of Crop Science and Horticulture, Nnamdi Azikiwe University, Awka, Anambra State, Nigeria. Awka is characterized by tropical rainforest with temperature range of 27°C - 30°C. It is located at 52 metres above sea level, between latitude 06^0 15^1 N and longitude 07^0 08^1. The average annual rainfall ranges from 1650-2775mm. The variety of tomato used was the PADMA 108 F1. The tomato seedling received four treatments of varying rates of Neem leaf as mulch material. The treatments include: 0kg/ha, 2775kg/ha, 5550kg/ha and 8338kg/ha applied at the rates of 0kg/plot, 2.22kg/plot, 4.44kg/plot and 6.67kg/plot three (3) replications. The plots were raised beds with measurements of 4m x 2m and a 1m space between them. The total land area used for the experiment was $210m^2$, and there were four plots.

A media comprising of top soil, poultry manure and sharp sand in the ratio 3:2:1 respectively was used to raise the seedlings in nursery trays after decomposition. Healthy and good quality seedlings were selected and transplanted at the field at three weeks after planting. Transplanting was done in the evening at a spacing of 40 x 40cm giving a plant density of 62,500plants per hectare. Weeding was done at two weeks intervals by hand weeding and use of hoe while staking was done using ropes tied to wooden poles.

Data collection

Data collection started three weeks after transplanting, and lasted throughout the duration of the experiment to assess the effect of the neem mulch on the growth and yield of the tomato plants. The data collected were: Percentage establishment (%), Plant height (cm), Leaf area (cm^2), Number of leaves, Plant girth (cm), Number of Fruits, Fruit Weight, Fruit Length, Circumference and Diameter

All the data collected were subjected to analysis of variance (ANOVA) for a factorial experiment in RCBD using the Genstat version 4 analytical software. Mean separation was done using the Least Significance Difference at 5% level.

RESULTS

Effects of Neem Leaves as Mulch Material on the growth parameters

Table 1 shows the effect of the different Neem leaf mulch rates on the heights and girths of tomato at the different weeks after transplant. The mean of the plant heights at the different levels of Neem leaf mulch showed no significant difference at 4WAT, 5WAT and 6WAT, but showed significant difference at 3WAT. Treatment 5550kg/ha recorded the highest mean plant heights at 5WAT and 6WAT (71.40cm and 76.60cm respectively). In plant girth, there was no significant difference between the Neem leaf mulch rates at 3WAT, 4WAT and 5WAT, but was significantly different at 6WAT. Treatment 5550kg/ha also recorded the highest plant girth at 4WAT, 5WAT and 6WAT (3.23cm, 3.40cm and 3.59cm respectively).

Table 2 shows the result of the mean values of Tomato leaf area and number of leaves per plant. The tomato leaf area shows significant difference at all the stages of observation. Treatment 8338kg/ha recorded the highest at 4WAT, 5WAT and 6WAT (24.70cm^2, 27.10cm^2 and 27.10cm^2 respectively) while 2775kg/ha Neem Leaf Mulch rate recorded the least leaf area mean at 4WAT, 5WAT and 6WAT. The Number of Leaves shows significant difference between the rates at all the weeks, with 2775kg/ha Neem Leaf Mulch rate recording the least number of leaves at 3WAT, 4WAT, 5WAT and 6WAT (86.7, 113., 132 and 170) and 5550kg/ha Neem Leaf Mulch rate recording the highest number of leaves at 3WAT, 4WAT, 5WAT and 6WAT (181.2, 344, 468 and 561).

Effect of Neem Leaf as Mulch on yield parameters

Table 3 shows significant difference in the fruit circumference, fruit length and fruit weight between the different Neem Leaves Mulch Rates. Treatment 8338kg/ha recorded the highest mean fruit circumference (15.83cm), fruit length (8.49cm) and fruit weight (54.3g). However, 5550kg/ha recorded the highest mean number of fruits (16.70), while 0.00kg/ha recorded the least number of fruits (4.90)

DISCUSSION

Mulch is generally used to enhance the growth of plants. In this experiment, we demonstrated the most effective much rate that could improve the growth and yield of tomato. This result agrees with previous studies which showed the superiority of mulched plants over the unmulched plants (Awodoyin and Ogunyemi, 2005), and the report that tomato benefited from mulching (Hochmuth et al., 2001). The increased growth and tomato fruit yield under the mulches may be attributed to the conservation of moisture and reduction of temperature of top soil and suppression of weed growth. The experiment also revealed that the different growth parameters of tomato recorded variation due to the different levels of Neem leaf mulch Rates. The highest increase in the growth parameters of Plant girth, number of branches and number of leaves by the 5550kg/ha Neem Leaf Mulch rate could be due to the water conserving effect of the mulch in addition to the release of nutrients from its decomposition, adding to the available nutrients in the soil. The high plant height observed in the 8338kg/ha NML rate is as a result of soil water conservation and gradual nutrient release, the low plant height recorded by same rate at the first 3weeks could be as a result of transplant stress/shock and increase in temperature due to decomposition of the fresh leaves.

The result on Leaf Area showed that Neem leaf mulch rates significantly affected the length and width of the tomato leaves. The observation could be attributed to the additional nutrient made available to the plants and the water conserving property of the mulch. This enhancement in the growth parameters by the higher neem mulch rates might be explained to be as result of addition of organic matter turned into humus and resultantly into increased nutrient retention capacity of the soil by increasing effective cation exchange capacity. The fact that mulch covers the soil surface preventing evaporation, and also protects the soil and its organic content from direct contact with warm air thus increasing soil microbial activity and consequently encouraging decomposition, is probably the reason for high growth. Similar findings were also made by Kuldeep (2016).

Yield attributes which determine yield is the resultant of the vegetative development of the plant. Yield is as a result of the coordinate interplay of the yield attributes: number of fruit per plant, weight of fruit per plant etc. which were improved due to mulch application. The maximum record of number of fruit per stand and number of flower per stand observed in 5550kg/ha Neem Leaf Mulch rates could be related to the maximum branching and relatively strong growth performance of the plants. similarly, 8338kg/ha Neem Leaf Mulch rates recorded the maximum fruit weight, length and circumference as it produced the largest fruits. This could be said to be as a result of it's decomposition being slow due to the quantity,

releasing maximum additional nutrient for use by the plants as well and the tendency of it providing maximum soil cover therefore having better moisture conservation property.
In general, the cover of mulch creates a favorable micro climate for the activities of soil micro organisms which helps in maintaining and improving the soil physio-chemical and biological qualities, thereby improving the performance of growth and resultantly in yield attributes and yield. Similar findings were also made by Kuldeep (2016).

CONCLUSIONS

The different rates of neem leaves used as mulch for the experiment revealed that Neem leaves influences the growth and yield qualities in Tomato production. The neem as mulch material conserved moisture and maintained temperature of the soil. The higher Neem leaf mulch rate was effective in the control of diseases of tomato in Awka. The result of the experiment therefore shows that commercial production of tomato in Awka is possible with appropriate neem mulch rates.

RECOMMENDATION

8338kg/ha of neem leaf as mulch material is recommended for tomato farming in Awka and its environment. It is also recommended that further research be carried out on the use of 5550kg/ha and 8338kg/ha of Neem leaf for mulching in other areas in Southeastern Nigeria as they recorded the highest number of fruits, highest mean fruit weight and size.

ABSTRACT
An experiment was conducted with a view of promoting grounded dry cashew leaves (GDCL) as organic fertilizer for raising cocoa seedlings. The experiment was laid out in a complete randomized design with three replications. The treatments consisted of 0g (Control), 5g and 10g of grounded dry cashew leave (GDCL). The duration of the experiment was 12 weeks. Among the treatments, 10g GDCL recorded superiority in almost all growth parameters measured. The results obtained show that better cocoa seedling growth could be achieved with the use of GDCL as growing media for nursery, as well as improving the soil. It was concluded that apart from being a waste, GDCL is recommended to be incorporated into the soil for nutrient enhancement and to solve its disposal problems as a waste. Future research should be considered to study other nutrient composition of GDCL not captured in this study and the rate of decomposition of GDCL.

INTRODUCTION

Tree crops usually take several years to reach the peak of their production, particularly cocoa trees. Cocoa supports the livelihoods of individuals (Agbongiarhuoyi *et al*., 2013) as it plays a significant socio-economic role in Nigeria. In Cocoa production, (Ajewole and Iyanda, 2010) optimum motivation is a sensitive requirement for best practices. This has led to farmers and farmer groups producing their cocoa seedlings through community-based nursery schemes (Kehinde Ajao, 2011). On the other hand, soil amendment has been observed to be one of the solutions to soil fertility and over-cultivation problems (Aina *et al*., 2018), because it is believed that decaying plant materials adds nutrients to soil which is an act of soil amendment. Cashew (*A.occidentale)* tree leaves waste disposal is among some global problems affecting farmers. Even though they are genetically fixed in nature, it has flammable risks, and handling issues. Tan and Chan (2014) reported that leaves of *A.occidentale* inhibit the growth of *Brevibacillus brevis*, *Micrococcus luteus*, *Staphylococcus cohnii*, *Escherichia coli* and *Pseudomonas aeruginosa* and more from the bark extract (Manasa *et al*., 2013).
De Medeiros *et al*., (2021) stated that the improvement of physical, chemical, and biological attributes of the soil leads to creating an adequate environment for healthy plant development. More so, they are abundant; thus, it becomes an undeniable waste that may not be detrimental to the soil's physico-chemical properties. It was reported (Barna *et al*., 2015) that plants grown with biological sources of nutrients such as manures and composted organic waste are less susceptible to the attack of insects. Besides, Anderson *et al*., (2005) reported that organic fertilizer is cheaper and has more efficacy than inorganic fertilizer. Ayeni, (2011) reported that chemical fertilizer increased crop yield, but its cost implication affects farmers positively. Negatively it enhanced yield and contributed to food security (Park *et al*., 2008). Furthermore, Williams, (2009) stated that the choice of new technologies and discoveries to improve the farm yield positively may not be readily accepted by non-literate farmers. Hence an appropriate agronomic practice, adaptation, consisting of the use of grounded dry cashew leaves as manure to boost cocoa nursery plants should be a strategy that not only cob the challenges of cashew leaf disposers but can be used as inorganic fertilizer or soil amendment. Thus, the objective was to establish the fact that

grounded dried cashew leaves (GDCL) can enhanced cocoa growth, and at the same time served as amendment to improved soil fertility.

MATERIALS AND METHODS

The experiment was carried out in the greenhouse of Cocoa Research Institute of Nigeria (CRIN), Ibadan. The soil was collected from a depth of 0-15cm in a continuously cultivated farm plot that has little amount of composite plant materials, organic content, and low nutrient status after soil analysis. The soil collected was mixed with cashew leaf litters, which was air dried, grounded and filled into the soil in a ratio of 0g (control), 5g and 10g, in a polythene bag of 14.2 and 16.8 cm radius and length respectively, arranged in a randomized complete block (RCD) in three replicates. Pre/Post leaf and soil samples were analyzed in the lab to obtain their nutrient composition. The experiment was monitored for 12 weeks. Vegetative data was collected at 4 weeks after sowing (WAS), 6WAS, 8WAS, 10WAS, and 12WAS on growth morphological parameters (plant height, number of leaves, stem girth and leaf area). Data collected was subjected to statistical analyses (Genstat 17 Version). Analysis of variance was performed using a range test of 0.05% probability level.

RESULTS AND DISCUSSION.

The physico-chemical properties of the soil (Table 1) all fall below the critical levels; hence fertilization becomes appropriate. The soil pH (H_2O) was 4.25, not quite suitable for optimum cocoa production. N 0.08 compared to 0.09 and1.8gkg-1, K Potassium 0.49 also fall below the critical level of 1.2cmolkg-^{1} used to raise cocoa plant according to Egbe, N. E, *et al*., (1989) and wessel M (1971) respectively. Moreso after the experiment the soil was richer in nutrients when fertilized with the application of 5g of GDCL, an indication of easy absorption of the nutrient present from GDCL for growth. The incorporation of grounded dry cashew leaves (GDCL) as shown in Table 2 on the pre and post GDCL was not significantly different, but it was efficiently utilized by cocoa seedlings when mixed with the nursery soil. This was in cognizance of the report of Tanimu *et al*., (2007) and Murphy (2015) in their report that organic materials apart from being a major source of organic matter and plant nutrients resulted in improved soil physical and chemical attributes. The different types of treatments applied (Table 3) was not significantly different for cocoa seedling emergence. Subsequently, treatments with the application of GDCL emerged lesser when compared to the control (0g).

The cocoa seedling's morphological parameters at the nursery stage and plant vigor were influenced by GDCL as shown in Fig. 1 to Fig 4, although not significantly. 10g of GDCL produced the tallest plant height (Fig 1). Also, at 12WAS, 5g and 10g GDCL were similar (Fig 2) in leaf production (10.10) when compared to the control (8.8). 4WAS (Fig 3), the use of 10g GDCL improved the stem girth of the cocoa seedling, though not significantly with continuous elongation till 12WAS. This supported Pandit *et al*., (2018) report that dried cashew leaves may have the potential for enhancing soil nutrient availability. The already observed trend did not continue in Fig. 4 (leaf area), because the smallest leaf area was recorded from 10g of GDCL (37.48cm^2) plot, closely followed by 5g (40.53cm^2). However, the highest leaf area (40.79)) was recorded in seedlings sown without (NCL) the application of GDCL.

CONCLUSION

Cashew leaves litter can easily be sourced from farms due to their abundance as Agro-waste. The awareness of it as manure can solve waste disposal problems and can improve cocoa soil structure and texture. From this study, no exceptional impact of grounded dried cashew leaves on cocoa seedlings was observed using both application rates. However, application using higher rates is recommended for trial as the organic fertilizer have been observed to have basic nutrients that can support plant growth. The study provides a reasonable amount of information about the nutrient status of cashew dry leaves. Nevertheless, future studies on the rate of decomposition and its economic value to cocoa productivity should be shared with farmers through training toward best agronomy practices on cocoa farms.

ABSTRACT
The study assessed the efficacy of leaf and the root extracts of African Marigold for the management of nematode infestation on tomato (Solanum lycopersicum L.). The experiment was conducted at the Horticultural nursery of Crop Production Department, Federal University of Technology, Minna, Nigeria. Data collected on the following parameters: number of leaves, flowers, and fruits, leaf area, height, girth, and fruit weight were subjected to analysis of variance (ANOVA) using Statistical Analysis Software (SAS) and means were separated using Duncan Multiple Range Test (DMRT). Tomato plants treated with the root extract of African Marigold showed significantly higher number of leaves (74), flowers (8), and fruits (6), thicker stem (1.1cm), tallest plant (48.9cm), broadest leaf area (9.3cm^2) respectively, and they were statistically higher than other treatments. It was observed that 30 ml of African marigold root extracts performed better in suppressing the activities of the nematode thus translating to improved growth and yield of tomatoes. The study revealed that extracts of African marigold possess nematicidal properties that can be explored as alternative to synthetic nematicides in the control of nematode infection in tomatoes cultivation. It is recommended based on the findings from this research that 30 ml root extract of African marigold is required to improve the growth and fruit yield of tomato/pot against nematode infection. Further study is recommended for the evaluation of the exacts in the open, to be able come up with recommended dose.

INTRODUCTION

Tomato (*Solanum lycopersicum*) is a member of the Solanaceae family (Ercolano *et al*., 2012). All over the world, tomato is part of a healthy diet because it contains calcium and Vitamin K which helps maintain strong bones. It also contains vitamin B and Potassium which helps reduce cholesterol levels and lowers blood pressure (Bhowmik *et al*., 2012). Tomatoes are warm-season crop that require direct sunlight for optimum production, it do not thrive in cold weather or extreme heat. Fruit set will not occur at prolonged temperatures below 14 °C or above 30 °C. Tomatoes will produce good yields on a wide range of fertile, well drained soils with pH of 5.5 –7.5 (Yadav and Tungpu, 2012). The fruit is rich in lycopene which may have beneficial health effects. The tomato is a major vegetable crop that has achieved tremendous popularity over the last century. It is grown in practically every country of the world – in outdoor fields, greenhouses and net houses. The tomato plant is very versatile and the crop can be divided into two categories; fresh market tomatoes and processing tomatoes. In both cases, world production and consumption has grown quite rapidly over the past 25 years. Tomatoes, aside from being tasty, are very healthy as they are a good source of vitamins A and C. it also contains Lycopene; which is a very powerful antioxidant that can help prevent the development of many forms of cancer. Cooked tomatoes and tomato products are the best source of lycopene since the lycopene is released from the 3 tomato when cooked. A raw tomato has about 20% of the lycopene content found in cooked tomatoes. However, raw or cooked tomatoes are considered the best source for this antioxidant.

MATERIALS AND METHODS

Study Location

The experiment was conducted in the Horticultural Research and Nursery, Department of Crop Production, Federal University of Technology, Minna, Nigeria on latitude 9°40'N and 6°3'E.

Source of Seed

The Ibadan local seed cultivar was purchased from an Agro-Input store in Minna, Niger State, Nigeria. .

Preparation of Experimental Plots

The grasses and weeds of experimental nursery plot were removed and the land tilled to a depth of 15-30 cm. The soil was sterilized and was filled into polyethylene bag.

Seedlings planting and transplanting

The seedlings were planted using broadcasting method and were transplanted in the evening for better establishment of the seedlings after 21 days to 8 kg top soil into the polythene potting pots at one plant per stand. Planting was done.

Introduction of the Egg Mass of Nematode

The egg masses of the nematode were gotten from an infected (*Glycine max*) soybean plant and were picked and was introduced into the already sterilized sand filled potting bags at five (5) egg mass per pot.

Preparation of Crude Extract

The collected African marigold shoots and roots were shade dried under normal environmental condition and thereafter ground into uniform powder using a mortar and a pestle. Hundred grams from each of the dried powdered shoots and roots were weighed and mixed in 1000 ml distilled water separately. The solution was boiled, cooled and filtered using the Whatman No. 1 filter paper. Then filtrate was kept under room temperature and injected into the soil using a syringe fortnightly from the 7th day after transplanting.

Treatments and Experimental Design

The treatment levels were factorial combined, resulting to (4×5) and was applied at 10, 20, 30 ml and control. Completely randomized design (CRD) was adopted with five replications.

Data collection

Data were collected on number of leaf, leaf area, plant height, stem girth, number of flowers, number of fruits and fruit weight.

Data Analysis

The data collected on all the parameters were subjected to analysis of variance (ANOVA) using Statistical Analysis Software (SAS) and means were separated using Least Significant Difference (LSD) at 5 % level of probability.

RESULTS

The effect of the shoots and roots extract of African Marigold on the management of Nematode on the number of leaves of tomato in Table 1 was not significantly different at the first three weeks after transplanting. However, at 6, 7 and 8 WAT shoot extract recorded highest significant ($p \leq 0.05$) number of leaves compared to control but not significantly difference from 10 and 30ml. At 4, 5, 6, 7 and 8 WAT 30 ml of root extract recorded highest significant ($p \leq 0.05$) number of leaves compared to control but not significantly difference from 10 and 30 ml.

Table 2 shows the effect of the shoots and roots extract of African, marigold on the management of Nematode on the leaf area of tomato was not significantly different at 1 WAT. At 2 WAT, 10 ml of shoot extract recorded highest significant ($p \leq 0.05$) leaf area compared to control but not significantly difference from 20 and 30ml. Also at 3 WAT control has the narrower significant ($p \leq 0.05$) leaf area compared to other treatments. While, at 4 WAT 20 ml of shoot extract recorded highest significant ($p \leq 0.05$) leaf area compared to control. At 5 WAT pots treated with 10 ml of shoot extract recorded highest leaf area compared to control but not significantly difference from 10ml. At 6 WAT 20 ml of shoot extract treated pots recorded highest significant ($p \leq 0.05$) leaf area compared to control but not

significantly difference from 10 and 20 ml and at 7 and 8 WAT 30 ml of shoot extract recorded highest significant ($p \leq 0.05$) leaf area compared to control but not significantly difference from 10 and 20 ml.
Result presented in Table 3 revealed that at 1 and 2 WAT plant height of tomato planted in pots treated with shoots and roots extract of African Marigold was not significantly different. At 3 WAT, 30 ml of shoot extract recorded the tallest significant ($p \leq 0.05$) plant compared to control but not significantly difference from 10 and 20 ml. In a related development, 20 ml of root extract recorded highest significant ($p \leq 0.05$) plant height compared to control and 10 ml at 3 WAT Also, at 4WAT tomato treated with shoot extract in control had shortest significant ($p \leq 0.05$) plant height compared to other treatments. Root extract dosage of 20 ml recorded highest significant ($p \leq 0.05$) tallest plant compared to control but not significantly difference from 10 and 30 ml at 4, 5, 6 and 8 WAT.
The effect of the shoots and roots extract of African Marigold on the management of Nematode on the Number of tomato flower from plant treated with 20 and 30 ml of shoot extract produced significant ($p \leq 0.05$) highest number of flowers compared to control but not significantly difference from tomato treated with 10 ml at 5 WAT (Table 4). Table 5 revealed that 30 ml of shoot extract recorded highest significant ($p \leq 0.05$) number of fruits compared to control but not significantly difference from 10 and 20ml at 7 WAT. Likewise, at 8 WAT 10 ml and control has the lowest significant ($p \leq 0.05$) number of fruits compared to other treatments while 30 ml has the highest number of fruits and was significantly different from 10 and 20 ml. Shoot extract applied 30 ml recorded highest significant ($p \leq 0.05$) fruits weight compared to control but not significantly difference from 20ml treatment at 8WAT (Table 6). While at 8WAT 30 ml of root extract recorded highest significant ($p \leq 0.05$) fruits weight compared to control and also significantly different from 10 and 20ml.

DISCUSSION

This study showed that there was higher overall performance of plants treated with the botanical extracts than the untreated ones. The plants treated with 30 ml of the extracts gave overall performance compared to plants treated with 10 and 20 ml and the plants that was not treated had low yield. The study also showed that the plants treated with roots extracts gave overall higher performance when compared with the plants that was treated with shoots extracts. The mechanisms of plant extracts action may include denaturing and degrading of proteins, inhibition of enzymes and interfering with the electron flow in respiratory chain or with ADP phosphorylation (Susan and Noweer, 2005). These chemicals either affected the embryonic development or killed the eggs. Chitwood (2002) suggested that the nematicidal properties of plant species vary considerably with plant species and cultivar, the plant tissue used, plant growth stage, application method and the nematode species tested. The botanical extracts reduced the formation of galls caused by root-knot nematode, number of eggs/egg mass and final nematode population density in the soil. With the increase in concentration levels of the botanicals, there was corresponding significant increase in overall plant performance. This significant increase in overall plant performance could be due to the chemicals present in the extracts that possess ovicidal or larvicidal properties resulting in inhibition of the multiplication of the nematodes present in the soil.

CONCLUSION

From the results obtained from this study, it was observed that the tomato plants treated with extracts of African marigold performed better in terms of growth and yield performances. The botanical extracts, root extract in particular can therefore be recommended to serve as alternative to synthetic nematicides because they are eco-friendly, easy degradable, cost effective and easily available. However further research is needed to evaluate their efficacy under field condition of different agro ecologies

ABSTRACT
This study assessed the effect of N and K fertilizer application on the growth and yield of turmeric. It was a pot experiment using 5 levels of nitrogen (0, 45, 90, 135 and 180 kg N/ha), and 5 levels of potassium (0, 45, 90, 135 and 180 kg K/ha). The experiment was arranged in a 5 × 5 factorial fitted into a completely randomized design with three replications. Data were obtained on the plant height, number of leaves, number of tillers, biomass and rhizome yield. Applications of nitrogen and potassium significantly enhanced the growth and yield of turmeric. The highest biomass (7.61 g/plant) and rhizome (46.67 g/plant) was obtained with the application of 135 kg N/ha, and 180 kg K/ha There was an interactive effect between nitrogen and potassium application which enhances the growth and yield of turmeric.
Keywords: *Fertilizer application, N fertilizer, potassium fertilizer, turmeric, rhizome yield*

INTRODUCTION

Turmeric (*Curcuma longa* Linn.) is a spice crop native to tropical Southeast Asia. Its economic importance ranges from its use as culinary to its medicinal potentials. It is the major ingredient in curry powders, giving curlinary dish a characteristic peppery taste (Ravindran *et al*., 2007). It is also used in the pharmaceutical industries for the treatment of various kinds of diseases. (Sugiyama *et al*., 1996; Ishimine *et al*., 2003) due to its active ingredient curcuminiods.
Turmeric responds well to fertilizer application (Bose *et al*., 2008). Among the most important nutrient element required by turmeric are nitrogen (N) and potassium (K). Various researchers have reported different recommendations for turmeric production particularly in India where it is being cultivated on a large scale. Jagadeeswaran *et al*., (2005) noted that the nutrient exploiting property and applied nutrient efficiency of turmeric despite its economic importance has not been studied in details. In view of this, the experiment was aimed at determining the effect of N and K on the growth and yield of turmeric.

MATERIALS AND METHODS

A pot experiment was conducted at the National Horticultural Research Institute (NIHORT), Ibadan using 5 kg soil. Pre-cropping soil analysis was done using standard procedures. The experiment was a 5 × 5 factorial arranged in a completely randomized design. The experiment was replicated three times. The factors include 5 levels of N (0, 45, 90, 135 and 180 kg N/ha), and 5 levels of K (0, 45, 90, 135 and 180 kg K/ha). The N and K were applied at 2 equal split dose at 1 month and 3 months after planting. The source of the N was urea and that of K was muriate of potash. Data were collected on plant height, number of leaves, number of tillers, rhizome yield, and biomass yield.
All data were subjected to analysis of variance using SAS software 9.2 version and significant treatment means separated using LSD and DMRT.

RESULTS

The pre-cropping soil analysis indicates a pH of 6.9, the values of the major nutrient elements are as follows: total N 0.06 %, available P 3.65 mg/kg, exchangeable K 0.26 cmol/kg, Ca 12.44 cmol/kg and Mg 0.95 cmol/kg.

At 8 and 12 WAP the highest plant height was obtained with the application of 45 kg N/ha, but this was not significantly different from the applications of 90, 135 and 180 kg N/ha (Table 1). However, the control (0 kg N/ha) had a similar plant height with the use of 90 and 135 kg. The highest plant height at 16 WAP was obtained with the application of 180 kg N/ha which was not significantly different from the applications of 45 and 135 kg N/ha. The plant heights under the applications of 45, 90 and 135 kg N/ha at 16 WAP were not significantly different from each other. The highest plant height at 20 WAP also resulted from the application of 180 kg N/ha. This was not significantly different from the applications of 45 and 135 kg N/ha while a significantly lower plant height at 20 WAP was obtained with the control when compared with other treatments.

There was no significant difference in the plant height at 8 and 12 WAP with the application of potassium at different rates (Table 1). The use of 180 kg K/ha gave the highest plant height at 16 WAP but this was not significantly different with the applications of 45, 90 and 135 kg K/ha. The control gave the lowest plant height at 16 WAP but this also was not significantly different from the applications of 45, 90 and 135 kg K/ha. The highest plant height at 20 WAP was with the application of 180 kg K/ha, which was significantly higher compared with the control and the application of 45 kg K/ha but was similar with the applications of 90 and 135 kg K/ha. A significantly lower plant height at 20 WAP was obtained with the control but this was not significantly different from the applications of 45, 90 and 135 kg K/ha.

The highest number of leaves at eight WAP was under 180 kg N/ha but this was not significantly different from the applications of 45 and 135 kg N/ha (Table 1). The control gave the least number of leaves at eight WAP. At 12 WAP a higher number of leaves resulted from the application of 180 kg N/ha but this was not significantly different from the applications of 45 and 135 kg N//ha while a significantly lower number of leaves resulted from the control, but this was not significantly different from the applications of 45, 90 and 135 kg N/ha. At 16 and 20 WAP, a higher number of leaves was obtained with the application of 180 kg N/ha but was not significantly different from the application of 135 kg N/ha. The control gave a significantly lower number of leaves at 16 and 20 WAP.

At eight WAP, application of 135 kg K/ha gave a significantly higher number of leaves but this was not significantly different from the control and the applications of 45 and 180 kg K/ha. The highest number of leaves with potassium application at 12 WAP resulted from 135 kg K/ha but this was not significantly different from the control and the use of 180 kg K/ha. The application of 90 kg K/ha gave a significantly lower number of leaves. At 16 and 20 WAP the highest number of leaves resulted from the application of 135 kg K/ha. The lowest number of leaves resulted from the use of 90 kg K/ha but this was also not significantly different from the control and the applications of 45 and 180 kg K/ha.

The highest number of tillers obtained at eight weeks after planting was with the application of 180 kg N/ha but this was not significantly different from the applications of 45 and 135 kg N/ha (Table 2). The lowest number of tillers at eight weeks after planting resulted from the control. At 12 WAP a significantly higher number of tillers was obtained with the use of 180 kg N/ha when compared with other treatments while a significantly lower number of tillers resulted from the control. Application of 180 kg N/ha gave the highest number of tillers. A significantly lower number of tillers at 16 WAP resulted from the control compared with other treatments. At 20 WAP, a significantly higher number of tillers was observed with the application of 180 kg N/ha when compared with other treatments except 135 kg N/ha while a significantly lower number of tillers was obtained with the control.

With potassium application, the highest number of tillers at 8 and 12 WAP resulted from the application of 135 kg K/ha but this was not significantly different from the control and the applications of 45 and 180 kg K/ha. The lowest number of tillers at 8 and 12 WAP resulted from the application of 90 kg K/ha. The number of tillers with potassium application at 16 and 20 WAP were not significantly different.

The highest biomass yield resulted from the application of 180 kg N/ha but this was not significantly different from the application of 135 kg N/ha (Table 3). A significantly lower biomass yield resulted from the control but this was not significantly different from the application of 45 kg N/ha. In terms of K application, the biomass yields were not significantly different from each other with the applications of 45, 90, 135 and 180 kg K/ha, but application of 180 kg K was significantly better than the control.

The rhizome yields obtained with the applications of 45, 90, 135 and 180 kg N/ha were not significantly different from each other while a significantly lower rhizome yield compared with other application rates was obtained with the control (Table 3). A significantly higher rhizome yield was obtained when 180 kg K/ha fertilizer was applied compared with other application rates but this was not significantly different from the application of 135 kg K/ha while the application of 45 kg K/ha gave a significantly lower rhizome yield but was not significantly different from the control and the application of 90 kg K/ha. Significant interaction ($p<0.05$) existed with the combine application of N and K on the parameters examined

DISCUSSION

Application of 180 kg N/ha to the turmeric plant gave the best vegetative growth although it is not different with the application of 135 kg N/ha, this corroborates the findings of Haque *et al*. (2007), where they noted a better performance in the vegetative growth and rhizome yield of ginger with the application of N up to 180 kg/ha. Pawar and Gavande (1992) also observed the best vegetative and rhizome yield of ginger with 160 kg N/ha. The highest shoot biomass and rhizome yield was obtained when 135 kg N/ha was applied, although they were similar with the application of 180 kg N/ha. Tisdale *et al*. (1995), noted that N responses varies with soil type, plant varieties, duration of the growing season, type of fertilisers, time and method of application, moisture supply and nutrient interaction. The response of Turmeric to N fertiliser application resulted in an increase in dry matter production and yield. This however was in contrast to the findings of Gill *et al*. (1999), where they noted that N levels have no significant effect on the performance of turmeric.

It was observed that K significantly influenced the vegetative growth and yield of Turmeric. This was in agreement with the findings of Banafar and Tiwari (1995), who stated that plant height, number of leaves, number of tillers and rhizome yield increased due to an increase in the rate of K application. Razzaque and Mohamed (2001) however, reported that vegetative growth responses to K fertiliser were not significant. Behura (2001) noted that K alone cannot increase vegetative growth in Turmeric.

The significant interaction between N and K enhanced the vegetative and yield parameters of turmeric, this is in agreement with Akamine *et al*. (2007), where they observed that N in combination with K enhanced the growth of Turmeric than either N or K alone.

CONCLUSION

The study showed that interaction of N and K enhances the growth, biomass and rhizome yield of turmeric. The N enhances the growth and biomass yield of the plant while, the K enhances the rhizome yield.

ABSTRACT
This study focused on economic analysis of turmeric production among women farmers in Jaba Local Government Area of Kaduna State. Multistage sampling was used to select 20 women from each village making a total number of hundred (100) women that was used for the study. Primary data was used through the use of well-structured questionnaire. Descriptive statistics and gross margin analysis were used to analyse the data. The results shows that (76%) of the women turmeric farmers are between the age range of 21-40years of age, the majority of the farmers (74%) are married. Majority (42%) had secondary education and the rest had one form of formal education or the other. Majority (97%) had farm size ranged from 1-3. Majority of the farmers 74.4 % uses personal capital in turmeric production. Majority of the farmers (58%) indicated that their major problem is inadequate credit. The study recommends the presence of extension agents is need and agricultural loan facilities should be made accessible to turmeric women producers to ensure timely and adequate utilization of agricultural inputs, Government should provide grants and other facilities needed by the women and credit facilities from the study carried out has been a problem confronting them a relief and solution to this from government will encourage women farmers to continue in the production of turmeric.
Keywords: *turmeric, women, farming, kaduna state, economic analysis*

INTRODUCTION

Turmeric (*Curcuma Longa L*) is a herbaceous plant, believed to originate from South Asia and is grown for its rhizome that contains essential oil responsible for flavor and preservative quality. Turmeric is essentially a tropical crop and a perennial monocotyledonous herb belonging to the family *Zingiberaceae* (Sigrist *et al*, 2011; Jilani *et al*, 2012). Turmeric the golden specie is widely cultivated in different countries such as Nigeria, India, China, Sri-Lanka, Taiwan and Pakistan. It is a cross pollinated, triploid species which can be vegetatively propagated using its underground rhizomes (Sasikumar, 2005). Olojede and Nwokocha (2011) reported that in Nigeria, turmeric can be found growing from low attitude (5m above sea level) in the southern coastal plains from the rainforest to the mid latitude 4°37'N - 10°04'N. The yellow colour of turmeric is due to presence of crystalline substance known as curcumin. It is an important commercial spice crop grown in Nigeria and it considered the best in the World due to the presence of high curcumin content. Turmeric rhizome are rich in aromatic oil called tumerol, which finds its use in food and pharmaceutical industries. Turmeric is prescribed for the treatment of many medical problems ranging from constipation to skin diseases. It is used as a digestive aid and treatment for fever, inflammation, wounds infection, dysentery, arthritis, injuries, trauma, jaundice and other liver problems. Turmeric is also used as a dye in textile industries, in cosmetics, preparation of medical oil and ointment.

Turmeric affectionately called "KITCHEN QUEEN", the main spice of kitchen (Lal, 2012). In Nigeria, turmeric is cultivated mostly on subsistent bases in about 19 states and given different local names depending on the area. It is called *atale pupa in Yoruba 'gangamau in* hausa,; nwandumo in Ebonyi; *ohu boboch* in Enugu (Nkanu East); *gigir* in Tiv; *magina* in Kaduna; *turi* in Niger State; *onjonigho* in Cross River (Meo tribe). In Nigeria, women play roles in both family and household activities besides farming activities. They are the household managers but their work is considered as non- productive, unorganized, and undocumented. Hence, development assistance has failed to reach women in the rural areas both in absolute and relative terms compared to men for two reasons: Agricultural development programs were traditionally focused on men as producers and a lack of knowledge or false assumption about the role of women in agriculture. The level of women participation in decisions making process not only varies from region to region. Male dominance in decisions making in the household and economy has continued even in areas women are the key provider of labour because the influence of women has not been recognized due to lack of education, less awareness of their civil/ human rights, traditional norms and lack of credit facilities from the government. Nigeria is the fourth largest producer of turmeric with about 3 percent of the global annual production, and also according to the Federal Ministry of Agriculture and rural development women account for 75 percent of the farming activities.

With the present challenges facing the production of turmeric in Kaduna State, turmeric happens to be one of the most economic and efficiently utilized crop for generating income. Turmeric production is one of the major activities carried by women in Jaba Local Government Area of Kaduna State. Rural women play a key role towards turmeric production activities, despite these immense achievements, women are not given attention in production which can serve as means of generating income and livelihood activities, they are faced with gender bias encountered when compared with their male counterpart in the study area. Also, in the study area based on the importance of turmeric and the role women play in agricultural production. A study of this nature has not been carried out in the study area, in view of this, this study brought about the following objectives.

Objectives of the Study

The objectives were to describe the socio-economic characteristics of the women involve in turmeric production in Jaba Local Government Area, determine the costs and returns of turmeric production in the study area and identify the constraints militating against turmeric production in the study area.

METHODOLOGY

The Study Area The study was conducted in Jaba Local Government Area. It lies between latitude 90°N and longitude 8°E. The Local Government Area shares boundaries with Zango Kataf Local Government Area in the North, in the East by Jama'a Local Government Area, in the West by Kachia Local Government Area and in the South by Kagarko and Nasarawa State. The population of Kaduna State is 6,066,562 people according to 2006 census and the population of Jaba is 61,000 people according to Nation population Commission (NPC 2006) census. The Local Government Area is marked with distinct dry and wet seasons. The dry season is between November to March while wet season falls between April to October. The major occupation of the inhabitants of the Local Government Area is farming. Majority of the farmers practice small scale agriculture and other occupation which includes fishing, hunting, weaving, trading and many others etc. Crops grown in the area includes; turmeric, sorghum, millet, maize, rice, cocoyam, groundnut, acha, beans, ginger, cassava, soya beans, sweet potatoes, beni-seed and sugar-cane. During the dry season, farmers in Jaba Local Government Area are involved in the production of vegetables such as cabbage, spinach, tomatoes and pepper.

Sampling Technique

Multi-stage sampling was used for selection of respondents for the study. In the first stage five (5) district (Kwoi, Chori, Samban daji, Samban gida and Nok) were purposively selected out of the 21 districts because of the high production of turmeric. In the second stage one village each was further selected from each district making a total of five (5) villages. Simple random sampling was used to select 20 women farmers from each of these villages making a total number of hundred (100) women that was used for the study. But 94 questionnaires were retrieved which was the number of respondents used for the study.

Data Collection:

Primary data were collected by the use of structured questionnaire administered to the respondents.

Descriptive statistics

Descriptive statistics such as frequency distribution, percentages were employed.

Gross margin analysis

This was used to analyzed costs and returns of turmeric production in the study area Gross margin analysis was used because the respondents in the study area were subsistence farmers with negligible fixed capital cost, according to Olukosi and Isitor (1990). Stated that fixed capital for subsistence farming enterprise is always negligible.

This is expressed as follows:-

GM= TR-TVC Where: GM. = Gross Margin, TR= Total Revenue {output (kg) multiply by price (₦)} and TVC = Total variable cost

RESULTS AND DISCUSSION

Socio Economic Characteristics of the Respondents in the Study Area

Table 1 below shows 43.3% of the respondents were between 31-40 years. This shows that the women that farm turmeric in the study area are in their youthful ages. This result is in line with the finding of Taru *et al* (2008), this shows that, the eligibility of one's performance in certain activities or role including agricultural activities is determined by the age. This means that youth are more in turmeric production activities. Table 1 shows that majority of the respondents are married which makes a percentage of 70.1%. This implies that majority of the women in turmeric production in the study area are married. This result justified the high premium Nigerian society placed on marriage (Maisamari, 2008) and also (Asabe, 2005) deducted that the reason why married people had the highest respondents while the singles are only busy on how to migrate from rural to urban area and married are busy booking and securing for income to sponsor their children to schools medical bills, feeding and their shelter. The Table also shows attended tertiary institutions. This shows that the women in turmeric production in the study area are learned. Ogungbile *et al* (2003) and Njoku (2012) observe that one of the incentives of innovation adoption is high literacy rate and attainment of tertiary education. From this study it was observed that the respondents have varying sizes in relation to availability of farm land ranging from 1-8 hectares. Table 1 shows that 89.08% cultivates land between 1-3 hectares. Majority of the women turmeric farmers have small farm holding and are therefore small scale farmers. Furthermore, the table below shows the distribution of farmers by sources of capital 79.4% of the respondents use their personal savings as source of capital. Capital is an important factor of production and the respondents source their capital for their turmeric production from their personal savings.

Table 1: Frequency distribution of the women farmers based on their ages

Characteristics	Frequency N=100	Percentages
Age		
21-30	28	28.0
31-40	48	48.0
41-50	22	22.0
51- 60	2	2.0
Marital Status		
Married	74	74.0
Single	21	21.0
Divorced	2	2.0
Widowed	2	2.0
Separated	1	1.0
Education		
No formal education	7	7.0
Primary education	23	23.0
Secondary education	42	42.0
Tertiary education	27	27.0
Farm size		
1-3	97	97.0
4-6	2	2.0

7-9	1	1.0
Source of Capital		
Personal saving	83	83.0
Family	13	13.0
Cooperative society	4	4.0

Cost and Returns

The gross margin per hectare represents the difference between gross revenue and total variable cost per hectare. The gross return was ₦165,906.92. Table 2 shows that the variable cost of turmeric production among the women in the study area, seed ₦20,440, NPK ₦43,023.94, pesticides ₦820.85, labour ₦20,000 and total variable cost was ₦95,105 rent on land ₦11,125 and total cost of ₦106,230. The net farm income was ₦59,676.92. The operating ratio was 0.295. Further analysis showed that on every naira invested in turmeric production by women ₦0.63 was realized. Meaning that on every one naira invested there was a profit of 0.63 kobo. This shows that farming turmeric among the women farmers in Jaba Local Government Area was economically viable and profitable.

Table 2: Profitability Analysis

Items	Value (₦)
Gross return	165,906.92
Variable Cost	
Seed (₦)	20,440
Fertilizer(₦)	43,023.94
Pesticides (₦)	820.85
Labour	20,000
Total Variable Cost	95,105
Fixed Cost	
Rent on land	11,125.0
Total Cost (TFC+TVC)	106,230
Net Farm Income (GR-TC)	59,676.92
Operating ratio (TVC÷GR)	0.57
Return per capital invested NFI÷ TVC	0.63

Constraints encountered by the women farmers in turmeric production

The table below gives the constraints faced by the women farmers in the study area. The major constraints encountered by the women in turmeric production is inadequate credit with 53.5% the respondents have inadequate access to credit which causes production in their production because of lack of access to loans and funds to encourage as increase their production, 29.9% of the respondents faced season problem due to price fluctuations, 8.46% faced pest and disease problem and 3.76% of the respondents have the problem of poor transportation.

Table 3: Percentage distribution of respondents by constraints they encountered in Jaba Local Government Area

Constraints	Frequency	Percentage
Pest and disease	9	9.0
Poor transportation	4	4.0
Inadequate credit	58	58.0
Seasonal problem	29	29.0
Total	100	100

CONCLUSION

Based on the findings of this study, it could be concluded that turmeric is an important food crop in Nigeria, any attempt to increase its productivity would be a right step towards the resolution of food crisis; jobs can be directly created from enhanced turmeric production. Apart from ensuring food security and improving women participation in turmeric, increased turmeric production will provide more employment opportunities for the unemployed citizens in the study area.

RECOMMENDATIONS

The presence of extension agents is needed, because from the research carried out it showed that the Jaba women are blessed with the natural resources (turmeric) but have not exploited it much, also skills and knowledge which will be extremely important to their turmeric farming will be enhanced, Majority of the women farmers finance their production through personal savings which is mostly not adequate for appreciable production. Government should provide grants and other facilities needed by the women, this will give them sense of belonging and it will encourage their level of participation the more in turmeric farming and Credit facilities from the study carried out has been a problem confronting them a relief and solution to this from government will encourage women farmers to continue in the production of tumeric.

PROFITABILITY OF CITRUS PLANTING MATERIAL PRODUCTION AMONG PRIVATE NURSERY OPERATORS IN BENUE STATE, NIGERIA

***Ngbede, S.O and Igbegwu, F.C**
National Horticultural Research Institute Otukpa Sub-Station, Ogbadibo LGA, Benue State

*Correspondent email: ngbedesamson@yahoo.com

ABSTRACT
The study was carried out to determine the profitability of citrus planting material production among private nursery operators in Benue state, Nigeria. Responses were obtained from 60 citrus nursery operators through a multi-stage sampling technique. Data such as socio-economic features of the nursery operators, quantities and prices of inputs and outputs were obtained. Data were analyzed using simple descriptive statistics and gross margin analysis. The result of the study revealed that majority of the respondent are male (95%),(50.0%) of the respondents were within the age bracket of 41-50,(76.7%) are married,(36.7%) of them had secondary school education with household size of 6-10 (58.3%), (81.7%) had no access to credit they finance their operation from personal savings and had between 6-10 years experience (58.3%), while (65.0%) rented land for their operation. Budgetary analysis result showed that gross margin, net returns and returns on investment accrued to the nursery operators were ₦886,000.00, ₦ 815,440.00 and 2.70 indicating that citrus planting material production was a profitable business in the study area. It is recommended that government should assist the operators with appropriate incentives to boost production that will increase income generation while also encouraging them to form cooperative so that they can gain from the use of pooled resources and finances in cooperatives.
Keywords: *Citrus, nursery, gross margin, return on investment.*

INTRODUCTION

Citrus Spp was introduce to Nigeria in the colonial era and has become a major fruit crop planted in the country. The commonly grown citrus species belong to the family Rutaceae (Iroabuchi *et al.,2022).* Basically, two major rootstocks are used in Nigeria. They are Cleopatra Mandarin in the south and Rough Lemon in the north. This is due to genetic resistance to soil borne diseases, rootstock/bud wood compatibility and weather hazards (Afolayan, 2016). In the early twentieth century, the multiplication of citrus was made by seeds, originating non-grafted plants, with many thorns and beginning of delayed production due to the long period of juvenility of plants obtained by this method. The production of grafted plants enabled the size reduction plants, few thorns and early production. In addition to these advantages, the grafting/budding enabled the production of clones, genetically identical plants, better adaptation to different environments and production systems and disease tolerance, through the proper selection of the rootstock, which attracted the interest of growers. For these reasons, vegetative propagation, by bud/ grafting of scion varieties of commercial interest in selected rootstocks, was established as the main method of commercial multiplication of citrus plants in the world (Horst *et al.,* 2016).

The establishment of an orchard is a long-time venture and mistakes committed at the initial stages for orchard establishment are very difficult to correct at later phases as they cause an unbearable loss to the growers. Therefore, production of substandard planting material plays a limiting role in the growth of fruit industry. Orchards established from inferior planting material are responsible for the poor income to farmers. Complications like low fruit production, severe fruit drop, poor fruit quality and reduced productive life span of plants are also associated with the superiority of the available planting material.

Consequently, production of healthy nursery plants must be ensured for prosperous future (Tanjeet et al.,2019).

Nurseries have the common goal of producing plant material for improving sites. They are established to produce seedlings, grown under favorable conditions at germination and early growth stage before transplanting to the field for planting purpose. Plant nurseries can be an informal, small- scaled arrangement or a large commercial enterprise that vary in size, facilities (supplies, tools, equipment, etc.), types of seedlings produced, and operations (Larinde and Ruth, 2014).

A number of available literatures had only dealt with studies of nursery establishment with primary focus on its environmental protection benefits, conservation and sustainability of landscaping and urban forestry around the residential areas (Ortese *et. al.,* 2012; Iroabuchi, *et. al.,* 2022). All these studies failed to provide necessary awareness and sensitization for people in seeing the prospects and hidden opportunities in the enterprise. Such revelation is necessary to relieve the pressure on the government to provide jobs to the teeming unemployed individuals through awareness creation on how people could become self-employed in the enterprise, reduction in poverty gap and reducing rural-urban drift.

Objectives of the Study

The general objective is to analyze the profitability of private citrus nursery operation in Benue State, Nigeria. The specific objectives are to:

1. describe the socio – economic features of private citrus nursery operators in the study area
2. estimate the cost and return of private citrus nursery production

MATERIALS AND METHODS

The study was carried out in Benue state, Nigeria. Benue State is delineated into three agricultural zones, namely; Northern zone (A), Eastern zone (B) and Central zone (C). The state comprises (23) local government areas with Makurdi as the state capital. It is located between longitude 7° 47' and 10° 0' East and latitude 6° 25' and 8° 8' North. It shares boundaries with five other states namely; Nasarawa state to the north, Taraba state to the east, Cross-River state to the south, Enugu state to the south-west and Kogi state to the west. The state also shares a common boundary with the Republic of Cameroon on the south-east. Benue state occupies a landmass of 34,059 square kilometers. Benue State has an estimated population of 5,741,815 million persons (NBS, 2016).The state enjoys a tropical climate which manifests into two distinct seasons. The rainy season is from April to October with total annual amount ranging between 1120 – 1500mm, while the dry season is from November to March. Temperatures are constantly high averaging between 28° – 32°C. Physiographically, the land is level and made up mainly of undulating plains at elevations ranging from 150m to 300m above sea level. The major crops grown here include, rice, yam, cassava, groundnut, millet, soybeans, maize, citrus, mango, sorghum, sweet potatoes, cocoyam, guava, oil palm, tomatoes, cowpea, cashew and okra. Small ruminants such as goat, sheep, and non-ruminants such as swine, rabbits and poultry are also reared in the state.

Sampling technique and data collection

Multistage sampling technique was employed in the selection of citrus nursery operators in the study area. The first stage involved the purposive selection of Gboko, Ushongo and Vandekeiya LGAs, because of their contribution to citrus production in the state. Second stage also used purposive selection of one major urban town in each of the selected LGAs due to the fact that plant nursery businesses were usually concentrated in urban areas. The final stage was the random selection of twenty citrus nursery operators in each LGA, resulting into a total of 60 respondents. The data for the study were collected with the aid of a well structured questionnaire.

Data analysis

Descriptive and inferential statistics such as frequency, percentage and gross margin analysis were used for data analysis. The Gross Margin model was specified from the point of view of estimation of total expenses (costs) as well as various returns or revenue within the production period. Gross margin (GM) analysis according to Olukosi and Erhabor (2005), gross margin (GM) analysis is the difference between gross income (revenue) and total variable cost (TVC) of production. This was used to determine the costs, returns as well as profitability of citrus nursery operation.

GM = TR-TVC,

where: GM = Gross margin, TR = Total revenue, TVC = Total variable cost.

The net return represents the total profit and was determined using:

Net return (profit) = TR-TC,

where: TR = Total revenue, TC = Total cost and

Rate of return to investment (ROI) = GM/TC. The variable cost comprises of cost of inputs such as planting materials, fertilizers, labour, pesticides, watering can among others, while fixed cost comprises of land rent and depreciation on fixed inputs.

RESULT AND DISCUSSION

The socio-economic characteristics of the citrus nursery operators presented in Table 1 showed that the nursery operators were mostly male as 95.0% of them were male. The mean age in the study area was 45.5years. About 76.7% of the nursery operators are married. About 36.7% of nursery operators had attained secondary education. About 58.3% of the nursery operators had between 6-10 persons in their household. About 81.7% of the nursery operators used their personal savings to fund their operation. About 58.3% of the nursery operators had between 6-10 years of experience with mean year of experience of 8 years. About 33.3% and 65.0% of the nursery operators acquired their nursery plots through inheritance and rent respectively.

As indicated in the results the citrus nursery operation is dominated by male who could supply the high physical labor requirement involved in nursery operation, also the enterprise is dominated by individuals in their productive age. This finding is similar to that of Fakayode *et. al.* (2008). Majority of the farmers are married which is an indication that they are responsible. High educational level indicated that attainment of formal education in different degrees of education would enhance the ability of the respondent to easily understand technical operation involve in nurseries production. Equally, large household size has positive indication that most of the farm hands (labor force) can be sourced within the household thus reducing cost of hiring labor for their operations as consistent with the findings of Larinde & Santus (2014). Majority of them use personal savings which is often meager to establish a large scale citrus nursery business because of the huge capital requirement involved. The years of experience is also a good signal that more experienced operators could predict the future outcome of production with some probability by considering performance of past years as argued by Enesi *et. al.* (2016). Most of the operators use rented land which affects the total cost of operation.

In Table 2, it was indicated that the total variable cost was ₦258,000 comprising the cost of rough lemon fruits purchased, cost of polybags, cost of fertilizer, cost of pesticides, cost of labor used, budding tape and cost of bud wood used for budding. The fixed cost was ₦70,560.00 comprising of transportation cost, depreciation cost on fixed assets and annual rent on land used for production. The total cost was ₦ 328,560.00. The total revenue from the sales of citrus seedlings was ₦ 1,144,000.00 and this implies that gross margin of the ventures was ₦886,000.00 and net return (profit) was ₦815,440.00 which is a good indication of profitability of the nursery operation and rate of return on investment was 2.70 showed that an average nursery operator earned ₦2.70 per ₦1invested in the business. These results implied that the production of citrus planting material among private nursery operators is a profitable business in the study area and should be encouraged.

CONCLUSION

Citrus nursery operation is dominated by middle - aged, educated, experienced with moderate household size. Majority of them rented the nursery plots they used and finance their enterprise with personal savings. The citrus nursery operation was profitable with high return on investment. Necessary provision and assistance should be given by the government to the nursery operators in the State. Such supports include provision of soft loans at reduced interest rate to help the nursery operators to acquire necessary equipment in their operations. Nursery operators should mobilize themselves into viable cooperatives so that they can gain from the use of pooled resources and finances in cooperatives. More so, there is need to educate the youths and others alike as regards the gains derivable from nursery production business especially considering its profitability to reduce unemployment of youth in the study area.

VITAMINS AND MINERALS COMPOSITION OF SOME VEGETABLES CONSUMED IN NIGERIA

Adeniyi A. B, Ademoyegun O . T, and Fasuan T. M
National Horticultural Research Institute, PMB 5432, Ibadan, Oyo state, Nigeria

ABSTRACT
Vitamin and mineral composition of some vegetables consumed in Nigeria; Telfaria occidentalis, Amaranthus hybridus, Solanum macrocarpon, Talinum fruticusum, Launaea taraxacifolia, Vernonia amygdalina, Cucurbita pepo, Senecio biafrae, Basela alba, Ocimum gratissimum were investigated. The β-carotene content of the samples ranged from 37.52 to 10.29 mg/100g FW, Tocopherol ranged from 4.15 to 0.74 mg/100g FW, and Vitamin C content ranged from 50.30 to 4.19 mg/100g FW. Mineral analysis showed that Solanum macrocarpon contains highest amount of calcium (762.33 mg/100g DW), Telfaria occidentalis contains highest magnesium and zinc (388.23, 34.90 mg/100g DW) respectively while Senecio biafrae contains highest amount of iron (2.80 mg/100g DW). Nigerian vegetables are a rich source of nutrient most especially Telfaria occidentalis (Ugwu) examined in this study which is more nutrient dense than the other vegetable samples.
Keywords: *Vegetables, Vitamins, Minerals.*

INTRODUCTION

Vegetables are defined as consumable parts of herbaceous plants; either wholly or in parts, raw or processed, or as portion of main dish or salad. They may be bitter, sweet, or tasteless [1]. They contain low levels of fat and high levels of vitamins, minerals and fibers [2]. Vegetables have also been described to be good sources of nutrients such as carotene and protein with appreciable amount of trace minerals [3]. George et al., [4] reported that available proteins in vegetables are higher than those in fruits but lower than those in grains. Recently, there has been increasing demand in the consumption of fresh vegetables mainly for their health benefits [5]. Dietary antioxidants such as vitamins E and C, carotenoids and polyphenolic compounds found in vegetables are reported to be effective nutrients in the prevention of some oxidative and degenerative diseases [6]. Aside serving as a source of micronutrient, vegetables are a rich source of carotenoids such as β-carotene, zeaxanthin, lutein, lycopene [7]. The potassium content of vegetables are also very important in the management of diuretic and hypertensive difficulties. In countries like Nigeria, where the daily meals are mostly carbohydrate foods, aside spicing up meals with vegetables they are an inexpensive and most readily available source of vital nutrients such as proteins, vitamins, minerals and essential amino acid [8]. The levels of these vitamins and minerals in leaves however vary from one plant to another and from one location to another. This study therefore aimed at examining the level of vitamin and mineral in some vegetables consumed in Nigeria.

MATERIALS AND METHOD

Vegetables were harvested from National Horticultural Research Institute Ibadan environment. Some of the green leafy vegetables were rinsed in water and the edible portions were separated from the inedible portion. Fresh leaves were then analysed for beta-carotene, tocopherol and vitamin C. The other fresh leaves were further oven dried at 60^0C for 24h and milled using a blender before packing in polyethylene bags for mineral analysis.

Determination of vitamins

The extraction and determination of vitamin A and E were according to the method described by Okonwu et al. [9], [10] while vitamin C was determined using titrimetric method [11].

Determination of minerals

The mineral contents (Ca, Mg, Zn, and Fe) of the leave samples were determined using Atomic

Absorption Spectrophotometer (AAS).

Statistical analysis

Data from this research (n=3) were subjected to one-way analysis of variance at 95% confidence interval.

RESULTS AND DISCUSSION

As presented in Table 1, *significant* difference was observed in Beta-carotene, Tocopherol and Vitamin C content among the leafy vegetables. *Telfaria occidentalis* and *Solanum macrocarpon* gave highest value for beta-carotene and tocopherol respectively; these qualifies them as a good source of antioxidant needed by the body to prevent free radicals activities. β-carotene is the most common form of carotene in plants and it is the best known provitamin A carotenoid [12]. β-carotene values obtained in this study are higher when compared with values presented by Viviane et al on fresh weight basis. This increase in value can be as a result of difference in species, location, degree of maturity at harvest, cultivation, and postharvest handling practices [13]. However, Viviane et al., [14] reported lower β-carotene values for *Talinum fruticusum* (12.52)*, Vernonia amygdalina* (13.16)*, Cucurbita pepo* (12.25)*, Amaranthus hybridus* (11.15) mg/100g DW after sundrying the leaves for about 24h. This confirms the report of Gomez [15] that drying conditions results in a decrease in concentration of carotenoids in some vegetables when compared with the unprocessed samples. Sundrying process causes photooxidation of both trans- and cis carotenoids thereby resulting into epoxidation and cleavage to apocarotenals before dividing into sets of low mass compounds thus losing their biological activities. This means certain percentage of β-carotene has been lost during drying due to photooxidation. Vitamin C value for *Telfaria occidentalis* (50.30 mg/100g) was significantly different from other leave samples and this was followed by *Cucurbita pepo* (48.62 mg/100g) while Launaea taraxacifolia (4.19 mg/100g) gave the lowest value. These vitamin C values were lower when compared with values obtained by Oboh et al., [16] for both fresh and sundried leave samples of *Telfairia occidentalis*, *Solanum macrocarpon, Occimum graticinum* and *Vernonia amygdalina*. These lower values may be attributed to difference in leave treatment before analysis.

Table 1: Beta-carotene, Tocopherol and Vitamin C content of the vegetables

Vegetables Local name	Scientific names	Beta-carotene mg/100g (Fw)	Tocopherol mg/100g (Fw)	Vitamin C mg/100g (Fw)
Ugwu	*Telfaria occidentalis*	37.52^{a}	0.74^{g}	50.30^{a}
Tete	*Amaranthus hybridus*	26.48^{c}	1.03^{ef}	24.82^{d}
Water leaves	*Talinum fruticusum*	13.71^{g}	1.10^{ef}	10.53^{f}
Yanrin/wild lettuce	*Launaea taraxacifolia*	15.18^{g}	1.84^{d}	4.19^{g}
Bitter leaves	*Vernonia amygdalina*	18.71^{e}	2.63^{b}	42.17^{c}
Elegede/Pumpkin	*Cucurbita pepo*	24.50^{d}	0.94^{f}	48.62^{b}
Worowo	*Senecio biafrae*	17.50^{f}	2.11^{c}	10.61^{f}
Indian spinach	*Basela alba*	10.29^{h}	1.97^{cd}	24.02^{d}
Igba leaves	*Solanum macrocarpon*	34.80^{b}	4.15^{a}	4.46^{g}
Scent leaves	*Ocimum gratissimum*	20.47^{e}	1.13^{e}	19.83^{e}

Table 2: Mineral contents of the vegetables under studied

Local names	Scientific names	Calcium mg/100g (dw)	Magnesium mg/100g (dw)	Zinc mg/100g (dw)	Iron mg/100g (dw)
Ugwu	*Telfaria occidentalis*	63.66^{f}	388.23^{a}	34.90^{a}	2.45^{b}
Tete	*Amaranthus hybridus*	75.32^{e}	255.81^{b}	3.68^{d}	2.12^{c}
Water leaves	*Talinum fruticusum*	48.00^{g}	205.20^{c}	3.40^{d}	1.09^{e}
Yanrin/wild lettuce	*Launaea taraxacifolia*	433.67^{c}	102.00^{e}	4.60^{c}	0.50^{g}
Bitter leaves	*Vernonia amygdalina*	460.33^{b}	112.00^{d}	0.66^{f}	0.97^{f}
Elegede/Pumpkin	*Cucurbita pepo*	18.88^{h}	12.00^{i}	0.92^{f}	1.31^{e}
Worowo	*Senecio biafrae*	61.00^{f}	13.23^{i}	2.20^{e}	2.80^{a}

Indian spinach	*Basela alba*	197.00^{d}	27.11$_{h}$	3.48^{d}	0.38^{h}
Igba leaves	*Solanum macrocarpon*	762.33^{a}	35.33^{g}	5.80^{b}	1.54^{d}
Scent leeavs	*Ocimum gratissimum*	45.00^{g}	81.03^{f}	0.87^{f}	0.03^{i}

Minerals are important in human nutrition. It is well known that enzymatic activities as well as electrolyte balance of the blood fluid are related to adequacy of Na, K, Mg and Zn. As presented in Table 2, all the values were significantly different for calcium with Solanum macrocarpon having the highest value 762.33mg/100g and Cucurbita pepo having the lowest value 18.88mg/100g. Calcium functions in bone and teeth formation, it also regulates nerve and muscle function [17]. This value was higher when compared with value obtained by Achikanu et al., [18] for Solanum macrocarpon 712.33mg/100ml. For magnesium, values ranged from 12.00 to 388.23mg/100g, being highest in *Telfaria occidentalis* and lowest in *Cucurbita pepo.* Iron content ranged from 0.03 to 2.80mg/100g with *Senecio biafrae* having the highest and *Ocimum gratissimum* having the lowest value.

CONCLUSION

Data from this study shows that vegetables such as *Telfaria occidentalis*, *Solanum macrocarpon*, *Vernonia amygdalina*, and *Senecio biafrae* contain appreciable amount of minerals and vitamins. Thus, it can be concluded that these vegetables can contribute significantly to the nutrient requirements of man and they should be used as a source of nutritional supplement.

ABSTRACT
Proximate and phytochemical compositions of testas of Cola acuminata and Cola nitida fruits were determined using standard laboratory procedures. The testas were shade-dried at room temperature, grounded to powder which was extracted with methanol. Saponins, steroids, coumarins, flavonoids, glycosides, terpenoids, tripterpenes and alkaloids were detected and quantified. Testas of C. nitida fruit had higher alkaloids content ($P < 0.05$) (0.91 ± 0.00) when compared with that of C. acuminata while other phytochemicals detected showed no significant difference ($P > 0.05$) when compared. The carbohydrate and crude protein contents of C. acuminata fruit testa (28.02 ± 0.29 and 14.72 ± 0.37 respectively) are significantly higher ($P < 0.05$) compared to that of C. nitida fruit testa (26.99 ± 0.27 and 12.13 ± 0.01 respectively). The presence of these bioactive components in relative and reasonable quantities is an indication that the testas are of medicinal and nutritional importance most especially as an anticancer and probable source of protein.
Keywords: *Phytochemicals, Proximate, Cola acuminata, Cola nitida, seed testa*

INTRODUCTION

Cola plants are native to West Africa and sub-region of Africa and it is used for several purposes among different ethnic groups such as entertainment of tribal chiefs and guests at ceremonial gatherings in Nigeria (Unya, 2021; Ogunsowo *et al.,* 2023). Traditionally used in treatment of diseases, fruits of cola plants are used to treat diseases such as asthma, whooping cough, low libido e.t.c. (Asogwa *et al.,* 2011; Ezuruike and Prieto, 2014). It is also scientifically proven to moderate activities of some key glycolytic enzymes *in-vitro* which suggests its antidiabetic claims (Oboh *et al.,* 2014). Kola is a tree crop, also referred to as a cash crop and is known to be localized to Africa, particularly Nigeria, Ghana and Ivory Coast with Nigeria as the world's largest producer (Olubamiwa *et al.,* 2011). Although, over 50 species of kola have been discovered, about seven are edible nuts out of which only two, namely: *Cola acuminata* and *Cola nitida* have been exploited commercially. According to Brickell *et al.* (2002), it was reported that the annual production from the African countries in which they are localized is estimated to be in excess of 250,000 tons. Likewise, *C. nitida* and *C. acuminata* have been of trade importance for at least a thousand year and mostly known as one of the constituents for the production of soft drinks.
Kola tree grows up to 40fts (12m) tall and there are some with excess of 75fts (25m) with small buttress root and very dense foliage, the flowers are white or cream and usually with red markings at the base and also has fleshy, irregular-shaped, pink or red and sometimes white seeds (Brickell *et al.,* 2002; Ogunsowo *et al.,* 2023). The pod of kola nut also referred to as the husk, accounts for more than half of the kola fruit and is often considered as farm waste (Olubamiwa *et al.,* 2011). The husk is mostly regarded as an agricultural waste because it has little or no economic importance or specific purpose (Adeyi, 2010) and same goes for the testa. Although, taken as a farm waste, kola nut husk and testa has been found to be rich in protein, fibre and to some extent lipids (Fabunmi *et al.,* 2019). The South Western Nigeria especially, states like Oyo, Ondo, Osun and Ekiti are the highest producers of these agricultural wastes (Asogwa, 2011). These wastes, which are also referred to as farm by-products from plants like kola, cocoa, coffee, cashew and cassava have been used in production of animal feeds (Fabunmi and Arotupin, 2015). Most of the life science researches on *Cola* plants are based on the seeds (Kola nut) because it is the part of the plant which has more economic importance. There is therefore a need to explore the economic importance

of other parts of the plant such as; the leaf, shoot, flowers and also some parts of the fruit e.g. the testa and the pod/husk which has been shown to be a very good constituent in broiler feed formulation (Olubamiwa *et al.,* 2011).

MATERIAL AND METHODS

The fruits of *C. acuminata* and *C. nitida* were obtained from a local market in Osogbo, Osun State of Nigeria. A standard high speed blender was also used to grind the dried Cola testas so as to increase the surface area for detection of bioactive ingredients.

Sample Preparation: The pods of the *Cola* fruits were opened, the seeds were removed, and then washed with distilled water to remove exudates and other unwanted particles. The seeds were soaked in water for few days after which the testas were removed and air dried at room temperature under the shade to avoid loss of bioactive components through irradiation. Dried Cola testas were then pulverized to fine powder using the high speed blender and finally extracted using methanol as solvent. The methanolic extract was dried and stored in the refrigerator for further analysis.

Determination of Moisture, Ash, Lipid, Protein and Crude Fiber Content.

These were determined by the methods according to AOAC (2005).

Qualitative and Quantitative Phytochemical Screening

The methanolic extract of the cola testas were screened for their secondary metabolites following the methods described by Odebiyi and Sofowora (1978) and Harbone (1973) respectively.

RESULTS AND DISCUSSION

Values are expressed as mean of three replicates ± S.E.M and those with different superscript along column are significantly different ($P<0.05$) from each other.

Table 3: Proximate Analysis of *Cola acuminata* and *Cola nitida* Fruit Testa

Parameter	***C. acuminata***	***C. nitida***
Moisture Content (%)	12.64 ± 0.24^a	14.90 ± 0.21^b
Ash (%)	4.23 ± 0.38^a	3.70 ± 0.10^a
Carbohydrate (%)	28.02 ± 0.29^a	26.99 ± 0.27^b
Calorific Value (Kj/100g)	703.94 ± 0.91^a	701.92 ± 1.30^a
Lipid (%)	1.95 ± 0.04^a	1.21 ± 0.09^b
Crude Fibre (%)	40.26 ± 0.48^a	40.66 ± 0.02^a
Protein (%)	14.72 ± 0.37^a	12.13 ± 0.01^b

Values are expressed as mean of three replicates ± S.E.M and those with different superscript along column are significantly different ($P<0.05$) from each other.

Results from this study indicated the presence of secondary metabolites such as: flavonoids, glycosides, alkaloids, triterpenes, saponins, terpenoids, coumarins and steroids in the methanolic extracts of both *C. acuminata* and *C. nitida* seeds testas (Table 1). Alkaloids of *C. nitida* seed testa was significantly higher ($P < 0.05$) than that of *C. acuminata* seed testa with no significant difference ($P>0.05$) observed in other phytochemicals (flavonoids, glycosides, triterpenes, saponins, terpenoids, coumarins and steroids) investigated. Of all the phytochemicals investigated quantitatively (Table 2), flavonoids are found to be most abundant in testas of *C. acuminata* and *C. nitida* fruits (186 ± 0.29 mg/100g and 185.85 ± 0.16 mg/100g respectively). This is followed by steroids (133.70 ± 0.74mg/100g and 131.13 ± 0.69mg/100g for testas of *C. acuminata* and *C. nitida* respectively). Also found in significant quantities are triterpenes, glycosides and terpenoids with values of 15.36 ± 0.04mg/100g, 10.82 ± 0.17mg/100g and 9.50 ± 0.03mg/100g respectively for *C. acuminata*; 15.10 ± 0.05 mg/100g, 11.27 ± 0.01mg/100g and 9.74 ± 0.08 mg/100g respectively for *C. nitida.* The presence of these phytochemicals suggests that the testas of *C. acuminata* and *C. nitida* seeds can serve as a good source of bioactive components of greater medicinal value. For instance, saponins and coumarins have been said to be of immense importance as anticancer agents (Vianna *et al.,*2012).

Terpenoids and terpenes are significant for maintenance of membrane structure, repellant and attractants in plant (Kempinski *et al.,* 2015). The crude protein for *C. acuminata* and *C. nitida* testas (14.72 ± 0.37 and 12.13 ± 0.01 respectively) are higher compared to the one reported for kolanut testa by Fabunmi *et al.* (2019) the ones reported for *C. acuminata* and *C. nitida* seeds by Okeke *et al.* (2015) and Olorundare *et al.* (2023) while the ash content and lipid content of the testas are lower when compared to that of the seeds as reported by Okeke *et al.* (2015) (Table 3). Finally, this study recommends further purification and utilization of these phytochemicals for pharmaceutical purposes and exploration of the nutritional value of these testas.

CONCLUSION

The testa is a major part of the *Cola* fruit but commonly considered as unimportant agriculture waste by many farmers. With the results obtained above, testas of both *C. acuminata* and *C. nitida* seeds are rich in phytochemicals of medicinal importance and can be explored using their therapeutic potentials in the development of novel drug in pharmaceutical industries. The results from the proximate analysis of these testas also indicated that they are of nutritious value and can be useful nutritionally especially in the development of feeds for livestock.

ABSTRACT
This study was carried out to assess the growth performance and qualitative traits of seven selected NIHORT okra genotypes. The study was carried out at the vegetable research field of the National Horticultural Research Institute, Ibadan, using randomized Complete Block Design (RCBD) with three replicates. Plant height and number of leaves were taken at 2, 4 and 6 weeks after sowing (WAS). Morphological characterization of the cultivars was also carried out following IBPGR (1984) descriptor for okra. The results showed significant variation in terms of plant height (2 and 6 WAS) as NHOKRA1 recorded the highest plant height at 2 and 6 WAS with 5.64 cm and 40.25cm respectively. The number of leaves was significantly higher in NHOKRA1 at 2 WAS and NHAe47-4 at 4WAS. The qualitative traits as revealed by the morphological characterization evaluation showed that similarities were observed for the seven cultivars in terms of growth habit, fruit position, stem and fruit colour, branching habit among others. Distinct variations were observed for stem pubescence, leaf shape, number of nodes, fruit type among others. The distinct morphological variations observed among the cultivars can still be tapped by breeders for okra improvement. Although, cultivars like NHOKRA1 and NHAe47-4 have been registered and released and are currently being cultivated by farmers across the country, improvement of other cultivars with good potential is also important to expand okra genetic base. However, there is need to evaluate the yield potential to be able to make a good conclusive comparison among the cultivars.
***Keywords**: characterization, growth habit, okra cultivars, okra improvement.*

INTRODUCTION

Okra originated from the Abyssinian center, an area that includes Ethiopia, a portion of Eritrea, and the eastern higher part of the Anglo-Egyptian Sudan (Atchison, 2018). Presently, okra is grown nearly all over the world. Although, in Africa, the crop is cultivated in Kenya, Nigeria, Sudan, Gabon, Cote d'Ivoire, Mali, Mauritania, Senegal, Cape Verde, and Chad (Atchison, 2018)**.** Okra (*Abelmoschus esculentus*) belongs to the Malvaceae family and it is cultivated in all agro-ecological zones in Nigeria for its immature fruits and leaves which are consumed as vegetable. The dried seeds provide oil, protein, vegetable curd, and a coffee additive or substitute. Okra dry seeds contain 18–20% oil and 20–23% crude protein (Dantas *et al.*, 2021). Foliage can be used for biomass, and the dried stems serve as a source of paper pulp or fuel. To a limited extent, okra is used in canned, dehydrated or frozen forms. The world production volume of Okra as fresh fruit vegetable is estimated at 8.90M tons (Tridge, 2016). Although Nigeria accounts for 22.5% of the total world production of okra (FAOSTAT, 2019). Variations in flowering and fruiting depends on variety as early flowering and fruiting may commence within five weeks after planting.

There are numerous cultivars of okra grown throughout Nigeria and some are more prevalent in certain regions. The National Horticultural Research Institute (Ibadan) has developed many okra cultivars. Some have been registered while concerted research efforts are still ongoing to ensure development of new cultivars of improved traits in order to meet Nigerian farmers' and consumers' traits of preference such as earliness, tolerance to diseases, high yield, canopy structure among others. This study compares the growth performance of seven NIHORT okra lines and their qualitative traits.

MATERIALS AND METHODS

The study was conducted at the vegetable research field of the National Horticultural Research Institute (NIHORT), Jericho Reservation Area, Ibadan (lat. 7.398980 and long. 3.920400). Seven Okra genotypes developed by NIHORT (NHAe47-4/K, LD 88/K, NHOKRA 1, Bagauda Spineless, NHAe47-4, IK11, LD88) were evaluated at the early cropping season of 2023. The experiment was laid out in Randomized Complete Block Design (RCBD) with three replications. The plot size for each cultivar was 2m × 2m and a plant spacing of 50cm × 50cm was used. All recommended crop management practices to raise a healthy crop were carried out. Data were collected on plant height and number of leaves at 2, 4 and 6 weeks after sowing (WAS). Morphological characterization of the genotypes was carried out following IBPGR (1984) descriptor for okra. Data collected on quantitative traits were subjected to analysis of variance and significant means were separated using Duncan Multiple Range Test.

RESULTS AND DISCUSSION

The result in table 1 revealed that NHOKRA1 recorded the highest plant height (5.64 cm) at 2 WAS, but this was not significantly different from plant height of NHAe47-4 (4.94 cm) at 2 WAS. LD 88 had the lowest plant height at 2 WAS but it was not significantly different from IK11. The result also indicated that the number of leaves at 2WAS varied between 4.24 in NHOKRA1 (which was the highest) and 2.62 in LD 88 (which was the lowest). However, four genotypes (NHAe47-4/K, Bagauda Spineless, LD88/K and NHAe47-4 had statistically similar number of leaves. Similarly, LD 88 had the least number of leaves which was not significantly different from IK11 (Table1). At 4 WAS, no significant variation was recorded among the seven cultivars in terms of plant height. However, NHAe47-4 recorded the highest number of leaves at 4 WAS but this was not significantly different from IK11, LD88, Bagauda Spineless, NHOKRA1 and LD88/K. The lowest number of leaves was recorded in NHAe47-4/K with five leaves. At 6 WAS, NHOKRA1 had significantly highest plant height (40.25 cm) above all the other genotypes. NHAe47-4 had the lowest plant height but this was not significantly different from height of NHAe47-4/K (Table1). There was no significant difference in the number of leaves of the 7 genotypes at 6 WAS although IK11 had the highest number of leaves (10) while NHOKRA1 had the lowest number of leaves (8).

The results obtained in this study is supported by the findings of Ibrahim *et al*., (2020), where significant differences were observed between LD88 and NHAe47-4 regarding vegetative parameters like plant height. The significance observed could be as a result of differences in genetic make-up of the cultivars as reported by Elhag *et al*., (2014) who observed significant among okra genotypes in their previous study. The morphological characterization result also revealed variations and similarities among the cultivars as shown in table 2. All the cultivars have erect plant growth and position of fruit but with sparse branching habit at vegetative stage. Their stems, leaves and petiole colours are all green meaning that there is no other type of pigmentation. The shape of calyx was spiny, and the corolla colour was generally golden yellow. Major variations among the cultivars were observed for stem pubescence where they exhibited intermediate (2 cultivars), smooth (4 cultivars) and glabrous (1 cultivar). Distinct leaf shape, number of nodes and fruit type were also observed. Among the cultivars, two have smooth fruit while three are slightly spiny. The remaining two are spineless.

The results of this study agrees with that of Anyaoha *et al*., (2023) where the fruit surface (spinelessness) of NH47-4 was reported to be prickly. Ogwu *et al.,* (2018) also reported variations in the fruit type of selected okra genotypes as seen in this study. Furthermore, Anyaoha *et al*., (2023) and Osawaru *et al.,* (2013) reported similarities and morphological differences between accessions. The growth parameters evaluated also indicated that at least two or more cultivars have similar growth rate which may be due to the parental lines used to develop them. The distinct morphological variations observed among the cultivars can still be tapped by breeders for hybridization program. Although, cultivars like NHOKRA1 and NHAe47-4 have been registered and released for public use and are currently being cultivated by farmers across the country improvement of other cultivars with good potential is also important. However, there is need to evaluate their yield potential to be able to make a good conclusive comparison.

Table 1: Growth parameters of seven okra genotypes at 2, 4 6 weeks after sowing

Variety	**2 WAS**		**4 WAS**		**6 WAS**	
	Plant Height (cm)	**No of leaves**	**Plant Height (cm)**	**No of Leaves**	**Plant Height (cm)**	**No of Leaves**

INFLUENCE OF BIOCHAR ON Celosia argentea PERFORMANCE IN ATRAZINE AND NICOSULFURON-TREATED SOIL

Ayodele O. P*, Udemba I. O, Aluko O.A
Institute of Agricultural Research and Training (IAR&T), Obafemi Awolowo University, PMB 5029 Moor Plantation, Ibadan, Nigeria.

ABSTRACT
This study evaluated the performance of celosia in atrazine and nicosulfuron-treated soil amended with biochar. A 5 × 4 factorial experiment was laid in the screen house using a completely randomized design. Biochar at the volume rate of 0% (control), 5%, 10%, 15%, and 20% was incorporated into different potted soils which were subsequently treated separately with four levels of herbicides namely control (no herbicide), atrazine at 3.0 kg a.i ha-1, nicosulfuron at 40 g a.i ha-1, and a mixture of atrazine and nicosulfuron at 750 g a.i ha-1 and 60 g a.i ha-1. These treatments were replicated four times. Celosia was transplanted into the treated soils six weeks after application, coinciding with 2 weeks after sowing in the nursery. Data were collected from 3-6 weeks after transplanting (WAT) on plant height and number of leaves, while fresh and dry weights were determined at 8 WAT. The result showed that nicosulfuron residues significantly increased the number of leaves and the fresh and dry weights of celosia, whereas atrazine resulted in the lowest values from 3-6 WAT. Also, a 10% biochar inclusion rate significantly enhanced the growth and yield of celosia over biochar-free. However, celosia in soil treated with nicosulfuron and 10% biochar had the highest height, number of leaves and fresh weight. Hence adoption of this treatment in multiple cropping systems involving follow-up of maize with celosia is recommended.

INTRODUCTION
Maize (Zea mays) holds a pivotal position in the Nigerian farming system, with approximately 50% of the nation's farming households engaged in its cultivation (Sasu, 2023). Consequently, the adoption of selective herbicides such as atrazine and nicosulfuron for cost-effective weed management in maize fields is widespread across the country. These herbicides, aside from disrupting critical physiological processes of photosynthesis and acetolactate synthase in weeds, exhibit prolonged persistence within the soil, leading to an adverse phytotoxic "carryover" effect on subsequent crops (Jablonowski *et al*., 2011; Ahmadi *et al*., 2017). Furthermore, in rainfed multiple cropping systems, it is common practice to plant vegetables such as Celosia argentea following the maize crop to capitalize on the available soil moisture (Aladesanwa *et al*., 2001). However, Celosia argentea's vulnerability to atrazine and nicosulfuron residues in the soil can result in crop injury and reduced yields. Therefore, the extended persistence of these herbicides poses significant challenges in relay intercropping and rotational cropping systems, which are prevalent in Nigeria's agricultural systems.
Biochar, typically created through pyrolysis, is an exceptional soil amendment capable of enhancing soil quality by increasing pesticide adsorption potential (Kamila *et al*., 2021). Remarkably, biochar has been reported to have a high affinity for atrazine and nicosulfuron (Wang *et al*., 2020). Therefore, this study aims to investigate the implications of incorporating biochar into the soil as a potential crop injury mitigation strategy for cultivating celosia on herbicide-treated maize farms.

MATERIALS AND METHODS
The screen house study was conducted as a 5 × 4 factorial experiment using a completely randomized design and was situated at Adekunle Ajasin University, Akungba-Akoko, Nigeria. Four plots were marked in the screen house, each measuring 1 × 1 m. Five polythene pots, measuring 5 × 3 cm each, were filled with a mixture of 2 mm sieved topsoil and biochar, employing volume mixing ratios of 0% (control), 5%, 10%, 15%, and 20% biochar inclusion rates. This procedure was replicated four times

per plot, placing twenty pots within each plot. The physicochemical properties of the topsoil and biochar are presented in Table 1. The soil and biochar were slightly acidic and alkaline, respectively. Meanwhile, the organic carbon content of the soil was low. However, biochar had a relatively high quantity.
Subsequently, herbicide levels, including control (no herbicide), atrazine at 3.0 kg a.i ha-1, nicosulfuron at 40 g a.i ha-1, and a mixture of atrazine and nicosulfuron at 750 g a.i ha-1 and 60 g a.i ha-1, were separately applied to the plots using a knapsack sprayer. For the control treatment, water was solely applied. Six weeks after herbicide application, Celosia argentea (TLV 8) seedlings were transplanted into the potted soil at the two-leaf stage two weeks after sowing in the nursery. Data were collected on the height and number of leaves from 3-6 weeks after transplanting (WAT). The fresh and dry weights of the plants were determined at 8 WAT through destructive harvesting. The collected data were subjected to Analysis of Variance (ANOVA) using SPSS software, and significant means were separated using the Duncan multiple range test (DMRT) at a 5% probability level.

RESULTS AND DISCUSSION

Across weeks of evaluation, the performance of celosia was significantly influenced by the applied herbicides, biochar and their interactions. This highlights the potential role of soil residual activities of nicosulfuron and atrazine and the growth-promoting efficacy of biochar in Celosia production. Celosia in nicosulfuron-treated soil had the highest number of leaves, height, fresh and dry weight, though statistically similar to values from other herbicide treatments (Table 2). The exception was atrazine treatment from 4-6 WAT and herbicide-free at 5 WAT for the number of leaves (Tables 2). Comparable performance of celosia in nicosulfuron and herbicide-free treatment suggests that the soil residue of the former had no phytotoxic effect on the plants. Conversely, in line with Aladesanwa *et al*. (2001) and Hanson *et al*. (2020), the least growth (except for plant height at 3-4 WAT) and yield of celosia from atrazine treatment at the time of evaluation (Tables 2) might be connected to the boomerang effect of atrazine's prolonged persistence in the soil and associated phytotoxicity. The persistence of atrazine in the soil could be due to its resistance to abi dotic hydrolysis and direct aqueous photolysis (Liu, 2014).
Notably, the height, number of leaves and fresh weight of celosia in biochar-free treatments were lowest and differed significantly from values obtained from biochar treatments except 5% biochar at 4 WAT for number of leaves and 15% and 20% biochar for fresh weight (Table 3). The substitution of 10% of the soil volume with biochar significantly enhanced the number of leaves, height, and fresh and dry weight of celosia compared to the biochar-free treatment (Table 3). Meanwhile, this performance could be attributed to the substantial amount of organic matter in biochar, improving soil physical, chemical and microbial properties (Quilliams *et al*., 2013; Ghidotti *et al*., 2017). However, the numerical observations from the 10% biochar treatment were similar to the height observed in the 5% biochar treatment at 3 WAT and in 15% and 20% biochar treatments at 3 and 4 WAT, as well as the number of leaves in all biochar-inclusive treatments at 3 and 6 WAT, and the 15% biochar treatment at 4 WAT (Table 3). Additionally, the weights (both fresh and dry) of all biochar-treated soil were comparable to 10% biochar, except for the dry weight in the 5% inclusion (Table 3).
Furthermore, a critical appraisal of the herbicide-biochar interaction on the performance of celosia showed that 10% biochar in herbicide-treated soil promoted the growth of celosia over biochar-free soil with herbicide application as seen in the number of leaves and plant height of celosia at 3 to 6 WAT, except for the number of leaves in atrazine treatments without biochar at 5 and 6 WAT (Table 4). In contrast to soil treated with biochar, using atrazine and a mixture of atrazine and nicosulfuron in soil without biochar led to a decrease in the number of leaves at 4 and 5 WAT, respectively. Therefore, it appears that the application of biochar helps mitigate phytotoxicity. This finding agrees with the report of Clay *et al*. (2016) that the application of biochar to soil increases herbicide sorption and reduces phytotoxicity.
Notably, celosia in soil treated with nicosulfuron and 10% biochar consistently had the tallest plants with numerically highest leaves and fresh weight, but the best dry weights were recorded from herbicide-free + 10% biochar treatment (Tables 4). The adoption of nicosulfuron and 10% biochar by farmers can enhance their profitability and ensure the safe cultivation of celosia in maize farmlands that are subjected to intercropping and rotational cropping. Conversely, soils treated with atrazine-

nicosulfuron mixture in biochar-free soil produced the shortest plants with the least number of leaves across the weeks of evaluation except at 4 and 6 WAT when soils treated with atrazine + 0% biochar, and herbicide-free + 0% biochar produced celosia with least number of leaves, respectively (Table 4).

CONCLUSION

The residual effects of nicosulfuron in the soil six weeks after application did not negatively impact the growth and yield of celosia. In contrast, atrazine residue and residues from atrazine-nicosulfuron mixtures may temporarily hinder Celosia growth. Nicosulfuron proved to be more effective in enhancing Celosia performance compared to atrazine. Additionally, the growth-promoting potential of biochar for celosia became evident in biochar-amended soil. Enriching atrazine-treated and atrazine-nicosulfuron-treated soil with biochar creates a secure environment for cultivating celosia as a subsequent crop after maize.

QUANTIFYING KENAF VEGETABLE YIELD ACROSS DIVERSE PLANT STANDS IN FIBRE KENAF FIELD

ABSTRACT
Kenaf (Hibiscus cannabinus) is often sown with multiple seeds per stand to compensate for low germination rates, leading to variability in plant density per stand. Consequently, thinning and supplementary sowing are required to mitigate competition and achieve the recommended plant population per stand. This study aims to estimate the effects of different plant densities on kenaf's growth and vegetable yield when thinned to two plants per stand. Kenaf (Ifeken 400) seeds were sown in the field following a Randomized Complete Block Design for the arrangement of experimental plots. Subsequently, kenaf plants from plant stand densities ranging from 1 to 5 plant(s) were observed. Findings indicate that stand density significantly influenced ($p<0.05$) kenaf growth and yield parameters. Single-plant stands exhibited superior height, leaf count, and stem girth. Moreover, individual kenaf plants in single-plant stands exhibited higher fresh and dry weights compared to individual kenaf plants in multiple-plant stands. The highest total fresh weight per stand was recorded in stands with 5 kenaf plants. Additionally, a fresh kenaf vegetable yield ranging from 16 to 20g per stand was obtained by thinning the stand densities to 2 plants per stand. These findings contribute to a better understanding of how to optimize kenaf cultivation for fibre and vegetable purposes while simultaneously promoting sustainable agricultural practices.
Keywords: *Competition, Plants per Stand, Thinning, Supplying, Vegetable Kenaf*

INTRODUCTION

Kenaf (Hibiscus cannabinus), a plant of significant agricultural interest, offers versatile applications as a consumable vegetable and a valuable fibre source. (Kujoana *et al*., 2023). This dual utility underscores its vital role in addressing various societal needs, ranging from nutrition to industry. However, the high oil content in kenaf seeds leads to a rapid decrease in viability (Akinbode *et al*., 2022). In response, farmers employ the practice of sowing multiple seeds per stand to counteract reduced germination rates. This leads to densely populated stands where plants engage in complex interactions, including competition for essential resources like soil nutrients, water, sunlight, and airflow (Zhai *et al*., 2018). The growth and yield of kenaf are intricately influenced by various factors, with the number of plants per plot playing a pivotal role (Yusoff *et al*., 2019). This factor is crucial as it directly affects interactions within the stands, significantly impacting the crop's overall health and development.

In Nigeria, kenaf cultivation for fibre production typically involves a spacing of 20cm x 50cm, with two plants per stand following thinning (Olanipekun *et al*., 2019). Thinning, which is the selective removal of surplus plants within a stand, plays a fundamental role in kenaf production. Notably, Webber III *et al*. (2002) emphasized that the optimal kenaf plant population for maximizing fibre yield is 187,500 to 375,000 per hectare. Therefore, the significance of thinning lies in its ability to achieve ideal plant spacing and optimize plant stand density for various end purposes. Additionally, thinning reduces competition and fosters the development of thicker stems and higher-quality fibre (Reta-Sánchez *et al*., 2010).

Researchers and farmers have explored thinning practices to maximize kenaf cultivation's benefits for fibre and vegetable purposes. However, the repurposing of thinned kenaf plants as a consumable vegetable has been underexplored in kenaf cultivation for fibre production. The adaptive utilization of thinned kenaf plants for consumption offers the opportunity to turn waste into wealth. Nevertheless, the literature lacks comprehensive insights into the potential vegetable yield based on the number of kenaf plants per stand in fibre kenaf fields. Hence, this study addresses this knowledge gap by investigating the effect of varying plant counts per stand on kenaf's agronomic performance and vegetable yield from thinned kenaf plants.

MATERIALS AND METHODS

A field trial was established at the Institute of Agricultural Research and Training (IAR&T) Ibadan in 2023. This was layout in Randomized Complete Block Design. After thorough ploughing and harrowing, 2m x 10m plots were set up within three blocks. Kenaf seeds (Ifeken 400 variety), sourced from the Seed Store Unit of IART, were sown in 20cm x 50cm spacing, with five seeds sown per hole. At the five-week mark following sowing, plant stands varying from 1 to 5 plant(s) per stand were sampled in triplicate from each block. Data on height, number of leaves, stem girth, as well as fresh and dry weights were collected from the samples. In stands containing more than two kenaf plants, the fresh weight of kenaf plants intended for vegetable use was determined by subtracting the combined weight of two plants designated for fibre kenaf production from the total weight per stand. The data were subjected to Analysis of Variance (ANOVA) using SPSS® software, and significant means were separated using the Duncan Multiple Range Test at a 5% significance level.

RESULTS AND DISCUSSION

The findings from this study indicate a significant impact ($p<0.05$) of stand density on kenaf growth at 5 weeks after sowing (Fig. 1). Specifically, kenaf plants in single-plant stands exhibited the best performance in terms of height, leaf count, and stem girth. These kenaf plants showed significantly better growth compared to plants in other densities, except for the height of the kenaf plants in 2 and 3 plant stands and the number of kenaf leaves from stands with 3 plants (Fig. 1a). This result aligns with the report of Yusoff *et al*. (2019), which suggests that as plant stand density rises, there is heightened competition for crucial soil nutrients, water, sunlight, and proper airflow, consequently leading to a decrease in kenaf growth. Similarly, for both fresh and dried measurements, the lignified stem, edible shoot, root, and whole plant of kenaf plants from single-plant stands exhibited significantly greater weight compared to corresponding plant components from individual plants in different stand densities. The exceptions to this trend included the fresh weight of lignified stems and root plants in stands with 3 plants, the dry weight of lignified stems per plant in stand densities of 2-5 plants, and the edible shoot weight per plant in the 2-plant stand density (Fig. 1b and 1c). These observations further emphasize the impact of intraspecific competition on kenaf performance.

Conversely, the cumulative weights of the whole kenaf plant and its component parts from stands with 5 plants were the highest, significantly different from observations for other stand densities, except for the fresh weight of lignified stem in stands with 3 and 4 plants, the fresh weight of roots in stand densities of 1-4 plants, the dry weight of lignified stem in stand densities of 1-4 plants, and the dry weight of the edible shoot, root, and whole plant in stand densities of 3 and 4 plants (Figs. 1d & 1e). Remarkably, the fresh and dry weights of all kenaf plants and plant components, except for the fresh weight of roots per stand, were significantly influenced ($p<0.05$) by stand density (Figs. 1d & 1e). Furthermore, the fresh edible shoot weight of kenaf plants per stand significantly increased with the addition of two kenaf plants within the stand (Fig. 1d). The results emphasize the advantage of cultivating multi-plant stands to achieve optimized vegetable yield, even in cases where seed germination is not a challenge. Notably, these findings are consistent with the report by Acreche *et al*. (2005), which highlights the influence of plant density on kenaf yield per unit area of production.

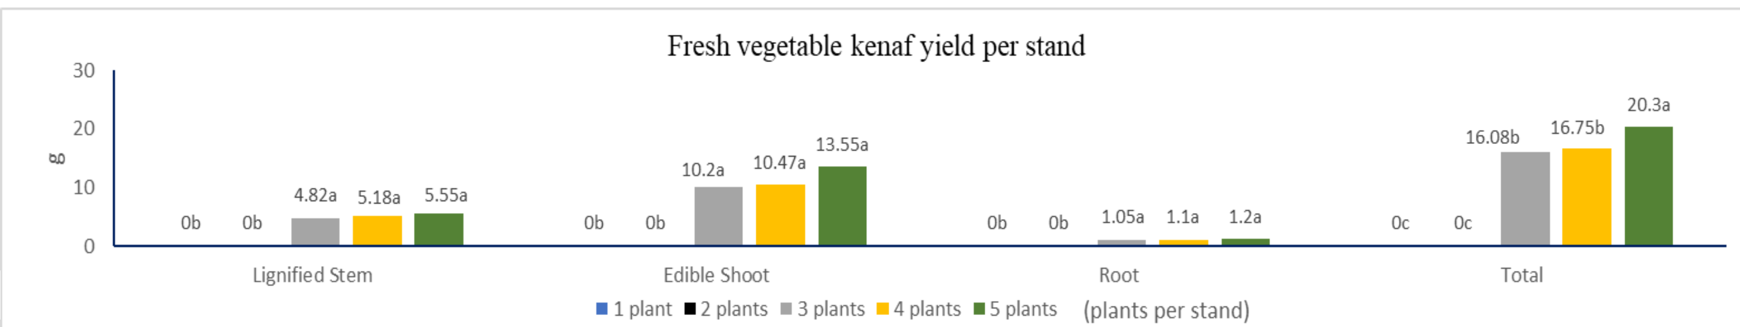
Figure 1: Effect of Plant Stand Density on Kenaf Growth



f

Figure 2: Effect of Plant Density on Kenaf Vegetable Yield

Considering the naturally varying densities of kenaf plant stands from the same seeding rate in this study, the potential for non-uniform and underpopulated kenaf stands for fibre production is evident. Therefore, it may be necessary to ensure uniform kenaf plant distribution for fibre production by supplying kenaf stands with single plants and thinning multi-plant kenaf stands comprising 3 to 5 plants. Following stand thinning to 2 plants per stand, stands where only 1 or 2 plants emerged yielded no vegetable (Fig. 2). This deprives the farmers of the short-term immediate benefit of food or income that can be generated from vegetable kenaf sales prior to fiber production. In contrast, weight of lignified stem, edible shoot, root and whole plant of kenaf vegetable that was obtainable after thinning increased with kenaf stand density (Fig. 2). Stands with 5 plants had significantly higher total fresh weights than stands with 3 and 4 plant densities. However, the latter two plant densities compared favorably with the 5-plant density for the fresh weight of lignified stems, edible shoot, and root (Fig. 2). As the numerical vegetable yield from thinned plants increased proportionally with the number of plants per stand, with the highest fresh kenaf vegetable biomass achieved in stands containing 5 kenaf plants, it can be inferred that the potential yield of kenaf vegetables from thinned plants depends on the initial plant population per stand and increases with higher seed germination rates per stand. Notably, fresh kenaf vegetable yields from thinned stands ranged between 16 and 20g per stand. Excluding border plants, a planting spacing of 20 cm x 50 cm results in 100,000 stands per hectare. This study's findings suggest that, with a kenaf seed viability of 100 percent, fibre kenaf fields have the potential to yield up to 2 tonnes of fresh vegetable kenaf per hectare in addition to the fibre yield. This can generate an additional revenue of about ₦200,000 per hectare at the rate of ₦100/kg.

CONCLUSION

While acknowledging the significant challenge posed by seed viability in kenaf production, this study lays the groundwork for estimating the potential yield of vegetable kenaf through thinning practices in fields initially designated for fibre kenaf cultivation. This introduces an alternative source of income and food for farming families and the broader Nigerian population while highlighting the significance of improving seed viability in kenaf production.

ABSTRACT
*Experiment was conducted at the Teaching and Research Farm of Oyo State College of Agriculture and Technology, Igbo-ora. To assess the effect of different rates of NPK 15:15:15 fertilizer on the growth and seed yield of sesame (Sesamum indicu). Treatments were allocated to pots in Complete Randomized Design (CRD) and replicated five times. Treatments were; Control (0kgNPK/ha), 30, 60, 90 and 120 kg NPK/ha. At harvesting data collected were; Total dry matter (stem, root and seed) weight. Data collected were subjected to Analysis of variance **(ANOVA)** and significant means separated by Duncan Multiple Range Test **(DMRT)** at 0.5%. There was significant difference among the treatments examined and the use of 120kg/ha N gave the highest response followed by 60kg/ha N. Similarly, 120kg/ha N > 60kg/ha N was shown by all characters considered but with no significant difference. Thus, 60kg/ha N is recommended for optimum yield to minimize cost of production.*

INTRODUCTION

Sesame (*Sesamum indicum* L.), otherwise known as *sesamum* or benniseed, is a member of the family *Pedaliaceae*. It is one of the most ancient oilseed crops known to mankind. Sesame plays an important role in human nutrition. Most of the sesame seeds are used for oil extraction and the rest are used for edible purposes (El Khier *et al.,* 2008). The major world producers include India, Sudan, China and Burma (that contributes about 60% of the total world production) (El Khier *et al.,* 2008). It is cultivated for its edible seeds, used for bread, biscuits, Crackers, and so forth and as seasoning in food and complement to many dishes all over the world due to the quality of its oil, protein, antioxidant, anti-proliferative properties as well as its high adaptability in harsh climatic and extreme environment (Namiki, 2007). In Nigeria, the seeds are consumed fresh, dried, fried or when blended with sugar. It is also used as a paste in some local soups (Fariku, *et. al.,* 2007).

However, the demand for sesame seeds has increased in the last two decades due to high oil quality, protein and antioxidant contents, and wide adaptability in extreme climatic and edaphic environments. Recently, Olatunji, *et. al.* (2022) in their work concluded that sesame enriched biscuits provide a viable means to obtain good quality nutrition and minimal risk of heart or organ disabilities. In spite of its multi-dimensional uses, the commercial and mechanized cultivation of sesame in Nigeria is not encouraging and its yield is very low. On the average 500kg of sesame seeds are harvested per hectare in Nigeria (Alegbejo, *et al*., 2003) which is much lower than the average yield of other countries such as Egypt (1120 kg ha^{-1}), Mexico (960 kg ha^{-1}), and China (900 kg ha^{-1}) (Anonymous, 1996). Poor growth of locally cultivated sesame can be traced to low soil fertility. Among the measures adopted to increase the production of sesame is the introduction of new varieties with high yield potentials as well as application of suitable cultural practices such as fertilization and weed control.

Paucity of information on the appropriate fertilizer recommendation for sesame is one of the major production problems in Nigeria. Fertilizer is usually not applied to sesame by traditional farmers in

Nigeria (Van Rheenen, 1973). Previous trials have, however, shown varietal and location differences in response to N and P fertilization in Northern Nigeria (Voh, 1998). The purpose of this present study therefore, was to evaluate the effects of different rates of NPK 15:15:15 fertilizer on the yield of sesame *(Sesamum indicum).*

MATERIALS AND METHOD

The experiment was carried out during early 2021 dry season at the Teaching and Research Farm of Oyo State College of Agriculture and Technology, Igboora, located on latitude 7°30N and 3⁰45E. It was conducted under a Complete Randomized Design (CRD), replicated five (5) times. The test crop used is (*Sesamum indicum)* varieties named NCRIBEN- 05E (Kenena 4), obtained from NCRI, Badeggi. Seeds were plant drill in the poly-bag and later thin to one seedling per stand at three (3) weeks after planting. NPK 15.15.15 was applied two weeks after planting. The rates of application were; T1 (00\kg/ha) as control. T2, (30kg/ha), T3 = (60kg/ha), T4 = (90kg/ha) and T5 = 120kg/ha) respectively.

Soil sample and sampling analysis

Soil samples were taken randomly in the field by using soil auger at the depth of 0-15cm; the soil was air dry for three weeks. The dried soil was sieved using 2mm mesh size sieve and mixed to obtain a composite sample soil. Sample of the composite soil was therefore taken to the laboratory for soil analysis. Weeding was done manually by hand-weeding throughout the period of the research. Data collected were yield and yield components which include; Number of pods, stem dry weight, total dry matter, root dry weight and seed dry weight. All data collected were subjected to Analysis of variance (ANOVA) and the significant means were separated using Duncan Multiple Range Test (DMRT) at 5% probability level.

RESULT AND DISCUSSIONS

The result obtained in Table 1, indicated that the soil of the experimental site was slightly acidic with pH value 0f 6.20 and low in Organic carbon 17.6. Total N available P, K, Ca and Mg were low. The TN, Available P as well as Org. C contents of this soil were an indication of poor fertility status of a tropical soil. The result recorded in Table 2 also indicated that the soil has 76.2% sand, 9,7 % silt and 1.41% Clay and textural class was loamy sand. Table 3 showed that the use of N fertilizer at different rates had significant difference ($P \leq 0.05$) on the yield of *Sesamum indicum.* Treatment (T1) control had the lowest *Sesamum indicum* yield whilst treatment (T5) fertilized with 120kgN/ha gave the highest *Sesamum indicum* seed dry weight yield respectively. The order of response for the seeds dry weight was T5> T3 > T2 & T4 > T1. From all the yield and yield components evaluated T5 always gave the best response followed by T3 in all the characters examined but with no significant difference.

However, there was no significant ($P > 0.05$) difference between 60kgN/ha and 120kgN/ha rates of application. This indicated that 120kgN/ha had greatest influence on the yield than other rates applied but with no significant difference when compared with yield due to application of 60 kg N ha^{-1}. From the total number of pods considered, the order of response by the treatments was T3 > T5> T4> T2>T1 respectively. Thus, it means for maximum economic returns, the use of 60 kg N/ha should be considered. Hence, it can be concluded that the effects of N fertilizer applied at different rates had significant difference ($P < 0.05$) on the yield and yield components of *Sesamum indicum* plants.

The result obtained in Fig. 1, showed that treatment T1 had the lowest number of pods/plant with mean value of 32.5 whilst treatment T5 produced the highest mean number (79.2) pods/plant followed by T3 (76.8) with no significant treatment mean difference throughout the period of investigation up to 12 weeks after planting (WAP). Hence, the use of 60 kg N/ha should be considered for optimum production of *Sesamum indicum.* The observed results corroborated the findings of Gebregergis and Amare (2019) that affirmed that in the potential areas, application of 46-100 kg N/ha gives optimum yield and the application of less than 46 kg N/ha is economical in the marginal areas.

ABSTRACT

The study evaluates the influence of poultry litter biochar and poultry manure on the performances of okra in South-Western Nigeria. The experiment consists of 5 treatments: 7.5 t/ha biochar, 7.5 t/ha poultry manure, 2.5 t/ha biochar + 5 t/ha poultry manure, 5 t/ha biochar + 2.5 t/ha poultry manure and control (no application) laid out in Randomized Complete Block Design (RCBD) and replicated three times. Data on growth and yield attributes were collected from six randomly selected okra plants/treatments and were subjected to Analysis of Variance (ANOVA) with significant treatment means compared using Duncan Multiple Range Test (DMRT) Results of this study revealed that, 7.5 t/ha poultry litter biochar and 2.5 t/ha poultry litter biochar + 5 t/ha poultry manure best improved the soil compared to all other soil amendment with the combination of 2.5 t/ha poultry litter biochar +5 t/ha poultry manure observed to have an edge compared to the other treatments in the improvement of growth and yield performances . Therefore, it is recommended that to improve the soil as well as the performance of okra, combination of 2.5 t/ha poultry litter biochar + 5 t/ha poultry manure should be adopted, however due to the low radical scavenging power of the fruits from that treatment, it is recommended that further study should be carried out with other rates of application combination especially with the free radical scavenging power of the fruits as the main parameter.

Keywords: *Poultry manure, Poultry litter Biochar, performance, okra.*

INTRODUCTION

Okra (*Abelmoschus spp*, (L) Moench), is a very important vegetable crop in the tropical and sub-tropical regions (Bisht and Bhat, 2016). The crop is a dicotyledonous plant, of the family *Malvaceae* (Schippers, 2000) which comprise a number of species including other foods, fibre, and medicinal crops such as cotton and kenaf (Anderson and Pharis, 2013). It is one of the oldest cultivated crops and presently grown in many countries and is widely distributed in Asia, Africa, Southern Europe and America (Oyelade *et al*., 2013). It is reported to have originated in tropical Africa (Akanbi *et al*., 2015). The continuous need for enhanced and improved crop performance creates the need for the increasing demands on soil fertility all around the world (Mosier *et al*., 2021; Wild, 2013). This shows that, the soil is the most important input for optimum crop performance. To maintain good soil fertility requires skills and technical knowledge of soil quality and health which generally refers to the soil's fitness for good crop growth without depleting or environmentally hazardous (Acton and Gregorich, 2015). A number of researchers have shown that inorganic fertilizers have deleterious effects on the soil environment, which has made it a necessity for organic sources like poultry litter biochar and poultry manure for soil amendment more popular in recent times.

The use of biochar for soil improvement for crop yields in agricultural fields is lately recognized (Srinivasara *et al.,* 2013). Biochar is carbon rich product obtained from different feedstock such as wood chip and wood pellets, tree bark, crop residues, and organic wastes (Srinivasara *et al.,* 2013) at low temperatures (<700∘C) (Lehmann and Joseph, 2012). It stores carbon for long time to improve soil fertility and optimized soil pH (IBI, 2012). Application of biochar not only increases crop productivity and soil cation exchange capacity (CEC) but also is possible to increase soil macro- and microelement (Glaser, 2014). Different studies reported that biochar increases soil pH, plant growth, and yield (Sohi *et al.,* 2019) but few studies reported the influence of biochar on early stages of plant growth such as on seed germination and seedling growth in different regions of the world (Lehmann and Joseph, 2012).

Poultry dropping is a good fertilizer containing nitrogen, phosphorus, potassium and micro-nutrients with high photosynthetic activities and thus promotes root and vegetable growth (John *et al.*, 2014). . Magkos *et al.* (2013), reported that poultry manure is a good source of macro and trace elements not contained in other organic manure. It is a reservoir of nutrients, released during humidification that is eventually made available to the growing plants. Organic manure such as poultry manure can be used to ameliorate the amount of toxic compound produced by the chemical fertilizers. Poultry manure increase the organic matter (OM) content of soil and in turn releases the plant nutrients in available form for the use of the plants. Deskissa *et al.* (2018) emphasized that manure enable a soil to hold more water, improve the drainage, organic acids that help to dissolve soil nutrients and then made available for the crops.

Enhancing crop production is of global issue, this will require new innovations to improve crop productivity through soil amendments practices (Liang *et al*. 2014). To achieve optimum crop growth, the soil should contain high amount of nutrients because plants absorb nutrients from the soil for optimum performance. Therefore, the need to research into these organic sources hence the need to experiment on their effects on the soil and performance of crops. Therefore, the main objective of this study was to evaluate the influence of poultry litter biochar and poultry manure on the growth and yield of okra in South-Western Nigeria.

MATERIALS AND METHODS

Experimental site and Land Preparation

The study was carried out on 171m^2 (19m x 9m) area of land at the Teaching and Research farm of Lagos State Polytechnic, Ikorodu. The experimental site was ploughed and stumps were removed. A total number of 15 beds with a dimension of 3m x 2m was constructed with 1m discard from outside and 0.5 m discard between each experimental bed.

Experimental Design and Layout

The experiment was laid out in Randomized Complete Block Design (RCBD) with 5 treatments: 7.5 t/ha biochar, 7.5 t/ha poultry manure, 2.5 t/ha biochar + 5 t/ha poultry manure, 5 t/ha biochar + 2.5 t/ha poultry manure and control (no application) replicated three times.

Treatment application and Crop Maintenance

Okra V35 variety seeds were planted at two (2) seeds per hole using dibbling method at a spacing of 50 cm x 50 cm (Ogundiran 2013) which was later thinned to one vigorous plant per stand two weeks after planting to give a plant population of 24 plants per plot and a total of 360 plants for the whole experiment. The biochar and poultry manure were prepared and applied to each experimental plots two weeks before planting to allow for mineralization. Manual weeding was done every two weeks to eliminate weed infestation. While Pirimiphos-methyl + cypermethrin insecticide as well as Mancozeb fungicide were applied to prevent insect and fungi infestation as at when necessary.

Pre-planting and post-harvest Soil Sample collection and analysis

Soil samples were collected at random from 10 different locations on the experimental site prior to cropping and after harvest from each treatment plots. The soil samples were analyzed for soil physiochemical properties following routine laboratory procedures.

Data Collection

Six (6) plants were selected randomly from each experimental plot for data collection. Data were collected on, number of leaves, plant height (cm), stem girth (cm) at 2, 4 and 6 weeks after planting (WAP). Number of days to 50% flowering, number of fruits per plant and fruit weight (kg) were collected to determined yield performance. Data collected were subjected to Analysis of Variance (ANOVA). Means of treatments were compared using Duncan Multiple Range Test (DMRT) at 5% level of probability using SAS 9.1 statistical software (SAS, 2012).

RESULTS

Pre-Experimental soil physio-chemical properties

The pre-cropping soil physio-chemical analysis revealed that the site to be slightly alkaline soil (pH 8.69), low in Organic Carbon (2.62%), organic matter (0.18%), Total N (0.16%) and Available P (5.28 ppm) as well as low in exchangeable bases Na (0.15 cmol/kg), K (0.17 cmol/kg), Ca (2.45 cmol/kg) and Mg (1.96 cmol/kg). The soil was observed to have a CEC of 4.76 and the particle size percentage of sand, silt and clay (62.78%, 20.10% and 17.12% respectively) with soil textural class of sandy loam.

Effects of poultry litter biochar and poultry manure on soil chemical properties

The soil chemical properties was significant differences ($p \leq 0.01$) influenced by poultry litter biochar and poultry manure application (Table 1). Sole application of poultry litter biochar (7.43) significantly improved the soil pH compared to other treatment. While sole application of poultry manure and 2.5 t/ha PLB + 5 t/ha PM did not differ significantly and the least pH (6.60) was observed in the control.

The highest total organic matter (2.7%) was observed in 7.5 t/ha poultry litter biochar amended plots closely followed by 7.5 t/ha poultry manure (2.64%) and the lowest value (2.13%) was observed in the control. Total N value in amended soil ranges between 0.21 – 0.24%, with the highest total observed in 7.5 t/ha poultry litter biochar (0.24%) and the minimum (0.19%) was observed in the control (Table 1).

Available P significantly increased from 5.28ppm pre-cropping to a range of 17.92 – 21.75ppm in the plots incorporated with poultry litter biochar and poultry manure with the maximum available P recorded with application of 7.5 t/ha PLB (Table 1).

From the result in Table 1, exchangeable bases (K, Ca, Mg and Na) value was significantly improved with the different levels of the PLB and PM incorporated into the experimental plot. Plot supplied with 7.5 t/ha PLB recorded the highest exchangeable bases value, while the least was observed in the control plot.

Table 1: Effects of poultry litter biochar and poultry manure on soil chemical properties

Treatments	pH	TOM (%)	N (%)	P (mg/kg)	K (mg/kg)	Ca (mg/kg)	Na (mg/kg)	Mg (mg/kg)

PLB = poultry litter biochar, PM = Poultry manure

Effect of poultry litter biochar and poultry manure on okra growth performance

Result in table 2 shows that poultry litter biochar and poultry manure significantly ($p \leq 0.05$) influenced okra growth performance. At 2 and 4 WAP, 2.5 t/ha poultry litter biochar + 5 t/ha poultry manure had the highest number of leaves (3.38, 5.61) while the least number of leaves (2.83, 4.44) was observed in the control. No significant difference ($p \geq 0.05$) was observed at 6WAP

Tallest plant (5.78 cm) was recorded for okra planted in plots amended with 7.5 t/ha poultry litter biochar at 2 WAP and the shortest plant (4.26 cm) was observed in 7.5 t/ha poultry manure. At 4 and 6 WAP, the tallest plants (9.26 cm and 15.6 cm) were observed in 2.5 t/ha poultry litter biochar + 5 t/ha poultry manure with the shortest plants (7.33 cm and 12.15 cm) were observed in control (Table 2).

Table 4: Effect of poultry litter biochar and poultry manure on okra growth

Treatments	Week After Planting (WAP)

PLB = poultry litter biochar, PM = Poultry manure

Effect of poultry litter biochar and poultry manure on the stem girth (cm) of okra

Stem girth was not significantly affected by poultry litter biochar and poultry manure application. However, stem girth 4 WAP significantly ($p \leq 0.05$) influenced (Table 2). At 4 WAP the thickest stem (2.49 cm) was recorded from 5 t/ha poultry litter biochar + 2.5 t/ha poultry manure and the thinnest stem (1.80cm) was recorded in the control (Table 2).

No significant difference($p \geq 0.05$) was observed in the stem girth of okra at 2 and 6 WAP.

Effect of poultry litter biochar and poultry manure on days to 50% flowering of okra and okra fruit yield attributes

Result presented in Figure 2 shows that the treatments significantly influenced the number of days to 50% flowering of okra with the okra in plots treated with 2.5 t/ha poultry litter biochar + 5 t/ha poultry manure and 5 t/ha poultry litter biochar + 2.5 t/ha poultry manure flowered first (49.68 days) followed by 7.5 t/ha poultry litter biochar (50 days) while it takes 52 days for okra in control flowered. Significant differences ($p \leq 0.05$) were observed in the number of harvested okra pods as influenced by poultry litter biochar and poultry manure soil amendment (Figure 3). The highest number of pods (29.33) was observed in 2.5 t/ha poultry litter biochar + 5 t/ha poultry manure while the least was observed in the control (13.00). Statistical analysis of the data indicated that pod width and length were not significantly ($p \geq 0.05$) affected by poultry litter biochar and poultry manure application (Figure 2). Okra pod weight was observed to be significantly ($p \leq 0.05$) affected by poultry litter biochar and poultry manure application (Figure 4) with 2.5 t/ha poultry litter biochar + 5 t/ha poultry manure having the heaviest pod (354.00 g) and the poorest performance (135.67) in terms of pod weight was observed in control.

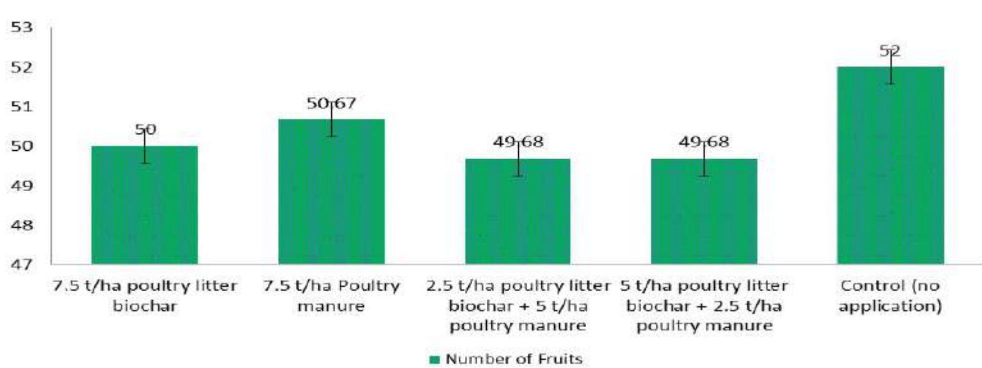

Figure 1: Effect of poultry litter biochar and poultry manure on days to 50% flowering of okra

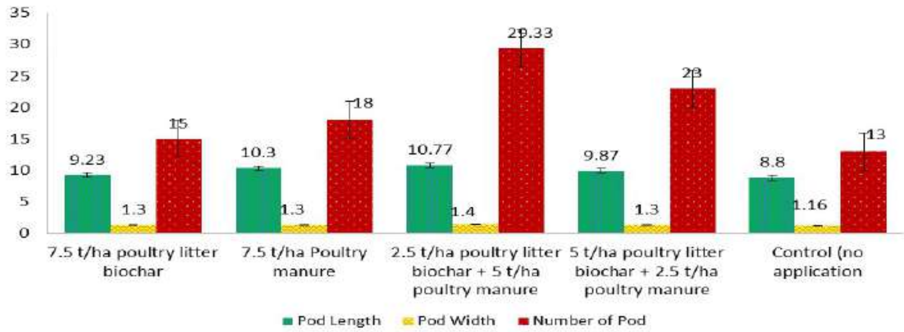

Figure 2: Effect of poultry litter biochar and poultry manure on pod length (cm), pod width (cm), and number of pods of okra

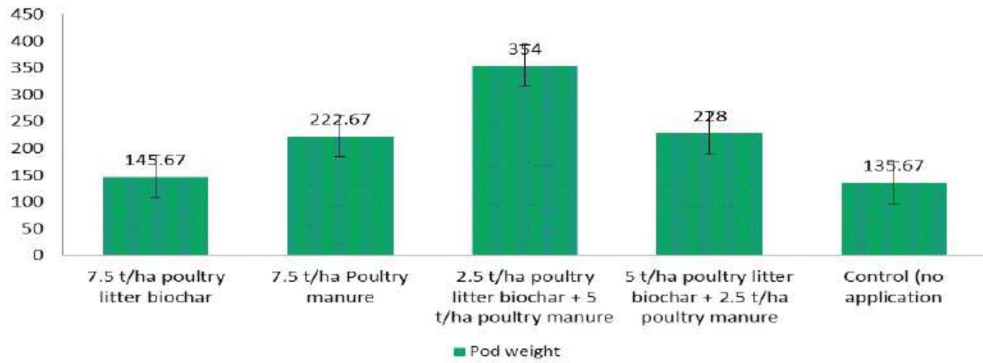

Figure 3: Effect of poultry litter biochar and poultry manure on pod weight (g) of okra

Effects of poultry litter biochar and poultry manure on the free radical scavenging power of okra fruits

Significant difference ($p \leq 0.01$) was observed in the Free radical scavenging ower of okra fruits (Table 2) was observed to be lowest in 2.5 t/ha poultry litter biochar + 5 t/ha poultry manure amended plots and was significant difference ($p \leq 0.01$) compared with other treatments that recorded higher value. However, non-significant difference was observed in 7.5 t/ha poultry manure, 7.5 t/ha poultry litter biochar, control and 5 t/ha poultry litter biochar +2.5 t/ha poultry manure respectively.

Table 2: Effects of poultry litter biochar and poultry manure on the free radical scavenging power of okra fruits

Treatments	**Free radical scavenging power of fruits (%)**
7.5 t/ha poultry litter biochar	46.89a
7.5 t/ha Poultry manure	55.76a
2.5 t/ha poultry litter biochar + 5 t/ha poultry manure	27.59b
5 t/ha poultry litter biochar + 2.5 t/ha poultry manure	45.42a
Control (no application	46.29a
Significance	**

DISCUSSION

According to the results obtained from this study, 7.5 t/ha poultry litter biochar and 2.5 t/ha poultry litter biochar + 5 t/ha poultry manure best improved the soil as compared to all other soil amendments. This might be due to the biochar ability to reduce soil pH thereby unlocking more nutrients thus making them available in the soil for plant uptake, this is in line with the studies of Van Zwieten *et al.,* 2010; Stephen *et al.,* 2011; Halim *et al*. (2016) who in their respective experiments found out that biochar application increases the soil pH, N, P, K, Mg, Ca, and organic matter content of the soil. In the growth and yield attributes of okra considered in this experiment, plots treated with the combination of both poultry litter biochar and poultry manure (2.5:5 as well as 5:25) were observed to perform best followed by plots treated with 7.5 t/ha poultry manure then 7.5 t/ha poultry litter biochar while the control gave the poorest performances. The performance of the combination of 2.5 t/ha poultry litter biochar + 5 t/ha poultry manure was observed to have an edge compared to the other treatments this is hypothesized to be due to the biochar making the nutrients present in the poultry manure be readily available for the plant to absorb easily. This aligned Sanni *et al.,* (2022) who reported that biochar application increases the yield of cowpea.).

In the free radical component of okra fruits, 7.5 t/ha poultry litter biochar, 7.5 t/ha poultry manure, 5 t/ha poultry litter biochar x 2.5 t/ha poultry manure as well as the control all had high free radical scavenging powers while the least which is rather very low as compared to all others was observed in 2.5 t/ha poultry litter biochar+ 5 t/ha poultry manure which is against the finding of Raffaella (2015) who found out that biochar application increases the free radical scavenging power of tomato fruits. This result might be due to the rate of application or a synergetic effect of poultry litter biochar and poultry manure.

CONCLUSION

From the result of this study, it is revealed that application of 2.5 t/ha poultry litter biochar + 5 t/ha poultry manure improved the experimental soil fertility and okra performances. Thus, it is recommended for adoption by okra farmers in the study area. However, as a result of the low radical scavenging power of the fruits, it is suggested that further study should be carried out with other rates of application combination especially with the free radical scavenging power of the fruits as the main parameter.

ABSTRACT

The bioactivity of Hippocratea velutina leaf and stem powders was tested against Balanogastris kolae adult emergence on stored Cola nitida. The quantitative phytochemical screening of H. velutina leaf powder gave the following mean absorbance values: Total tannin (1.6885 mgTAE/mL); Total phenolic (1.8387 mgGAE/mL); Total alkaloids (4.1600 mg/mL) and Total flavonoids (2.0510 mgRE/mL) while that of the stem powder was as follows: Total tannin (0.9135 mgTAE/mL); Total phenolic (1.8395 mgGAE/mL); Total alkaloids (5.0000 mg/mL) and Total flavonoids (1.3797 mgRE/mL). Powders were applied at 5 g, 10 g, 15 g and 20 g concentrations. Data were recorded at 2, 4, 6, 8, 10 and 12 weeks after treatment application. Kolanuts protected with 15 g leaf powder and stored for 12 weeks had the lowest number of emerged adults (2.00), which was significantly different ($p < 0.05$) from other treatments. The least number of adults (0.67) was recorded from 5 g stem powder-coated nuts, while the highest number of adults (26.67) was recorded from 15 g coated nuts. However, there was no significant difference ($p > 0.05$) in the number of adults found on untreated (control) kolanuts and all other treatments. The few numbers of adult weevil emergence obtained from nuts coated with 15 g and 20 g H. velutina leaf powder showed it successfully restricted adult weevil emergence which may be due to its higher flavonoid content. H. velutina stem powder did not significantly reduce adult emergence from treated nuts compared with the untreated.

***Keywords**: Adult emergence, Balano gastris kolae, Bioactivity, Cola nitida, Hippocratea velutina leaf.*

INTRODUCTION

In the last few decades, chemical pesticides have been used to control agricultural insect pests. As a result of massive and repeated applications, these synthetic pesticides have brought a lot of detrimental effects on the environment and caused contamination of non-target organisms. Hence, they are termed ecologically unsafe as they persist for a more extended period in the environment and exhibits residual effect as they enter into the food chain, where they cause serious havoc on non-target organisms, most especially humans (Alavanja *et al*., 2004; Upadhyay 2016; Ifebueme *et al.* 2020). One of such insect pest usually controlled by these chemical pesticides is *Balanogastris kolae*, a significant pest of kolanuts. It is the most common and economically important weevil of kolanut. *B. kolae* is a destructive field-to-store pest of kolanuts in West Africa, as they are capable of causing close to 100% damage if not checked on time (Asogwa *et al*., 2015; Azeez, 2015; Popoola *et al*., 2020). Several kinds of research have been carried out on using different plant parts to control *B. kolae*. Azeez (2015) reported that ethanolic plant extracts of *Lycopersicon esculentum* Mill*, Hyptis suaveolens* (L) Poit*, Cymbopogon citratus (*Stapf)*, Loranthus braunii* (Spaague Var)*, Alstonia boonei* (De Wild) and *Sarcocephalus latifolius* (Sm) resulted into 100% mortality of the weevils. A similar trend was observed by Ugwu *et al*. (2019) when 100% concentrations of *Azadirachta indica* (A Juss), *Piper guineense* (Schum and Thonn) and *Afframomum melegueta* (K Schum) caused 100% mortality of the adult *B. kolae*. Despite the array of plant extracts reported to be effective in decimating this weevil's population, there is a need to explore other plant species having insecticidal properties to reduce pressure on the existing ones.

The insecticidal property of *Hippocratea*, a genus of flowering plants belonging to the family Celastraceae, has been documented. They are distributed across all the tropics and comprise more than a hundred genera and 1300 species. Most of them are climbers, using their branchlets to twist around their supports (Okwute *et al*., 2018; Onyekere *et al.,* 2019). The common species of *Hippocratea* are*; H. africana, H. indica, H. excelsa, and H. velutina*. The use of this plant family in controlling insect pests of stored products has been studied, though not extensively. Methanolic leaf extract *of H. africana* exhibited suitable insecticidal property against *Sitophilus zeamais* (Oboho *et al*., 2022) and beta-cell cytotoxicity effects (Okokon *et al.,* 2013). Ndem *et al*. (2013) reported that the crude root extract of *H. africana* has anti-plasmodial properties. More so, Folawewo *et al*. (2017) investigated the antibacterial activities of the hexane and methanolic root bark extract of *H. africana* and discovered that the crude methanol extract exhibited the largest zone of inhibition against *Morganella morganii.* According to Reyes-Chilpa *et al.* (2003), the root cortex of *Hippocratea excelsa* possesses antifeedant and toxic properties against *Sitophilus zeamais.*
Information on the biological activities of *Hippocretea velutina* Afzel, a member of this family, is not currently available; hence, the need to assess its insecticidal activity on *B. kolae.* Therefore, this research aims to investigate the efficacy of the stem and leaf powder of *Hippocratea velutina* in the control of kolanuts weevils, *Balanogastris kolae* adult emergence.

MATERIALS AND METHODS

Study Area and preparation of the plant materials

This work was carried out at the Insect Chemical Ecology Laboratory, Department of Crop Protection and Environmental Biology, University of Ibadan, Ibadan, Oyo State, Nigeria. The plant material, *Hippocrates velutina,* was obtained from the Forest Research Institute of Nigeria in February 2022. It was sorted into leaves and stems, air-dried for two weeks, and the dried plant materials were ground to a coarse powder using an electric corn mill grinder M6FFC-160. The leaf and stem powders were then stored separately in airtight containers and kept in a dry place until needed.

Quantitative phytochemical analysis

Total flavonoid content: Procedure to determine the total flavonoid content of the plant extracts was as described by Deepika & Savita (2017). To 0.5 mL of extract (5mg/mL), 2 mL of distilled water and 0.15 mL of Sodium Nitrite (5% $NaNO_2$w/v) was added, and the mixture was allowed to stand for 5 mins. To the mixture, 0.15 mL of Aluminium chloride (10% $AlCl_3$) was added and left to stand for 6 min. 1 mL of sodium hydroxide (4% w/v, NaOH) was added. The mixture was made up to the 5 mL mark, and incubated at room temperature for 15minutes. The absorbance was measured at 510 nm. The procedure was repeated to obtain the blank and calibration curve for standard flavonoid Rutin (5-100 µg/mL) (Kavitha *et al.,* 2016).

Total phenolic content: Procedure from Deepika & Savita, (2017) was used to determine the total phenolic content of the plant extract. To 2 mL of Folin- ciocalteu (1:10) was added to 0.5 mL of the plant extract (5 mg/mL) in a test-tube, and incubated for 5minutes at room temperature (in the dark). Sodium carbonate (7.5% w/v, 4 mL) was added to the mixture. The resultant mixture was incubated in the dark for 30 mins at room temperature with intermittent shaking. The absorption was measured at 765 nm. Calibration curve for Gallic acid (1-20 µg/mL) and blank was also determined using the same procedure.

Total tannins: Total tannin content was determined with procedure from Kavitha *et al.* (2016). Folin ciocalteu (0.25 mL) was added to 3.75 mL of distilled water. The extract (0.05 mL of 5 mg/mL) and 0.5 mL of Na_2CO_3 was added to the solution. The mixture was made up to 5 mL mark with distilled water. The mixture was well shaken and incubated at room temperature in the dark for 30 mins. Absorbance was measured at 700 nm. Calibration curve was obtained for Tannic acid (20 -100 µg/mL). **Total alkaloids content:** Alkaloid content of the extracts were determined by titrimetric method. Obtained supernatant of the samples (10 mL of each) were taken into 10 mL of 0.1 N HCl in a flask and shaken thoroughly for 2-3 min. The lower layer contains alkaloids neutralized with 0.1 N HCl. The HCl portion (10 mL) was collected in a beaker and 2-3 drops of methyl red were added giving a slightly reddish colour. This was then titrated against 0.1N NaOH till colour changes from red to pale yellow. This was done in triplicate. The total amount of alkaloids was calculated by considering the following equivalent: 1 mL 0.1 N HCl = 0.0612 g of alkaloid (Taiwo *et al.* 2020).

Source of kolanuts

Freshly skinned kolanuts (*Cola nitida*) was purchased from a local market in Osogbo, Osun State, Nigeria. The kolanuts were cured for three days (72 hours) before the application of treatments.

Experimental set up

The method described by Akunne *et al*. (2018) was followed with some modifications. Exactly 140 g of clean uninfested kolanuts was measured into 1.5 L transparent plastic cylindrical containers with perforated lids to allow aeration. The leaf and stem powders in the proportions of 5 g, 10 g, 15 g and 20 g were added separately into the containers holding the 140 g kolanuts and then shaken vigorously to mix thoroughly. Another 140 g kolanuts, not treated with plant material, was also measured in a container and served as a control. Each of the treatments was replicated thrice. All treatments were arranged in a completely randomized design (CRD). The set-ups were kept in the laboratory at 28±2 °C and 80±2 % relative humidity.

Data Collection and Statistical Analysis

The number of emerged adults from the different treatments was counted and recorded fortnightly from 2 weeks after storage until 12 weeks (3 months). Data generated were subjected to one-way analysis of variance (ANOVA) using Genstat Release 12.1 at a 0.05 significant level. The ANOVA results were used to determine the most effective concentration of the powders that could mitigate adult weevil emergence from kolanuts.

RESULTS

The quantitative phytochemical analysis of the leaf and stem powder of *Hippocretea velutina* revealed the presence of flavonoids, tannins, alkaloids and phenols (Table 1). Total tannin (1.6885 mgTAE/mL); Total phenolic (1.8387 mgGAE/mL); Total alkaloids (4.1600 mg/mL) and Total flavonoids (2.0510 mgRE/mL) while that of the stem powder was as follows: Total tannin (0.9135 mgTAE/mL); Total phenolic (1.8395 mgGAE/mL); Total alkaloids (5.0000 mg/mL) and Total flavonoids (1.3797 mgRE/mL).

Table 1: Quantitative phytochemicals analysis of *Hippocretea velutina* (HV) leaf and stem powders

Phytochemicals	*Hippocreatea velutina*		T-test value	Significance
	Leaf	Stem		
Total Flavonoids	2.0510	1.3797	0.001252	$P < 0.05$*
Total Phenols	1.8387	1.8395	0.978686	$P > 0.05^{NS}$
Total Alkaloids	4.1600	5.0000	0.087012	$P > 0.05^{NS}$
Total Tannins	1.6885	0.9135	0.084513	$P > 0.05^{NS}$

Adult weevil emergence from Kolanuts treated with *Hippocratea velutina* Leaf Powder

The number of adults that emerged from kolanuts protected with *Hippocratea velutina* Leaf Powder (LP) from 2 Weeks After Storage to 12 Weeks After Storage (WAS) is depicted in Figure 1. The number of weevils that emerged from the treated and control kolanuts increased with time. At 10 and 12 WAS, more weevils were recorded from 5 g (13.67, 24.0) and 10 g (14.67, 22.67) and control (13.33, 13.7), respectively. A few weevils emerged from kolanuts stored with 15 g (2.0, 2.0) and 20 g (3.0, 10.0) LP at 10 WAS, and 12 WAS, respectively. Adult weevil emergent from kolanuts treated with *H. velutina* LP and stored for three months are displayed in Table 2. Kolanuts protected with 15 g LP had the lowest number of emerged adults (2.00), significantly different ($p < 0.05$) from other treatments. Also, kolanuts coated with 20 g LP and stored for three months (12 weeks) had a low number of weevils, 10.0, and it was significantly ($p < 0.05$) lower than the control (untreated) (13.67). The number of emerged adults on kolanuts decreased in the order of 10 g (22.67) > 5 g (20.67) > Control (13.67) > 20 g (10.00) > 15 g (2.00) (Table 2).

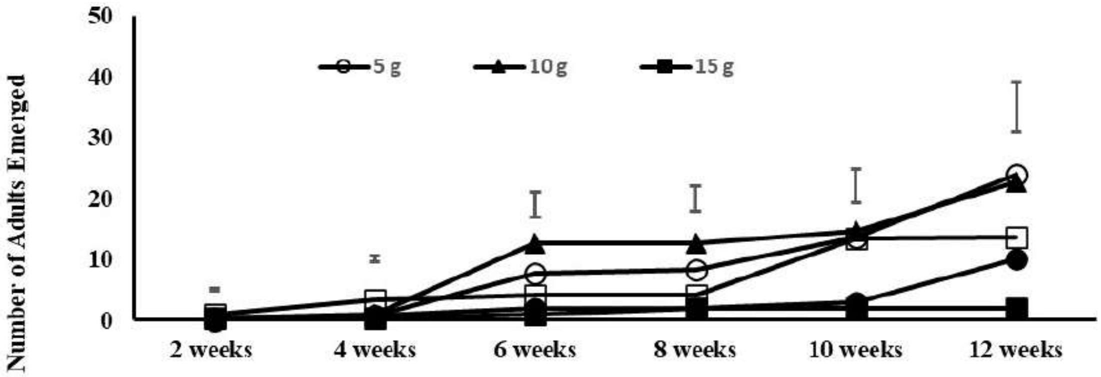

Figure 1: Adult emergence from Kolanuts protected with *Hippocratea velutina* leaf powder

Table 2: Number of Adults emergent from kolanuts protected with *Hippocratea velutina* leaf powder after 3 months of storage.

Concentrations	Number of emerged Adults
5 g (4%)	4.0 ± 1.6 ab
10 g (7%)	3.78 ± 1.7 a
15 g (11%)	0.33 ± 0.14 d
20 g (14%)	1.67 ± 1.1 c
Control	2.27 ± 1.1 b

Means ± SE with the same letters are not significantly different at $p < 0.05$ using SNK test.

Adult weevil emergence from Kolanuts treated with *Hippocratea velutina* Stem Powder

Figure 2 shows the number of adults that emerged from kolanuts coated with *H. velutina* Stem Powder (SP) and stored for 12 weeks (3 months). Adult weevils were recorded fortnightly from 2 weeks after storage to 12 weeks after storage (Figure 2). The least number of adults emerged from kolanuts coated with 5 g, while the highest number of adults was found on kolanuts coated with 15 g SP. At six weeks of storage, the number of emerged weevils increased tremendously compared to the number of weevils at 2 and 4 weeks of storage from kolanuts coated with 15 g and 20 g SP. Adult emergent from kolanuts coated with different concentrations of *H. velutina* SP are shown in Table 3. There was no significant difference at $p > 0.05$ in the number of adults found on control (untreated) kolanuts and all other treatments. However, the least number of adults (0.67) was recorded from 5 g (4% w/w) coated nuts, while the highest number of adults (26.67) was recorded from 15 g (11% w/w) coated nuts (Table 3).

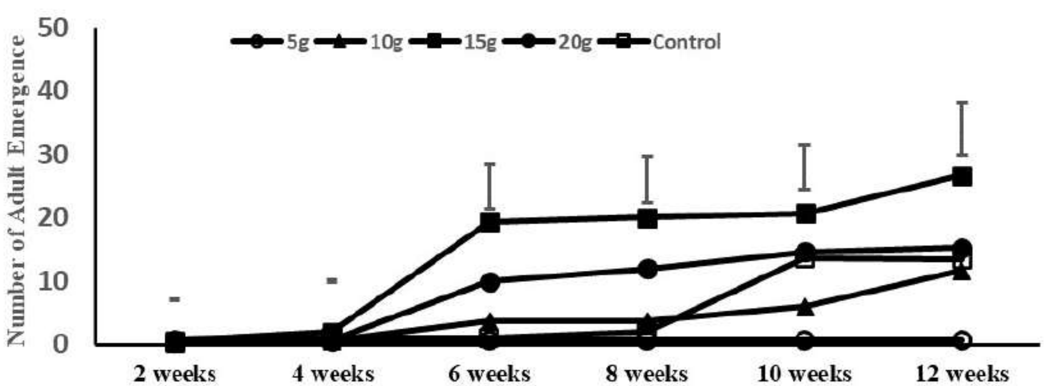

Figure 2: Adult emergence from Kolanut protected with *Hippocratea velutina* stem powder

Table 3: Number of Adults emergent from Kolanuts protected with *Hippocratea velutina* Stem powder after 3 months of storage.

Concentrations (w/w)	Number of emerged Adults
5 g (4%)	0.11 ± 0.1 b
10 g (7%)	1.94 ± 0.7 ab
15 g (11%)	4.44 ± 2.1 a
20 g (14%)	2.56 ± 1.1 ab
Control	2.28 ± 1.9 ab

Means ± SE with the same letters are not significantly different at $p < 0.05$ using SNK test.

DISCUSSION

The present study established the insecticidal ability of the *Hippocratea velutina* plant samples which can be attributed to their phytochemicals constituents. Phytochemicals such as flavonoids, tannins, alkaloids and phenols found in this plant sample have been reported to possess pesticidal activities against a host of insects (Zain *et al*., 2022; Maazoun *et al*., 2019; Ghosh *et al*., 2010). Flavonoid has been documented to have strong insecticidal activities (Maazoun *et al*., 2019; Ghaly *et al*., 2014). From this study, there is a significant difference in the quantity of the flavonoids present in the leaf powder of the botanical sample as it is higher (2.0510 with p> 0.05) than that of the stem (1.3797). This may account for the reduced number of adult emergence in *H. velutina* leaf compared to that of the stem powder observed in this study. The effect of the various concentrations of the leaf and stem powders of *H. velutina* could mitigate the rate of kola weevil emergence from cured stored kolanuts. The number of adult weevils emerging from nuts coated with 15 g (11% w/w) and 20 g (14% w/w) *Hippocratea velutina* Leaf powder was few, which suggests that these powders successfully restricted adult emergence. The phytochemical constituents in the leaf powder would be responsible for the low adult emergence. The protection of kolanuts achieved by *H. velutina* leaf powder is in agreement with Oboho *et al.* (2022), which reported the severe disruption of *Sitophilus zeamais* (Mots.) mid-gut sections by *Hippocratea africana* plant extract. Also, Reyes-Chilpa *et al.,* (2017) further corroborate this present study as it was noted that *H.excelsa* root cortex was equally toxic to *Sitophilus zeamais*.
Similarly, Onyekere *et al.,* (2019) found that crude methanolic extracts of *H. welwitschii* leaves showed activity against a broad spectrum of microorganisms, including gram-positive – *Staphylococcus aureus, Pseudomonas aeruginosa*, *Bacillus subtilis* and gram-negative – *Escherichia coli* and *Salmonella typhi.* It also exhibited antifungal activities against *Candida albicans* and *Aspergillus niger.* The plant species *Hippocratea africana, H. excelsa* and *H. welwitschii* all belong to the same genus as *H. velutina.* Hence the bioactivities of the members in the genus Hippocratea against organisms could be similar. Meanwhile, Anikwe *et al*, (2004) reported that the fruit powder of *tetrapleura tetraptera* (Shum and Thonn) was toxic to the adult *B. kolae* resulting in high mortality of the insect pests. Also, Akunne *et al,* (2018) investigated the effect of the root powder of *Derris elliptica* (Wall.) Benth in controlling *B. kolae* infestation and discovered that across all the concentrations, a very high mortality was observed. The root powder application at the 10g and gave the most increased mortality of *Balanogastris kolae.*
More so, the insecticidal ability of the leaf powder of *H. velutina* reported in this study can equally be attributed to the mode of action of powder samples as the particles of the powder may cause blockage of the adult weevil spiracles resulting in to anoxia, a condition in which there is no sufficient oxygen for normal respiration which consequently leads to suffocation of the insects (Chougourou *et al*., 2015, Fernando *et al*., 2012). Furthermore, plant powder could also act as an antifeedant as well as a repellent because the odour emanating from it can repel the adult weevil from colonizing the nuts after the application of treatments thus, hindering the insects from penetration and feeding on the kolanuts (Chougourou *et al*., 2015). Powdered plant products may also penetrate the insect body via the *respiratory system causing poisoning of the adult weevil and resultant death (Kedia et al*., 2015). Also, Sousa *et al.* (2005) reported that the plant powders caused dehydration to insects by gradualy removing the cuticle layer and their subsequent death. *Hippocratea velutina* stem powder did not significantly reduce adult emergence from treated nuts compared with the untreated (control)

kolanuts. Secondary metabolites in the stem powder were not potent in forestalling adult emergence compared to the leaf powder from the same plant, *H. velutina.*

CONCLUSION

The study evaluated the efficacy of *Hippocratea velutina* at 4, 7, 11, and 14% w/w (5, 10, 15, and 20 g, respectively) leaf and stem powders in protecting kolanuts in storage from Kola weevil infestation and damage. Clean, uninfested kolanuts (140 g) were coated with varying concentrations of leaf and stem powders of *H. velutina*. Leaf powder at 15 and 20 g / 140 g Kolanut (11 – 14% w/w) was superior to stem powder of *H. velutina* in reducing the number of emergent adult kola weevils after three months. Plant extracts and powders of plant origin are biodegradable and leave no residue on crops; hence 11 – 14% *H. velutina* leaf powder could be increased and reapplied repeatedly to ensure its ability to protect kolanuts against weevils' infestation and damage. Reduction in the number of emerged adults from kolanut coated with 15 g and 20 g Leaf powder over 12 weeks (3 months) will subsequently reduce damage to nuts by the activities of the kolanut weevils. Identifying the chemical compounds in *Hippocratea velutina* leaf powder responsible for reducing adult emergence in stored kolanuts is necessary. These findings on the insecticidal potential of *H. velutina* are the first report because there is no accessible documentation of any research work conducted on this plant at the time of writing this report. Hence the need to investigate further the phytochemical properties of *Hippocratea velutina*..

INFORMATION AND COMMUNICATION TECHNOLOGIES: A HORTICULTURIST COMPANION FOR ENHANCED PRODUCTIVITY IN NIGERIA

Adeniyi R. T.
Department of Agricultural Economics and Extension, Ajayi Crowther University,
Oyo, Oyo State, Nigeria.

Correspondence: rt.adeniyi@gmail.com; +234 8027640111

ABSTRACT
This study examined the contributions of Information and Communication Technologies to horticultural enterprises in Nigeria. The study uses secondary data to examine the importance of horticulture to Quality of life, information need, available ICTs, sources of information, benefits derived, and the constraints to ICT utilization. The study found that quality diets and sustainable livelihood come from horticulture; while production and marketing information were the most needed. The available ICT for them were Radio, Television, and Android with information sources being Radio and mobile money payment. The ICT benefits derived were the provision of timely information on market links. However, the constraints encountered in the use of ICT were insufficient funds and poor electricity supply. The study concludes that ICTs are useful for information dissemination and gathering though with a lot of constraints. Hence, horticulturist should form a cooperative society to pool their resources together to overcome the challenges

INTRODUCTION

Horticulture is the branch of Agriculture that deals with the cultivation of garden crops (fruits, vegetables, and ornamental plants) for food, aesthetics, and medicine (Lab Innovation, 2023). Its importance for food security is unveiled in its ability to provide food that enriches the human diet with balanced meals, healthy living, and a good-looking environment; hence its contributions to sustainable development cannot be overemphasized. The sector in agriculture has been useful for employment generation of various kinds, as it has been a source of livelihood for as many that engaged in horticultural practices across the value chain. The sector has been a steady source of income for those who cultivate varieties of high-valued fruits, vegetables, and ornamental plants (BYJU'S Exam Prep, 2023).

However, the sustainability of this sector of agriculture depends on the availability of resources such as land, water, human, financial, and reliable information as insufficient information on horticulture has been a great reason for its low productivity in Africa (Lab Innovation, 2023). Information is power, assets, and valuable resources that are indispensable for the maximum productivity of horticulture. Furthermore, it is a means to attain the global sustainability of agribusiness among the horticulturist who needs information on horticultural practices of fruits, vegetables, and ornamental plants across its value chain. The information needed for uptimum production by a horticulturist includes market information, agricultural extension information, information on post-harvest practices, sources of credit, pests and diseases management, food safety practices, access to inputs, and weather reports among others. According to Bhusal, Sagar and Khatri, (2021) effective and efficient information for agribusiness could easily be harnessed by ICTs such as Radio, Television, App for horticulture, GPS, print media, internet, and mobile phones among others; as ICTs have been a bridge that links the researchers, extension officers, and horticulturist together.

ICT information comes with bountiful benefits for the horticultural sector of agriculture for enhanced efficiency and productivity of fruits, vegetables, and ornamental plants as it renders timely access to information for higher productivity (Ramanna, 2020 and Khaliq, Naeem, Abbas, Khalid, 2016). However, there are various challenges and limitations to the use of ICTs by the horticulturist in developing nations which include fluctuation services and inadequate access to ICTs (Naik, Rao, Rambabu and Rekha, 2022 and Obinna, Udeanya and Chinwendu, 2023). To this end, this study reviewed the contributions of horticulture to Quality of life, information needs of the horticulturist, sources of information, types of ICTs available for horticulturist, benefits to ICT utilization, and constraints to use of ICTs by the horticulturist.

METHODOLOGY

Secondary data was used for the study using past studies as found in websites, research reports, annual reports, and already conducted survey analyses.

a. Contributions of horticulture to Quality of Life

Picture 1: Horticultural food product
Source: Feed the Future Innovation Lab for Horticulture. https://horticulture.ucdavis.edu/horticulture-overview

The great role of horticulture in sustainable development that enhances a good quality of life is as follows;

Enhances Human diets: Fruits, vegetables, and ornamental plants are the product of Horticulture. These products specifically contribute nutrients like vitamin, minerals, antioxidants, fiber, and roughage to sustain and enhance the intake of balanced diets, and prevents most of the disorders that inadequate nutrients in fruits, vegetables, and ornamentals can cause in man.

Provision of sustainable livelihoods: Horticulture has proven to be a good job provider for people across its value chain. Employment offered by this sector of agriculture includes; input suppliers, (seed, manure, pesticides, fertilizer, and herbicides); extension officers, labourers (Farm hands), transporters, processors, industries that use the horticultural produce as raw material, and marketers among others. Fruits, vegetables, and ornamental plants increase farmers' profits as affirmed by Obinna, Udeanya, and Chinwendu, (2023)

B. Information needs of the horticulturist

Horticulturist needs to be abreast of the following information for the smooth running of the enterprise. These include;

a. Market information: This will enable the horticulturist to know the available market, current price, and marketing strategies needed for the successful production of horticultural crops (Obinna, Udeanya, and Chinwendu 2023.)

b. Production information: This involved having ample information about the varieties of fruits, vegetables, and ornamental plants as per the suitable land source, soil well-being and soil nutrients.

c. Agricultural extension information: The agricultural extension is a link between the researcher and the horticulturist in the dissemination of agricultural information and the adoption of technology by farmers using various methods (Narasimha, 2021).

C. **Types of ICTs available for horticulturist practices**

The available ICT will determine the type and mode of horticultural information that farmers could receive. Also, this will determine the format through which the information could be accessed. The sources available and accessible by the horticulturist includes; Radio (Horticultural Radio programme and, Radio jingle, marketing information); Television, Short service message (SMS); Android phones, videos, and video conferencing with the scientist and researchers (Obinna, Udeanya, and Chinwendu 2023).

D. Sources of ICT-based information

ICT-based information on horticultural practices could get to the end user through the following services as follows; a. Mobile Money Providers. b. Radio. Television. c. Telecommunication companies (Telcos) d. Smart/Precision agriculture solution service providers (Sensor and wireless sensor network, Geographical Information System, Remote Sensing) e. Internet Service Providers f. Mobile Money Providers (Obinna, Udeanya, and Chinwendu, 2023).

E. Benefits of ICT utilization

There are a lot of benefits that a horticulturist can enjoy from the use of available and accessible ICTs in their enterprise. Through the use of ICT, the horticulturist has access to timely and accurate information. ICTs link horticulturists to local, urban, regional, and global markets either for selling their produce or for getting farm input via reliable market information; as well as promoting horticultural innovations and precision farming (Bhusanar and Singh, 2019). Utilisation of ICT improves the management of land and natural resources at their disposal ICTs support the sustainability of the rural economy via its efficiency and productivity and Provide information about pest and disease control (Ramanna, 2020). The use of ICTs offers better and cheaper access to finance and the provision of weather information. ICT has been a renowned tool that enhances livelihood, productivity, and poverty reduction (Khaliq, Naeem, Abbas, Khalid, 2016).

F. Constraints to ICT utilization by the horticulturist.

According to Obinna, Udeanya, and Chinwendu, (2023) and Naik, Rao, Rambabu, and Rekha, (2022), the constraints to the use of ICT information by farmers include insufficient funds, high cost of possessing ICTs, insufficient supply of electricity, ignorance of available useful ICT tool, poor network, insufficient access to ICTs, high cost of ICT maintenance and poor ICT skills of farmers. These constraints when at a high level could inhibit the effective use of ICT among the horticulturist and hence prevent maximum productivity (Yekinni, Adeniyi, Ladigbolu and Adebisi, 2020 and Lab Innovation, 2023)

EVALUATION OF WEED SUPPRESSIVE ABILITY OF FLUTED-PUMPKIN *TELFAIRIA OCCIDENTALIS* HOOK F. ACCESSIONS

***Taiwo, S. O., Akin-Idowu, P., Ikoro, J., and Akinleye, O.C.**
National Horticultural Research Institute, Ibadan, Nigeria.

*Corresponding author: stephentaiwoo@yahoo.com, sundaytaiwo1968@gmail.com

ABSTRACT
Crop cultivars with enhanced weed suppressive abilities could play a key role in Integrated Weed Management (IWM) strategy. A field experiment was conducted at the National Horticultural Research Institute, Ibadan to evaluate the Weed Suppressive Abilities (WSA) of fluted-pumpkin Telfairia occidentalis Hook F. accessions. Thirty-eight accessions from all the major fluted-pumpkin production areas in Nigeria were evaluated. The experiment was laid out in Randomised Complete Block Design with three replications. Data were collected on weed species composition, weed density, weed biomass, weed ground cover and fluted-pumpkin canopy cover. Results indicated that 57% of the weed species were broadleaves, 33.3% were grasses while 9.1% were sedges. Results also indicated significant differences in weed density, weed biomass, weed ground cover, and fluted-pumpkin canopy cover ($p < 0.05$). Accession 38 had the lowest weed density, weed biomass and weed ground cover. The result suggested that the accessions with high canopy cover could suppress weeds, reduce weed competition with fluted-pumpkin, and hence reduce the frequency of weeding.
Key words: *Accession, Fluted-pumpkin, weed density, weed biomass, canopy-cover.*

INTRODUCTION

Fluted pumpkin (*Telfairia occidentalis*), commonly known as iroko or ugu in Yoruba and Igbo languages respectively in Nigeria is an important vegetable crop belonging to the plant family Cucrbitaceae.(Prota, 2006). It is a nutritious vegetable of tropical West Africa widely cultivated for its leafy shoots and immature edible seeds (Akoroda, 1990). The leaves are rich in iron and used to cure anaemia while also being high in protein content (Okoli and Mgbeoku, 1983). Weed competition is a major limiting factor to its production as weed competition with the crop adversely affects the crop. Although fluted pumpkin is a poor competitor with weeds, the variation in its genetic composition could play an important role in integrated weed management. Weed competitiveness comprises of the major elements namely Weed Tolerance (WT) and Weed Suppressive Ability (WSA). Weed Tolerance is the ability of a crop to maintain high yields in the presence of weeds while weed suppressive ability is the ability to suppress weed growth (Rodenburg *et. al.* 2009). The major objective of this paper therefore is to evaluate the weed suppressive ability of fluted-pumpkin accessions.

MATERIALS AND METHODS

The field trial was conducted around vegetable nursery building of the National Horticultural Research Institute headquarters, Ibadan in the 2022 cropping season between March and November. The experimental site was slashed, ploughed and harrowed with tractor-mounted implements. The plot size was 2m by 2m (4m^2) with 38 fluted-pumpkin accessions. The seedlings were transplanted at a spacing of 1m x 0.5m, making a population of 20,000 plants ha^{-1}. The experiment was laid out in Randomised Complete Block Design (RCBD) with three replications. At 4 weeks After Transplanting (WAT), inorganic fertilizer (NPK 20:10:10) mixed with organic fertilizer (poultry manure) was applied at 100 and 300 kg ha^{-1} respectively to supply the necessary nutrients to the plants as the site has been in use for planting fluted-pumpkin over many years. Staking was also done at 4WAT using teraga or table method and the crop was trailed appropriately using rope. Weed removal was done at intervals of 4, 8, 12 weeks after transplanting when crop canopy had been fully formed, and prior to pod harvesting. Data were collected on weed species composition, weed density, weed biomass, weed ground cover and fluted-pumpkin canopy cover. Weed species composition, density, and biomas were obtained from two 50cm x 50cm quadrats randomly thrown in the diagonal transects of each plot. Weeds within each quadrat were counted and cut at the base with sharp knife, sorted by species, and bulked together to form a sample. The samples collected were oven-dried at a temperature of 80^0C for 48 hours to obtain weed biomass. Weed ground cover and fluted-pumpkin canopy cover were obtained using the Line Intercept Method (LIM) used in vegetation assessment (Coulloudon *et. a*l. (1999). Statistical analysis of the data collected was performed using GenStat release 4.23 Discovery Edition Statistical software package. Means were separated using Least Significant Difference (LSD) at 5 percent probability level.

RESULTS

Nineteen weed species were frequently (more than 10%) observed in the plots. The most dominant ones were *Cleome viscosa, Mitracarpus villosus, Euphorbia heterophyla, Commelina benghalensis, Peuraria phaseoloides, Panicum maximum, Paspalum scrobiculatum and Tridax procumbens.* Of the weedspecies observed, 57.1 per cent were broadleaves, compared to grasses and sedges which were 33.3 and 9.5% respectively. This observation corroborates the findings of Olorunmaiye *et al*. 2010 that broadleaves are dominant in vegetable fields.
Weed density differed significantly among the accessions at 4, 8, and 12 WAT (table 1).

Table 1: Weed suppressive ability of fluted-pumpkin *Telfairia occidentalis* Hook F. accessions

Accessi on no.	Weed density (m^{-2})			Weed biomass ($g\ m^{-2}$)			Pumpkin canopy cover (%)	Weed cover (%)

P (0.05)	**	**	**	NS	**	**	**	**

WAT-Weeks after transplanting. LSD- Least Significant Difference, **Significant P at 0.05, NS Not significant

At 2 WAT, accession 15 had the highest weed density which is significantly similar to that obtained in accession 1, 5, 10, 27, and 28. The lowest weed density was obtained in accession 38. At 8 WAT, the highest weed density was obtained in accession 22 while the lowest was obtained in accession 38. At 12 WAT, the highest weed density was obtained in accession 32 and it differed significantly from all other accessions (LSD = 47) while the lowest weed density was obtained in accession 38. Weed biomass also differed significantly among the accessions at 8 and 12 WAT but did not differ at 4 WAT. At 8 WAT, the highest weed biomass (367.2 gm^{-2}) was obtained in accession 25 which is significantly higher than those obtained in all other accessions. Accessions 8, 22, and 29 had similar weed biomass (293, 255, and 276 gm^{-2}respectively). At 12 WAT, accession 29 had the highest weed biomass while accession 38 had the lowest. By implication, accession 38 is the most superior accession in weed suppression while accession 25 is the weakest accession in weed suppression. The differences in the variation in weed suppressive abilities of the accessions could be attributed to the differences in the weed and fluted-pumpkin's canopy cover (Table 1).

ABSTRACT
The morphological evaluation of ten accessions of pepper was conducted in a Complete Randomized Design (CRD) with four replicates in the screen house at the National Horticultural Research Institute (NIHORT), Ibadan, Oyo state. Pepper seeds were sown and raised in the nursery for 4-5 weeks before transplanting. 15 qualitative and 9 quantitative traits were assessed. The quantitative data were subjected to analysis of variance and mean separation was done with the aid of Duncan's multiple range test at 5% probability level. The result indicated significant variations for plant height, canopy width, unit fruit weight, 100 seed weight among others. plant height ranged between 78cm in NHSMB-F1/R4 and 33.5cm in NHRod-D/R2. The widest canopy was recorded in NHRod- Frt/R1 (62.5cm) while NHTTS-5/R3 had the smallest canopy width (33cm). Highest 100 seed weight was observed in NHBawa-Frt/R1 (0.49g) which is significantly different from other accessions. The qualitative data showed that leaf and Stem pubescence were observed to be sparse for all the accessions. All the accessions except NHSMB-F1/R1 have intermediate branching habit. NHSMB-F2/R1, NHSMB-F1/R4 and NHRod-D/R2 have purple nodal anthocyanin while the remaining accessions have green. Variations among the cultivars were also observed for fruit shape where they exhibited triangular (3 accessions), elongate (4 accessions), blocky (1 accession), almost round (1 accession) and campanulate (1 accession). The information from this study can be used to formulate methods and strategies for conservation and in turn genetic improvement of the pepper crop. Further studies on wider range of pepper accessions in order to establish their morphological distinctness, genetic diversity and relatedness may provide higher opportunities for selection and hybridization for the development of improved cultivars.
Keywords: *accessions, morphological evaluation, pepper, qualitative trait*

INTRODUCTION

Pepper (Capsicum spp.) is an economically important horticultural crop that has been widely used in cuisines worldwide as both a vegetable (bell peppers) and as spices (chili peppers) for condiments purposes (Zimmer *et al*. 2012). Although many peppers from the Capsicum genus of the Solanaceae family are known, only five are cited in literature as fresh or culinary spices: *C. annuum, C. baccatum, C. chinense, C. frutescens* and *C. pubescens* (Kantar *et al*., 2016; Meckelmann *et al*., 2013; Rigon *et al*., 2012) and only two are most commonly used: *C. annuum* and *C. frutescens* (Fernández-Bedmar and Alonso-Moraga, 2016; Gurnani *et al*., 2016). The genus Capsicum, has a great nutritional and economic value, and is widely grown in the whole world (Hill *et al*., 2013). The species of the Capsicum genus have great variability in its main morphological characters, such as form, size, color and position of flowers and fruits. Pepper plants are autogamous, diploid with 2n=2x=24 or 2n=26 chromosomes and have pungency as a marking characteristic, which is attributed to the alkaloid substances, more specifically the capsaicinoids (Moscone *et al*., 2007).

Various constraints have been identified for the low productivity of pepper in Nigeria and among these is inadequate high yielding and diseases tolerant cultivars as well as poor seed quality. Therefore, breeding improved varieties which satisfies the preferences of farmers and consumers has become a necessity. But, this will be impossible without identifying suitable parental pepper genotypes. Terefe *et al*, (2022) has reported that crop improvement heavily relies on a comprehensive understanding of the genetic variability and their genetic relationships which could be used in breeding programs (Furthermore, studying and understanding the qualitative and quantitative traits of pepper enables researchers to identify, classify, and assess the performance of different genotypes in order to facilitate selection of superior accessions for specific purposes and provides insights into genetic diversity present among pepper accessions. In addition, this will also contribute to the expansion and conservation of pepper germplasm for future research and breeding efforts. The objective of this study was to assess morphological characteristics of ten accessions of pepper collection and document them for further research activities.

MATERIALS AND METHODS

The evaluation of pepper morphological characters was conducted following a complete randomized design with four replications. Ten pepper accessions obtained from the Seed Technology Unit, National Horticultural Research Institute (NIHORT), Ibadan, Oyo state, were evaluated in the screen house at NIHORT, Ibadan. Seeds from this collection were sown in trays, monitored for 4-5 weeks and later transplanted into pot filled with sterilized top soil. Required crop management practices for pepper (irrigation, weeding fertilizer application etc) were carried out at the required periods. Data were collected using the IPGRI, AVRDC and CATIE (1995) Capsicum spp descriptor on 24 characters (15 qualitative and 9 quantitative) covering vegetative, flowering and yield traits. The quantitative data for vegetative and yield were subjected to analysis of variance (ANOVA). Mean separation was done with the aid of Duncan's multiple range test at 5% probability level.

Plate 1: Reference descriptor for Variation in calyx margin (IPGRI, 1995)

RESULTS

The result in table 1 showed significant variations among the ten accessions for plant height which ranged between 78cm in NHSMB-F1/R4 and 33.5cm in NHRod-D/R2. Furthermore, the widest canopy was recorded for NHRod- Frt/R1 (62.5cm) while NHTTS-5/R3 had the smallest canopy width (33cm). With respect to mature leaf length, highest mature leaf length was recorded in NHRod-C/R1 (12.38cm) which was significantly different from all other accessions. The lowest value for mature leaf length (4.50cm) was recorded in NHBawa-Frt/R1. The same trend was observed for mature leaf width as NHRod-C/R1 had the highest while NHBawa-Frt/R1 had the lowest (1.8cm). A cursory look at table 2 showed that highest unit fruit weight was observed in NHRod-C/R1 (4.69g) but it was not significantly different from that of NHTTS-5/R3 (4.59g), NHRod-D/R2 (4.56g) and NHRod-Frt/R1 (4.40g). The Table further showed that fruit width ranged from 2.53cm to 0.67cm among the 10 pepper accessions and NHRod-Frt/R1 recorded the highest value. In addition, NHSMB-F2/R1 had the highest fruit length (6.93 cm) which was statistically different from all other accessions. Results of the seed data (Table 2) showed that the highest 100 seed weight was observed in NHBawa-Frt/R1 (0.49g) which is significantly different from other accessions. It is followed by NHTTS-5/R3 (0.44g) and NHSMB-F2/R1 (0.44g) which are not significantly different from NHSMB-F1/R4 (0.42g). The table also showed variation in the number of seeds per fruit with NHTTS-5/R3 having the highest number of seeds (47.50).

Results on morphological characterization in Table 3 showed that there were variations and similarities among the pepper accessions. Leaf and Stem pubescence were observed to be sparse for all the accessions. Similarly, stem colour, lamina margin and stem shape were generally green, entire and cylindrical respectively. All the accessions except NHSMB-F1/R1 have intermediate branching habit. NHSMB-F2/R1, NHSMB-F1/R4 and NHRod-D/R2 have purple nodal anthocyanin while the remaining accessions have green. NHRod-C/R1 and NHTTS-5/R3 have their stigma exsertion on the same level while other accessions are exserted. variations among the cultivars were also observed for fruit shape where they exhibited triangular (3 accessions), elongate (4 accessions), blocky (1 cultivar), almost round (1 cultivar) and campanulate (1 cultivar).

Table 1: Growth parameters of 10 pepper accessions evaluated for morphological traits

Accessions	Plant height (cm)	Canopy width (cm)	Mature leaf length (cm)	Mature Leaf width (cm)

DISCUSSION

High variations have been observed in the morphological traits assessed among the ten selected accessions of pepper which could due to genetic components. Variations in cayenne pepper genotypes have also been reported by Abdul-Rafiu *et al*, (2018) in which number of fruits and seed yield and other traits were assessed. In 2012, Maga *et al*., utilized multivariate analysis to study agro-morphological traits in aboriginal Nsukka yellow pepper (Capsicum annumm) genotypes and observed wide diversity for all the characters studied. The pepper accessions evaluated in this study based on morphological variations and similarities can be classified into three different species; Capsicum annuum, C. chinense and C. frutescens. These three species are generally grown in Nigeria with varying degree of uses. Proper documentation of the data generated from this study will be useful for further research as the potential use of each of the accession can easily be identified. This information can be used to formulate methods and strategies for conservation and in turn genetic improvement of pepper crop. Further studies on wider range of pepper and addition of more accessions in order to establish their morphological distinctness, genetic diversity and relatedness may provide higher opportunities for selection and hybridization for the development of improved cultivars.

Table 2: Fruit and seed parameters of 10 accessions of pepper evaluated for morphological traits

Accessions	Unit fruit weight (g)	Fruit width (cm)	Fruit length(cm)	100 seed weight(g)	Number of seed per fruit

EMERGENCE AND SEEDLING GROWTH OF *Irvingia gabonensis* AS AFFECTED BY POSTHARVEST HANDLIING

***Ajayi E.O., Agaku T.D., Ngbede S.O. and Igbegwu F.C**
National Horticultural Research Institute, Otukpa. Benue State

Corresponding author: oluwakayodefunmi@gmail.com

ABSTRACT
A nursery trial was set up to determine the appropriate storage period and postharvest practices for optimum seed germination of Irvingia gabonensis. The experiment which was carried out at the nursery of National Horticultural Research institute, Otukpa Benue State, was a factor experiment in randomized complete block design (RCBD) with eight treatments replicated three times. The treatments include: fruits picked and planted immediately (T1), fruits picked, depulped and planted immediately (T2), fruits picked and stored for 1 week before planting (T3), fruits picked, depulped and stored for 1 week before planting (T4), fruits picked, stored for 1 week then depulped before planting (T5), fruits picked and stored for 2 weeks before planting (T6), fruits picked, depulped and stored for 2 weeks before planting (T7), fruits picked, stored for 2 weeks then depulped before planting (T8). Data collected were subjected to analysis of variance (ANOVA) and significant means were separated by Duncan Multiple Range Test (DMRT) at 5% probability level. Storage and post harvesting handling significantly affected percentage emergence, seedling height, number of leaves and seedling vigour. At 9 weeks after sowing (WAS), T2 had significantly higher germination percentage (95%) then T1 (70%), T7 and T8 did not germinate throughout the period of observation. It can then be concluded that Irvingia gabonensis are best sown immediately the fruits are picked from orchard or forest floor and depulped.
Keywords: *Depulped, fruits, germination, Irvingia gabonensis, storage.*

INTRODUCTION

Irvingia gabonensis (bush mango) is one of the most important Non-Timber Forest Products (NTFPs) in West and Central Africa especially in Southern Nigeria (Ladipo, 2000; Lowe *et al.,* 2000; Atangana *et al.,* 2002). It is ranked as the most important species for its food and commercial value in Cameroon and West Africa (Leakey, 1999; Ladipo, 2000). It is an African indigenous fruit tree that produces edible fruits and seeds (Atangana *et al.,* 2002). Bush mango is a valuable source of income for farmers and traders in Nigeria, where the fruit is traded locally (Ladipo, 2000). The kernels, which fetch a higher price than the fruits are traded regionally and internationally, which has given it the potential for a true commercial crop, and this has led to a more intensive collection in the forests. The most important part of *I. gabonensis* to most people is its nutritious seeds, which have also been found useful in the reduction of cholesterol and body weight in obese patients (Ngondi, 2005). The seeds constitute an important part of the rural diet in Nigeria, the sun-dried seeds are ground into flour and used as soup thickeners (Ekpe *et al.,* 2007). Despite the nutritional importance of *I. gabonensis*, there is a scarcity of large-scale plantations of the species for mass seed and fruit production. Most of the trees have been growing in the wild, as they have not been domesticated. Although, bush mango is recently being domesticated, less than 10 percent of the total annual harvest of fruits or kernel is harvested from planted trees while the rest are collected from the natural forests (Ladipo, 2000). Constraints to domestication of the species include the long gestation period of seed sown trees (Moss, 1995; Ladipo *et al*., 1996), poor germination capacity (Nya *et al*., 2000) variability of fruits and kernel characteristics, variability in tree size (Ladipo *et al*.,1996, Schreckenberg *et al*., 2001) and limited knowledge base (Tchoundjeu *et al.,* 2002). According to Nya *et al.* (2006), one major difficulty in *Irvingia* domestication is related to its poor seed germination potential which is less than 50% germination capacity when freshly collected and sown. The objective of this study was therefore to the appropriate storage period and postharvest practices for optimum seed germination of *Irvingia gabonensis.*

MATERIALS AND METHODS

The experiment was carried out at the nursery of National Horticultural Research institute, Otukpa (7º6´4.30776" N and 7º38´47.25924" E 436 m a.s.l) in Ogbadibo Local Government Area of Benue State, Nigeria. Two hundred and forty (240) matured fruits of *Irvingia gabonensis* were collected from existing orchard in the Institute for the trial. The trial was a one factor experiment set up in randomized complete block design (RCBD) with eight treatments replicated three times. The treatment include: Fruits picked and planted immediately (T1), Fruits picked, depulped and planted immediately (T2), Fruits picked and stored for 1 week before planting (T3), Fruits picked, depulped and stored for 1 week before planting (T4), Fruits picked, stored for 1 week then depulped before planting (T5), Fruits picked and stored for 2 weeks before planting (T6), Fruits picked, depulped and stored for 2 weeks before planting (T7) and Fruits picked, stored for 2 weeks then depulped before planting (T8).

Ten fruits were planted into each plot of 30 cm x 30 cm with sawdust as the growth medium. The nursery was watered regularly and kept weed free. All the ten plants in each plot were tagged for data collection starting from 4 weeks after sowing (WAS). Data collected included emergence count, plant height and number of leaves. The seed emergence criterion was visible protrusion on the sawdust surface of at least 0.5cm of the cotyledon and hypocotyls of the seedlings. Data collected were subjected to analysis of variance (ANOVA) and significant means were separated by Duncan Multiple Range Test (DMRT) at 5% level of probability, using SAS.

RESULTS

Result from this study showed that germination of Irvingia started from 4 weeks after sowing (WAS) but significant effect of storage and depulping was observed at 5 WAS where seed germination has occurred in all the treatments except T7 and T8. These two treatments (i.e. T7 and T8) did not germinate throughout the period of observation (10 WAS). At 5WAS, T3 and T5 had the highest germination percentage (30%), though these were not significantly different from T1 and T2 which had 25% germination percentage (Figure 1). At 6 WAS, T1 and T2 had the comparable germination percentage (60%) which were significantly higher than other treatment, this was followed by T5 which had 50% then T3 which has 45% germination (Figure 1). At 7 WAS, germination percentage of T2 has increased to 80% while that of T1 only increased to 65%, T5 increased to 55% and T3 increased to 50% (Figure 1). At 8 WAS, only the germination percentage of T2 increased to 90% while there was no increase in other treatments (Table 1). At 9 WAS, only T1 and T2 had increase in germination percentage (70% and 95% respectively), no increase in germination was observed on other treatments. Beyond 9 WAS, no increase in germination was observed in any of the treatments, indicating that they have reached their maximum germination percentage at 9 WAS. At this stage, T2 had significantly higher germination percentage (95%) than any of the treatments, this was followed by T1 which had (70%) T5 and T3 which had 55% and 50% respectively. T4 and T6 had germination percentage of 45% and 20% respectively while T7 and T8 did not germinate at all throughout the period of observation (Figure 1).

Storage and post harvesting handling significantly affected seedling height, number of leaves and seedling vigour of Irvingia at both 6 and 8 WAS (Table 1). At 6 WAS, seedlings of T3 were observed to be significantly taller (20.78 cm) than other treatments, this was followed by T5 (19.62 cm) then T2 (18.64 cm) while T6 had the shortest seedlings of 15.00 cm. As growth advanced to 8WAS, T5 were the tallest (21.33 cm) but not significantly different from T3 (21.32 cm) and T1 (20.98 cm). T6 was also the shortest with height of 17.93 cm (Table 1). At 6 WAS, T6 produced the highest number of leaves (4) while T1, T2 and T4 produced the least number of leaves (3). At 8 WAS, T4 produced the highest number of leaves (5) while other treatments produced 4 leaves (Table 1). At 6 WAS, T2 had the highest seedling vigour (11.18) while T6 had the lowest (3.00) but at 8 WAS T2 and T6 had the highest and the lowest seedling vigour (18.23 and 3.59 respectively) while no significant difference existed among other treatments in terms of seedling vigour (Table 1).

DISCUSSION

From this study, germination of Irvingia seeds started at 4 WAS which could be as a result of the hard seed coat. This observation supports the report that germination of *I. gabonensis* seeds takes upwards of 14 days and first requires that the seeds are extracted from the fruit and dried for at least 2 days (Ainge and Brown, 2001). This study also revealed that fruits picked, depulped and planted immediately had the highest percentage emergence (95%) this corroborates the report of Okafor (1997) who reported 80% germination for seeds that are extracted from the fruit and dried for at least 2 days. It was observed from this study that fruits of Irvingia depulped before planting immediately after picking had higher percentage of emergence than those that were not depuled. This could probably be as a result of the fact that removal of the fruit mesocarp exposed the seeds early to suitable environments like water and oxygen for seed germination as reported by Mbakwe (2004). Nzekwe et. al. (2002) observed that the long periods taken by seeds of undepulped fruits to begin germination were expended on the decay of the fruit mesocarp. MacDonald, (1986) opined that the fleshy tissues or pulp should be removed to prevent damage to the embryo from spontaneous heating or an imbibiting substance. Vihotogbé *et. al.* (2014) opined that sowing fresh seeds in less depth than 1 cm hole guarantees better performances (germination rate of 98 -100%) for any provenance and for both bitter and sweet trees. This study further revealed that fruits depulped before storage or after storage for 2 weeks before planting did not germinate throughout the period of observation, this implies that Irvingia fruits stored for two weeks (i.e. 14 days) before planting is not likely to germinate. This result support the report of Joseph and Aworh (1991 and 1992) that, fresh fruits of *I. gabonensis* have a shelf life of less than 2 days if picked when ripe and not more than 10 days if harvested at the mature green stage due to high respiration rate, moisture loss and microbial attack. Also, Lowe *et al*. (2000) reported that attempting to dry these high oil content seeds (up to 70%; Joseph, 1995) in a tropical high moisture environmental condition exposes them to rapid moulds colonisation, jeopardising the viability of seeds after few days of conservation under ambient conditions.

CONCLUSION

This study revealed that *Irvingia* fruts picked, depulped and planted immediately has the higher percentage germination followed by those picked and planted immediately without depulping. It can then be concluded that *Irvingia* seeds are best sown immediately the fruits are picked from orchard or forest floor and depulped.

PHENOLIC CONTENT AND ANTIOXIDANT ACTIVITIES OF DIFFERENT TEAS AND THEIR SYNERGIES POTENTIALS.

Ademoyegun, O. T. and Owolade, S. O.

ABSTRACT

Plant nutrients having antioxidant sources have been a major focus of research in recent years because they were regarded as magic bullets that could help to prevent many human diseases such as cancer, arthritis, Alzheimer, cardiovascular diseases e.t.c. In the present research the seven plant namely: Moringa leaves "Moringa oleifera", roselle calyx "Hibiscus sabdarifa", Ugu leaves "Telfaria occidentalis", Ginger rhizomes "Zingiber officinale", Tumeric rhizomes "curcuma longa", Lemon grass "Cymbopogon citratus" and Bitter leaves "Vermonia amygdalina" have been selected as all these plants show antioxidant potential individually. People used to drink tea often by insert tea bag into boiled water. These infusions release the extract into the hot water. Ginger tea is most often tea like to drink because of its smell and health benefits. Ginger rhizome extract was combined with the extracts of fore-mentions plants extracts in ratio 1:1 in weight, and only ginger rhizomes as control. The results of the study showed ginger and bitter leaves combinations displayed significant polyphenolic strength, antioxidant potential in DPPH and Nitrous oxide assay, while ginger and moringa leaves shown the highest potential in reducing power assay. Organoleptic studies showed ratio 1:1 of ginger and turmeric exhibited highest in colour and for overall acceptability, aroma and taste combination of ginger with Roselle calyx extracts exhibited the best. Generally, the ratio of ginger 1:1 with others extracts proportion, showing the highest radical quenching ability and strongest synergism in in-vitro. Thus, this study provides the scientific basis for combining aqueous infusions to attain maximum antioxidant potential.

Keywords*: Phenolic, antioxidant assays, teas, synergies, ginger.*

INTRODUCTION

The health benefits of tea are widely recognized by medical and nutritional experts (Adesokan *et al*., 2013 and Shirwaikar *et al.*, 2006). Indeed, tea is well known as a nutritional source of bioactive compounds, namely polyphenols that provide antioxidant activity. These chemicals can play an important role in adsorbing and neutralizing free radicals, quenching singlet and triplet oxygen, or decomposing peroxides. They act as radical scavengers and are able to inhibit lipid peroxidation and other free radical-mediated processes, protecting the human body from several diseases attributed to the reactions of radicals. The combination of various plant products may exhibit different types of interactions (synergistic and additive) among their different phytochemicals, and may change their biological properties Wang *et al.,* 2011. Although these combinations are flooded in the market, limited scientific data is available that whether these combinations will act in a synergistic or additive manner. It was found that Chamomile flowers and tumeric tea showed synergistic antioxidant interaction Kilima *et al.*, 2014. Whereas, binary combinations of ginger rhizome extract (GRE) and green tea polyphenols (GTP) demonstrated synergistic to additive interactions.

Some studies also pointed out that the ratio of the herbs would influence the antioxidant properties Monga *et al.*, 2017. It is important to investigate the modulation of antioxidant properties depending on the proportions of herbs in a mixture that can be used to design functional foods and pharmaceutical products at different concentrations Asesokan *et al.*, 2013. The ratio of the extracts significantly influenced the antioxidant capacity of a binary mixture and the type of interaction between their bioactive components Ademoyegun *et al.*, 2013. Among these studied combinations, green tea and O. gratissimum combination showed the highest antioxidant potential and maximum synergistic interaction (Awah FM 2010). Ginger rhizome is a valuable medicinal plant that has been used since ancient times. It is well known due to its medicinal properties such as antioxidant, antifungal, antimicrobial, anti-inflammatory, antiviral and anticancer Ademoyegun *et al.,* 2013 and Joshi *et al.,* 2017. However, there is no scientific literature about the interaction with other herbs tea at different ratios. The proportion of individual herb could play an important role in determining the chemo preventive potential or bio efficacy in a health-promoting herbal combination. The aim of the present study was to study the antioxidant potential of ginger base tea with different combination with others mentions above plants in ratio of one to one and using the ginger tea without combination as the control.

METHODOLOGY

Preparation of Leaf Extracts

The leaves of *the selected plants, the calyx of Roselle and rhizomes of ginger and turmeric* after collection were cleaned and then oven dried at 50°C for seven days. After that, the sample was coarsely grinded, sieved through 2 mm and then stored in an air-tight container till further used. After which 2g of the ginger powder was sealed inside the tea bag (G) and 1g of ginger powder was combined with 1g of others prepared powder was different combined, sealed in the tea bag. Which are ginger with bitter leaves (GB), ginger with lemon grass (GL), and ginger with Moringa (GM), ginger with Roselle (GR), ginger with turmeric (GT) and ginger with Ugu (GU). The herbal infusion was prepared by the hot water extraction method was used to prepare the herbal tea. Two bags of which were infused in 200 ml of distilled water at the temperatures 100°C for 10 minutes. Afterward, the sample infusion mixture was let cool for 5 minutes, the infusion teas were used to carry out the mentioned analysis with the organoleptic test.

Sensory Analysis

Acceptance test was conducted on three herbal teas infused at different temperature by 48 untrained panelists of students and staffs at National Horticultural Research Institute. Panellists used plain water between samples. The hedonic scale of 1 - 9 was used to evaluate the overall acceptability, flavour, aroma, aftertaste, mouthfeel, and color of the tea, where 1 = extremely dislike and 9 = extremely like. Scoresheet was given to each panelist. The analysis was done on each of the attributes by calculating the mean point from the result.

Determination of Phytochemical Contents

The phytochemical contents such as the total phenolic content and total flavonoids contents were determined using folin-ciocalteu and aluminum-chloride methods respectively.

Determination of Free radical Scavenging Activity

The free radical scavenging activities were determined using DPPH assay; FRAP assay, total antioxidant assay, and Nitrous oxide scavenging assay according to standard methods.

Statistical Analysis

The statistical analyses were performed by a one-way ANOVA using Microsoft Excel 2016. The results were expressed as means ± SD to show variations in the various experiments. Differences are considered significant when $p < 0.05$.

RESULTS

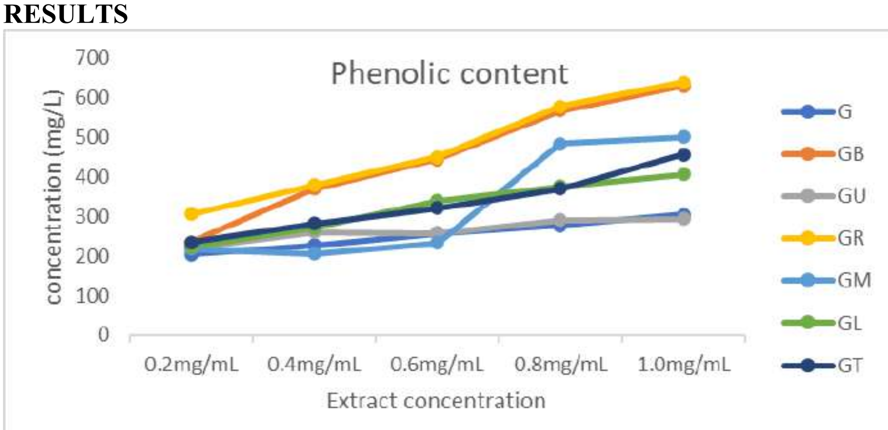

Figure 1: Phenolic content of the seven tea extracts at different concentration.

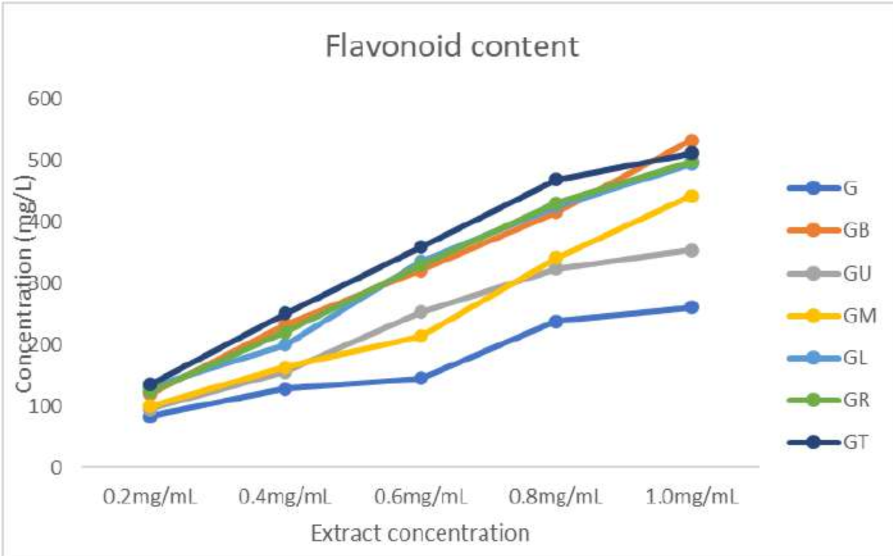

Figure 2: shown the flavonoid content of the seven tea extracts at different concentration.

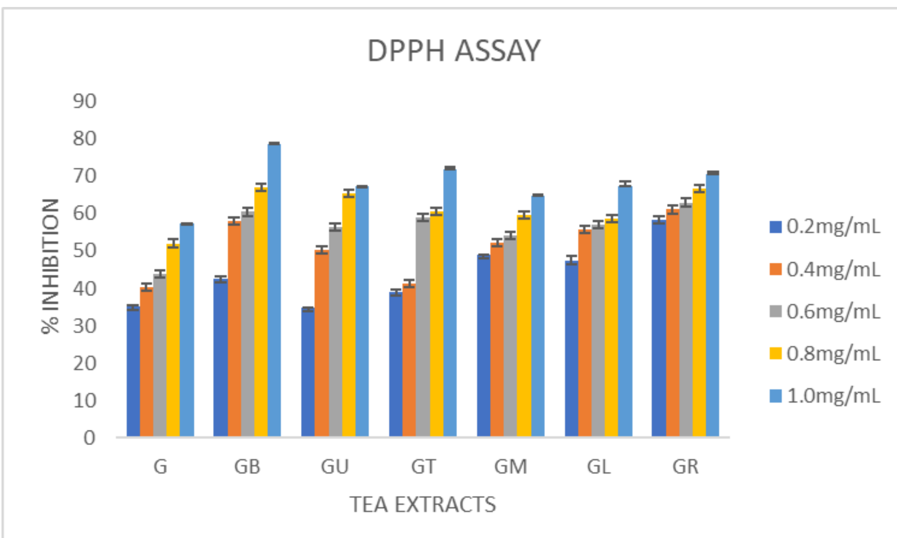

Figure 3: 1, 1-Diphenyl-2-picrylhydrazyl (DPPH) radical scavenging activity (RSA)
The ability of the extracts to scavenge DPPH free radicals

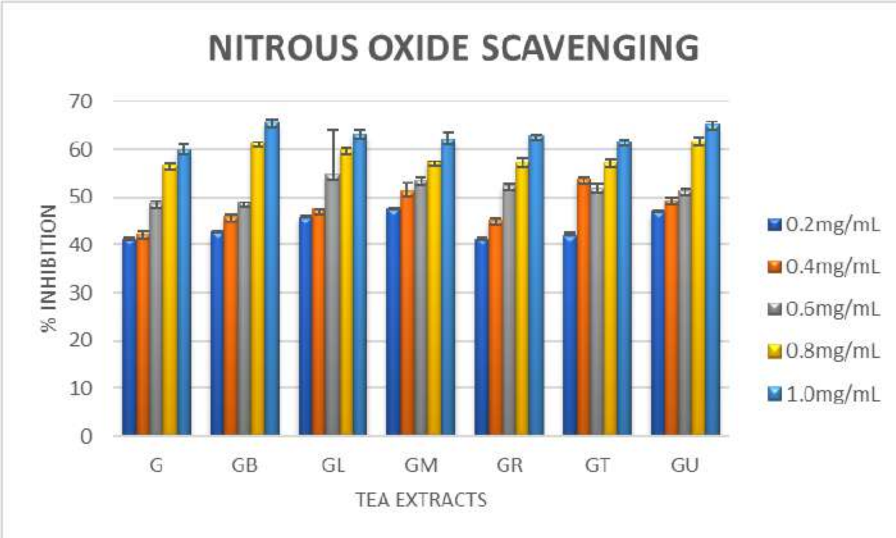

Figure 4: Nitric oxide scavenging activities of the seven tea extracts at different concentration.

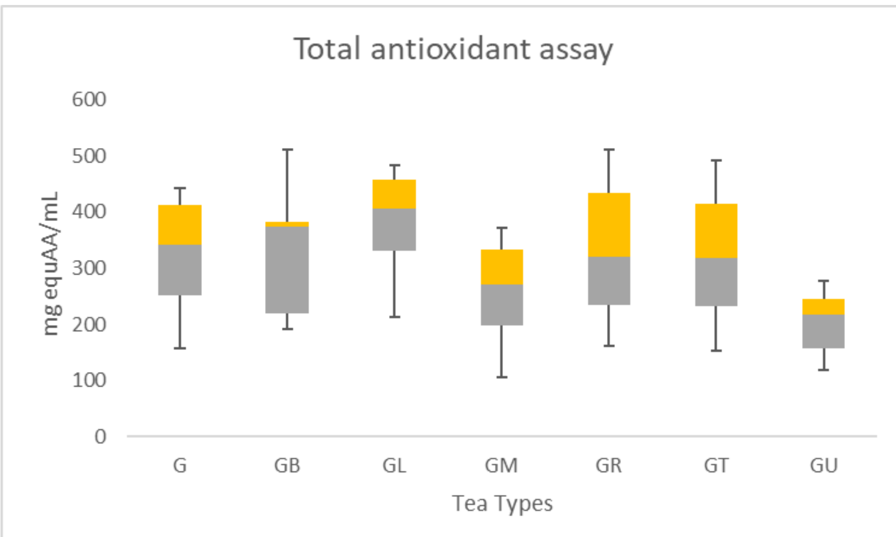

Figure 5: Box and whisker plots represent the mean concentration range (lowest, 25 percentile, median, 75 percentile and highest) of different concentration extracts of tea types graphically shown the total antioxidant assay

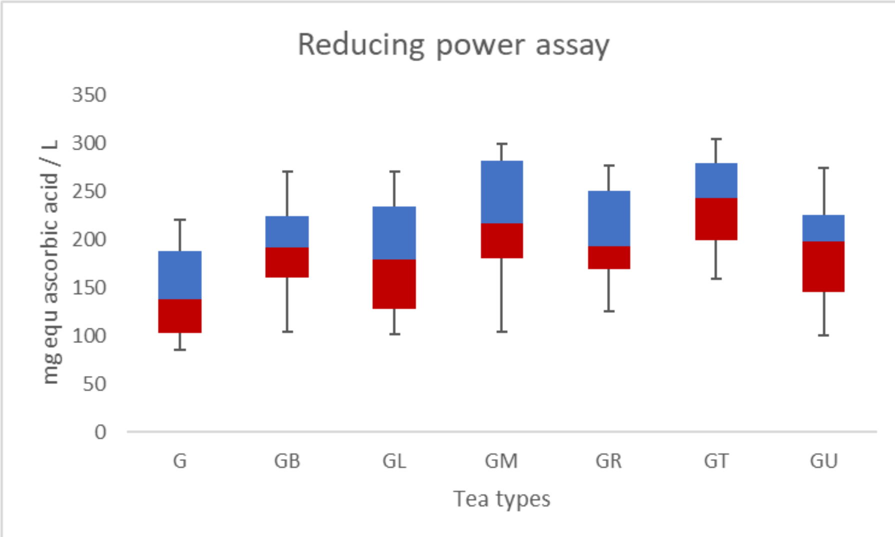

Figure 6: Box and whisker plots represent the mean concentration range (lowest, 25 percentile, median, 75 percentile and highest) of different concentration extracts of tea types graphically shown the reducing power assay.

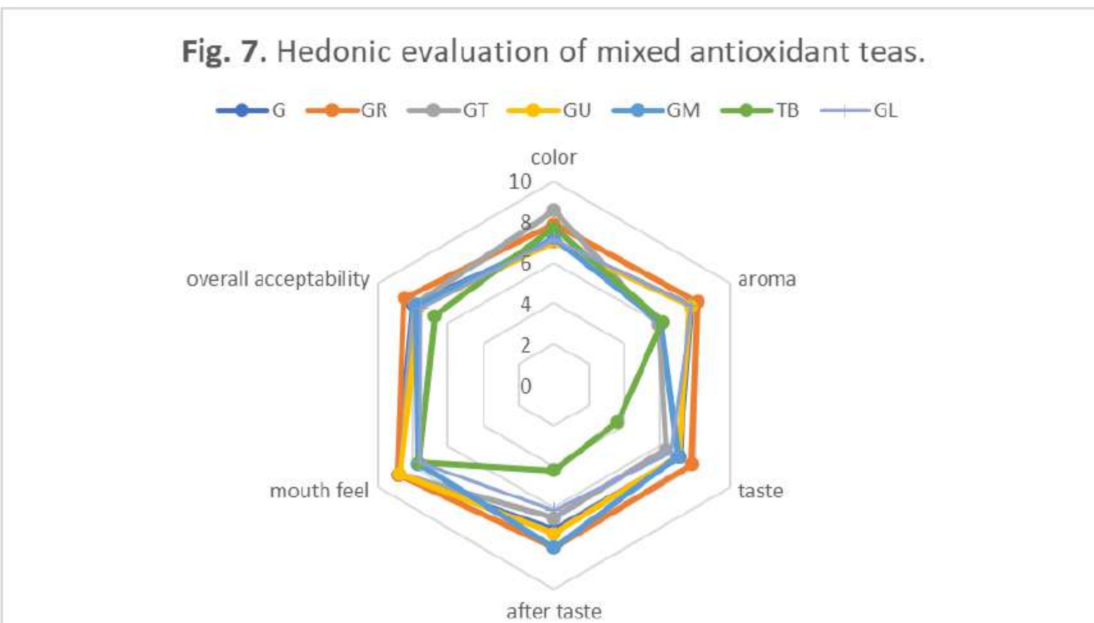

DISCUSSION

In our study we determined the total phenolic and flavonoid content of infusion tea extracts of ginger (control) and ginger mixed with others herbs and both of the extracts showed high phenolic and flavonoid content. Antioxidant activity of these infusion tea extracts may be attributed to the high phenolic and flavonoid content. In our study the mixed tea extracts showed comparatively higher antioxidant activity than the ginger tea extract only (control), which is in accordance with the total phenolic and flavonoid content in fig 1 and 2. Figure 3 and 4 showed the ability of the infusion tea extract to scavenge the free radical pose by the stable radical of DPPH and the nitrous oxide scavenging. The results showed the potential of both the control and effect of synergies others mixed on both scavenging the DPPH and nitrous oxide scavenging radical. Ginger with Moringa (GM), Ginger with Turmeric (GT), Ginger with Bitter leaves (GB) and Ginger with Roselle (GR) showed distinct and higher scavenging potential than the infusion ginger tea only (control).

Fig 5 and 6 showed the graphical presentation of the different concentration extracts of the tea types from the minimum value, median and the maximum value in milligram ascorbic acid equivalent per millimeter. For the total antioxidant called phosphpmolybdate assay showed the control and others mixed tea having different potential antioxidant among them, but for the reducing power assay, the infusion ginger tea only (control) has the lowest antioxidant value compared with others infusion that combined ginger with other teas extracts. Sensory evaluation is an important criterion in the development of new products. It meets consumer requirements in terms of organoleptic quality. The enrichment of Ginger with Roselle (GR) improved taste, aroma and overall quality. Taste and aroma were the most important sensorial descriptors that influenced the overall appreciation of antioxidant teas. Infusion tea of Ginger with bitter leaves scored lowest and was completely rejected in all sensory attributes by panelists as shown in the hedonic evaluation fig 7 probably of the bitterness exhibited by the leaves of *vernomia amygdalina*.

CONCLUSION

The present study thus lent credence to the fact that addition of such herbal additives might reduce oxidative stress to some extent, which could be helpful for human consumption. This was also partially substantiated by the potentiation of the free radical inhibitory properties and antioxidant potential of the infusions.

ABSTRACT
The study assessed the usage of Information Communication Technology (ICT) tools among horticultural crop farmers in Akinyele Local Government Area, Oyo state. Agbeka area of the Local Government was purposively selected for the study from which 30 farmers were randomly sampled. Data was collected using well-structured questionnaire and analyzed with descriptive statistics (frequencies and percentages). The results revealed that most of the farmers were males (60.0%), in the 31-40 years age group (66.7%), 46.7% possess secondary education, 93.3% had farming as primary occupation, and 83.3% had 1-10 years of farming experience. Mobile phone was used by 66.7% of the farmers. These mobile phones were used by 46.7% of the farmers to transact business with their customers, and as sources of information on credit facilities; 30.0% use mobile phones as electronic diary and reminder for meetings and other events. As regard the constraints faced in effective use of ICT tools, 40.0% of the farmers stated that high cost of devices and inadequate funds was always a constraint. The study thus recommends that the government should make other ICT tools apart from mobile phones accessible to farmers. This would enhance production and improve their income and ultimately welfare.
Keywords: *Information and Communication Technology (ICT), ICT tools, horticulture*

INTRODUCTION

Information and Communication Technology (ICT) plays a principal part in every aspect of human activities, including horticulture. In growing and interchanging information, ICT provide the future to increase efficient yield, competitiveness and extension in various forms of agricultural sectors. Farmers that take part in commercial agriculture in large scale might be look forward to be using cameras, computing devices, digital imaging, the internet and Wide Area Networking (WAN), Wi-Fi, SMS services, computing devices, Wireless Access Protocol (WAP) based internet access (Oke *et al.*, 2019). Oke *et al*, 2019 noted that farmers make use of forms of Information and Communication Technology such as mobile phones, computer and the internet.

The ICT tools includes mobile phones, computers, internet, and the older tools such as radio, television, and video are communication channels used by the farmers of today (Nwobodo *et al*., 2023). The difficulty in obtaining information due to a general trimming in funding for the extension has also entailed that farmers take interest of the ICTs in communicating production, marketing and financial information with other actors in agricultural value chains. Moreover, approach to production and marketing information can be greatly enhanced through the use of ICT tools. However, poorly disseminated information and knowledge as a result of certain constraints may hinder agricultural development of any community (Li, 2013; Ajayi, 2022). In Oyo State, like other areas, farmers are faced with some constraints which are limiting them in the use of ICTs in order to gain access to relevant information on improved technologies for enhanced productivity and improved income. Some of the constraints to the use of ICT among farmers are irregular power supply, high cost of ICT devices, poor network connection, inadequate funds, poor training on ICT use, language barrier, lack of awareness on ICT tools, negative attitude towards ICT tools just to mention a few (Shreya, 2020).

Thus, this study investigated the usage of information and communication technology tools among horticultural crop farmers in Akinyele Local Government Area, Oyo State. Specifically, the study described the personal characteristics of farmers in the study area; assessed the ICT tools used in their farming activities as well as the constraints to effective use of ICT.

MATERIALS AND METHODS

This study was carried out in Akinyele Local Government Area (LGA) of Ibadan, Oyo State, Nigeria. According to Oyo State Government website, Akinyele Local Government has the population of 211,811 in 2006 with 105,594 males and 106,217 females at 4.14% population growth rate. It is 222km^2. The local government is divided into three which are Akinyele main local government headquarters which is at Moniya, Akinyele East at Ikereku and Akinyele south is located at Igbo Oloyin. The LGA is dominated by Farming as Agriculture claims major engagement of the population. Akinyele LGA in its entirety comprises a number of Historic and Ancient settlements of Yoruba origins established. The study area is specifically located at Agbeka Dam, Agbeka Area which comes from Ajeja and it flows through Agbeka in Akinyele. Thus, Agbeka area was purposively sampled for the study as it is well noted for the production of horticultural crops; 30 farmers were randomly sampled from the area. Well-structured questionnaire was used to elicit information from the respondents most of who were farmers. Information collected include personal characteristics of the respondents, the ICT tools used in their horticultural activities and constraints to effective use of ICT. Descriptive statistics such as frequencies, percentages, mean scores and standard deviation were adopted to analyze the data collected were used to analyze the data collected.

Personal characteristics of the farmers

The results (Table 1) reveals that most of the farmers were males (60.0%) in the 31- 40 years age group (66.7%), married (76.7%), possess secondary education (46.7%), and had farming as their occupation (93.3%). Also, 83.3% of them have spent 1-10 years in farming, 50.0% source seedlings from the open market and 80.0% produce on 1-5 acres of farmland. This implies that the horticultural farmers sampled were young, married, male farmers who were educated and are

expected to have some knowledge on horticultural practices they are engaged in. This finding supports Oke *et al.*, (2019) which confirmed that males are more engaged in farming with most of them being in the 31 to 40 years age group. Also, sixty percent of the sampled farmers grow tomato, while 30.0% grow cucumber as well as other horticultural and non-horticultural crops.

Table 1: Personal characteristics of farmers (n=30)

Variable	Frequency	Percentage
Sex		
Male	18	60
Female	12	40
Age		
21-30	5	16.7
31-40	20	66.7
41-50	1	3.3
51-60	4	13.3
Marital Status		
Married	23	76.7
Single	7	23.3
Education Status		
Primary Education	1	3.3

Source: Field survey 2023

Information Communication Technology Tools used by farmers

The result further showed that mobile phones were the most used ICT tools by 66.7% of the farmers, forty percent of them opined that they use the internet (Table 2). Nwobodo *et al.*, (2023) also confirmed that mobile phones were used by 93.1% of sampled rice farmers in Nasarawa and Benue states. However, all the farmers do not make use of computer or newspaper as an ICT tool. This could imply that mobile phones are not only used for communication by the farmers, they are also useful tools in horticultural crop farming.

Table 2: Information Communication Technology Tools used by farmers (n=30)

ICT Tools	Yes	No
Radio	5 (16.7)	25 (83.3)
Mobile Phone	20 (66.7)	10 (33.3)
Television	2 (6.7)	28 (93.3)
Computer	-	30 (100)
Internet	12 (40)	18 (60)
Newspaper	-	30 (100)

Source: Field Survey 2023. Percentages in parentheses

Usage of ICT tools

The study elicited information from the farmers about the extent of their usage of ICT tools (Table 3). The results revealed that 60.7% of the farmers rarely use radio as a medium of advertisement, 46.4% rarely use radio to listen to horticultural related programmes. This is unlike the findings of Oke *et al*. (2019) which revealed that 46.3% of sampled maize farmers occasionally used radio to listen to horticultural related programmes. Moreover, 46.7 percent of the farmers always use mobile phones to transact business with their customers, and use mobile phones as sources of information on credit facilities. This is similar to the finding of Oke *et al*, 2019 which found that 62.5% of the maize farmers use mobile phones to source for information from extension agents. Thus, it infers that mobile phones are used by farmers to source for information. One-third of the farmers also use mobile phones as always as electronic diary and reminder for meetings and events. This result buttresses the fact that mobile phones are the most used ICT tool by the farmers.

Table 3: Usage of ICT tools by farmers(n=30)

Usage of ICT Tools	Always	Occasionally	Rarely	Never
The use radio to listen to horticultural related programme	-	9 (32.1)	13 (46.4)	6 (21.4)
I use radio as a medium of advert	2 (7.1)	2 (7.1)	17 (60.7)	7 (22.9)

I use mobile phone to transact business with customers	14 (46.7)	15 (50.0)	-	1 (3.3)
I use mobile phone for sources of information on credit facilities	14 (46.7)	11 (36.7)	4 (13.3)	1 (13.3)
I use mobile phone as electronic diary and reminder for meetings and events	9 (30.0)	15 (50)	6 (20)	-
Have you ever received market information via ICTs	4 (13.3)	15 (50)	4 (13.3)	7 (23.3)
Do you have any challenges associated with using ICTs to access information	6 (20)	9 (30)	13 (43.3)	2 (6.6)

Source: Field Survey 2023. Percentages in parentheses

Constraints to Effective Use of ICT tools

The major constraints are of inadequate funds (X=1.87), high cost of ICT devices (X=1.93) and poor network connection (X=2.38) in the effective use of ICT tools were some of the constraints experienced by the farmers (Table 4). Lack of awareness on ICT tools (X=2.59), irregular power supply (X=2.60), poor training on ICT use (2.87) and language barrier (X=3.33) are the minor constraints to the effective use of ICT tools. This implies that cost related to ICT tools is a major constraint to its effective use. Obinna *et al*. (2023) confirmed that inadequate fund was the major constraint to effective use of ICT tools among maize farmers.

Table 4: Constraints to Effective Use of ICT tools (n=30)

Constraints	Always	Occasionally	Rarely	Never	Mean (X)	Std. Dev.
Irregular power supply	3 (10)	15 (50)	9 (30)	3 (10)	2.60	1.037
High cost of ICT devices	12 (40)	13 (43.3)	5 (16.7)	-	1.93	1.048
Poor network connection	2 (6.9)	20 (69)	6 (20.7)	1 (3.3)	2.38	0.903
Inadequate Funds	12 (40)	14 (45.2)	4 (46.7)	-	1.87	0.973
Poor training on ICT use	3 (10)	12 (40)	14 (46.7)	1 (3.3)	2.87	1.137
Language Barrier	-	6 (20)	12 (40)	12(40)	3.33	0.884
Lack of Awareness on ICT tools	7 (24.1)	10 (34.5)	12 (41.4)	-	2.59	1.268

Source: Field Survey 2023. Percentages in parentheses. X=2.5; X<2.5 are major constraints and X>2.5 are minor constraints

CONCLUSION

The findings of this study revealed that although farmers play a key role in horticultural sector and application of ICT to aid production, there is need for government at all levels to amass political will to empower farmers with financial assistance and other useful inputs in the use of ICT to enhance production.

ABSTRACT
This research investigated the effects of poultry manure application rates and plant population on growth and yield of tigernut (Cyperus esculentus) in pot. Two combined treatment factors including three poultry manure rates (0, 2.5, and 5.0 t/ha) and three plant populations (1, 2, and 3 plants per pot) were evaluated. Growth and yield parameters were measured in response to the treatment combination. The results revealed that increased application of poultry manure significantly (p<0.05) influenced the growth and yield of tigernut, although not significantly. Poultry manure at the rate of 5.0t/ha had the highest leaf count, number of tillers and plant height as well as most of the yield parameters measured except overall number of tubers where poultry manure at the rate of 2.5 t/ha did better. Furthermore, increasing plant population similarly increased growth and yield of tigernut. The growth parameters measured were significantly (p<0.05) influenced by population except leaf length at four weeks. On the other hand, the yield parameters except above ground biomass and length of longest root were significantly (p<0.05) influenced by population. The pots with three plants demonstrated better performance in terms of growth and tuber yield. It was conclusive that increasing application of poultry manure and plant population to the limit of this experiment had a better result on growth and yield of tigernut.
Keywords: *Poultry Manure, Plant Population, Tigernut Tubers*

INTRODUCTION

Tigernut, scientifically known as Cyperus esculentus, is a tuber crop from the Cyperaceae family. These tubers, ranging from 0.3 to 1.9 cm in diameter, are rich in dietary fiber and carbohydrates (Adejuyitan, 2011). It's a versatile crop, capable of growing both annually and perennially, reaching heights of up to 3ft (90cm) from its tuber. Tigernuts or yellow nutsedge (Cyperus esculentus) has many names in English, it is called tigernut, yellow nut sedge, earth almond, ground almond, and yellow nutgrass. In different regions, it's referred to as Habelaziz in Arabic, Chufa in Spanish, and Ayaya or Zulu nuts in Africa. In Nigeria, it's known as Akiawusa in Igbo, Ofio in Yoruba, and Aya in Hausa (Bamishaiye *et al*., 2011). Despite its nutritional potential, Tigernuts are often underutilized and considered a mere weed in many areas.

Tigernut cultivation typically occurs between April and May, influenced by the previous harvest (https://www.greses.net/en/tigernuts/cultivation/). Planting can be either direct into the field or started in a well-prepared nursery medium before transplanting. Vegetative propagation via rhizomes, preferably those with sprouts, is recommended (Lee, 2021). Tigernuts are deemed a superfood due to their rich nutrient profile, including calcium, magnesium, potassium, sodium, phosphorus, zinc, and vitamins E, C, and folic acid. They are also a source of natural energy, thanks to their starch and sucrose content (Jose, 2018). Tigernuts require enough planting space for growth because of its multiple shoots production. Tubers should therefore be planted adequately to avoid overpopulation, which reduces yield. Recently, there's a growing interest in organic manure due to the rising cost of inorganic fertilizers. Poultry manure, also known as chicken manure, stands out as an excellent soil amendment. It enriches the soil with organic matter and nutrients, improving soil quality (Van *et al*., 1993). Poultry manure has been reported to contain more plant nutrients than all other organic manures (Ayoola *et al*., 2006). Organic matter plays a crucial role in soil fertility in tropical regions, making poultry manure a valuable resource (Ikpe *et al*., 2002). This study is needed to provide agronomic information on the growth and yield of tigernuts in response to different poultry manure rates and plant population.

MATERIALS AND METHOD

Experimental site: The experiment was conducted in a controlled environment at Nsukka, Enugu state between July and November 2022. Collection and preparation of sample: Freshly harvested and dried tiger nut tubers were obtained from Jos, Plateau State, located in the North Central region of Nigeria. A nursery medium was prepared, comprising sawdust that underwent thorough washing to eliminate impurities. The cleaned sawdust was then packed into four black polyethylene bags. Prior to planting in the nursery medium, the seeds underwent a 24-hour water soaking process to break dormancy and assess their viability through the floatation test. Planting, emergence and transplanting: The tiger nut tubers were planted on July 15, 2022, and it began to emerge on July 19, 2022, three days after planting. The emergence process continued steadily for the next two weeks until it was ready for transplant. The seedlings were transplanted from the nursery to the treatment combination pots on July 29th, 2022. A total of 45 polyethylene bags, each containing approximately 10-12kg of soil, were prepared for this purpose.

Experimental design: The experiment was a 3×3 factorial experiment, employing a completely randomized design. Factor A represented plant population density with 1, 2, and 3 plants per pot, while factor B represented poultry manure rates at 0, 2.5, and 5 t/ha. This resulted in a total of nine treatment combinations, each of which was replicated five times. Therefore, the experiment comprised a total of 45 experimental units. Treatment application: The experiment was a two-factor experiment, incorporating plant population density and poultry manure rates as the variables of interest. The initial treatment, pertaining to plant population density, was administered on the day of transplant. Specifically, 15 pots were assigned to each of the following: one plant population, two-plant population, and three-plant population. The second treatment, involving poultry manure rates, was applied on August 12, 2022, precisely two weeks after transplanting. The rates used for this treatment were 0, 2.5, and 5.0 tons per hectare.

Data collection: Parameters measured included the number of leaves, number of tillers, plant height, whole plant biomass weight, above ground biomass, below ground biomass, tuber fresh weight, length of longest leaf and root, number of leaf and number of tubers.

Soil and plant analysis: The soil and poultry manure used for the experiment were analyzed and shown in Table 1.

Statistical analysis: All the data collected in the experiment were subjected to Analysis of variance (ANOVA) following the procedures outlined for a two-way design (completely randomized design) using Genstat 12.0. Differences between means were determined using Fischer's Least Significance Difference (F-LSD) at 5% Probability level.

RESULT

Table 1 shows that percentage of clay, silt and sand (fine and coarse) in the soil sample was 22%, 11%, 35% and 32% respectively, sand having the highest value followed by particles of clay with silt being the least. The pH of the soil sample measured in KCl indicates that the soil is slightly acidic while pH of the poultry manure (PM) sample measured both in water and KCl showed neutrality. The organic Carbon, organic matter content, Nitrogen content and exchangeable bases were higher in the PM sample. The cation exchange capacity and percentage base saturation recorded a moderate value. The soil had a higher phosphorous content than the PM sample analyzed. Table 2 revealed the effect of plant population on the growth of tigernut. The growth parameters measured included leaf length, number of leaves, and number of tillers were not significantly ($p>0.05$) influenced by poultry manure. However, statistical data measured revealed a gradual increase in the growth parameters over time. The number of leaves decreased between the 10th and 12th week after transplanting (WAT).

Among all treatments, poultry manure at the rate of 5.0t/ha showed the highest values for all growth parameters. The growth parameters were significantly ($p<0.05$) influenced by population except leaf length at the 4 WAT. The mean data indicated that 3-plant population had the highest value for all growth parameters measured across week of transplant. The growth parameters measured were not significantly ($p>0.05$) influenced by the interaction of poultry manure and plant population except leaf

length at 4 and 6 WAT. No particular trend was observed, however three plant population and poultry manure at the rate of 5t/ha manifested a more pronounced effect on growth. Various yield parameters, such as above ground biomass, below ground biomass, length of longest leaf and root, tuber fresh weight, number of leaves, number of tubers, and whole plant biomass weight were measured. These parameters were not significantly ($p>0.05$) influenced by the different rates of poultry manure used.
Based on the statistical data analyzed, poultry manure at the rate of 5.0t/ha had the highest values, except for number of tubers where poultry manure at 2.5t/ha showed the highest value. Most of the parameters measured were significantly ($p<0.05$) influenced by population. However, the 3-plant population outperformed the rest as seen in Table 3. The yield parameters were not significantly ($p>0.05$) influenced by the interaction effect of poultry manure and plant population. From the statistical data measured, the application of poultry manure at 5 t/ha to pots with two plants had a pronouced effect on the above ground biomass, below ground biomass, tuber fresh weight and whole plant biomass. Applying 2.5 t/ha of poultry manure to pots containing three plants resulted in the highest number of tubers. On the other hand, pots with three plants that didn't receive poultry manure, and pots with two plants that received 2.5 t/ha of poultry manure, produced the longest leaf and root, respectively.

DISCUSSION

This study revealed a notable effect of poultry manure and plant population on growth and yield of tiger nut tubers. Increasing application of poultry manure led to increase in growth and yield of tiger nut. Statistical data analysis however revealed a non significant effect at the probability level tested but from the mean of the data measured, an increase in poultry manure led to increase in number of leaves, number of tillers, leaf length and yield except for number of tubers produced where application of poultry manure at 2.5t/ha resulted in higher number of tubers. Therefore, application of poultry manure beyond 2.5 t/ha may have become counterproductive to yield (Oladele *et al*., 2019). Generally, increasing the application of poultry manure provides essential nutrients to the plants, leading to improved growth and yield. Additionally, the organic matter present in poultry manure can enhance soil structure, increase water-holding capacity, and create an optimal environment for root development and nutrient absorption (Mohamed *et al*. 2010).
The findings from the population studies suggest that increasing plant population density to the limit of this experiment can have a positive impact on tiger nut growth and yield. Higher plant density can increase competition for resources such as water, nutrients, and sunlight. This competition can stimulate the plants to grow taller, develop more roots, and produce more biomass, which can translate into higher yields (Tollenaar and Lee, 2002). A higher plant density can also have a positive effect on soil health. Study by Goodfriend *et al*., (2000) on the response of soil microorganisms to planting density of Salicornia bigelovii revealed that increased root density of plants could stimulate microbial activity in the soil, which can improve soil structure and nutrient availability. This, in turn, can lead to healthier and more productive plants.

CONCLUSION

This study aimed to assess the optimal rate of poultry manure for cultivating tiger nut and determine the ideal plant population density for tiger nut tuber growth. The aforementioned findings inferred that the application of poultry manure at a rate of 5 t/ha and a plant population of three plants exhibited a significant enhancement in the growth and yield of tiger nuts grown in pots.

***ABSTRACT**:*
Two experiments were conducted at Department of Crop Science, University of Nigeria, Nsukka to study the effect of storage duration, nursery substrates and seedling emergence and early seeding growth of Tiger nut. The experiment on storage duration involved freshly harvested tiger nut tubers subjected to varying storage duration of one, two and three weeks of air drying at room temperature and another stored in a refrigerator for an extended period. Result revealed a non-significant (p>0.05) effect, however tubers dried for two and three weeks had better emergence compared to other storage duration. The second experiment on substrates and sterilization was a 3 x 3 factorial involving 3 levels of substrates (rice husk, sawdust and a combination of rice husk and sawdust) and 3 Sodium hypochlorite (NaOCl) sterilization levels of 0, 5 and 10%. Seedling emergence was significantly influenced by substrate at 1 and 2 weeks after sowing, while sterilization enhanced triple shoot production. Seeds sown in combination of rice husk and sawdust at 10% NaOCl dilution gave the highest number of emergence. Seed storage at two weeks under room temperature and combination of sawdust and rice husk at 10% sterilization level were found most suitable, and hence, recommended.
Keywords: *Early seedling growth, Emergence, Sterilization, Storage Duration, Substrates, Tiger nuts tubers*

INTRODUCTION

Tiger nut, scientifically known as *Cyperus esculentus*, is a tuber crop belonging to the Cyperaceae family. These tubers range in size from 0.3 to 1.9 cm in diameter and notably high in dietary fiber and carbohydrates (Adejuyitan, 2011). It's a versatile crop, capable of growing both annually and perennially, reaching heights of up to 3ft (90cm) from its tuber. Tiger nuts are known by various names like earth almond, ground almond and yellow nut grass. In different regions, it's referred to as Habelaziz in Arabic, Chufa in Spanish, and Ayaya or Zulu nuts in Africa. In Nigeria, it's known as Akiawusa in Igbo, Ofio in Yoruba, and Aya in Hausa (Bamishaiye *et al*., 2011). Despite its nutritional potential, Tiger nuts are often underutilized and considered a mere weed in many areas. Seed is an important means of dispersal of *C. esculentus.* It can be propagated through the basal bulb, tubers or the rhizomes (Holm *et al*., 1977). Tiger nut are superfood due to their rich nutrient content, which includes calcium, magnesium, potassium, sodium, phosphorus, zinc, vitamins E, C, and folic acid. Their starch and sucrose content make them a natural energy source (Jose, 2018).

The germination vigour of seeds can decline with increasing seed age due to the breakdown of the seed's metabolic system, even when stored under optimal conditions. This can lead to slower or even inhibited germination and result in weaker seedling development and reduced establishment. This decline in sprouting ability as tubers age poses a significant obstacle to Agricultural production, resulting in loss of production potential. To prevent staggering germination, the choice of sterilization agent is crucial to obtain high germination rate and ensure proper plant growth. Sterilization plays a key role in breaking dormancy in tubers and removing toxic inhibitors found in the seeds. (Mohammad *et al*., 2012; Marcello *et al*., 2020). Another critical factor after seed storage duration and sterilization agent is the choice of substrate or growth medium. Substrates play a pivotal role in developing the root system and providing essential nutrients for the plant. This is among the most significant external factor influencing both seed germination and seedling growth in the nursery,

ultimately favoring production at low cost in a short period of time (Nogueira *et al*., 2012; Dutra *et al*., 2012).
In this study therefore, we evaluated the effects of four storage durations and a factorial combination of three substrate types and three sterilization levels on seedling emergence and early seedling growth. The specific objective was to determine the best storage duration, growth medium and sterilization level that would increase emergence and early seedling growth quality.

MATERIALS AND METHOD

The two experiments were conducted at the Department of Crop Science Teaching and Research farm, University of Nigeria, Nsukka, Enugu State, Nigeria between September and December 2022. The experiment on storage duration was a completely randomized design, with four distinct treatments: tubers dried for 1, 2 and 3 weeks, and tubers stored in a refrigerator for 5 months and were replicated three times. The tubers were soaked for 24 hours and planted on a weekly basis and each set lasted for a period of four weeks. The second experiment was a factorial laid out in a completely randomized design. The factors were substrates (rice husk, sawdust and rice husk + sawdust) and sterilization (0, 5 and 10% NaOCl dilution). There were therefore, 9 treatment combinations, each replicated 3 times, and each replicate were sown with 10 seeds. The tubers were also soaked for 24 hours and viable seeds selected through flotation method. The tiger nut tubers were then sterilized with NaOCl, which is the common household bleach. Ninety seeds were soaked for 10 min in each level of sterilization treatment. The substrates were properly washed and soaked for 24 hours to remove debris before planting.
Data were collected daily for each experiment, which included the number of seedling emergence and the number of tillers produced. Data were also collected at four and six weeks through destructive sampling. Parameters such as the number of leaves, fresh weight of the leaf, whole plant biomass weight, length of the longest leaf, length of the longest root, seed rot (by carefully examining tubers that did not sprout for signs of rot), seedling vigor (assessed through observations of leaf count and the length of the longest leaf), and the number of tubers formed were recorded.
Data measured were subjected to Analysis of variance (ANOVA) using the procedures outlined for a one-way design (completely randomized design) for the first experiment and a factorial laid out in a completely randomized design for the second experiment using Genstat 12.0. Differences between means were determined using Fischer's Least Significant Difference (F-LSD) at 5% probability level.

RESULTS

Statistical analysis from the experiment on seed storage revealed that tubers dried for three weeks prior to planting showed the highest percentage emergence during the first and second week after planting and tubers that were dried for two weeks had the highest percentage emergence at third and fourth week after planting. The tubers that were stored in a refrigerator had the lowest emergence rate (Table 1). The analysis of variance (data not shown) revealed that the main effect of substrate on emergence was significant at one and two weeks after sowing while sterilization had no significant effect ($p>0.05$) at 1, 2 and 3 weeks after sowing (Table 2). The combined effect of substrate and sterilization was only significant at one week after sowing (Figure 1). Seeds sown in rice husk + sawdust and 10% sterilization gave the highest number of emergence. On the multiple shoot production shown on Table 3, substrate significantly influenced single shoot and double shoot production but had a non-significant effect on triple and quadruple shoot. Seed sterilisation greatly influenced triple shoot production but had no effect on other variates, while the interaction effect was only significant ($p<0.05$) on single shoot production. Seeds sown in rice husk + sawdust at 10% seed sterilization gave the highest on single and triple shoot production.
Effect of substrate and sterilisation on tiger nut growth at 4 and 6 weeks is shown on Table 4. At 4 weeks, substrate greatly influenced fresh weight of leaves and number of tubers but had no significant difference on other growth parameters. At 6 weeks, substrate had no significant effect on length of longest root and number of tubers. The table showed that at 4 weeks, sawdust performed better numerically than other substrate followed by rice husk + sawdust while at 6 weeks, combination of rice husk and sawdust had higher influence on length of longest root and number of tubers. Sterilisation had significant effect on all yield parameters at 4 weeks except on the length of the

longest root and number of tubers. While at 6 WAS, there was no significant difference. Plants in 10% dilution had better growth in all growth parameters except on length of longest root, and then followed closely by 5% dilution. Combined effect of substrate and sterilisation is shown on Table 5. Fresh weight of leaves at 4 weeks was significantly influenced. Other growth parameters were not influenced by substrate and sterilisation. Rice husk + sawdust at 10% sterilisation influenced the fresh weight of leaves and whole plant biomass. Longer leaf length and root were observed in plants grown in sawdust and sterilised at 5% sodium hypochlorite dilution. On the average, sawdust at 0% sterilisation gave greater yield followed by rice husk at 10% dilution.

DISCUSSION

The results obtained from this experiment showed variation in emergence rate among the different sets of tiger nut tubers. This could be attributed to alterations in the physiological and biochemical processes that occurred while the tubers were drying and in storage (FAO, 1981). Drying of tubers leads to a reduction in water content, which, in turn, stimulates metabolic processes that initiate growth upon planting (FAO, 1981). Tubers that were dried for one week had lower emergence rates than those dried for two and three weeks. This could be due to the fact that one week of drying may not have been enough to achieve the optimum water content required for optimal emergence. When tubers are not dried enough, they may contain excess moisture, which can result in fungal and bacterial infections that can lead to rot and low emergence rate. Moreover, the tubers stored in the refrigerator for five months experienced prolonged exposure to cold temperature leading to a reduced temperature which could have induced dormancy and slowed down metabolic processes. Dormancy is a survival mechanism adopted by some plants to ensure that germination occurs under favorable conditions. However, this process could delay emergence, as was observed in this study (FAO, 1981).

Sawdust as a standalone mix had a significant effect on germination and emergence but had poorer quality than rice husk. This could stem from the elevated C/N ratio, which results in nitrogen immobilization. This is in relation with Garcia *et al*., (1992) who reported that a higher C/N ratio increases the likelihood of nitrogen being unavailable to plants. Rice husk had longer leaves and more greenish than the seeds sown in sawdust alone, as a result of its high nutrient content and high moisture retention capacity. A combination of sawdust and rice husk gave higher emergence than the other substrates, which could be reflection of the effect of the combination of high moisture retention and significant air spaces in the media, that is the combination of the properties of both sawdust and rice husk. Sawdust numerically performed better in increasing the fresh weight of leaves, number of tubers and other above ground properties while a combination of both rice husk and sawdust influenced length of longest root.

Sterilization at 10% had higher percentage of emergence when compared to other levels, and also had higher number of triple shoot emergence and influenced other growth parameters. It increased the foliage of the tiger nut, gave greater yield, higher fresh weight of leaves, length and more number of leaves. This result is in agreement with Baiyeri and Mbah (2006), which reported that sterilization likely improved the foliage development of African breadfruit seedlings due to reduced competition with pathogens, which might have otherwise slowed down the rate of growth and development of those seedlings.

Findings from the experiments show the efficacy of seed storage duration, substrates and sterilisation in increasing seedling emergence, production of multiple shoots and early seedling growth. Tubers can be cultivated within a period of two to three weeks after harvest and air-drying at room temperature. Sodium hypochlorite (NaOCl) solution was found to be the best at 10% dilution level. Rice husk and sawdust combination at 10% NaOCl dilution is ideal as it significantly had higher emergence and promoted triple shoot production. Also sawdust at 5% seed sterilisation could be used as a close substitute, but there should be incorporation of fertilizer to make up for the low nitrogen content.

ABSTRACT

Tea is a globally accepted beverage consumed for its health and stimulating benefits. However, poor knowledge of processing and handling of this product leads to fungal contamination and one of such metabolites was deoxynivalenol toxin, a contaminant of health concern. Curcuma longa spice is known to possess antimicrobial potentials; although, there is fewer scientific report on the use of this spice at mitigating mycotoxins in Nigeria grown tea. This study, quantify and reduce deoxynivalenol toxin in tea using Curcuma longa spice. Black teas were sampled from ten different warehouses, five each from Ibadan, Oyo state and Mambilla, Taraba state respectively. The obtained samples were screened for deoxynivalenol toxins using HPLC. DON-spiked tea was treated with curcuma longa spice and stored for six months at room temperature and efficacy of the spice treatment at reducing DON contaminant level was evaluated.

Keywords: *Black-tea contamination, deoxynivalenol, reduction, Curcuma longa, quantitation*

INTRODUCTION

Tea, leave of *Camellia sinensis* plant, is a popular and widely relished beverage for its characteristic antioxidant property and specific aroma, considered suitable for human wellness around the world (Li *et al*., 2013). Tea is an everyday drink cherished by everyone, an evergreen bush, largely grown in East Asia and prepared by hot water infusion of the cured leaves of the camellia. Its consumption has a growing outlook among the middle class of the urbanized population and within the new order societies of developing markets (Chang, 2015; Hilal and Mubarak, 2013). Many agricultural commodities used in food and beverage production may be contaminated by mycotoxinogenic fungi, which synthesize mycotoxins, as a result of poor agricultural practices, inadequate knowledge of processing, poor handling, packaging, transport and storage conditions. Uncontrolled fungal growth; aided by poor storage conditions, may increase risk of mycotoxin contamination (Marin *et. al*., 2013).

Objective

The objective of this work was to detect, quantify and reduce DON contamination in black-tea commodity obtained from Ibadan, South western part of Nigeria and Mambilla, North eastern Nigeria, using Curcuma longa spice.

Justification for the study

This effort comes to bare as a result of the limitations of age long conventional approach, such as significant alteration in food colour, flavor, texture and nutritional contents of such food materials (Haque et al, 2020). Moreover, issues of thermal stability of mycotoxins and chemical residues during food processing, necessitated increased innovative approach, devoid of direct application of heat on food matrices. Embracing the use of spices such as Curcuma longa, a botanical rich in phenolic compounds becomes promising in reduction of mycotoxins contamination in food and beverages (Ajewole, 2023).

MATERIALS AND METHODS

Black-teas intended for human consumption were collected randomly from five (5) different warehouses in Ibadan and Mambilla respectively and 10 samples from each warehouse. These were pooled together, screened and quantified for deoxynivalenol toxin, a contaminant of health concern. Deoxynivalenol contaminated tea was treated with *Curcuma longa* spice, and stored at ambient temperature for six months. High performance liquid chromatography method with DONtest in DON WB instruction manual for sample extraction was employed. This method was modified by evaporating the sample extract to dryness over nitrogen gas and thereafter reconstituted in 0.5 mL mobile phase.

RESULTS AND DISCUSSION

Deoxynivalenol (DON) toxin was detected in black-tea commodities at an amount higher than the specified threshold for substances intended for direct consumption or use. About 90% of the black tea commodity from Mambilla had deoxynivalenol contaminant ranging from 1.30 µg/kg to 5.18 µg/kg while about 20% of the black-tea commodity obtained from Ibadan were contaminated, with DON. Contamination ranged from 2.19 µg/kg to 2.50 µg/kg. Mitigation approach employed, revealed tropical spices has potential to reduce DON contamination in stored black tea commodity. *Curcuma longa* powder added to black tea at concentration of 4000 µg/g, reduced DON contamination by 53.2% and at 1000 µg/g, DON was reduced by 40.6%.

Table 1: Quantitation of deoxynivalenol toxin (DON) in tea

Sample	**Variety**	**FDA Advisory Limit (µg/kg)**	**DON (µg/kg)**
MC5B	Black tea	≤1.0	5.18^{a}
MC3B	Black tea	≤1.0	1.30^{e}

Table 2: Effects of *Curcuma longa* spice treatments on deoxynivalenol (DON) reduction in spiked tea stored for six months

10

Concentration (µg/g)	Spiked tea (5 ppb)	DON (µg/kg)	* % RE
00	5	2.97	40.6
2000	5	-	-
3000	5	2.50	50.0
4000	5	2.34	53.2

*RE- reduction efficiency. *- values obtained after treatment with spice powder

CONCLUSIONS

Although significant differences exists in deoxynivalenol contamination in black tea commodities from Ibadan and Mambilla, sixty percent (60%) of the black tea commodity screened were contaminated with DON and at a threshold above FDA advisory limit (≤ 1.0 µg/kg). Therefore, need to mitigate contamination during storage cannot be over-emphasized. Also, processors can take advantage of the potentials of *Curcuma longa* spice in mitigating DON contamination of black tea during handling and storage. Spiced black tea can also be taken as a novel product.

EFFECTS OF NITROGEN AND PHOSPHORUS FERTILIZERS ON THE GROWTH, FRUIT YIELD AND NUTRITIONAL QUALITIES OF TOMATO (*Lycopersicon lycopersicum*) IN OGBOMOSO

Olaniyi, J. O. Subairu, N.A. and Okilo, S.I.
Department of Crop Production and Soil Science, Ladoke Akintola University of Technology, Ogbomoso.

Email: joolaniyi@lautech.edu.ng

ABSTRACT
The trial was conducted to assessed the growth, fruit yield and nutritional quality of tomato as affected by different fertilizers rates at the Teaching and Research Farm, Ladoke Akintola University of Technology, Ogbomoso. The treatments investigated were three nitrogen fertilizer rates (0, 30 and 60kg/ha and five phosphorus fertilizer rates (0, 15, 30, 45 and 60kg/ha) and their various combinations. The factorial experiment was laid out in a completely randomized design replicated three times. Data collected on plant height, number of leaves, yield attributes and nutritional qualities were subjected to analysis of Variance. The findings revealed that the application of N and P fertilizer rates had a significant (p0.05) impact on the growth, fruit yield, and nutritional value of tomato. The optimum growth parameters, fruit yield and quality were obtained at 60 kg N and 45 kg P_2O_5*/ha and at combine application of 30 kg N and 45 kg* P_2O_5*/ha. The highest fruit yield and nutritional quality of tomato was recorded at combine application of 30 kg N and 30 kg* P_2O_5*/ha fertilizers rates. Therefore, these fertilizers rates could be recommended for the cultivation of tomato in the study region.*
Keywords*: Fertilizer, nutritional quality, tomato, yield attributes.*

INTRODUCTION

One of the three significant annual fruits and vegetables of the tropical zone that originated in South and Central America is the tomato (*Lycopersicum lycopersicum*), a member of the solanaceae family (Julel, 2001). Tomato is the most popular and consumed vegetables worldwide. Like other vegetables, tomatoes are particularly important to human diets because they make up for some of the nutrients that are missing from their dietary sources, such as the minerals and vitamins found in tomato fruits (Biwasi, 1999). Additionally, it is calorie and nutrient dense. It is a good source of vitamin A, B, and C and iron. Lycopene and vitamin C, two nutrients that are major sources of antioxidants, may be found in tomatoes.

The plant nutrients are given to the soil as amendments in the form of manures and fertilizers because soil is unable to supply a suitable amount of N, P, and K for the best growth and output of tomatoes (Abdel-Samad *et al*., 1996a). Because tomatoes consume a lot of nitrogen from the soil, nitrogen is the most limiting nutrient for tomato growth and is needed in significant quantities for optimum production. Lack of nitrogen in the soil can cause browning of the leaves at the tomato plant's base and stunted, spindly growth. It might decrease fruit output. Without nitrogen, essential processes in the growth and reproduction of plants would not be feasible (Morris, 1993). Nitrogen is a component of protein and amino acids.

Phosphorus is a fundamental component of adenosine triphosphate (ATP), which serves as the energy currency in plant cells. Tomato plants require energy for various physiological processes, including photosynthesis. Adequate phosphorus levels enable the efficient conversion of sunlight into energy, promoting robust growth and higher yields (Krupa *et al*., 2022).

MATERIALS AND METHOD

The experiment was carried out at the Teaching and Research Farm, Ladoke Akintola University of Technology, Ogbomoso (latitude of 8^0 10N and longitude of 4^0 10E). The region experiences yearly rainfall of more than 100mm, a maximum temperature of 33^0, and a low temperature of 28^0. The treatments involved tomato variety UC82B subjected into three Nitrogen fertilizer rates (0, 30 and 60) and their various combinations. The experimental design was Completely Randomized Design (CRD) with three replicates. The experimental site was manually cleared and 45 beds were made with the use of hoe. These were divided into three replicates with each replicate containing 15 beds. The size of each bed was 2m by 2m ($4m^2$) with the spacing of 0.5m within and 1m between replicates. The nursery for tomato was established four weeks before planting date. The seedling were raised in the nursery bed and transplanted after four weeks to the field. Uniform and healthy seedlings were transplanted into the field in other to ensure uniformity at the spacing of 50cm x 50cm giving a plant population of 4000 stands per hectare. Supplementary water supply was carried out after transplanting and continued during the drying period of the experiment. A basal recommended application of 45 kg K_2O/ha (Curah and Proctor, 1990; Olaniyi, 2019), and application of N and P to their respective plots was applied by ring method, at 3 weeks after transplanting (WAS). Weeding was carried out manually by using hoe. Insect pest were controlled with cypermethrin insecticide at 10 ml per 10 litres of water, sprayed at two weeks interval with the use of knapsack sprayer.

Four plants were randomly selected within the net plots, in each plot and tagged. Data were collected at two weeks after transplanting continued fortnightly interval. The tagged plants were assessed for growth parameters: plants height were measured with the use of meter rule and number of leaves obtained by counting each green and functional leaves on each plant, yield attributes; number of fruits by counting the harvested fruits, fruit diameter by measured with the use of venier caliper and fruit weight by the use of sensitive weighing scale; and nutritional quality was assessed by collecting 6 fruit samples from each treatment and taken to the laboratory for the determination of nutrient elements, crude protein, fat, dietary fibre, antioxidants such as vitamin A, B and C and lycopene (AOAC, 1999).

Data collected were analysed using Standard Analysis System (SAS, 1990) for analysis of variance and means separated using least significant difference at 5% probability level.

RESULT AND DISCUSSION

The tomato growth responses (Table 1) revealed that the sole application of N and P rates had significant ($p \leq 0.05$) influence on the plant height and number of leaves of tomato at various sampling occasions. The mean plant height and number of leaves increased as the sampling occasions increases up to 8 weeks after transplanting. The highest plant height and number of leaves was obtained at sole application of 60 N kg/ha and 45 P_2O_5 kg/ha fertilizers rates. The interaction effects of N and P fertilizers rates showed a significant influence on both the plant height and number of leaves at all sampling occasions (Table 2). The highest plant (28.00cm) and number of leaves (128.30) was recorded at 30 N by 45 P_2O_5 kg/ha combined application of N and P rates.

Table 1: The sole effect of Nitrogen and Phosphorus on the height of tomato plants at different sampling periods.

		Plant Height (cm)		Number of Leaves	
		Weeks After Transplanting			
Treatments		4	8	4	8
Nitrogen (kg/ha)	0	9.87	23 80	19.70	69.00
	30	10.90	25.40	29.30	79.30
	60	14.20	34.30	31.30	84.00
LSD (p≤0.05)		3.00	11.11	10.38	34.51

30N x $60P_2O_5$	10.07	27.10	29.30	92.00
LSD ($p \leq 0.05$)	6.44	10.93	16.49	66.30

The sole application of N and P fertilizer rates significantly influenced ($p \leq 0.05$) the nutrient elements, nutritional value and antioxidant contents of tomato (Table 3). The value of these nutritional qualities increases as the fertilizer rates increases, except at 60 kg/ha P_2O_5. The highest crude protein, nutrient elements, carotene, lycopene and vitamin C was obtained at sole application of 60 kg N/ha and 45 kg P_2O_5/ha fertilizer rates. According to Schann (1992), minerals, protein and vitamin content of crops were well improved by soil fertilizers. The various interaction effects of combined N and P fertilizer application rates had significant ($p \leq 0.05$) influence on the nutrient elements, crude protein, carotene, lycopene and vitamin C contents (Table 4). Although, the highest value of most of these quality attributes was recorded at 30 N by 45 kg P_2O_5 /ha, but there were no significant difference between the values obtained at this rate and that recorded at 30N by 30 kg P_2O_5/ha combined applied fertilizer rates. Ronga *et al.,* (2020), also documents that N and P affects the quality of fruits.
The application of N and P rates had significant influence ($p \leq 0.05$) on the yield and yield components of tomato fruits (Table 5). The fruit yield (t/ha) increases as N and P application rates increases, except at 45 kg/ha P_2O_5. The highest fruit of tomato was obtained at sole application of 60 N kg/ha and 60 P_2O_5/ha. This observation is in line with (Edosa *et al.,* 2013), which stated that N and P applications enhances the yield and yield-related traits of tomato. The various interaction effects of combined N and P fertilizer application rates had significant ($p \leq 0.05$) influence on the fruit and yield components of tomato (Table 6). This is in line with (Gemechis *et al*., 2012) which states that the interaction effect of N and P fertilizer rates had a significant effect on marketable and total fruit yield, mean fruit weight, and fruit length. . The highest fruit yield (0.85) was recorded at 30N by 30 kg P_2O_5/ha combined applied fertilizer rates. Nitrogen and Phosphorus are the two essential macronutrients to crops which improve their growth, yield and product quality (Chen *et al*., 2008).

30N x $45P_2O_5$	1.00	2.37	11.67	11.70	0.81
30N x $60P_2O_5$	1.33	1.67	11.33	7.90	0.35
LSD ($p \leq 0.05$)	1.02	1.20	3.46	0.20	0.51

CONCLUSION AND RECOMMENDATION

In conclusion, the result shows that for optimum growth, fruit yield and nutritional quality of tomato, sole application of Nitrogen fertilizer at 60kg N/ha, Phosphorus fertilizer at 45kg P_2O_5/ha, and combined application of Nitrogen and Phosphorus fertilizer at 30kg/ha and 30kg/ha are appropriate and thus could be recommended for the tomato cultivation in the study area.

ABSTRACT
The potential of coffee as good source antioxidants which is needed in curbing degenerative diseases is well known, yet its utilization in terms of incorporation into a variety of food products is limited. However, its inclusion in jelly was explored in this study with the aim of making jelly a functional food. Pineapple fruits were washed, peeled, sliced, blended, sieved and packaged. Dried coffee beans were roasted at 180°C for 26 minutes, milled and incorporated into the extracted juice in the ratio of 2.5, 5. 7.5 and 10% of coffee inclusion into whole mass of jelly samples. The jelly samples were produced by cooking the mixtures to a desired texture following a standard procedure. The jelly samples were cooled and packaged. The antioxidant and sensory properties of the resulting jelly samples were evaluated following standard procedures. The DPPH of the coffee pineapple jelly samples ranged between 69.50 -93.27%. The total antioxidant capacity of the coffee- pineapple jelly samples varied from 4.76-5.88 mg/g. The reference sample (jelly without coffee inclusion) had the lowest DPPH and flavonoid values as compared with the formulated coffee jelly samples but possess higher value as its total antioxidant. Conclusively, panelists preferred sample with 2.5% coffee powder inclusion, which also contained appreciable antioxidant properties, that might contribute to daily intake of phyto-chemicals needed in curbing degenerative or life threatening diseases.

INTRODUCTION

Fruits and vegetables processing into squashes, juices, jams, jellies, marmalades, pickles, fruit in syrup and so on, offers several ways of consuming fruits and vegetables (Khanum *et al.,* 2007).. The demand of such products is on increase. Jam and jelly, and fruit-in–syrup are being consumed increasingly by more people as dessert (Khanum *et al.,* 2007). Fruit jellies are semi solid preserves produced from mixtures of fruit juice and sugar. Jelly making provides a good way to preserve fruit flavors for enjoyment throughout the year (Syed Masood *et al*., 2017). A good jelly should be transparent, well set, not too stiff, but should have the original flavour of the fruit and possess attractive colour. It should not be gummy, sticky, syrupy or have crystallized sugar. They are nutritious foods and can play a significant part in a healthy diet because they offer good taste and a variety of nutrients found naturally in fruits. Fruit jelly is a relatively easy-to-prepare product for the beginning canner and may be made at home without special equipment. (Syed Masood *et al.,* 2017). In recent times, jellies are achieving high popularities among the community, but they are not fulfilling the nutritive value and appear to be very hazardous to human health (Syed Masood *et al*., 2017).

Pineapple (*Ananascomusus*) is from Bromeliaceae family and it is one of the fruits from the tropics with the highest production in the world, estimated at around 20% (Lu *et al.,* 2014)

The largest fruit producers are countries such as Thailand, Philippine, Indonesia, India, China, Costa Rica, Brazil, Nigeria and South Africa (Lobo and Paull., 2017). World pineapple production was around 25 million tonnes, in 2017, while in Brazil about 284,000 tons were produced, corresponding to about 11% of all fruit production (FAO., 2019). In Brazil, most of pineapple production (97%) is typically for fresh consumption, being one of the six most consumed fruits (IBGE, 2013). This fruit has a high nutritional profile, with appreciable levels of vitamins, minerals, fiber, flavonoids and carotenoids (Ancos *et al.,* 2017). Generally, pineapple can possibly be consumed dehydrated, canned, as a juice, jam and compote. After harvesting, the fruit has a reduced shelf life, which leads to nutritional and economic losses.

Plant foods had been reported as natural sources of anti-oxidants (Shukla and Singh, 2007). Coffee is one of the most common beverages and largest traded commodities worldwide (Lachenmeier, 2020). Based on its aromatic flavor and the beneficial effects of caffeine, millions of people consume coffee on a daily bases. Coffee contains appreciable amount of bioactive compounds (Król, *et al.*, 2020). The bioactive compounds present in coffee are mainly phenolic antioxidants in the hydrocinnamic family, which are caffeic, chlorogenic, p- coumaric and ferulic acids (Gorecki and Hallman, 2020). It is worthy to note that the consumption of coffee reduces incidence of cancer, liver cirrhosis and type 2 diabetes (Van-Dam and Feskens, 2002). Therefore, there is need to research into the potential of improving the value pineapple jellies using coffee powder. The aim of this research is to determine anti-oxidative potentials and sensory properties of coffee – pineapple jelly.

MATERIALS AND METHODS

Materials

Coffee beans were obtained from Cocoa Research Institute of Nigeria, Idi Ayunre, Ibadan, Oyo State, while other ingredients were purchased from Oja Oba Market, Ibadan, Oyo State.

Methods

The mixture of pineapple juice and coffee powder (coffee inclusion between 2.5 to 10%) was boiled for 15 minutes and sugar, pectin, citric acid and ascorbic acid were added, followed by stirring using a glass rod. The mixture was rapidly cooled to ambient temperature by immersing the plastic container in the refrigerant.

Antioxidant Potential

DPPH scavenging assay

The scavenging activity of DPPH radicals in the sample solution was determined using the method of Shen *et al.* (2010).

Ferric reducing power

The reducing power was measured spectrophotometrically by assessing the ability of the sample to reduce iron chloride (Pulido et al., 2000).

Total flavonoid content

The total flavonoid content of the coffee- pineapple jelly samples were estimated by the method described by Zhishen et al. (1999) with slight modification.

Total antioxidant capacity

The total antioxidant capacity of the samples was determined using the method described by Prieto *et al.,* (1999) with minor changes.

Determination of ascorbic acid (TAA*)*

The method of AOAC 967.21 was adopted to determine ascorbic acid content. The principle of the method bases on the oxidation of ascorbic acid into dehydroascorbic acid and colourless lenco derivatives using 2,6 dichlorophenolindophenol (DCPIP) (Puwastien *et al.*, 2011).

Statistical analysis

SPSS version 23.0 software (Coakes, 2017) was used to analyze the data obtained in this study.

RESULT AND DISCUSSION

The DPPH result of the coffee pineapple jelly samples is presented in Table 1. There were significant differences in the samples except samples with 7.5 and 10% coffee inclusion. The value of the DPPH of the coffee pineapple jelly samples ranged between 69.50 -93.27 % with the control sample having the lowest value, whereas the sample with 7.5% coffee powder possessing the highest value. All formulated samples had higher DPPH values than the reference sample of 100% pineapple juice. Sample with higher coffee inclusion exhibited higher DPPH values. The flavonoid content of the samples ranged between 0.75 - 4.43 mg/g. The control sample exhibited the lowest flavonoid content, while the highest flavonoid content is found in the samples with 10% coffee powder inclusion. The result obtained showed that the flavonoid content increases with increasing level of coffee powder addition. The addition of coffee powder showed significant effect in the flavonoid content of the coffee jelly samples.

Sample with 2.5% coffee inclusion had the lowest FRAP value; it is also significantly different from the reference sample and other formulated samples. However, the sample with 2.5 % inclusion of coffee had comparable total antioxidant value with the reference sample, but significantly different from the other formulated samples. Ascorbic acid contributes to the product appearance and palatability (Cvetkovic and Marija 2009). There are no significant differences in all the formulated coffee pineapple jelly samples. It was observed that all the formulated samples were significantly higher than the vitamin C content of the reference sample. The vitamin C content of the samples ranged between 11.46 - 12.37 mg/100g. This value is lower than the vitamin C content (15.00 to 58.00 mg/100g.) reported by Mumtaz *et al.,* (2019) who studied jams and jellies available in Bangladesh, but higher than the range (7.74 to 9.9 mg/100g) reported by Chalchisa *et al.,* 2022 who worked on the effect of sugar, pectin, and processing temperature on the qualities of pineapple jam. The control was significantly different from all the formulated samples. This means that the coffee powder addition influences the vitamin C content of the formulated jelly samples.
The total anti-oxidant capacity result of the coffee pineapple jelly samples ranged between 4.76-5.88 mg/g. There were significant differences in the total antioxidant capacity of the coffee- pineapple jelly samples except the control. There is no significant difference between the total anti-oxidant capacity of the control sample and the sample with 2.5% coffee powder inclusion. The antioxidant capacity reduced with increased addition of coffee powder. This might be due to the absence of mailard reaction. This reason was in line with the report stated by Tadros *et al.* (2011), *that* in theory, attempts to inhibit the Maillard (non enzymatic browning) reaction as a possible means to minimize the formation of acrylamide might lead to a decrease in the antioxidant capacity of coffee.

Table 1: Anti-oxidant properties of coffee pineapple jelly

Samples	DPPH (%)	FRAP (mg/g)	Flavonoid (mg/g)	Total Antioxidant (mg/g)	Vitamin C (Ascorbic acid) (mg/100g)

Key: P= Pineapple C= Coffee powder

CONCLUSION

The study revealed that panelists preferred sample with 2.5% coffee powder inclusion, which also contained appreciable antioxidant properties, that might contribute to daily intake of phyto-chemicals needed in curbing degenerative or life threatening diseases.

DECLARATION OF INTEREST

No known potential conflict of interest was reported by the authors in this manuscript.

ACKNOWLEDGEMENTS

This study was carried out under the Value Addition Research Programme of Cocoa Research Institute of Nigeria. The authors are indebted to the Executive Director, Dr. Adebola P.O Cocoa Research Institute of Nigeria, Ibadan, Nigeria. Also, the programme leader, (Dr. (Mrs) C.O Jayeola) is highly appreciated for providing the opportunity to carry out this research work under her supervision.

ABSTRACT
Bioactive component of NIHORT formulated botanical pesticides; Nihort-Raktin (a.i Azadirachtin) and Nihort-Lyptol (a.i Cineole) and Minty (a,i menthol) and their relative stability over the period of 6 months was investigated. Freshly prepared NIHORT Lyptol, Raktin and Minty collected from Biopesticide Centre of National Horticultural Research Institute were used for the study. The biopestides were stored on the shelf for the period of six months while Phytochemical analysis was being carried out at 0, 3 and 6 months interval. Phytochemical analysis revealed the presence of phenols, flavonoids, tannins, saponins, Phytate, Cardiac glycoside, Oxalate, anthraquinones and terpenoids at varying concentrations in all the biopesticides. At 0 and 3 month storage period, bio constituent in NIHORT Lyptol was consistently and significantly higher, followed by NIHORT Raktin and NIHORT Minty in that order. It was observed that saponin, oxalate and terpenoid could not be determined in all the bio pesticides at six months after storage. Generally, there was decrease in the phytochemical constituents of the all the bio pesticides as storage period increased.
Keywords*: bioactivity, biopesticides, phytochemical, storage*

INTRODUCTION
Bio pesticides are certain type of pesticides that are derived from natural materials like plants, bacteria, fungi, virus and certain materials (Saxena and Pandey, 2001). For many years, plants and plant-derived metabolites have served as the starting point for the discovery and development of new antimicrobial agents. They are less toxic than conventional pesticides and only affect target pest without any hazard to animals and humans. They are group of pesticides which is effective in very small quantities and often decompose quickly; resulting in lower exposure and largely avoiding the pollution problems caused by conventional pesticides (Raja, 2014). Chemical pesticides have provided protection required for crops to help satisfy the world demand for food, feed, and fiber but over years, increase in usage has led to various issues such as resistance in pests and diseases, negative impact on human and animal health, ecological imbalance, pest resurgence and residues in foodstuff (Karim *et al*., 1999). In view of these problems, there is need to look for new and promising alternatives that are biodegradable, specific towards target organism, low likelihood of resistance development and at the same time suitable for incorporation into integrated pest management practices, and practically no known health risks (Bailey and Mupondwa, 2006). This work was carried out to assess the bio constituents of NIHORT biopesticides (Lyptol, Raktin and Minty) and their relative stability over a period of time.

MATERIALS ANS METHODS
Freshly prepared NIHORT Lyptol, Raktin and minty collected from Bio pesticide centre of National Horticultural Research Institute were used for the study. The bio pesticides were stored on the shelf for the period of six months while Phytochemical analysis was being carried out at 0, 3 and 6 months interval. Total phenolic content extracts was measured using the Folin–Ciocalteu reagent method as described earlier (Kaur and Kapoor, 2002). Total flavonoid was determined using the aluminium chloride colorimetric method as described by Chang *et al*., 2002.Tannin was determined according to the method of AOAC with some modifications. The Spectrophotometric method of Brunner (1984) was used for saponin analysis. Extraction of phytate from the sample was carried out following a modified procedure of Harland and Oberleas (1977). Steroid content was determined using the

method described by Trease and Evans (1989). The quantity of cardiac glycoside in the sample was evaluated using Baljets reagent (95ml of aqueous picric acid + 5ml 10% aqueous NaoH) as described by El-olemy *et al* (1994) while oxalate was determined as described by Oke (1966).

RESULTS AND DISCUSSION

Phytochemical analysis of NIHORT Lyptol, NIHORT Raktin and NIHORT Minty revealed the presence of phenols, flavonoids, tannins, saponins, Phytate, cardiac glycoside, oxalate, anthraquinones and terpenoids. At 0 month, NIHORT Lyptol had the highest quantity of all the pyhtochemicals except phytate where highest quantity 70.3 mg/100g was recorded in Raktin. NIHORT Minty ranked second in terms of phytochemical quantity while the least was recorded in Raktin (Table 1). High bio constituent displayed by Nihort Lyptol in this study was in accordance with the reports of Huang *et al*, (2015) where it was stated that Eucalyptus genus is known as important reservoir of a wide range of secondary metabolites many of which harbor a diverse range of biological activities. At 3 month after storage, similar trend was observed in NIHORT Lyptol in terms of phytochemicals quantity where amount of total phenolic total, total flavonoid, tannin, cardiac glycoside, steroid, anthraquinone and terpenoid was significantly $P \leq 0.05$ higher compared to NIHORT Raktin and NIHORT Minty (Table 2).

However, amount of saponin, Phytate, and oxalate was lowest in NIHORT Lyptol. NIHORT Raktin ranked second in terms of Total phenolic, total flavanoid, tannin, saponin, phytate, cardiac glycoside, steroid, anthracquinone and terpeoid. However, saponin and phytate and oxalate contents was significantly $P \leq 0.05$ higher in Minty compared to the amount recorded in NIHORT Lyptol and NIHORT Raktin (Table 2). At 6 month, bio constituent in NIHORT Lyptol was consistently and significantly higher. It was observed that saponin, oxalate and terpenoid could not be determined in all the bio pesticides at six months after storage. However, Total phenolic, tannin, phytate, cardiac glycoside and steroid, was highest in NIHORT Lyptol, followed by NIHORT Minty and NIHORT Raktin in that order (Table 3). Generally, there was decrease in the phytochemical constituents of the all the bio pesticides as storage period increased. Great potentials of azadirachtin as a natural source of bio agents have been documented (Girish *et al.,* 2008). Extracts of various parts of neem and their potential antifungal, anti viral and antibacterial due to their bio constituents deposit have been reported by earlier investigators Llyod *et al*., (2005). In addition, biological activity of Menthol as good source of anti bacteria and anti fungal due to their bio constituent have been reported (Moghtader, 2013).

CONCLUSION

All these bio pesticide can present feasible and viable alternative to synthetic fungicides. This will help to combat fungicides resistance by pathogens, minimize the effect of pesticides on non target organism and also reduce pesticides residues in the environment and commodities.

INDUSTRIAL REVOLUTIONISM AND HORTICULTURE IN NIGERIA

Adeyi, O. E., Odubanjo-Francis, A. O; Oladunjoye, M. O and Adelowo E. O.
Library Unit, National Horticultural Research Institute,
Idi-ishin, Ibadan, Oyo State

ABSTRACTS
The world is fast changing since the advent of Information and Communications Technology. The development brought unprecedented changes to the ways people go about carrying out operations and the resultant effects of deploying technologies to operations are outrageous. Horticulture, being an important source of food, raw materials and employment is not left behind in the torrent as technologies leaves no stone unturned. Industrial Revolution 4.0 is trending with pronounced effect on all human activities in the developed nations of the world as evident in reports and scholarly publications. This paper describes artificial intelligence and other components of Industrial Revolution 4.0.; reviews the contributions of artificial intelligence to horticultural development around the world; and identifies merits and demerits of deploying artificial intelligence to carrying out horticultural activities in Nigeria.
Keywords: *Artificial intelligence (AI); Horticulture; Industrial Revolution 4.0. (Fourth Industrial Revolution or 4IR); Nigeria*

INTRODUCTION

Artificial intelligence is transforming the agricultural sector by optimizing processes and resources. AI is an evolving set of technologies that are used to solve a variety of applied problems and has been extensively applied in farming recently. Horticulture, a branch of agriculture produces fruits, vegetables and ornamental plants for subsistence, commercial and industrial uses. The importance of this sub-field of agriculture to humanity cannot be overemphasized. Horticulture provides nutritional, economic, health and aesthetic benefits to local, national and international communities. Horticultural activities require the interactions of human and material resources. The qualities of tools, machines, materials and human elements deployed to horticultural procedures determine the quality of outputs. Applications of AI to the horticulture industry are diverse. From planting, watering, and harvesting to experimenting with new systems, machines can often be created to be more efficient than people. The horticulture industry requires people with artificial intelligence acumen to enable them to improve yield. Artificial Intelligence technologies are helpful to yield healthier crops, provide information on prevailing weather conditions such as temperature, rain, wind speed, wind direction, solar radiation, pest control, monitor soil, and growing conditions, organize data for farmers, help with the workload and improve food supply chain (Manaware, 2020).

Artificial intelligence (AI) also called machine intelligence is a domain in computer science that instructs machines on how to replicate human physical actions and react like humans. In the past, machines were fabricated to ease human activities but artificial intelligence is removing human involvement even in human activities: such that, only machines do what hitherto, were done by human or a combination of human and machines. In Nigeria, we are familiar with mechanized horticulture but deploying AI to horticulture seems to be untapped goldmine. There are reports of wonders that AI is doing in horticulture in the developed parts of the world but most developing countries are lagging behind. It is very important we join the moving train of industrial revolution. This paper assesses the adoption of Artificial Intelligence as component of industrial Revolution 4.0 in Nigeria with reference to horticulture.

Artificial Intelligence and Industrial Revolution 4.0

Industrial Revolutionism refers to eras that introduced and developed technologies that have to do with changes in technologies that are connected to digital transformation. Schwab (2016) and Zambon et al (2019) posited that Industry 4.0, also known as Fourth Industrial Revolution or 4IR was preceeded by the First Industrial Revolution that used water and steam power to mechanize production. The Second used electric power to create mass production. The Third used electronics and information technology to automate production. Now a Fourth Industrial Revolution is building on the Third, the digital revolution that has been occurring since the middle of the last century. It is characterized by a fusion of technologies that is blurring the lines between the physical, digital, and biological spheres. . Industrial Revolution 4.0 is developed based on three main factors as Artificial Intelligence (AI), Internet of things (IoT) and Big Data (Big Data), of which the foundation is the application of Information and Communication Technology (ICT).

Industrial Revolution and Horticulture

Industrial revolution has to do with changes brought about by new technologies that were developed and adopted to the way people live and work. Industrial revolutionism affects horticulture as a sub-field of agriculture in many ways. Recall that, farming operations were subsistence and manual. Since the advent of industrial revolution 1.0, when farming moved from subsistence or manual to commercial and mechanized; industrial demand for agricultural outputs became more popular (Industrial Revolution 2.0); to digital, where computers were introduced industrial activities (Industrial Revolution 3.0) and now we have industrial revolution 4.0 that is popularly described as advanced Industrial Revolution 3.0 that is totally. Stages of industrial revolutions according to Times Agriculture (2023):

1. The first stage is the agricultural revolution, which took place from 1750 to 1850. In this period, technologies were developed that allowed for increased food production.
2. The second stage is the industrial revolution proper, which took place from 1850 to 1900. This was when factories began to replace farms as the main source of employment.
3. The third stage is electrical age, which took place from 1900 to 1945 and electricity became widely available and was used to power machines in factories.
4. The fourth stage is the digital age which took place from 1945 to the present day. This is when computers and other electronic devices began to be used in the industries.

Different scholars described stages of industrial revolution and how agriculture was affected differently but the important thing to note is that industrial revolution had significant impact on horticulture. Invention of steam engine, combine harvester electric generator, tractor, refrigerators, microwave oven, planter, etc changed the ways crops were planted, harvested and processed. Industrial Revolution led to a decline in agricultural productivity at some time, as people farms to work in factories or relatively more lucrative industry. It led to the development of new technologies and machines that have improved the ways we produce and process horticultural crops; increased productivity and efficiency through the use of chemicals, machinery and modern transportation system; led to environmental and health challenges; and facilitated research and development in horticulture among others.

According to Marucci et al (2017), revolutions in agriculture can be hypothesized to have gone hand-in-hand with the innovations in the industrial sector in recent years. Agricultural technology revolution started with Agriculture 1.0 with animal power; then the combustion engine defined Agriculture 2.0, passing to Agriculture 3.0 in recent years with guidance systems and precision farming, starting when military GPS-signals were made accessible for public use. Agriculture 4.0 farm activities are connected to the cloud. Zambon et al (2019) posited that following European agricultural machinery in 2017, the next step with Agriculture 5.0 includes digitally-integrated enterprise, which rely their production processes using robotics and some forms of artificial intelligence and Internet of Things (IoT) where all kinds of devices-smart objects-are connected and interact with each other through local and global, often wireless network infrastructures. Therefore, precision agriculture results to be the most recent discipline of this development as an important driver for Big Data. Radical changes in farm management can be expected due to the access to clear information and decision-making abilities that before were not possible.

Artificial Intelligence and Horticulture around the world

According to Nijhuis and Hermann (2019), in Brazil, one firm was developing a swarm of miniature autonomous robots that could plant seeds. Controlled by a farmer's handheld tablet, which is operated with the help of satellites and cloud-based software, the swarm will be able to put each seed in the right place with greater precision than current approaches can. Not incidentally, the technology will eliminate the need for planter bars, tractors, and tractor operators. Because the swarm can adjust seed locations for changing conditions, it will increase yield, with lower costs, faster planting speeds, and a reduced impact on the environment.

Many pesticide and fertilizer companies, for example, are using Industrial Revolution 4.0 technologies to provide better products and roll them out faster than before. That might sound like a success story, but precision farming — which uses IoT sensors, high-resolution 3D aerial imagery from drones, and AI-powered analytics to analyze the characteristics of soil and the behavior of crops down to the square inch — may soon significantly reduce the need for fertilizers and pesticides altogether. According to Dushyant (2021) applications of AI in Agriculture includes: Computer vision technology, IOT and drone data can be combined to ensure rapid actions by farmers for disease detection, crop readiness identification and field management; health monitoring of crops; decrease use of pesticides; automation of techniques in irrigation; drone based technology for soil and field analysis, crop spraying and monitoring, irrigation and health assessment; models for farmers' services through chatbot, Agri-E calculator for suitable crop selection along with resource estimation, crop care services, Price prediction and market guidance, Crop loan and insurance service; and Robot Drone Tractor.

Challenges and opportunities of Industrial Revolution 4.0 in Horticulture

Horticultural mechanization brought tremendous gains in efficiency and productivity but digitization brought much more. Automation is faster and more effective than mechanization. Like the revolutions that preceded it, the Fourth Industrial Revolution technology made possible new products and services that increase the efficiency and pleasure of our personal lives. Ordering a cab, booking a flight, buying a product, making a payment, listening to music, watching a film, or playing a game—any of these can now be done remotely. In the future, technological innovation will also lead to a supply-side miracle, with long-term gains in efficiency and productivity. Transportation and communication costs will drop, logistics and global supply chains will become more effective, and the cost of trade will diminish, all of which will open new markets and drive economic growth. These, we are experiencing at a relatively low pace in Nigeria when compared to the developed worlds.

On the contrary, industrial revolution could yield greater inequality, particularly in its potential to disrupt labour markets. In addition to being a key economic concern, inequality represents the greatest societal concern associated with the Fourth Industrial Revolution. As automation substitutes for labor across the entire economy, the net displacement of workers by machines might exacerbate the gap between returns to capital and returns to labor. On the other hand, it is also possible that the displacement of workers by technology will, in aggregate, result in a net increase in safe and rewarding jobs. In the future, talent, more than capital, will represent the critical factor of production. This will give rise to a job market increasingly segregated into "low-skill/low-pay" and "high-skill/high-pay" segments, which in turn will lead to an increase in social tensions. Technology is therefore one of the main reasons why incomes have stagnated, or even decreased, for a majority of the population in high-income countries: the demand for highly skilled workers has increased while the demand for workers with less education and lower skills has decreased. The result is a job market with a strong demand at the high and low ends, but a hollowing out of the middle. The largest beneficiaries of innovation tend to be the providers of intellectual and physical capital—the innovators, shareholders, and investors—which explains the rising gap in wealth between those dependent on capital versus labor.

Dushyant (2021) posited that AI systems need a lot of data to train machines and to make precise predictions. Though Artificial Intelligence offers vast opportunities for application in agriculture, there still exists a lack of familiarity with high tech machine learning solutions in farms across most parts of the world. Data infrastructure takes time to mature, it requires a significant amount of time to build a robust machine learning model because temporal data is hard to get for vast agricultural land unlike spatial data.

CONCLUSION

The future of industry is progressing towards a 5.0 industry, while the primary sector is still inadequate. The 4.0 revolution in agriculture is still limited to rare pioneering firms. Horticulture in Nigeria is yet to be optimizing artificial intelligence as it is in countries such as Brazil, China, India, US and other developed nations of the world. Despite the attractive prospects of deploying AI to horticulture, Nigeria is still managing to measure up to Industrial Revolution 3.0 while others are getting ready for Industrial Revolution 5.0. We need to shape a future that works for all of us by putting people first and empowering them. In its most pessimistic, dehumanized form, the Fourth Industrial Revolution may indeed have the potential to "robotize" humanity and thus to deprive us of our heart and soul. But as a complement to the best parts of human nature—creativity, empathy, stewardship—it can also lift humanity into a new collective and moral consciousness based on a shared sense of destiny. It is incumbent on us all to make sure the latter prevails.

RECOMMENDATIONS

This paper recommends that stakeholders, policy and decision makers should invest in relevant technologies to promote productive, innovative and sustainable horticulture in Nigeria by identifying the position of horticulture in Nigeria as regards industrial revolutions; assessing gaps and opportunities; set path to close the gaps, optimize the opportunities and evolve culture to align the horticultural practices with trends in industrial revolutionism.

ABSTRACT

Despite the fact that horticulture crops are entirely composed of vitamins and minerals, evidence suggests that the majority of households lack access to and affordability for essential nourishment. Therefore, this study investigates the complex link between household food security and consumption of horticulture crops utilizing original information collected from 293 Fulani households in Oyo State. To guarantee that the samples of households for the study were representative, a multi-stage stratified random sampling approach was used. Descriptive statistics and a fractional regression model are two econometric methods that were used to analyze the goals that were established. The study also found that 32.8 percent of households consume horticultural crops moderately, 18.0 percent consume them lightly, and 49.2 percent consume them substantially. The ATE results show a significant negative coefficient (0.1179; p = 0.015), indicating a decline in food security of roughly 12%.

Keywords: *Consumption, Health, Leaf, Fruit, Stratified*

INTRODUCTION

The idea of an abundance of grains, roots, and tubers—the basic crops that offer reasonably priced sources of dietary energy—has long been linked to food security. But as the idea of food security has ingrained nutrition security into it and the need of dietary diversity for optimum health has risen to the forefront, this picture is shifting. Consuming a variety of food groups in the proper amounts is necessary for a healthy, high-quality diet. Horticultural crops have a significant impact on food; their nutritional value is crucial for a healthy lifestyle. Fruits and vegetables are the most important sources of the micronutrients needed for a healthy diet. Vegetables are rich in nutrients such as potassium, which supports healthy blood pressure, dietary fiber, which lowers blood cholesterol and may lower the risk of heart disease, folate (folic acid), which reduces the risk of birth defects, vitamin A, which supports healthy eyes and skin, and vitamin C, which not only supports healthy teeth and gums but also aids in iron absorption. According to Jena et al. (2018), vegetables are the main contributors to achieving global nutritional security by delivering nutrients, vitamins, and minerals. They are also the main drivers of a balanced human diet. They have the potential to alleviate poverty by creating jobs and generating revenue, as well as through increasing farm productivity and profitability.

By increasing the variety of edible foods, they can support sustainable lives by ensuring the food security of households. Ruel (2003) has also demonstrated that agricultural households may have access to a broader variety of highly healthy meals, such as vegetables and products of animal origin (milk, eggs, and meat), as well as to food that is relatively affordable. Since households with direct access to food may eat more food and have a more varied diet richer in essential micronutrients. In order to avoid chronic diseases (particularly heart diseases, malignancies, and diabetes) and provide necessary micronutrients (notably calcium, iron, iodine, vitamin A, and zinc), the World Health Organization (WHO) advises a minimum intake of 400 g per day (WHO, 2015). Consumers today, including those with higher earnings, are thought to be falling short of this goal. It is necessary to pay more attention to the nutritional value of horticulture crops, their dietary impact on household food security, and how to make them accessible to consumers.

METHODOLOGY

The study assesses dietary impact of horticultural crops and households' food security in Oyo State. In this study, primary data was used and it was obtained through a quantitative survey using structured questionnaire. Adopting a multistage sampling, the study sampled about 293 households from different clustered Fulani households in Oyo State, Nigeria. Both descriptive and inferential statistics (Average Treatment Effect and Fractional regression model) were used in the study to estimate food security status of the respondents.

Analytical framework

Fractional regression model as a response model was used in this study to estimate parameter which could influence food security in the study area. The explicit form of the regression model was presented below:

$Y = \beta_0 + \beta_1X_1 + \beta_2X_2 + \beta_3X_3 + \beta_4X_4 + \beta_5X_5 + \beta_6X_6 + \beta_7X_7 + \ldots\ldots\ldots + \beta_nX_n + e$

Where; Y_1 = Consumption index

$\beta_1, \beta_2 \ldots \beta_n$= (coefficient) which measures a corresponding change in dependent variable brought by a unit in independent variable. β_0 and $_{Ei}$ = intercept and error term respectively; X_1= Age of respondent (years); X_2 = Gender; X_3= Marital status; X_4= Educational level (years); X_5= Household size; X_6 = Primary occupation; X_7 = Years of livestock farming experience; X_8 = profit from sales of livestock; X_9 = Amount spent monthly on food; X_{10} = Purpose of livestock farming; X_{11} = Type of livestock reared

RESULT AND DISCUSSION

Table 1 revealed the summary statistics of some of the variables used in the study. The table showed the description of the variables together with the mean and standard deviation. From the result, the average age of the respondents stood at 46.3 years; this implied that most of the households' head were young and still within the productive age group. Marital status was measured based on the current status of the household head. This result showed that large number of the respondents were married. The average years of education was 7; indicating that most of the respondents had only primary school education as majorly Fulani tribe value-less formal education, believing that they are nomads. Furthermore, the result showed significant number of years of experience in livestock farming, the average years of experience stood at 34.8 years. Most Fulani were born to rear livestock, they are involved in cattle rearing and it has become generational profession.

Table 1*:* Summary statistics

Variables	Description	Mean	Std.dev
Age of respondents	The actual age of the household head as at the time of survey	46.3	26.9
Marital status	If the household head is married 1, otherwise 0	1.2	0.2
Gender	If the household head is male 1, otherwise 0	0.7	0.3
Educational level	The number of years spent in formal education	7.3	2.5
Years of experience in livestock farming	The number of years of experience in livestock farming	34.8	27.1
Food accessibility	If the households member could access food	1.8	0.9
Household size	Actual number of family members	8.3	4.2
Household income	Income generated by all household members	43376.4	12635.1

Horticultural crops consumption

The result presented in Table 2 showed the consumption pattern of horticultural crops in the study area. Respondents were asked the frequency of consumption of these crops. From the table, it is evidence that most of the crops were consumed by the households, though there is variation in acceptability and or the frequency of consumption of some of these crops. The study showed that more than 84 percent of the respondents consume amaranth/spinach, only 45.4 percent frequently consume corchorus while more than 93 percent claimed to frequently consume watermelon, 63.4, 60.4, 48.5, 100, 95.2, 96.9, 100, 98.6, 77.5, and 96.9 frequently consume lettuce, fluted pumpkin, cucumber, tomato, okra, spices, carrot, garden egg, garlic and ginger respectively.

Table 2: Consumption pattern of Horticultural crops among the respondents

Horticultural crops	Frequent	Seldom	Never
Amaranthus/Spinach	248 (84.6)	43 (14.7)	2 (0.7)
Corchorus	133 (45.4)	93 (31.7)	67 (22.9)
Water melon	275 (93.9)	13 (4.4)	5 (1.7)
Lettuce	186 (63.4)	103 (35.2)	4 (1.4)
Fluted pumpkin	177 (60.4)	108 (36.9)	8 (2.7)
Cucumber	142 (48.5)	127 (43.3)	24 (8.2)
Tomato	293 (100.0)	0 (0.00)	0 (0.00)
Okra	279 (95.2)	11 (3.8)	3 (1.0)
Spices (Bell pepper)	283 (96.6)	4 (1.4)	6 (2.0)
Carrot	293 (100.0)	0 (0.00)	0 (0.00)
Garden egg	289 (98.6)	0 (0.00)	4 (1.4)
Garlic	227 (77.5)	50 (17.1)	16 (5.4)
Ginger	284 (96.9)	2 (0.7)	7 (2.4)

Source: Author computation, 2023; Percentage in Parenthesis

Table 3 showed the classification of respondents' consumption pattern. Composite score was employed as a qualitative measure of food consumption. The result revealed that 49.2 percent of the respondents fell within the high consumption group. This indicated that about have of the population consume horticultural crop very well. About 33 percent of the respondent fell within the mid-range of the classification which depicted adequate consumption of horticultural while only 18 percent fell short the threshold of consumption; this may likely be an indication of a relatively unstable or poor income level of the respondents. The result, in contrary with Maxwell (2003) provides low direct access to a larger number of nutritionally richer foods (horticultural crops), a more varied diet and can also increase the stability of household food consumption against seasonality or other temporary shortage. This ultimately have a positive impact on the food security situation of the households.

Table 3: Consumption pattern of Horticultural crops among the respondents

Category	Frequency	Percentage
High	144	49.2
Medium	96	32.8
Low	53	18.0

Average Treatment Effect – Potential framework approach

In assessing the dietary impact of horticultural crops on household food security, this study considered problems that could be associated with selection biasness and particularly non-compliance or problem of endogeneity and used endogenous treatment-effects model to assess the impact. The Average Treatment Effect (ATE) on the sub-population was about 0.12. This implies that food security recorded reduction of about 12 percent as a result of inadequate consumption of horticultural crops of the respondents in the study area. This could translate to retrogression in quest to half food insecurity in the country as suggested by the development goals (SDGs).

Table 4: Endogenous treatment-effects estimation

Variable	Coefficient	Std. Err.	z	P>|z|
ATE				
Yes vs No	0.1179	0.0617	1.91	0.015**
PO mean				
0	0.5222	0.1024	5.09	0.000***

Source: Author computation, 2023

The result presented on Table 5 revealed the determinants of food security in the study area. The coefficient of marital status, years of experience in livestock farming, household size and food access were statistically significant on the model. This implied that the variable significantly affect food security of the respondents in the study area. From the table, the coefficient of marital status was positive and statistically at 10% level of confidence. The result indicated that married household heads are likely to be more food secure than the unmarried household heads; also, increasing years of livestock farming will increase the chance of the respondents to be more food secure provided all other factors are held constant. The coefficient of household size was negative and significant; the result implied that older livestock farmers are less likely to be food secure than the younger ones. And lastly, increased food accessibility will enhance food security among livestock farmers in the study area. This is evident from the result as more livestock farmers who have easy access to food will be more food secure than those with lesser food access provided that every other factors are constant.

Table 5*:* Parameter estimate of determinants of Food security in the study area

Variables	Coefficient	Std.Err	z
Age of respondents	0.0228	0.0047	-0.28
Marital status	0.1418	0.0810	1.75*

CONCLUSION

The study analyzes the dietary effects of livestock farming and horticulture crops on households' food security in Oyo State, Nigeria. The Fulani communities in the state were the focus of the survey because they make up the majority of Nigeria's livestock breeders. To get sufficient data for the investigation, various Gaa Fulani were however visited. The study found that inadequate intake of horticulture crops among respondents led to a decline in food security, and that improving access to food will have a big impact on food security in the study area. The study area should therefore strengthen proper sensitization of the nutritional benefits of horticulture crops.

ABSTRACT
A study was conducted in Kwara state to assess the extent of viral disease problems on existing and resurging sugarcane farms. A field survey was conducted in September 2019, collecting 50 sugarcane leaf samples from seven villages where sugarcane is planted. Serological indexing for SCMV, MDMV and MCMV by ELISA using their polyclonal antibodies was carried out at the Virology and molecular diagnostic Laboratory of the International Institute of Tropical Agriculture (IITA), Ibadan, Nigeria. ELISA results revealed (0%) MCMV and two viruses, (4%) 2 of 50 SCMV and (22%) 11of 50 MDMV, were associated with single infection of mosaic diseases of sugarcane in Kwara State. The study found a high prevalence of mixed infection of (70%) 35 of 50 SCMV and MDMV in the main sugarcane producing areas, with the highest incidence in Oro. This report provides insight into the current virus incidence in Kwara state.
Keywords: *Sugarcane Mosaic Virus, Maize Dwarf Mosaic Virus, Maize Chlorotic Mottle Virus and ELISA*

INTRODUCTION

Sugarcanes belong to the grass family Poaceae, an economically important flowering plant family that includes maize, wheat, rice, sorghum, and many forage crops. It is native to the warm temperate and tropical regions of India, Southeast Asia, and Guinea. It is one of the main sources of energy for humans; it is used in making commercial sugar for industrial sweetening and glucose syrup drips for medical purposes. It can be fermented to produce ethanol, which is used to make alcoholic drinks like rum and Chelsea gin, but also to make biofuel (Xu et al., 2005). It is a source of occupation for millions of people and is primary to the cost-effective expansion plan of sugar-producing countries (Xu *et al*., 2008; Dangora *et al*., 2014; FAO, 2015). All sugarcane species can interbreed, and the major commercial cultivars are complex hybrids (Monsoon *et al*., 2016). Sugarcane is grown in all the agro-climatic zones within the three senatorial districts in Kwara state, and this is due to the fact that the state is blessed with vast arable land in addition to favorable environmental and climatic conditions that are quite optimum for sugarcane cultivation (Wada *et al., 2003 ;* Olufolaji *et al., 2014).*

Some parts of the state still retained the commercial sugarcane farms inherited from sugar industries that were closed down. A drastic reduction has been recorded in the sugarcane farmer population over the years. This could be attributed most importantly, to biotic factors such as fungi diseases such as smut (*Sporisorium scitamineum),* red rot (*Colletotrichum falcatum*), leaf blast, and virus diseases such as sugarcane mosaic, ratoon stunting disease, and sugarcane wilt (Wada *et al*., 2017). Sugarcane mosaic disease, caused by sugarcane mosaic virus (SCMV), Johnsongrass mosaic virus (JGMV), maize dwarf mosaic virus (MDMV), and sorghum mosaic virus (SrMV), is an economically important viral disease of sugarcane worldwide (Dangora *et al*., (2014)). Sugarcane mosaic virus disease has been identified as one of the most important and deadliest pipe diseases in the world. SCMV is transmitted by mechanical means and aphids. Diagnostic symptoms include young leaf spots and bright green or yellow-green leaf spots (Saleem *et al*., 2011). As these viruses are transmissible through infected seed canes, they pose the risk of accidental introduction into previously disease-free regions.

The four distinct sugarcane viruses, SCMV, JGMV, MDMV, and SrMV induce similar pale green and yellow chlorotic stripes symptoms on the leaf blade and a white stripe on the stem in infected sugarcane and are indistinguishable based on the visible symptoms. Furthermore, symptom expression may also be confused for environmental disorders, as they both cause disruption in plant metabolism (Dangora *et al.*, (2014)).Virus diseases have been severally implicated up to date in sugarcane-producing areas in Guinea-Savanna, Nigeria (Dangora *et al.*, (2014)). Given the seriousness attached to a return to massive cane farming of late, this study was focused on finding out the extent of the viral disease problem on the existing and resurging farms in Kwara State. To this end, a field survey exercise was carried out on the major existing sugarcane-growing farms across Kwara State. In all, seven villages that were detected to still retain the sugarcane cultivation heritage within the state were visited, out of which the remaining five existing commercial sugarcane farms were also included in the survey.

MATERIALS AND METHODS

Indexing for virus diseases of sugarcane was carried out in seven villages that cover three ADP zones; three of the locations are commercial farms, and four are local sugarcane farmers. Oro, Egosi, and Oke-iya Ipo were visited on September 19, 2018; Shonga, Tsaragi, and Bacita were visited on September 25, 2018; and Lafiagi, Lade, and Patigi were visited on September 26, 2018. Field assessments were carried out by diagonal equidistance trekking on a W-shaped path across the field; fifty observations were observed per field (Aliyu *et al*., 2012; Oke *et al*., 2023a). Plants were assessed at every 5th step for disease incidence and severity of viruses. The survey and sample collection exercise was carried out on at least 1 hectare (1ha) of each of the commercial farms selected for the survey exercise. The incidence and severity of the viral diseases were determined based on the symptomatic expression of the viruses on the plants on each farm included in the survey.

Incidence and severity

Disease severity for each plant was calculated based on the actual number of leaves showing mosaic symptoms, divided by the total number of leaves on such a plant, expressed in percentage.

i.e. $$\text{Disease Severity on each plant} = \frac{\text{Number of diseased leaves}}{\text{Total number of leaves on the plant}} \times 100\%$$

Severity Rating

Virus symptom severity was scored on a scale of 1–5 based on the extent of leaf damage and percentage number of leaves showing symptoms, whereby 1 = 1-20% (very mild); 2 = 21–40% (mild); 3 = 41-60% (moderately severe); 4 = 61-60% (severe); and 5 = 81–100% very severe and dead (Alegbejo, 2006; Oke *et al*., 2012).

Unbiased, twenty leaves were randomly collected from the fresh apical region of the plant, whether symptoms were present or not. And the leaves were chopped into pieces with a sterile razor and kept on silica gel in sample vials for 24 hours. And were kept on Agdia-made silica gel in sample bottles and brought to the virology and molecular diagnostic laboratory of the International Institute of Tropical Agriculture (IITA), Ibadan, Nigeria, for serological diagnosis. Virus detection was carried out using a double antibody sandwich enzyme-linked immunosobent assay (DAS-ELISA), essentially as described by Dangora *et al.*, (2014), Ayo-John and Odedara (2017), and Oke *et al. (2023).*

The tests were conducted using different antibodies to detect various viruses such as SCMV (Sugarcane Mosaic Virus), MDMV (Maize Dwarf Mottle Virus), and MCMV (Maize Chlorotic Mottle Virus), respectively. One hundred microliters (100μl) of diluted IgG for each of the viruses in coating buffer containing 1.59 g sodium carbonate (Na_2CO_3) and 2.93 g sodium bicarbonate ($NaHCO_3$) per liter, pH 9.6, was dispensed to each well of the microtitre plates and incubated at 37 °C for 2 hours, after which the content was decanted. The plates were washed with phosphate buffered saline (Tween20, soaked for 3 minutes repeatedly three times, and blotted and dried. The PBS Tween 20 consists of 8.0 g of sodium chloride (NaCl), 0.2 g of monobasic potassium phosphate (KH_2PO_4), 1.15 g of dibasic sodium phosphate (Na_2HPO_4), and 0.2 g of potassium chloride per liter of distilled water, pH 7.4. From each of the sugarcane leaf samples, 100 mg were ground in 1 ml of extraction buffer (1:10 w/v). One hundred microlitre aliquots of this test sample obtained from the fields were dispensed into each of the wells and incubated at 4 °C overnight with a negative control provided. The plate's contents were discarded, washed three times, as stated above, and tapped dry. One hundred microlitres of appropriately diluted enzyme-labeled antibody IgG-alkaline phosphatase in conjugate buffer (1.0 g polyvinyl pyrrolidone (PVP) and 0.1 g egg albumin per liter of PBST) were dispensed into each well and incubated at 37 ^{o}C for 2 hours. The plate's contents were discarded, washed three times, and tapped dry. One hundred microliters (100 ul) of freshly prepared substrate with 50 mg para-nitrophenyl phosphate (Sigma, Fluka) dissolved in 50 ml of substrate buffer was dispensed into each well. The plates were incubated for one hour at room temperature and 4 ^{o}C overnight. Reading was carried out using an ELISA plate reader (MICRO READ 1000 ELISA plate analyzer) at a 405 nm absorbance wavelength filter against the blank air. The samples whose values exceeded twice the reading of the healthy control were considered positive for the viruses indexed (Xu et al., 2021).

RESULTS AND DISCUSSION

The survey results indicated sugarcane virus prevalence in all the 7 villages visited, the symptoms observed were ranged from pale green streak, yellow stripe to yellow chlorosis on a dark green leaves. The virus prevalence trends reveals low percentage incidence and severity across all the commercial farm with lowest incidence of 6.67% in Lafiagi and 35% disease severity, follow by 13.33% incidence and 40% severity at Shonga a local farm at Edu LGAs .The highest percentage incidence of 68 % and 70% severity was observed in Lade a local sugarcane farm in Patigi LGAs and followed by 65% incidence at Oro Irepodun LGAs and 69 % severity in Egosi Oke Ero LGAs (Table1).This presence of virus prevalence in all the surveyed sites could be attributed to the fact that, the prevailing virus pathogens are endemic in that locality and couple with presence of the alternative host as indicated by Oke *et al*.,(2023). The sugarcane mosaic diseases have been implicated as most devastating of sugarcane as exhibited in Makarfi LGA Kaduna, most especially where most susceptible landraces were dominated (Dangora *et al.*, (2014)).

The Table2 below shows the ELISA (Enzyme Linked Immuno Sorbent Assay) result obtained from the evaluation on the sugarcane plantations in Kwara state. Fifty leaves sample collected from survey sites were subjected to ELISA. The result shows that from the three viruses probe, only two virus were found to be associated with the mosaic of sugarcane diseases in Kwara State and they are the SCMV (Sugarcane Mosaic Virus) and MDMV (Maize Dwarf Mosaic Virus). The result indicated 2 positive single infection of SCMV (4%), 11 single infections of MDMV (22%), 35 mixed infection of SCMV and MDMV (70%) and 2 samples were negative to any of them (Table 2). Only two locations Egosi and Shonga were found with single infected sugarcane of SCMV and single infection of MDMV were implicated in Egosi, LADE, Lafiaji, Shonga and Tsarangi, with highest prevalence 3 out of 11 in both Egosi and Lafiaji. Very high prevalence of mixed infection SCMV and MDMV was observed in this 35 (70%), with the highest incidence 9 of 35 was observed in Oro, followed by 7 in Egosi and 6 in Unilorin research farm.(Table 2). The prevalence of mixed infection of SCMV and MDMV was observed to cut across all the survey regions under this study. This could be attributed to the presence of abundant viruliferous insect vectors and various alternatives host, which as the reservoir for the viruses' .This agrees with findings of Taiwo et al., (2006), in survey carried out to study viruses infecting maize in Lagos and its environment. Sharma and Mistra (2011) reported MDMV in China, South Africa and USA, Dangora *et al.*, (2014) implicated SCMV, Sorghum mosaic virus (SrMV) and MDMV through ELISA result as causative agent of steak and stripe diseases of sugarcane in Makarfi. Aphids gossypii was tagged responsible for the spread and to a large extent contaminated cutlass. The ELISA tithe values range from 0.016-0.206 for MCMVand none of the samples tested was found positive to the virusTable3.

ABSTRACT
Disease surveillance and tomato seed collections were carried out between October and December 2018 to develop high-yielding tomato lines of good qualities, resistance, and tolerance to virus diseases. The survey itinerary comprises Kano, Plateau, Oyo, Ondo, Ogun, Ekiti, and Lagos states Nigeria. The location ranges from Ihunbo Ipokia (Latitudes 07.04889^{0}N, Longitude 003.71209^{0}E) to Darowar-Sallae Kadawa Kano (Latitudes 11.6707^{0}N, Longitude 008.4195^{0}E). The symptoms observed on a tomato plant in the Northern and North central axis are leaf curl, leaf cupping, chlorosis, and leaf purpling, while in the southwest shoe string, leaf curl, mosaic, mottling, yellowing, purpling, leaf crinkling and leaf bunching were observed. The highest percentage field incidence of 90% was observed in Rafiki Village Jos North, followed by 85% and 80% in UtisanMalla Kadawa Kano and Gaando Village Gboko Benue respectively. The lowest percentage incidence of 50% was observed in RiyonKwallak Village and disease severity ranges from 2.25-4.00, the leaf samples collected were subjected to Double antibody sandwich ELISA (DAS-ELISA), CMV incidence 100% cut across all the areas, ToMV 25%, PVY 10%, and mixed infection was also found CMV+ToMV 5%, CMV+PVY 10%., ToMV+PVY 10% and CMV+ToMV+PVY 5%.
Keywords: *DAS-ELISA, ToMV, PVY, CMV+ToMV, CMV+PVY, ToMV+PVY,and CMV+ToMV+PVY*

INTRODUCTION

Tomato (*Lycopersicon esculentum*) is grown worldwide and its consumption provides nutrients in diets and medicinal phytochemicals like anthocyanin, lycopene, and carotene (Causse *et al*., 2002). Tomato grown both in home gardens and commercially is the world's most popular fruit ahead of a banana (FAO, 2013). The tomato crop is important as a source of vitamins A and C and contains antioxidants with some anticancer in the human diet (Turku, 2007), benefits local farmers, enhances food taste (Ibitoye et. al.,2009), and with some anticancer properties is also rich in vitamin C (Zhang, et al., 2001). They are consumed raw and are useful in making soups. It is also one of the major crops planted by all tribes in Nigeria creating job opportunities, income, and food for both commercial and subsistent farmers (Olaniyi *et al*., 2010). Nigeria is one of the major importers of tomatoes in the world due to low farm yields and variations in production output during the different seasons of the year. Low yields are caused by disease pathogens, inadequate education, lack of modern farm equipment, and poor irrigation systems among others. Tomato is imported into the country in the form of fresh tomato fruits and pastes Ogundari and Aarifalo. (2013).
When compared with the U.S.A. and Taiwan, where yields as high as approximately 180 tons per hectare has been recorded (FAO, 2013), the yield of tomato in Nigeria is low. The average in the western part of the country is only about 5 tons per hectare and 20 tons per hectare in areas of Northern Nigeria (Olaniyi *et al*., 2010). Many Nigerians therefore continually depend on imported processed tomatoes from foreign countries to meet the consumption demand for Taofiq. (2017). Annually, one of the major challenges of tomato cultivation in Nigeria is the high incidence of viral symptoms on tomato farms leading to meager crop yield and poor market value of harvested fruits (Mohammed *et al*., 2017). Because of the potentially devastating impact of plant viruses on tomato crop production and the meager perennial yield in Nigeria, there is a need for a thorough national survey program to map out the prevailing viral diseases endemic ina specific geographical area must be identified and characterized before developing sustainable, environment-friendly

disease management programs Green and Kim (1991),. Viral diseases have been reported to cause great economic loss to the tomato crop (Balogun 2008). Viruses in tomatoes cause severe and irreversible damage to tomato plants reducing crop yield. One of the major perennial challenges faced by tomato farmers in Nigeria is the high prevalence of observable viral-like symptoms on farms leading to very low crop yield, the poor market value of harvested tomato fruits, and post-harvest losses (Abimbola,2014; Mohammed *et al*., 2017). The production of virus-tolerant tomato lines is expected to go a long way to increase tomato yield in the study area. Therefore, this study aimed to develop high-yielding tomato lines of good qualities, resistance, and tolerance to virus diseases.

MATERIALS AND METHODS

Disease surveillance and tomato seed collections were carried out between October–December 2016 to develop high-yielding tomato lines of good qualities, resistance, and tolerance to virus diseases. The survey itinerary is UtisuamMallam and DarowarsallaeKadawa Local government area, Markwaro – Chiki village Kura Local Government Area Kano Northern Nigeria; Viraldisease surveillance was also carried out on 3 local government areas in Plateau State. They include RafikiVillage Jos North, MiangoBassaVillage and Dosan Kura VillageBassa and RiyonKwallakVillageRiyon local government areas. In Benue State, two local government areas were surveyed. These include Tahembe in Tarka Local Government Area, Gaando and AgirigiGaando village Gboko Local Government Area North central Nigeria. In Southwestern, Nigeria surveys were carried out in Abesan, Ikola, Ayobo, IpajaUso, Erio, Ohunbo, Ojikan, Ojuore, Ijoko, Igbesa, Ipokia, Owode, Osiele, Toba, and Iwo. In Southeast Mbato, Abia, Ebonyi. The location ranges from Ihunboipokia (Latitudes 07.04889^{0}N, Longitude 003.71209^{0}E) to Darowar-SallaeKadawa Kano (Latitudes 11.6707^{0}N, Longitude 008.4195^{0}E).

The field sizes vary from0.4 to 5 hectares. The random samplings were carried out from surveyed sites, by taking equidistant 5 steps W shaped diagonally across the field (Aliyu *et al*., 2012) and tomato plants with mosaic, turned tiny, squeezed, shoestring, mottling, and other virus-like symptoms observed are considered (Oke *et al.,*2012). The survey was carried out on tomatoes within the flowering and early fruiting stages. Tomato plants were visually examined on the field for viral symptoms expression and 10 representative leaf samples were collected from each of the survey into well-labeled sample bags and later kept on India-made silica gel in sample bottles. The leaf samples were brought to the Virology and Molecular Diagnostic Laboratory of the International Institute of Tropical Agriculture. A total of 300 leaf samples were collected from the survey sites whosesymptoms vary from leaf mottle, mosaic, turned tiny, crinkling, leaf purpling, leaf curl,shoe-string, vein clearing, and fruit deformation.

Virus disease detection was carried out using a Double antibody sandwich Enzymes Linked Immunosorbent Assay (DAS-ELISA) Five of the 10 leaf samples collected from eachfield were subjected to DAS-ELISA according to Clark and Adams 1977; Ayo-Johnand Odedara,2017; Oke et al,2023. The test was conducted using different antibodies to detect various viruses such as Potato virus Y, Tomato mosaic virus (ToMV), Tomato spotted wilt virus (TSWV), Cucumber mosaic virus (CMV), and Tomato yellow leaf curl virus (TYLCV). The plates were incubated for one hour at room temperature and 4 ^{C} overnight. Reading was carried out using an ELISA plate reader (MICRO READ 1000 ELISA plate analyzer) at a 405 nm absorbance wavelength filter against the blank air. The samples whose values exceeded twice the reading of the healthy control were considered positive for the viruses indexed (Ayo-John and Odedara,2017).

RESULTS

The results of the investigation demonstrated thata total of (100%) of fields that all cut across the three States in the southwest and three States in Northern Nigeria were surveyed, which include, 10 local government areas of Nigeria (Table1). In northern Nigeria, the observable field symptoms are predominantly leaf curls, leaf purpling, leaf cupping, chlorosis, and yellowing of leaves with curl. while in southern Nigeria is more mosaic, mottling, shoestring, dieback, and leaf bunching, The highest percentage field incidence of 90% was observed in Rafiki Jos North, followed by 85% and 80% in UtisanMallaKadawa Kano and Gaando Village Gboko Benue respectively. The lowest percentage incidence in the north 50% was observed in RiyonKwallak Village and disease severity ranges from 2.25-4.00. the highest percentage incidence in the south 75% was observed in Ihunbo followed by 65% and 50% respectively in ipokia and ipaja. The lowest incidence of 32.5% was observed in OkeOgun and disease severity ranges from 2.75-4.00. In areas where leaf samples were not available seeds were collected from all the areas such as in Abia, Ebonyi, Mbato, Abesan,IpajaUso, Erio, Ohunbo, Ojikan, Ojuore, Ijoko, Igbesa, Ipokia, Owode, Osiele,Toba, and Iwo. In the serodiagnostic screening, the majority of the samples collected from all were tested positive for CMV 100% farm incidence, while 25% of the fields were infected with ToMV, mixed infection of CMV+ToMV 5%, CMV+PVY 10%., ToMV+PVY 10% and CMV+ToMV+PVY 5% were also observed (Table3). The mixed infection was found in, the Ojikan, Ihunbo, Rafiki, and Agirigi Table3.

DISCUSSION

The results of the survey showed that 100% of the fields were infected with the virus and virus-like diseases,ofvarious kindsunder field conditions at various surveyedsites(Table 1).Thiscould be attributed to conducive environmental conditions that favourthe multiplication of insect vectors and alternative host which serves as the reservoir virus pathogens over a long period (Taiwo et al 2006, Oke et al,2012, 2017). The symptoms exhibited by diseased plants in the fields resembled those reported elsewhere (Gonsalves and Providenti, 1989, Green and Kim, 1991; Jones *et al.,* 1991 Godson, 2009, Kayode 2018). The high virus disease incidence observed in northern Nigeria could be attributed high density of tomato cropping per plot which can enhance the spread of disease. While the south could attribute continuous cropping on the same plot over a long period and unfavorable weather conditions as reported by Oke *et al*, 2017; Ayo-John and Odedara2017 and Kayode et al (2018). The disease incidence varies from 33-3-90% and severity 2-25-4.00 in the survey period (Table1), this suggests that there are abundance of sources of inocula that may influenced by the presence of many alternative hosts of the disease and viruliferous insect vectors population dynamics in the environment (Atiri,2004, Taiwo, *et.al*.,2006, Oke, *et.al*.,2012).

Most of the fields surveyed during the investigation are susceptible to different attack viruses which implies that the disease will continue to be a threat in tomato-growing areas.The survey resultsrevealed the prevalence of CMV in 100% of the 6 states surveyed in both South and North Nigeria that were assayed could be attributed to the viral inoculums, endemic in the surveyed areas, and presence of the alternative hostsand effective insect vectors thatpresent in the survey area Taiwo et al2006(Table 2). In this study, mixed infection of CMV +ToMV, CMV+PVY, ToMV+ PVY, and CMV +ToMV +PVY Was observedto be prevalent in Jos/North LGA at Rafiki North Central Nigeria Table 2. This could be attributed to the availability of the viral inocula available in every state and LGAs. This coupled with the presence of viruliferous vectors in abundance that interact with the alternative host in the areas and the air current could enhance the movement of viruliferous Aphids vectors and others such as whiteflies from the region of higher infection density to a new area (Taiwo et al., 2006, Gautam *et al*, 2020).

ABSTRACT
Field experiment was conducted at the Teaching and Research Farm, Ladoke Akintola University of Technology, Ogbomoso and Niger State College of Agriculture, Mokwa, in 2014 cropping season to examine the effects of mulch materials and mulching rates on fruit yield and nutritional qualities of tomato variety. The experiment had fifteen treatments viz: three mulch materials (rice husk, groundnut shell and dry guinea grass) and five mulching rates (0, 5, 10, 15, and 20 in t ha^{-1}), replicated three times. The experiment was laid out as factorial arranged in Randomized Complete Block Design. Data were collected on plant height, number of flowers, number of fruits and total fruit yield. The determination of fruit phytochemical contents at full ripening, 6 fruit samples were randomly selected per plot and analysed for nutritional qualities such as Crude Protein, Carotene, Iron, Phosphorus, Potassium, Calcium, Lycopene, Magnesium, Vitamin C contents. Data was analysed using analysis of variance (ANOVA) SAS package and treatment means compared using least significant difference (LSD) at 5% probability level. Mulching is beneficial to performance of tomato. Mulch types had no effect on fruit yield of tomato. Plants mulched with 15 t ha^{-1} produced the highest yield (23.30 t ha^{-1}) while control plots had the least value (8.13 t ha^{-1}). Nutritional qualities (Lycopene, phosphorus, potassium) were best at mulching rate of 15 t ha^{-1}. It could be concluded that mulching is beneficial to tomato production; mulch rate of 15 t ha^{-1} performed better than other rates evaluated and could be recommended for the farmers within the study areas.

INTRODUCTION

Tomato (*Lycopersicon lycopersicum*) belongs to the solanaceae family. It originated in Peru and Mexico, in the present day Central and South America from where it spread to other parts of the world (Zeidan, 2005). Tomato reached Europe from Mexico in the 16th century, and was initially used as ornamental plant. Its cultivation for edible fruits started at the end of the 18th century. Tomato was introduced to West Africa and Nigeria in particular, at the end of the 19th century (Villareal, 1980). It is currently considered to be one of the main vegetable crops in the world, and constitutes an economic force that influences the income of many growers in the world (Omar, 2005). In Nigeria tomato also finds its way into almost every kitchen. Tomato crop is very important in terms of diet and economy in Nigeria both during the rainy season (rainfed) and dry season using irrigation facilities. It is used as a condiment in stews and soup or eaten raw in salads. Industrially, the crop is made into puree, sauce, paste and powder (Balarabe, 2012).

Mulching is the process or practice of covering the soil/ground to make more favourable conditions for plant growth, development and efficient crop production. Mulch technical term means 'covering of soil' (Anon, 2009). While natural mulches such as leaf, straw, dead leaves and compost have been used for centuries, during the last 60 years the advent of synthetic materials has altered the methods and benefits of mulching. When compared to other mulches plastic mulches are completely impermeable to water; it therefore prevents direct evaporation of moisture from the soil and thus limits the water losses and soil erosion over the surface (Akhtar *et al*., 2001). In this manner it plays a positive role in water conservation and the suppression of evaporation also has a supplementary effect; it prevents the rise of water containing salt, which is important in countries with high salt content water resources (Enan, 2004). Mulching is a layer of material on the surface of the soil used to keep soil moist or to serve a wide variety of other purposes. Organic mulches are those derived from the dead plant and animal tissues, which apart from soil protection also serve as nutrient sources when they decay. Tomato plants subjected to mulching and fertilization exhibited the highest plant height when compared with the other treatment combinations (Liasu and Abdul Kabir, 2007).

Mulching has been identified by many researchers as a method to provide a favourable soil environment by minimizing crusting at the soil surface and keep it stable (Kayum *et al*., 2008). Influence of mulching on tomato production has been reported by many researchers (Hooda *et al*., 1999). This practice increases the infiltration of rain water and suppress the growth of weeds. Mulching is effective in reducing evaporation, conserving soil moisture and has been known to modify the hydrothermal regime of soil (Bhagat and Achanya, 1988). Mulching of tomato plants with Tithonia diversifolia leaves and fertilizer application together promoted growth and development i.e. number of nodes, number of leaves and height, as well as fruit production i.e. number of fruits, number of seeds per fruit, fruit size, fruit shape and duration of fruiting activity. In the experiment conducted by (Kayum *et al*., 2008), three tomato varieties namely, Ratan, BARI tomato-3 and BARI tomato-6 were experimentally evaluated to identify the potential mulch on growth and yield, where the experiment consisted of four mulching treatments: water hyacinth, straw, am-ada leaf and banana leaf with a control (no mulch).

The experiment was conducted under rainfed condition. The result showed that mulching significantly had effect on growth, yield components and thus on the yield of tomato. Mulching is effective in reducing evaporation, conserving soil moisture and has been known to modify the hydrothermal regime of soil (Bhagat and Achanya., 1988). The bad effects of water deficit could be overcome by irrigation or adopting in-situ moisture conservation techniques, such as use of mulches (Walter, 1988). Mulches are effective in reducing soil moisture loss from evaporation. Organic mulches are effective, but when moisture is applied by irrigation or through rainfall, the amount should be adequate to reach the soil. Organic mulches tend to settle with time. Some are less resistant and decompose after a short time. As such, it may be necessary to add fresh material to the original layer to make it effective in retaining moisture (George, 2004). The agronomic characteristics of tomato as influenced by irrigation and mulching were examined. Mulching and no mulching were evaluated. Rice straw was used as mulching material at the rate of 5 t/ha. The mulching significantly affected the fruit yield in such a way that mulched plots produced about two times more fruit yield than those without mulch (Gudugi *et al*., 2012).

The effects of L. Leucocephala and G. Sepium mulches (and their mixtures) on the growth and yield of okra was assessed. The mulches were applied at the rate of 0, 5 and 10 t ha^{-1}. The mulches did not significantly improve the chemical properties of the soil, but improved the growth rate and yield of okra. Generally, the higher the amount of mulch applied, the better the growth and yield of okra (Agbo, 2000). Mulching, using any of the materials like green leaves, dried leaves and coconut fronds significantly increased tomato fruit yield by 65.30% over the control and they attributed the increase to the slight improvement in the physical properties of soil (Ertek *et al*., 2004). Similarly, mulches applied at very low rates e.g. 2.5 t ha^{-1} or 5 t ha^{-1} can significantly increase growth and yields of highly valuable vegetable and fruits crops in the field (Norman and Edwards, 2005). Trash farming suppresses weed germination and retard growth and development of many weeds, reduces soil erosion and conserves soil moisture. In the low and intermediate rainfall areas, tomato is mulched with trash (FAO, 1999). This helps in conservation of soil moisture and fertility (Wood, 1991). Trash placed on the soil surface losses 55 – 60% of its organic matter after 270 days compared with 70 – 75% when it is incorporated in the soil (Linedale and Bull, 1995). Use of clear polythene and plastic present the potential advantage of soil solarisation (Schlesselma *et al*., 1985).

Application of organic materials such as dried papaya leaves could also make the plants grow fast and retard the growth of weeds around the plants. These organic materials which are added to the soil are collectively termed as organic mulch. Others organic mulches include grass clippings bark, sawdust and manure, hay, straw, shells, wood chips, shredded newspaper, cardboard and wool (Acayen *et al*., 2004). Despite many investigations in the area of nutrition, knowledge on how mulching material and mulching rates influence physical and phytochemical contents of tomato fruit is insufficient. This study determined plant growth, fruit yield and nutritional qualities of tomato variety in Ogbomoso and Mokwa, Nigeria as influenced by mulch material and mulching rates.

MATERIALS AND METHODS

The experiment was conducted at two locations; Teaching and Research Farm, Ladoke Akintola University of Technology, Ogbomoso (8°10^{1}N; 4°10^{1}E) and Niger State College of Agriculture, Mokwa (9° 18^{1}N and 5° 04^{1}E), during 2014 cropping season. The experimental plot was ploughed and harrowed after which lining out was carried out. There were 45 plots with three replications. Each replicate consisted of 15 plots. Each treatment was in a bed plot size of 2.5 m x 2.0 m (5.00 m^2). A plot contained 25 plants. The total experimental area was 405.00m^2 (0.041 ha^{-1}). The alley way between replicates was 1.0 m and within replicates was 1.0 m with inter and intra-row spacing of 50 cm x 50 cm. Three mulch materials that were used included: Rice husk, Groundnut shell and Dry guinea grass while the mulching rates involved: 0, 5, 10, 15 and 20 t ha^{-1}. The test crop used was UC82B tomato variety. The treatment was laid out as factorial arranged in Randomized Complete Block Design, replicated three times. The seeds were sourced from the Department of Crop Production and Soil Science, Ladoke Akintola University of Technology, Ogbomoso and from the Department of Agricultural Technology, Niger State College of Agriculture, Mokwa.

The tomato seeds were sown on nursery beds containing pulverized soil and the seedlings were raised for four weeks before transplanting to the field at the two locations. Watering in the nursery was done as at when needed. Healthy and vigorous seedlings were transplanted into the field in order to ensure uniformity. Watering was done using watering - can to supplement rainfall. Pesticide in form of cypermethrin was applied at the dosage of 25 ml per 15 litres of knapsack sprayer fortnightly to check caterpillars, worms and grasshoppers. Manual weeding was also carried out using hoe at three weeks interval starting from 2 WAT to reduce competition between weeds and plants. Data were collected on plant height, number of flowers, number of fruits and total fruit yield. The determination of fruit phytochemical contents at full ripening, 6 fruit samples were randomly selected per plot and analysed for nutritional qualities such as crude Protein, Carotene, Iron, Phosphorus, Potassium, Calcium, Lycopene, Magnesium, Vitamin C contents.

In order to assess these, 6 fruit samples were collected and dried in an oven at 85^{O}C for 72 hours. The dried fruit samples were separately ground with a Wiley mill, and passed through a 0.5 mm sieve for tissue analysis. Total P was determined by the Vanadomolybdate method, K and Ca was determined by the flame photometry and Mg and Fe were determined by atomic absorption spectrophotometer (IITA, 1989). Total N was analyzed by the micro-Kjeldahl procedure as described by IITA (1989) and crude protein was obtained by multiplying the total N by a factor of 6.25. Data collected were subjected to Analysis of Variance (ANOVA) using SAS statistical package. Treatment means were separated using the least significant difference (LSD) at 5% probability level.

Plant height (cm)

Application of different mulch material had no significant ($P \geq 0.05$) effect on the plant heights of tomato plants at all the sampling periods (Table 1). The plant heights of tomato was significantly ($P \leq 0.05$) influenced by mulching rate at 2 WAT. The plants mulched with 15 t ha^{-1} materials was significantly taller than that of 20 t ha^{-1}, 5 t ha^{-1} and control plots but was not significantly different from the plant mulched with 10 t ha^{-1} (23.9 cm). At 4 WAT, plant height of tomato was significantly ($P \leq 0.05$) influenced by mulching rate. The plants mulched with 15 t ha^{-1} (39.9 cm) was significantly taller than other mulching rates while the least mean value (30.5 cm) was obtained from the control plot which was not significantly different from the plants mulched with 5 t ha^{-1} (31.3 cm). The plant heights of tomato was significantly ($P \leq 0.05$) increased by mulching rate at 6 WAT. The highest mean value (39.9 cm) was obtained from the plants mulched with 15 t ha^{-1} which was not significantly different from the plants mulched with 20 t ha^{-1} (38.5 cm). Also, the plants mulched with 10 t ha^{-1} (35.4 cm) and 5 t ha^{-1} (33.6 cm) were not significantly different from each other while the least mean value (29.3 cm) was observed from the un-mulched plants. The interaction effects between mulch material and mulching rate at 2, 4 and 6 WAT were not significant ($P \geq 0.05$).

Number of flowers per plant

The mean number of flowers of tomato is presented in (Table 2). The number of flowers increased as the mulching rate increased and declined thereafter. The mulch material had no significant ($P \geq 0.05$) influence on the number of flowers of tomato plants. The plants mulched with 15 t ha^{-1} (24.5) and 20 t ha^{-1} (24.4) significantly had similar number of flowers which were significantly different from the plants mulched with 10 t ha^{-1} (19.4) and 5 t ha^{-1} (16.9). The plants mulched with 10 t ha^{-1} was significantly higher than the plots left un-mulched (control) but significantly had similar number of flowers with the plants mulched with 5 t ha^{-1}, respectively. The interactive effects of mulch material and mulching rate was not significantly ($P \geq 0.05$) influenced.

Number of fruits per plant

The mean number of tomato fruits is presented in Table 3. The number of fruits increased as the mulching rate increased and declined thereafter. The mulch material had no significant ($P \geq 0.05$) effect on the number of tomato fruit. The mulching rate significantly ($P \leq 0.05$) affected the number of fruits. The plants mulched with 15 t ha^{-1} (21.2) significantly gave higher number of fruits than the control plot (12.2), 5 t ha^{-1} (14.0), and 10 t ha^{-1} (14.6) but was not significantly different from that of 20 t ha^{-1} (18.8). The interaction effects of mulch material and mulching rate was not significantly ($P \geq 0.05$) influenced

Total fruit yield

The total fruit yield of tomato increased as the mulching rate increased and declined thereafter as shown in Table 4. The total fruit yield of the tomato was no significantly ($P \geq 0.05$) increased by mulch material treatments. The total fruit yield of tomato was significantly ($P \leq 0.05$) influenced by mulching rate. The plants mulched with 15 t ha^{-1} (23.30 t ha^{-1}) was significantly higher than other values of mulching rates. Mulching rate of 20 t ha^{-1} (17.57 t ha^{-1}) was significantly higher than the plants mulched with 10 t ha^{-1} (11.90 t ha^{-1}), 5 t ha^{-1} (10.80 t ha^{-1}) and the least was obtained from un-mulched plot (8.13 t ha^{-1}). But there was no significant difference between the values of these treatments. The interactive effect of mulch material and mulching rate was not significant ($P \geq 0.05$).

Crude Protein, Carotene and Iron contents

The protein content of tomato fruit was significantly ($P \leq 0.05$) influenced by mulching rate (Table 5). Plants mulched with 5, 15 and 20 t ha^{-1} (1.0 mg/100 g) were significantly higher than that of 10 t ha^{-1} (0.9 mg/100 g) and the control plot (0.8 mg/100 g), respectively. The interaction effects of mulch material and mulching rate was not significant ($P \geq 0.05$) on protein content. Mulching rate had significant ($P \leq 0.05$) influence on carotene content of tomato fruit with the highest mean value (0.8 mg/100 g) obtained with 15 t ha^{-1} which was significantly higher than other mulching rates. The plants mulched with 20 t ha^{-1} (0.7 mg/100 g) was significantly higher than that of 5 t ha^{-1} and 10 t ha^{-1} (0.6 mg/100 g) which had no significant difference from each other while the least carotene content 0.4 mg/100 g was received from un-mulched plot. The interactive effect of mulch material and mulching rate was not significant ($P \geq 0.05$). The result showed that iron content of tomato fruit was significantly ($P \leq 0.05$) influenced by mulching rate. The highest mean value (3.0 mg/100 g) was obtained with 5 t ha^{-1} which was significantly higher than the plants mulched with 10 t ha^{-1} (2.6 mg/100 g) and the control plot (2.0 mg/100 g) but significantly recorded similar iron content with the plants mulched with 15 t ha^{-1} and 20 t ha^{-1} (2.8 mg/100 g). The interaction effects of mulch material and mulching rate on iron content of tomato fruit was not significant ($P \leq 0.05$).

Phosphorus, Potassium and Calcium contents

Mulch material had significant ($P \leq 0.05$) influence on phosphorus content of tomato fruit (Table 6). The dry guinea grass mulch recorded the highest mean value (6.6 mg/100 g) which was significantly higher than the mean value (5.0 mg/100 g) obtained from the groundnut shell mulch and the least mean value (4.4 mg/100 g) was received from rice husk mulch. Mulching rate had significant ($P \leq 0.05$) effect on phosphorus content of tomato fruit. The highest mean value (6.8 mg/100 g) was obtained from the plants mulched with 20 t ha^{-1}

which was significantly higher than the mulching rates of 5 t ha^{-1} and 10 t ha^{-1}. But had no significant difference from that of 15 t ha^{-1} (6.2 mg/100 g) while the least mean value (3.8 mg/100 g) was observed from un-mulched plot. The interaction of mulch material and mulching rate was significant ($P \leq 0.05$) on phosphorus content with the highest mean value (7.9 mg/100 g) obtained from dry guinea grass mulch at 15 t ha^{-1}.

The potassium content of tomato fruit was not significantly ($P \geq 0.05$) affected by mulch material. Mulching rate had significant ($P \leq 0.05$) influence on potassium content of tomato fruit. The plants mulched with 20 t ha^{-1} (4.9 mg/100 g) was significantly higher than that of 5 t ha^{-1} (3.1 mg/100 g) and 10 t ha^{-1} (3.6 mg/100 g) but was not significantly different from 15 t ha^{-1} (4.8 mg/100 g) while the least potassium content of 2.5 mg/100 g was obtained from the un-mulched plot. The interactive effect of mulch material and mulching rate on potassium content was not significant ($P \geq 0.05$). The calcium content of tomato fruit was significantly ($P \leq 0.05$) increased by mulch material. The highest mean value (2.4 mg/100 g) was obtained from rice husk mulch which was significantly higher than that of dry guinea grass mulch (2.2 mg/100 g) while the least mean value (2.1 mg/100 g) was received from groundnut shell mulch. Calcium content of tomato fruit was significantly ($P \leq 0.05$) increased by mulching rate. Plants mulched with 20 t ha^{-1} (2.8 mg/100 g) was significantly higher than that of 10 t ha^{-1} (2.2 mg/100 g) and the least calcium content (1.5 mg/100 g) was received from the control plot. The interaction effects of mulch material and mulching rate was significant ($P \leq 0.05$) and the highest calcium content (2.9 mg/100 g) were obtained from rice husk and dry guinea grass mulches with 15 t ha^{-1}, respectively.

Lycopene, Magnesium and Vitamin C contents

The mulch material had significant ($P \leq 0.05$) influence on lycopene content of tomato fruit (Table 7). The plants treated with rice husk mulch recorded the highest mean value (2.9 mg/100 g) which was significantly higher than the plants treated with groundnut shell mulch (2.3 mg/100 g) but was not significantly different from the plots applied with dry guinea grass mulch (2.8 mg/100g). The lycopene content of tomato fruit was significantly ($P \leq 0.05$) increased by mulching rate. The plants mulched with 20 t ha^{-1} (3.6 mg/100 g) were significantly higher than other mulching rates. Also, plants mulched with 15 t ha^{-1} (3.3 mg/100 g) was higher than that of 10 t ha^{-1} (2.6 mg/100 g) and 5 t ha^{-1} (2.3 mg/100 g) while the least mean value (1.6 mg/100 g) was obtained from un-mulched plot. The interactive effect of mulch material and mulching rate on lycopene content was not significant ($P \geq 0.05$).

Magnesium content of tomato fruit was not significantly ($P \geq 0.05$) influenced by mulch material, mulching rate and their interaction effects. The vitamin C content of tomato fruit was not significantly ($P \geq 0.05$) influenced by application of mulch material. The vitamin C content of tomato fruit was significantly ($P \leq 0.05$) influenced by mulching rate. Plants mulched with 20 t ha^{-1} (25.9 mg/100 g) was significantly higher than that of 10 t ha^{-1} (19.5 mg/100 g) and 5 t ha^{-1} (18.9 mg/100g), but was not significantly different from 15 t ha^{-1} (24.2 mg/100 g) while the least mean value (15.9 mg/100 g) was obtained from the control plot. The interaction of mulch material and mulching rate on vitamin C content had no significant ($P \geq 0.05$) effect.

DISCUSSION

Reports by Liasu and Abdul Kabir (2007) stated that mulching is a layer of material on the surface of the soil used to keep soil moist or to serve a wide variety of purposes. Organic mulches are those derived from the dead plant and animal tissues, which apart from soil protection also serve as nutrient sources when they decay. Findings from Kayum *et al.* (2008) revealed that mulching tomato plants with the use of water hyacinth, straw, am-ada leaf and banana leaf showed significant effect on growth and yield components and thus increase the yield. The significant plant height of 39.9 cm obtained with the mulching rate of 15 t ha^{-1} from the present study agrees with the report of Liasu and Abdul Kabir (2007) who stated that tomato plants subjected to mulching exhibited the highest plant height when compared with control. The above authors in their findings also stated that the tomato plants subjected to mulching exhibited the highest number of leaves per plant than the control plot. In the current study, mulching rate of 15 t ha^{-1} and 20 t ha^{-1} produced number of flowers of 25.4 and 24.4 that were significantly higher than the values of other mulching rates. This may be attributed to the fact that the mulching application rate was higher thereby retaining moisture in the soil which promoted flower formation.

This is in agreement with Anon. (2009) who reported that the thicker the mulch material the more water is retained in the soil to serve as a good medium for plant growth, development and efficient crop production. The results obtained from this study revealed that rice husk mulch gave higher number of fruits than other mulch materials. This agrees with the report of Akhtar *et al*. (2001) who reported that natural mulches such as leaf, rice straw, dead leaves and compost have been used for centuries to increase fruit per plant, fruit length, fruit size, average fruit weight and yield. Findings in this study also agrees with those of Kayum *et al*. (2008) who stated that mulching showed significant effect on growth, yield components and thus on the yield of tomato. The significant highest total fruit yield of 23.30 t ha^{-1} produced from the plants mulched with 15 t ha^{-1} in this study was at the upper value of 14.00 t ha^{-1} reported by Gudugi *et al*. (2012) and 21.47 t ha^{-1} reported by Elkner *et al*. (1991). The results of the current study is in conformity with Ertek *et al*. (2004) who revealed that mulching tomato plants at the rate of 10 to 20 t ha^{-1} will give better yield using mulch materials such as green leaves, dried leaves and coconut fronds.

The significant increase in the fruit nutritional qualities parameters which mulch materials and mulching rates treatments were imposed showed the potentials involved in tomato variety. The nutritional composition increased as the mulching rates increased. The result obtained from this present study is in agreement with the findings of Olaniyi *et al*. (2010). There was no consistency in the nutritional qualities obtained in this current study for the tomato variety used. The plants mulched with 15 t ha^{-1} closely followed by 20 t ha^{-1} significantly recorded higher nutritional qualities than the other mulching rates evaluated. The result of this study is in line with the findings of Olaniyi *et al*. **(**2010) who confirmed that there was inconsistence in the nutritional values obtained in their study for the tomato varieties used. Ara *et al*. (2007) supported the result obtained in this study that tomato is a dependable source of Vitamin A, B, C and D, minerals, Ca, P and Fe. Result of the nutritional qualities revealed that tomato fruits are rich in phosphorus, potassium, calcium and vitamin C. This might be the reason of their intensive use for stew in meals.

CONCLUSION

Based on the research findings, it can be concluded that Rice husk mulch gave better fruit yield and nutritional qualities than groundnut shell and dry guinea grass mulches. More so, the plants mulched with 15 t ha^{-1} gave the highest fruit yield and nutritional qualities than other treatments. It is therefore recommended for the tomato farmers within the study areas.

ABSTRACTS

The field experiment was conducted at the Institute for Agricultural Research (IAR) Farm, Samaru Zaria. Treatment consisted of two varieties of tomatoes (Roma VF and UC82B), and two sources of organic manure (poultry manure and cow dung). The treatments were factorially combined and laid out in a Randomized Complete Block Design (RCBD) with plot size of 3m by 3m (9m^2), replicated three times. The data collected were subjected to Analysis of Variance (ANOVA) using general linear model GLM of the Statistical Analysis System package (SAS, 2003) and the means were separated using the Duncan's Multiple Range Test (5% probability level) (Duncan, 1955). The study revealed that variety ROMA VF out-performed variety UC82B in terms of growth parameters (plant height and number of leaves). Similarly, growth and yield parameters of tomato significantly responded to poultry manure and cow dung.

Keywords: *Roma VF, Tomato, Varieties and Poultry Manure*

INTRODUCTION

Tomato *(Lycopersicon lycopersicon*) is an edible vegetable, often red fruit of the nightshade family known as solanaceae (Spooner *et al.,* 2005: Encyclopedia of life, 2014) Tomato species originated from the south American Andes and the use of tomato as a food originated in Mexico, and sprea**d** from there throughout the world following the Spanish colonization of the Americas (Encyclopedia of life, 2014).It is many varieties are now widely grown, sometime in green houses in cooler and warm climate of the tropics. It is one of the important vegetable crops grown throughout the world and ranks next to Irish potato in terms of the area of cultivation, but ranks first as a processing crop (Mehdizaden *et al.,* 2013) in Nigeria, tomatoes are grown during wet and dry seasons which attract higher profit during the dry seasons when demand is higher than supply (FAO, 2010) Tomato is one of most important vegetables in Nigeria as it is consumed by almost every household. Total tomato production in Nigeria was about 1.7 million tones (FAO2010). Importation of tomato into Nigeria becomes a necessity especially when the annual population growth rate about 2% (FAO, 2006) which exceed food production. Among the factors that contribute to low tomato yield in Nigeria were low soil fertility and improper selection of appropriate varieties adaptable to the agro-ecological zones (Adekiya and Ojenityi, 2010). Tomato is one of the most widely vegetables in the world. It is considered as the second significant vegetable crop in the world after potato (Mohammed *et al.,* 2010) the fruits are commonly eaten raw in salad served as a cooked vegetable, used as an ingredient of various prepared dishes, and picked.

Manure is the decomposed form of dead plant and animals which is applied to the soil to increase production. It is a natural form of fertilizer and is cost effective. The human and animals exist is also used as manure. The livestock manure is rich in nitrogen, phosphorus and potassium. Manure is highly rich in organic matter and humus and thus, improves the soil fertility. This is better in the long run and does not cause any pollution. It is a valuable and renewable resource. Poultry manure is derived from the piece of chickens used as an organic fertilizer, especially for soil with low nitrogen; it has the highest amount of nitrogen, phosphorus and potassium. Cow dung manure is also known as cow's pats, cow piece or cow manure, is the waste product (feaceas) of bovine animal's species, these species include domestic cattle (cow), bison (buffalo) and water buffalo. Cow dung is the undigested residue of plant matter which has passed through the animals' gut. Tomato is one of the most important and popularly vegetable crops in the world. The request

and demand of tomato is increasing day after day. Tomato production is increase but the space on land for its production is less, therefore this research need to find better manure among these two sample manure to test the best on two different varieties of tomato for farmers to have high yield product. Based on the aforementioned this research was conceived with the following objectives:
To determine the best variety among the two (Roma VF and UC82B)
To determine the best organic manure among the two sources (poultry and cow dung)

MATERIALS AND METHODS

The field experiment was conducted during 2021 dry season at Samaru College of Agriculture, Zaria. Home and Rural Vegetable Garden (Latitude 11º 11 N, Longitude of 38º E) and 686 meters above sea level. The site is falls in the Northern Guinea Savanna Ecological Zone of Nigeria. Treatment consisted of two varieties of tomatoes (Roma VF and UC82B), and two sources of organic manure (poultry manure and cow dung) rate. The treatments were laid out in a randomized complete block design with three replications. The soil sample was collected from 10 point from the experimental site with an auger prior to land preparation. The sample was sieved and analyzed for physiochemical properties using the standard procedure as describe by Black (1965). The gross plot was 2m × 2m (4 m^2). The following observations were recorded; plant height, Number of leaves and Number of fruit per plot. All data collected was subjected to Statistical Analysis of Variance (ANOVA) using F test as directed by Snedecor and Cochran (1967) and the treatment means were compare using Duncan Multiple Range Test (DMRT) Duncan, (1955).

RESULT AND DISCUSSION

Table 1 shows plant height of tomato at 3, 6 and 9 weeks after transplanting as affected by variety and organic manure at Samaru home and rural demonstration field during 2021 dry season. Result of the study showed that variety had statistically different plant height at 3 and 6 weeks after transplanting with Roma VF having presented statistically the tallest plant. However, at 9 weeks after transplanting variety had statistically shown the same plant height. Similarly, all the organic manure sources presented plant with statistically the same plant height at 6 and 9 weeks after transplanting. However, at 3 weeks after transplanting, poultry litter presented significantly the tallest plants, followed by cow dung and control. Interaction had no significant differences among the factors. This may be due to pear shaped fruit and determinate to semi-determinate growth habit (Quinn, 1998). It was reported that plant height of tomato was not significantly affected when 90 and 120kg N/ha were applied.
Result on number of leaves of tomato as affected by variety and organic manure sources presented in table 2. The two varieties differed significantly ($P \leq 0.05$) in terms of their number of leaves at all the stages of sampling except at 9 weeks after transplanting. Roma VF gave higher number of leaves. However, number of leaves responded significantly ($P \leq 0.05$) to organic manure at 3 and 6 weeks after transplanting with poultry litter having significantly the highest number of leaves per plant while cow dung and control presented the least number of leaves per plant at 3 and 6 weeks after transplanting. Interaction between the factors; variety and organic manure sources was highly significant at 3 weeks and significant at 6 weeks while there was no significant interaction between the factors at 9 weeks after transplanting. The reason for the variation in terms of plant height of tomato with Roma VF as the tallest may be due to short variety (50-60cm) in nature with semi-determinate growth habit and spreading branches and open pollinated with short maturity period of 80 days after transplanting (Anon, 2009). (Adeniran *et al*., 1999) reported that varying level of poultry manure alone have no significant effect on the number of leaves.
The result of number of fruits per plant of tomato as affected by variety and organic manure is presented in table 3. The two varieties had no significant differences in their number of fruit during the period of harvest. Number of fruits was significantly affected by organic manure sources and control. This was significant during the harvest in which poultry liter treatments presented the highest number of fruit. Interaction between the factors at 3 and 6 weeks after transplanting was significant and highly significant at 9 weeks. The overall variability of the measured variables and yield tomato recorded in this trial affirms the assentation of Adediran et al (2003) who reported crop yield response to organic means as largely dependent and varies with crop type, soil type and climate.

CONCLUSION

From the result obtained, it could be concluded that variety ROMA VF out-performed variety UC82B in terms of growth parameters (plant height and number of leaves). Similarly, growth and yield parameters of tomato significantly responded to poultry manure and cow dung.

ABSTRACT
A survey of plant-parasitic nematode genera associated with rhizospheres of mango trees was conducted in Ganye and Girei LGA of Adamawa State. In this regard, a total of one hundred and twenty (120) soil samples each from the two (2) local government areas was collected at a depth of 10 - 15cm using auger. The soil samples were then transported to Crop Protection Department Laboratory, Modibbo Adama University Yola for extraction and identification at the generic level using the standard identification keys. Results showed a total of ten and eleven genera of PPNs were identified from the soil samples collected from around the root zone of mango trees in Ganye and Gire LGA respectively. Among the various genera of PPN encountered, Helicotylenchus spp. and Tylenchulus spp. were the most prominent species encountered. it is therefore recommended that management and control measures should implemented in order to curb the multiplication and spread of these nematode species to other regions.
Keywords: *Plant Parasitic Nematode, Mango trees, Soil samples, Population density*

INTRODUCTION

Mango (*Mangifera indica* L.) is one of the most popular fruits grown throughout the tropics and subtropics worldwide (Alemu *et al*., 2014). It belongs to the family of *Anacardiaceae*, and it is one of the most important species of the family and one of the most preferential fruit crops of the tropical and subtropical regions of the world (Vasugi *et al.,* 2012). Mango It is one of the most desirable fruits in the international market because of its delicious taste and high caloric value (Diedhiou *et al*., 2007). India is the world's largest producer; with shares around 56% of total global production. The other major mango producing countries are China, Mexico, Thailand, Indonesia, Pakistan, Nigeria, Philippines, Brazil, Egypt and Haiti (Swart, 2010).

According to Report Linker (2023), Nigeria was in twelfth place in 2021, producing 968,780 metric tons. However, the major producing states in the country include Benue, Jigawa, Plateau, Yobe, kebbi, Niger, Kaduna, Kano, Bauchi, Sokoto, Taraba, Adamawa, and FCT (Federal Capital Territory) (Yusuf and Salau, 2007). Mango has been acclimatized and adapted throughout the tropics and subtropics (Bally, 2006). Much of the spread and naturalization has occurred in conjunction with the spread of human populations, and as such, it plays an important part in the diet and cuisine of many diverse cultures. When ripe, mango fruit is particularly high in vitamin A (Bally, 2006). The fruit is also eaten green, processed into pickles, pulps, jams, and chutneys, and is frozen or dried.

Although grown widely, mangos prefer a warm, frost-free climate with a well-defined winter dry season. Rain and high humidity during flowering and fruit development reduces fruit yields (Bally, 2006). The tree generally flowers in mid- to late winter, with fruit maturing in the early to mid-summer month. Mangos are well adapted to cultivation and have been grown commercially for centuries (Bally, 2006). Mango is an important component of the diet in many countries in the subtropics and tropics (Alemu, 2014). In regions of the world that have experienced low living standards and serious nutritional deficiency, their attractiveness and flavor have also enhanced the quality of life (Mukherjee and Litz, 2009). However, mango production is limited by various pest and diseases at all stages of its development, right from the seedling in the nursery to the fruits in storage or transit (Alemu, 2014). Among the various pests limiting the successful production is plant parasitic nematode which are non-segmented microscopic, eel-like round worms, obligate parasite possesses stylets that live in soil causing damage to plants by feeding on roots or plant tissues. Zemtmyer *et al.* (2009). Ganye and Gire are among the 21 Local Government Areas of Adamawa State and are among the major production area of mango in the State. However, there is little or no study on plant parasitic nematode associated with mango. Therefore, this study was conducted to identify the different genera of plant parasitic nematode associated with Mango (*Mangifera indica* L.) and to determine the most prevalence nematode species in the study area.

MATERIALS AND METHODS

Survey Locations

The survey was conducted in two Local Government Areas of Adamawa State; Ganye and Girei. Ganye lies between latitude 8° 26' 5.89N and Longitude 12° 03' 3.85E. The mean annual temperature of the study area is between 32.3°C (maximum) and 19.6°C (minimum) while the average annual rainfall total is 1,231 mm (Kadams *et al*., 2020). While Girei lies between Latitude 9 0 11' -9 0 39'North and longitude 120 21' -120 49' East of the Greenwich Meridian. The area falls within the Northern Guinea Savannah Zone and has a tropical wet and dry climate (Adebayo, 2012).

Sampling Criteria

Mango farm was purposely selected from each location using Agricultural Development Project (ADP) structure as a guide to locate the representative of mango fields in the state and local government area. The criteria for selecting mango farms for sampling was based on the accessibility, availability of farmers and their willingness to allow the collection of soil sample (Ononuju, 2015).

Sampling Method and Collection of Samples

A total number of 120 soil samples were randomly collected for the survey (using random sampling method) from the rhizosphere of each tree showing symptoms of retarded growth and stunted growth by digging a hole with a radius of 3-5 cm from the base of the plant stand and at a depth of 0-30 cm. Two to 3 kg of soil samples were collected from each field, poured into polythene bags and labelled properly with details of the location of the farm, and transported to the laboratory of the Department of Crop Protection, Modibbo Adama University, Yola for nematode extraction and identification (Coyne *et al.,* 2007).

Nematode Extraction

Nematodes were extracted from 250 cm^3 of composite soil of each location using a modified Tray-technique as described by Bilgrami and Gaugler (2014). The extracted nematodes were identified and counted while viewing with a compound microscope at magnification of x10 in a Doncaster counting dish, and the mean nematode population was recorded. Identification of the plant parasitic nematode according to genera was done using a pictorial key as described by Mekete *et al*. (2012).

Data collection

Data were collected based on prevalence of plant parasitic nematodes, frequency of occurrence and nematode population density (Haougui *et al*., 2017). The data collected for frequency of occurrence was calculated in percentage frequency of occurrence formula described by (Haougui *et al*., 2017). The formula is indicated below:

FO=n/N×100

Where n= number of times an individual nematode occurred in the sample

N = sample size

S/N	Nematode Genera	(%) Frequency Of Occurrence	(%) Nematode Population (250cm^3)
1	*Helicotylenchus* spp.	35.54	25.5
2	*Tylenchulus* spp.	27.75	17.8
3	*Pratylenchus* spp.	18.12	12.1
4	*Rotylenchulus* spp.	16.82	10.8
5	*Trichodorus* spp.	11.66	8.7
6	*Meloidogyne* spp.	11.23	8.2
7	*Radopholus* spp.	8.06	6.1
8	*Longidorus* spp.	6.76	4.8
9	*Xiphinema* spp.	6.46	4.5
10	*Scutellonema* spp.	4.60	3.6

Table 2: Frequency of Occurrence and Nematode Population in Gboko LGA

S/N	**Nematode Genera**	**(%) Frequency Of Occurrence**	**(%) Nematode Population (250cm^3)**
1	*Tylenchulus* spp.	31.14	20.1
2	*Helicotylenchus* spp.	25.75	22.8
3	*Pratylenchus* spp.	22.57	13.8

10	*Histotylenchus sp.*	5.3	3.6
11	*Rotylenchulus* spp.	3.59	3.0

DISCUSSION

Results from the microscopic examination of the soil samples collected from the study areas (Ganye and Girei LGA) within the rhizosphere of mango trees (at a depth of 0-30 cm) indicated the presence of eleven (11) different genera of plant parasitic nematodes associated with mango tree. The genera include; *Tylenchulus* spp., *Helicotylenchus* spp., *Rotylenchulus* spp., *Meloidogyne* spp., *Radopholus* spp., *Scutellonema* spp., *Xiphinema* spp., *Scutellonema* spp., *Histotylenchus* spp., *Trichodorus* spp. And *Pratylenchus* spp. These aforementioned genera pf PPN have previously been reported by various researchers to be among the major PPN associated with horticultural tree crops across the globe (Santos and Martinelli, 2016; Pranaya *et al*., 2020; Rawhat *et al.*, 2021).

Among nematodes genera encountered from 120 soil samples, collected from Ganye and Girei LGA, *Helicotylenchus* spp. and Tylenchulus spp. had the highest frequency of occurrence value (35.54 and 31.14% respectively) and also the most prominent genera in terms of population density (25.5 and 20.1% respectively). However, Pranaya *et al.* (2020) while surveying for nematodes associate with big fruit trees in Odisha, India found *Rotylenchulus* spp. as the most prominent species in soil samples collected within the rhizosphere of mango trees with 96% frequency of occurrence and 25.54% population density. The variation in diversity and abundance might be due to various edaphic factor within the study area. These findings agree with the assertion of Rawhat *et al.* (2021) that the diversity of nematodes and other micro-organisms depends upon the ecological and edaphic factors of their habitat. Altitude, temperature, and moisture like ecological factors play a vital role; soil pH and nutrients also greatly affect nematode populations and abundance (Rawhat *et al.* 2021).

CONCLUSION AND RECOMMENDATIONS

From the result of this study, it is inferred that ten and eleven genera of PPN were discovered to be associated with mango tress in Ganye and Girei respectively. However, among the various genera of PPN encountered, *Helicotylenchus* spp. and *Tylenchulus* spp. Were the most prominent species encountered. More these species of PPN have high tendency of parasitizing mango tress especially when they come in contact with roots by syphoning water and essential nutrient from the plant vascular system. In light of this, it is recommended that management and control measures should implemented in order to curb the multiplication and spread of these nematode species to other regions. More so further studies should be conducted to ascertain the magnitude of damage caused by these aforementioned PPN.

ABSTRACT
This study investigated the nutritional composition of watermelon seeds and rinds for possible uses as food and animal feed. Field experiment was conducted between August and November 2019 in Ogbomoso to determine the variability of vitamins and phytochemical contents among the pulp, seed and rind of four watermelon varieties (Sugar baby, Kaolack, Grey belle and Collos F1). At fruit maturity, six fruits per varieties, weighting 3 kg, were randomly selected for analyses. The results showed that Kaolack pulp has the highest concentration of vitamin C (8.16 mg/100g) while the seeds and rinds of Collos F1 have the highest concentration of vitamin E (0.130 mg/100g) and A (450.00 µg/100g), respectively. For all varieties, the highest value of lycopene was obtained from the pulp when compared with rinds and seeds. This implies that, although the rind and seed are often discarded, they have sufficient vitamins and minerals for human consumption. This is in addition to being useful as animal feed.
Keywords: *Mineral Content, Pulp, Rind, Seed, Watermelon, Varieties, Vitamin Content*

INTRODUCTION

Watermelon (*Citrallus lanatus* (Thunb) Matsum. and Nakai) belong to the family cucurbitacea, Genus: citrullus and species: lanatus (Paris, 2015). It is an economical important fruit crops known for its sweet and juicy pulp (Munisse *et al.,* 2011). Watermelon fruit has both nutritional and medicinal values (Gwana *et al*., 2014). It is a rich source of phytochemical compounds, which are beneficial for human health and well-being (Abu-Reidah *et al.,* 2013). Watermelon rind which is usually light green or white contains many hidden nutrients and it is edible, but most times it is avoided and discarded due to its unappealing flavor (Johnson *et al.*, 2012; Mohan *et al.*, 2016). Its rind and seed have high carotenes (Alpha, Beta and Gamma) which can be converted to vitamin in the body.

Despite the availability of fruits and other sources of vitamin A, World Health Organization (WHO, 2009) database on vitamin A deficiency (1995-2005) showed that approximately one third of children under the age of five around the world is suffering from vitamin A deficiency, which is estimated to claim the lives of 670,000 children under the age of five annually (Black *et al*., 2008). The highest prevalence is in developing countries of which Southeast Asia and Africa continents are not spared. The rind and seed also contain high potassium and magnesium which help to relax nerves and muscle and keeps blood circulating smoothly (Amin et al., 2014). Sometimes the rind is applied as feeds to animals or as fertilizer materials to crops (Erukainure *et al.*, 2010). In Africa, watermelon seeds may be ground into a coarse flour and oil may be extracted from them (Lim, 2012; McGuire, 2011).

Watermelon fruit contains a significant amount of citrulline for improvement of erectile dysfunction (Mandel *et al.*, 2005). It possesses high level of antioxidant which helps to fight harmful free radicals that can damage the body cell. It has diuretic and cleansing properties that make it beneficial for those with certain kidney and bladder diseases and also contains sufficient amino acid, beta-carotene which prevents ailment such as heart diseases (Naz *et al.*, 2014). The lycopene content which gives the fruit its colour play a role in the protection of prostrate and oral cancer (Gwana *et al.,* 2014). The mineral contents are good for preventing

conditions such as lowering high blood pressure, stroke and help to decrease the risk of kidney stone and bone loss due to old age (Sabo *et al.*, 2013).
Watermelon fruit is an important fruit crops that is underutilized. When it is used as fresh fruit or processed into juice, it generates much waste in the form of rind and seeds (Asghar *et al.,* 2012). Although the seeds are considered waste and have been shown to be highly nutritive and contain large amounts of proteins and many beneficial minerals (Sonawane et al., 2016). The knowledge of the nutritive content of various parts of the watermelon fruit will encourage their consumption in diverse ways and re-utilization of the vast amounts of seeds and rind discarded as waste. The nutrient value of many fruits, seeds and their rind has not received much attention and these are at times discarded, even with their hidden nutrients (Johnson *et al.,* 2012). Recently, more attention has been paid to the utilization of by-products and wastes, as well as underutilized agricultural products. Such utilization will contribute to maximizing available resources and can also result in the production of new foods (De Corato et al., 2018; Stevens et al., 2018). In Nigeria, there is dearth information about watermelon and its seeds and rind, but the indications are that it has versatile uses.
This study focusses on four distinct watermelon varieties, known for their unique attributes, and analyze the variations in nutrient content among the pulp, seed, and rind of each variety. By investigating these differences, we aim to shed light on the potential health benefits associated with consuming various parts of the watermelon and explore novel opportunities for value addition in the food industry.

MATERIALS AND METHOD

Experimental site

A Field experiment was conducted in 2018 at the Teaching and Research Farm, Ladoke Akintola University of Technology, Ogbomoso, Nigeria Oyo State, Nigeria. Ogbomoso lies on latitude 18°10' N, longitude 4°16' E, and located in the Guinea savanna zone of Southwest Nigeria. The temperature of the area ranges from 28 to 33°C with relative humidity of about 75% all year except in January when the dry wind blows from the North. Rainfall distribution is bimodal and extends for eight to nine months of the year. On the average, the total annual rainfall is about 128 mm.

Treatment

The treatments consisted of four varieties of watermelon viz: Sugar baby, Kaolack, Grey belle and Collos F1. At fruit maturity, six fruits per varieties weighting 3kg were randomly selected to assess the nutritional contents. The selected fruits were cut vertically into two equal parts using a sharp kitchen knife, and the pulp, seeds and rind were extracted separately to determine their vitamin A, C and E, mineral, proximate and phytochemicals contents. Data collected were subjected to analysis of variance according to Statistical Analysis System (SAS Institute, 2021) and treatment means were compared using Duncan multiple range test at 5% probability level.

RESULTS

The results of vitamin contents of the pulp, seed and rind of fresh watermelon varieties is presented in (Table 1). Statistical assessment shows that the vitamin A was generally higher in the rind than the pulp and seed (Table 1). Vitamin A content of Collos F1 rind was the highest (450 µg /100g) while the lowest of 80 µg /100g was obtained from Grey belle pulp. Vitamin C content was the highest in pulp than the seed and rind (Table 1). The highest vitamin C content of 8.16 mg/100g was obtained from Kaolack pulp while the least of 1.14 mg/100g was obtained from Collos F1 seed. Vitamin E content was significantly($p>0.05$) higher in the seed than the pulp and rind. Kaolack seed had vitamin E content of 0.120 mg/100g which was significantly ($p>0.05$) higher than 0.034 mg/100g of Collos F1 pulp. Potassium content was highest in the seed and rind than the pulp, with Kaolack seed containing the highest concentration (1144.5 mg/100g) of potassium while Sugar baby pulp had the least (664.2 mg/100g) value. In terms of micro-minerals, the rind of all the four varieties had the highest iron. The highest iron content was obtained from Kaolack rind (11.3 mg/100g) while the least of 1.4 mg/100g was obtained from Sugar baby seed.

Table 1: Vitamin content of pulp, seed and rind of four varieties of watermelon

Treatment	Sugar baby	Kaolack	Grey belle	Collos F1

Vitamin A(µg/100g)				
Pulp	110.00b	130.00a	80.00d	100.00c
Seed	230.00d	290.00b	280.00c	350.00a
Rind	310.00c	430.00b	310.00c	450.00a
Vitamin C(mg/100g)				
Pulp	6.45d	8.16a	6.72b	6.51c
Seed	1.51b	1.65a	1.45c	1.41c
Rind	4.26d	4.88a	4.43c	4.78b
Vitamin E (mg/100g)				
Pulp	0.038b	0.043a	0.038b	0.034c
Seed	0.100c	0.130a	0.100c	0.120b
Rind	0.040b	0.040b	0.040a	0.060a
Potassium				
Pulp	664.2d	666.5c	686.9b	689.3a
Seed	1082.5c	1144.5	1126.3b	1044.4d
Rind	977.2c	972.1d	993.4b	1022.2a
Iron				
Pulp	0.61b	0.62a	0.55d	0.58c
Seed	0.14d	0.19b	0.17c	0.25a
Rind	1.44a	1.53b	1.35d	1.46c

Means along the row with the same letter(s) are not significantly different from each other using Duncan Multiple Range Test at 5% probability level

The result of phytochemicals content of pulp, seed and rind of four watermelon varieties are presented in Table 2. The result showed that highest lycopene content of 11.28 mg/100g was obtained from Kaolack pulp but significantly ($p>0.05$) different from what was obtained from Collos F1 pulp (11.25 mg/100) while the least of 2.49 mg/100g was obtained from Grey belle rind (Table 2). Highest Carotene content of 9.86 mg/100 g was obtained from Kaolack rind and significantly ($p>0.05$) similar to 9.84 mg/100g obtained from Grey belle rind while the least of 0.15mg/100 was obtained from the Sugar baby seed (Table 2). Generally, Phenol content was significantly($p>0.05$) higher in the rind than the pulp and seed of all the four watermelon varieties (Table 4). Phenol content of 0.114 mg/100g was obtained from Kaolack seed which was significantly ($p>0.05$) higher than 0.114 m/100g obtained from Grey belle seed that was the least phenol content but significantly ($p>0.05$) similar to 0.115 mg/100g obtained from Sugar baby seed (Table 2)

Table 2: Phytochemicals content of pulp, seed and rind of four varieties of watermelon

Treatment	Sugar baby	Kaolack	Grey belle	Collos F1
Lycopene (mg/100g)				
Pulp	11.03c	11.25a	11.21b	11.28a
Seed	6.69c	6.98a	6.65d	6.96b
Rind	3.05a	3.02b	2.49d	2.78c
Carotene C(mg/100g)				
Pulp	8.20c	8.69a	8.08d	8.27b
Seed	0.15d	0.18b	0.16c	0.28a
Rind	9.43d	9.86a	9.84b	9.81c
Phenol (mg/100g)				
Pulp	0.118b	0.119a	0.114d	0.116c
Seed	0.115c	0.121a	0.118b	0.124d
Rind	0.133c	0.144a	0.130d	0.141b

Means along the row with the same letter(s) are not significantly different from each other using Duncan Multiple Range Test at 5% probability level

DISCUSSIONS

The pulp, seed and rind of the four varieties of watermelon fruits were analyzed for vitamin and phytochemical contents. The value obtained for vitamin A content of Collos F1 watermelon rind (450

µg/100g) was higher than that of the findings of Johnson et al. (2013) for watermelon (15.73 µg/100g). The present result was also higher than the finding of Aremu and Nweze (2017) on watermelon (350.12 µg/100g). From the result, it was observed that all the watermelon fruits varieties studied are good sources of vitamin A. In general, this study showed that vitamin A content is higher in watermelon rind than the pulp and seed. This observation is in agreement with the findings of Setiawan et al. (2001), who reported that watermelon rind is an important source of vitamin A. Vitamin C was higher in the pulp than the seed and rind. Similar result was reported by Johnson et al. (2013) on watermelon. The highest vitamin C values obtained for pulp (8.16 mg/100g) in this study is close to the vitamin C content of watermelon (9.39 mg/100) reported by Johnson et al. (2013). The presence of Potassium helps to regulate high blood pressure (Daffodil *et al*., 2016). Iron is one of the important elements in the diet of infant, pregnant woman and nursing mother to prevent anemia (Oluyemi et al., 2006). This implies that watermelon seed and rind are good sources of minerals elements which play various physiological functions in the body.
This shows that the rind of watermelon which is often discarded can be used to provide feed supplement for livestock. Campbell, (2017) reported that fruit with low carbohydrate content are good for diabetic and hypertension patients.

CONCLUSION
The results of this study showed that watermelon fruits are good sources of vitamins, minerals, phytochemicals are in abundant in the rind and seed which are often discarded are good sources of vitamin and minerals elements which play various physiological functions in the human body. The vitamin A can help combating Vitamin A deficiency which has been a major public health problem in many developing countries including Nigeria. Also the presencce of potassium in abundant which is one of the important minerals in the body which helps to regulate fluid balance, muscle contractions, reduced blood pressure and osteoporosis. Also, the rind and seed can also be used in animal feed.

ABSTRACT

Horticultural crop production plays a significant role in the economic and health sectors of a country. The tremendous food loss despite increased production is a cause for concern to meet the no poverty and zero hunger target in developing countries by 2030. Green technology has brought tremendous change in revolutionizing agriculture in all its facets, ranging from planting to post-planting operations. The main concern of this paper is to present some applications of green technology in horticulture such as the application of edible coatings and films and light emitting diode (LED). Edible coatings enhance shelf life by reducing percentage weight loss, retarding physicochemical changes, and delaying fruit ripening, while edible films function as an effective carrier for antimicrobials, and led emitting diode (LED) with red light enhances the total phenolics, anthocyanins, lycopene, α-tocopherol, and other compounds in several fruits and vegetables. These technologies save produce from loss through microbial infection, respiration rate and improved antioxidant quality general management, which leads to eradicating hunger, increasing productivity and profits and improving nutrition. This overview is about the current novel technologies to be adopted for reducing postharvest loss and waste.

***Keywords**: Horticultural crops, No poverty, Zero hunger, Green technology*

INTRODUCTION

The Food and Agriculture Organization (FAO) has projected over the years that Nigeria, on average losses \$9 billion (about ₦3.5 trillion) annually to postharvest waste. Fruits and vegetable production is globally challenged by food loss and waste, economy, and climate change among others. Strokes have been passed on poor infrastructure, inefficient logistics, low technology know-how, insufficient skills, inadequate knowledge, poor managerial ability of supply/value chain actors, and lack of markets for the increasing rate of food loss during production, postharvest and processing stages of fruits and vegetables (Ncama et al., 2019). The acceptability and quality of fruits and vegetables accessed by consumers are based on the physico-chemical attributes. The properties range from produce maturity stage, physical appearance (shape, size and colour), attractiveness of the colour (vibrancy), absence of dirt, pest infestation and disease signs. Other quality attributes could be attributed to the sugar content of produce, both fresh or processed form Gholamipour et al., 2010; Mandal et al., 2018). There are a few innovative green postharvest technologies adopted to improve the shelf life, nutritional quality and physical attributes of fruits and vegetables.

Edible Coating

Edible coatings are regarded as green technology because it is safe, sustainable, and environmentally safe. A perfect coating material must be odourless, tasteless, safe for consumption and flexible (Prasad and Batra, 2005). Edible coatings act as a bar of exchange of gases and moisture between produce and its immediate environment. It is a thin layer of about 0.3 mm made from degradable materials either encased or covered around the surface of fruits. The essence of coating is to delay respiration process, slow down ethylene production and microbial growth as recorded by Kahramanoğlu et al., (2020); Wan et al., (2021). As shown in Table 1, edible coatings are categorized into three; Lipid-based material, protein-based material, and polysaccharide-based materials. A combination of different types can also be adopted to achieve optimum results (Pascall and Lin, 2013). Edible coatings have been widely accepted and observed to reduce weight loss by a range of fruits and vegetables sweet cherries, peaches, and plums (Hazrati et al 2017; Kumar et al 2018). Applying edible coatings also reduces loss of quality during storage of fruits and vegetables by forming a semipermeable gas barrier around the produce to obstruct transpiration process, regulate O_2 and CO_2 gases exchange between the in-situ atmospheric condition of the fruits and the ambient environment. Therefore, edible coatings can enhance shelf life by decreasing weight loss, retarding physicochemical changes, and delaying fruit ripening.

Edible Films

Edible film solutions are prepared by dissolving (plasticizer) in solvents (water, alcohol or a mixture of both). The essence of adding plasticizer to the solvent is to improve the flexibility and elasticity of the film. To improve the functionality, other additives (colors, flavours and antimicrobial agents) can be added to the solution (Janjarasskul and Krochta, 2010). According to Hambleton et al., (2009), edible films functions as effective carrier for antimicrobials, they vary from Polysaccharide-based edible films (carrageenan and chitosan), Hydrocolloid-based edible films (alginate and carboxymethylcellulose; CMC) which can be used as an effective barrier to non-polar aroma compounds thereby reducing aroma loss and oxidation and prevent moisture losses Dragich and Krochta, (2009) respectively. Edible chitosan film combined with bioactive compounds and essential oils reduces *Escherichia coli* and *Listeria monocytogenes* and quality enhancement of broccoli (Alvarez et al., 2013).

Light emitting diode (LED) Technology

This technology embraces the significance of light in plant growth and sustenance. Light is a significant factor that influences energy availability for photosynthesis and the leadway to a wide range of physiological and biochemical processes in plants. The led emitting diode (LED) technology produces monochromatic light (blue, red, blue and white light) within 400 nm and 700 nm wavelengths. According to Massa et al., (2008), the wavelength specificity, long lifespan, low thermal energy, and non-toxicity of LED lights are recently been observed for their postharvest techniques to increase the life span and sustain the quality of fresh produce. The quality of light has been proven to affect the quantity and rates of phytonutrients in plants (Yeow, 2020). Surrounding light with red enhanced the total phenolics, anthocyanins, lycopene, α-tocopherol, and other compounds in several fruits and vegetables.

CONCLUSION

Adopting the appropriate postharvest technologies can drastically reduce the economic loss caused by postharvest losses of produce. Reducing these losses has the potential to improve food availability and minimize waste to the lowest percentage. Over the years, green postharvest technology practices (use of edible coating and ultraviolet) have been adopted to enhance nutritional quality and sustain the postharvest properties of produce. Furthermore, to reduce food waste and loss due to postharvest diseases, antimicrobial application of LED technology could be applied. Edible coatings and films are regarded as alternative packaging and not a replacement for synthetic packaging methods. Edible films double as a method of reducing postharvest losses and environmental pollution in the long term. Nonetheless, to maintain the quality and extend the shelf life of horticultural produce, various technical hitches and economic challenges must be subdued to increase the chances of developing countries in modern trade. The various green technology methods have limitations, therefore integrated methods should be adopted for the desired result. The implementation of the combined treatments may be of future research focus especially for industrial use.

Increased effort on efficiency and cost-effectiveness is essential to provide efficiency and cost-effectiveness for the industry.

ABSTRACT
This research was designed to study the pathological effect of Cucumber mosaic virus (CMV) on Vernonia amygdalina plants. This was with the aim to determine the susceptibility status of the plant to CMV infection. Thirty five apparently healthy V. amygdalina plants were raised in the screen house for two weeks before mechanical inoculation with a virulent CMV strain. Enzyme linked immunosorbent assay (ELISA) and reverse transcription polymerase chain reaction (RT-PCR) methods conducted for viral detection in leaf samples, four weeks after inoculation both recorded zero CMV incidence. Symptoms severity/development evaluation after four weeks revealed 34 of 35 test plants with zero symptom severity scores. An extremely low percentage mean symptoms severity score of 0.571 % (1/175) was obtained with percentage disease resistance score of 99.429 %. The data obtained from this research were indicative of the tendency of V. amygdalina to present absolute resistance to the CMV.
Keywords*: Cucumber mosaic virus (CMV), Vernonia amygdalina, Disease resistance.*

INTRODUCTION

Vernonia amygdalina that many people call bitter leaf is a popular shrub that grows to a height between two and five metres. It is a commonly cultivated plant in Nigeria and other countries located in the African tropics (Igile *et al*., 1994). *Vernonia amygdalina* is a perennial, multipurpose, rapid, regenerating, soft-wooded plant with a bitter taste. Anti-nutritional phytochemicals within the plants are responsible for its bitter taste (Bonsi *et al*., 1995). The leaves are consumed as green leafy vegetable. Its richness in minerals and vitamins has made it an important human diet (Sobukola *et al*., 2007). It has a wide folkloric uses against diverse tropical diseases. More importantly it has gained wide application in the treatment of amoebic dysentery (Moundipa *et al*., 2000), gastrointestinal disorders (Akah and Ekekwe, 1995), blood sugar regulation, blood tonic, antimicrobial and antiparasitic activities (Akinpelu, 1999; Hladik *et al*., 2005). Some of the identified bioactive compounds of *V. amygdalina* responsible for its ethnobotanical uses include alkaloids, saponins, terpenes, flavonoids, phenolic acids, steroids, anthraquinone, coumarins, sesquiterpenes, xanthones and edotides (Izevbigie, 2003; Cimanga *et al*., 2004; Muraina *et al*., 2010). It is cultivated widely because of its nutritive, medicinal and economic values.

Cucumber mosaic virus (CMV) was first described in detail in 1916 on cucumber and other cucurbits simultaneously by Doolittle and Jagger (Zitter and Murphy, 2009). CMV is a plant pathogenic virus in the family Bromoviridae and a type member of the plant virus genus, *Cucumovirus*. CMV has a worldwide distribution (both in tropical and temperate climates) and noted to have the widest host range for any plant virus (Palukaitis & García-Arenal, 2003), including more than 1200 species in over 100 families of dicotyledonous and monocotyledonous angiosperms. It is transmitted by more than 75 species of aphids in a non-persistent manner and through the seed in some plant hosts. Experimentally, it is easily transmitted by mechanical inoculation of plant sap. It is an economically important disease in a large variety of crop plants. CMV causes a systemic infection in most host plants. Symptoms of CMV can vary greatly depending on the crop infected and the age of the plant when infection occurs. CMV causes mosaic in cucumber, melon and other cucurbits; blight (withering) in spinach; mosaic, string-like leaf and systemic necrosis in tomato; mosaic and ringspot in pepper; mosaic and stunting in clover, lupins and Lucerne. They also cause stunting in soybean; mosaic and infectious chlorosis in banana; and mosaic and dwarfing in many other species of dicotyledonous and monocotyledonous plants (Palukaitis, 2003). Subgroup I strains have been shown to be more virulent in crops than the subgroup II strains (Wahyuni *et al*., 1992; Zhang *et al*., 1994).

Annually, one of the major challenges of crop cultivation in Nigeria leading to very low crop yield and poor market value of harvested produce is the high perennial incidence of viral-like diseases on farms (Mohammed *et al*., 2017) with CMV among the predominant viruses. However, there is no report of any research work conducted to study the impact of CMV in *Vernonia amygdalina* production in Nigeria. In view of the potential devastating impact of CMV on many crop productions leading to severe economic losses, this research was designed to study the pathological effect of a virulent isolated Nigerian CMV strains on *Vernonia amygdalina* plants. The outcome of this research work will assist in the placement of the bitter leaf as either a part of host-range crops of CMV or otherwise. It may also be useful in the creation of biological agent(s) from the studied crop that may be helpful in the control of CMV on farms.

MATERIALS AND METHODS

Thirty five (35) *Vernonia amygdalina* plants were raised in the screen house from stems cut from apparently healthy plants. The stems were potted in 10 litre size perforated plastic buckets filled with sterilized manured loamy soil. The newly emerging shoot from the *Vernonia amygdalina* stems were mechanically inoculated after two weeks with the virulent CMV Group I strain with NCBI GenBank Accession KM091952 that was previously isolated from tomato and preserved in cowpea within the screen house.

Preparation of inoculation buffer (pH 7.2): To 1 litre of water, 14.2g sodium phosphate dibasic (0.1M), 13.61g potassium phosphate monobasic (0.1M), 3.722g EDTA (0.01M) and 0.121g L-Cysteine (0.001M) were added. Few drops of 2-Mecarpto-ethanol were added to the inoculation buffer just before use.

Protocol for inoculation of tomato seedlings: Inoculation of potted test plants was carried out 4 weeks after potting of plants. The inoculum was prepared by grinding the leaves obtained from CMV positive reservoir plants and homogenization with the inoculation buffer. Carborundum was sprayed on selected leaves of potted test plants and inoculum gently rubbed on leaves. The plants were rinsed with distilled water to enable clear observation of viral symptoms.

Evaluation of CMV symptoms development and severity rating in inoculated plants: The symptom severity evaluation was conducted for a period of 4 weeks after inoculation. Symptom severity in plants was evaluated according to the symptom severity scale described by Friedmann *et al*. (1998) as follows: 0 = no visible symptoms, inoculated plants showed same growth and development as uninoculated plants (control); 1 = very slight yellowing of leaflet margins on apical leaf; 2 = some yellowing and minor curling of leaflet ends; 3 = a wide range of leaf yellowing, curling and cupping, with some reduction in size, yet plants continue to develop; 4 = very severe plant stunting and yellowing, pronounced leaf cupping and curling, and plant growth stops and 5 = wilting, dryness or death of plant.

Serological indexing for CMV detection in inoculated plants: Leaf samples were collected from inoculated plants after 4 weeks and tested for the presence of CMV using the enzyme linked immunosorbent assay (ELISA) technique. ELISA antiserum set and the control were obtained from Plant virus collection centre of Leibniz-Institut Deutsche Sammlung Von Mikroorganism und ZellkulturenBraunschweig (DSMZ) Germany. Antigen coated plate enzyme-linked immunosorbent assay (ACP-ELISA) method was used for the detection of CMV as described by the manufacturer's manual available on: https://www.dsmz.de/fileadmin/_migrated/content_uploads/ACP-ELISA.pdf . Assessment of results were carried out by spectrophotometric measurement by placing the plate in the ELx 800 universal multiscan ELISA microplate reader provided with 405 nm filter and the reading was taken after 1 hour and overnight. Samples with values exceeding twice the reading of the healthy control were considered positive.

Nucleic acid Extraction: The cetyltrimethyl ammonium bromide (CTAB) method was used for nucleic acid extraction from the leaf samples as described by Abarshi *et al*. (2010) and Dellaporta *et al*. (1983). CTAB RNA extraction buffer pH 8.0 was made by mixing 2% molecular biology grade cetyltrimethyl ammonium bromide powder (Sigma H6269) (w/v), 100 mM Tris-HCl, 20 mM EDTA, 1.4 M NaCl, and 0.2% β-mercaptoethanol (v/v) (was added just before use). From each leaf sample, 100 mg was grinded in 1000 µl of nucleic acid extraction buffer in a sterile mortar and pestle. The sap was poured into new sterile tube and vortex briefly before incubating in water bath at 60 ºC for 10 mins. The plant sap was brought to room temperature and equal volume of the mixture containing phenol, chloroform and iso-amyl alcohol in the ratio 25:24:1 was added. Sap was vortexed, centrifuged at 12000 rpm for 10 mins and 450 µl of the supernatant were pipetted into new sterile tube**.** Cold isopropanol 300 µl was added, mixed and sap incubated for 1 hr at -20 ºC. The mixture was centrifuged at 12000 rpm for 10 mins to sediment the DNA. The supernatant was gently decanted to ensure the pellets were not disturbed. 500 µl of 70% ethanol was added to the pellets and centrifuge at 12000 rpm for 5 mins. The ethanol was decanted and the RNA was air dried at room temperature. RNA pellets were suspended in 50 µl TE buffer for further use and storage at -80 ºC.

Reverse Transcription Polymerase Chain Reaction (RT-PCR) : With the aim of amplifying the 3' end of the CP (Coat protein) gene and C-terminal noncoding region of RNA3 of CMV, RT-PCR was carried out using the CMV specific primers, 5' GCC GTA AGC TGG ATG GAC AA 3' and 5' TAT GAT AAG AAG CTT GTT TCG CG 3' as described by Wylie *et al*. (1993). The PCR mix used for cDNA synthesis and amplification in a one step reaction contains 2 µL of the template RNA, 1 µL of 10 pm reverse primer, 1 µL of 10 pm forward primer, 3 µL of 25 mM $MgCl_2$, 10 µL of PCR buffer, 1 µL of 10 mM dNTP, 0.24 µL of reverse transcriptase (1 U/µL) and 0.24 µL of Taq polymerase (1 U/µL) (Promega USA). RT-PCR was accomplished with the amplification programmed for one cycle cDNA synthesis of 44 ºC for 30 min and 95 ºC for 5 min and 35 cycles of amplification with 45 sec of denaturation at 95 ºC, 45 sec of annealing at 54 ºC and 45 sec of extension at 72 ºC followed by one cycle of final extension for 7 min at 72 ºC. The RT-PCR products were analyzed by 1.5% agarose gel electrophoresis.

RESULTS

CMV symptoms development/severity evaluation in mechanically inoculated *Vernonia amygdalina*: Out of the 35 mechanically inoculated test plants, only 1 plant presented very mild leaf mosaic symptom of a score of 1 as shown in Table 1. There were no symptoms of leaf mottling, distortion, filiformity, stunted growth, wilting and plant death in test plants. Thirty four test plants (34/35) recorded zero symptom severity scores with no observable defect. An extremely low percentage mean symptoms severity score of 0.571 % (1/175) was obtained. The percentage disease resistance score of 99.429 % was also recorded.

ELISA Test: The result of the ELISA (Table 2) for 35 tested leaf samples presented values between the range of 0.092 and 0.147 which are well below the reference value of 0.42 for the positive (twice the value of the healthy sample). The buffer sample recorded an ELISA value of 0.2 while the disease control produced a value of 3.102. This outcome revealed all tested samples as sero-negatives and disease control as sero-positive. Hence, all test plant samples were clean with zero CMV incidence (0/35) of CMV.

RT-PCR test: As shown on the agarose gel (Plate 1) and Table 3, the expected PCR amplicons of 500 base pairs were observed in only the disease control samples and not in any of the 35 test plants and buffer samples. This finding correlates with the ELISA results and further confirmed the absence of CMV in all tested samples.

DISCUSSION

The data obtained from the symptoms severity and development evaluation in test plants (Table 1) were indicative of the absolute or high degree resistance possess by the *V. amygdalina* to CMV and perhaps many other related viruses. The results of the ELISA (Table 2) and RT-PCR test (Plate 1 and Table 3) which revealed zero CMV incidence in inoculated samples (0/35) were also glaring pointers to the tendency of the plants to present absolute resistance to the CMV. The presence of numerous peculiar bioactive compounds in bitter leaf have been reported by Igile *et al*. (1995) and many other researchers (Farombi and Owoeye, 2011). More than thirty compounds belonging to several classes of compounds with different biological activities have been isolated and characterized from *V. amagdalina (*Oyeyemi *et al*., 2018). The list includes sesquiterpene lactones like vernolide, vernodalol, vernodalin, hydroxyvernolide, vernodalinol, vernomygdin, epivernodalol, 11,13-dihydrovernodalin and 3′deoxyvernodalol; flavonoids like luteolin, luteolin 7-O-β-glucuronoside and luteolin 7-O-β-glucoside; steriod glycosides like vernonioside B_1 and steriod saponins like vernoamyosides A, B, C and D (Quasie *et al*., 2016). The sesquiterpene lactones are unique to *V. amygdalina* (Abay *et al*., 2015) and have been shown to be the main active compounds responsible for most of the plant's activities ranging from antibiotics, antischistosomal, antiplasmodial, antioxidant, anti-inflammatory and anticancer activities (Luo et al., 2011). Oyeyemi *et al*. (2018) also reported that the activities shown by the plant were likely due to synergistic reactions of the individual components.

The biologically active compounds of *Vernonia amygdalina* are saponins and alkaloids (Muraina *et al*., 2010), terpenes, steroids, coumarins, flavonoids, phenolic acids, lignans, xanthones and anthraquinone (Cimanga *et al*., 2004), edotides (Izevbigie *et al*., 2003) and sesquiterpenes (Ohigashi *et al*.,1994). These compounds are likely to possess antiviral properties preventing viral replication and migration from the point of infection to other parts. Sudhanshu *et al*. (2023) reported the inhibition of virus by luteolin, luteolin-7-o-βglucoside, vernodalol, vernolepin, vernodalin. Although not yet to be proven, it is not out of place to presume that resistance to CMV is achieved through the inhibition of activities of CMV replicase enzyme and movement protein which are responsible for the replication of viral nucleic acid and cell-to-cell spread of the virus respectively, by bioactive compounds present in bitter leaf.

RECOMMENDATIONS

The findings of this research work are expected to educate farmers and stake holders on the resistance of *V. amygdalina* to CMV. This may also be an eye-opener to the use of bitter leaf as a natural, affordable biological agent in the sustainable control of the notorious CMV on susceptible crops. Hence, more researches along this line will be needed.

Table 1: CMV symptoms severity evaluation test in *Vernonia amygdalina*

SOCIO-ECONOMIC CHARACTERISTICS OF TURMERIC (*Curcuma Longa* L.) FARMERS IN OTUKPA, OGBADIGBO LOCAL GOVERNMENT AREA, BENUE STATE

Igbegwu, F.C., Ikoro, J.I., Ngbede S.O, Ogenyi M.O., Ajoba F.
National Horticultural Research Institute, Idi Ishin, Jericho, Ibadan Nigeria

Corresponding author: Ikoroj@gmail.com

ABSTRACT
The study was conducted to determine the socio-economic characteristics of turmeric farmers in Otukpa, Ogbadibo LGA of Benue State. Purposive sampling was used to collect data from forty-one (41) farmers across Otukpa and analyzed using descriptive statistics such as frequency and percentages. Results obtained indicated that 40.8% of the farmers are female and 59.20% are male. The mean age of the farmers was 45.5 years and 71.23% of the farmers are in their active ages (36 – 55). 58.5% of the farmers are married, 36.6% of the farmers are illiterate, 85.37% had farm size of >1 ha and the farmers earned an average annual income of ₦6,403.28. The constraints identified are inadequate finance (97.6%), lack of technical skill (95.1%), lack of improved varieties (95.1%), pest and disease (92.7%), bad road network (85.4%), high cost of transportation (73.2%). The study recommended that enlightenment programs be used to encourage more farmers to engage in the production of turmeric due to its numerous health benefits, the economic benefit derivable from its production and also the should mobilize themselves into viable cooperatives so that they can gain from the use of pooled resources and finances in cooperatives. This will go a long way in ensuring food security, increasing the earnings and improving the livelihood of the smallholder farmers.
***Keywords**: Socio-economic, Turmeric (Curcuma Longa L.), descriptive statistics, percentages*

INTRODUCTION

Turmeric (Curcuma longa L.) is a monocotyledonous, herbaceous, rhizomatous spice belonging to the ginger family Zingiberaceae. The genus name curcuma is probably derived from the Persian word 'kurkum' a name also applied to saffron. Turmeric is called as 'Yellow gold', 'Indian saffron', and 'The golden spice of life'. It is considered the “Queen of Spices” and one of the top most used spices in the world. It has diversified uses such as turmeric powder, dried rhizomes and as curry flavor preparation for meat, fish, vegetables, pulses etc. Besides, it is used in medicine and cosmetics and as dye in textile industries. In addition to its role in the colourants of curries, these compounds have been reported to have anti-inflammatory Lukita-Atmadja et al., (2002), anti-arthritic, anti-oxidant, anti-allergic, anti-bacterial (Chattopadhyay et al., 2004; Fagbemi et al., 2009), anti-cancer (Duvoix et al., 2005), and anti-viral (HIV) properties (Ammon and Wahl, 1991).
Literature revealed that India is the world’s largest producer of turmeric supplying 94% of the world’s demand and spread from India to Southeast Asia, China, Northern Australia, the West Indies, and South and Central America (Nwaekpe, *et al.,* 2015 and Gopalan , *et al.,*2000).
Nigeria can play a leading role in turmeric production considering the prevailing favorable soil and climatic conditions in the country. With increased awareness on the benefits of turmeric among the users and its use in a number of processed products, the demand for turmeric is increasing. Turmeric is a good cash crop for Nigerian and other African countries as its production requires low technology, less capital investment, and it can be grown with comparatively less use of fertilizer.
However, it is worthy of note that demands for agricultural produce (Tumeric inclusive) had for a long time out-strip supply especially in developing countries like Nigeria. Similarly, Tomato yields in smallholder cropping systems in Africa have generally been found to be far below potential (Maliwichi et

al., 2014). Hence, it may be said that domestic production of tumeric does not meet its high demand especially in developing countries probably because tumeric is not sustainably produced due to certain constraints. To ensure that smallholder farmers are consistent in their production, several issues need to be analysed and addressed. Action must therefore be taken to help small scale farmers in identifying and overcoming constraints that reduce the production of tumeric. It is therefore imperative to determine the socio-economic characteristics of turmeric farmers in the study area and also the constraints facing the farmers.

MATERIALS AND METHODS

The study was carried out in Otukpa, Ogbadibo LGA, of Benue state, Nigeria. Benue State is delineated into three agricultural zones, namely; Northern zone (A), Eastern zone (B) and Central zone (C). The state comprises (23) local government areas with Makurdi as the state capital. It is located between longitude 7° 47' and 10° 0' East and latitude 6° 25' and 8° 8' North. It shares boundaries with five other states namely; Nasarawa state to the north, Taraba state to the east, Cross-River state to the south, Enugu state to the south-west and Kogi state to the west. The state also shares a common boundary with the Republic of Cameroon on the south-east. Benue state occupies a landmass of 34,059 square kilometers. Benue State has an estimated population of 5,741,815 million persons (NBS, 2006).

The state enjoys a tropical climate which manifests into two distinct seasons. The rainy season is from April to October with total annual amount ranging between 1120 – 1500mm, while the dry season is from November to March. Temperatures are constantly high averaging between 28^{o} – 32^{o}c. Physiographically, the land is level and made up mainly of undulating plains at elevations ranging from 150m to 300m above sea level. The major crops grown here include, rice, yam, cassava, groundnut, millet, soybeans, maize, citrus, mango, sorghum, sweet potatoes, cocoyam, guava, oil palm, tomatoes, cowpea, cashew and okra. Small ruminants such as goat, sheep, and non-ruminants such as swine, rabbits and poultry are also reared in the state. Purposive sampling technique was adopted in selecting the farmers in the various districts in Otukpa. A total of forty-one (41) farmers were selected and data was collected through a structured interview guide which cover all aspect of the objective was used to elicit information from the farmers in the study area. Descriptive statistics such as frequency and percentage was used for data analysis.

RESULTS AND DISCUSSION

The Socio-economic characteristics of turmeric farmers such as gender, age, education, family size, occupation level, land holding and average on-farm income are presented in (Table 1). The result shows that 40.8% of the farmers are female and 59.20% are male indicating that there more female farmers engaged in the production of turmeric. The mean age of the farmers was 45.5 years. 71.23% of the farmers are in their active ages (36 – 55). This implies that most of the farmers in the study areas are in their active and productive age. Also, 58.5% of the farmers were married, 29.3% were single and 12.2% were separated / divorced. The predominance of married persons implies that these are responsible individuals who are ready to improve their livelihood and that of their families, since; marriage is often associated with occupational stability and responsibility Olojede, *et al*., (2011)**.**

A greater percentage of the farmers are illiterate 36.6%, followed by Diploma holders (22.0%) and primary education holders (17.1%). This implies that more respondents were illiterate with low possibility to utilize information on agriculture for enhanced food production. Kadte *et al*., (2018) also observed low level of education among turmeric growers in his study. A greater percentage (85.37%) had farm size of >1 ha, which implies that the respondents are small scale farmers. Commercialization of the sector is still an issue in Nigeria. Thus, farmers who have the monetary resources and ability to increase their farm size have the tendency to increase their farm outputs. The constraints to turmeric production are numerous and are shown in Table 2, it reveals that the major constraint as shown in the table 2 are inadequate finance (97.6%), lack of technical skill (95.1%), lack of improved varieties (95.1%), pest and disease (92.7%),bad road network (85.4%), high cost of transportation (73.2%).

CONCLUSION

Tumeric production is dominated by 30.8% of the farmers are female and 44.2% are male. The mean age of the farmers was 45.5 years and 77.23% of the farmers are in their active ages (36 – 55). 58% of the farmers are married, 35.50% of the farmers are illiterate, 82.0% had farm size of 1-2 ha and 75.0% of the farmers earned an average annual income of ₦6,403.28. The constraints witness by the farmers are inadequate finance (97.6%), lack of technical skill (95.1%), lack of improved varieties (95.1%) pest and disease (92.7%), bad road network (85.4%), high cost of transportation (73.2%). The study recommended that enlightenment programs be used to encourage more farmers to engage in the production of turmeric due to its numerous health benefits and also the economic benefit derivable from its production and also the should mobilize themselves into viable cooperatives so that they can gain from the use of pooled resources and finances in cooperatives. Turmeric is profitable to the growers especially when grown in a large scale with improved varieties. This will go a long way in ensuring food security, increasing the earnings and improving the livelihood of the smallholder farmers.

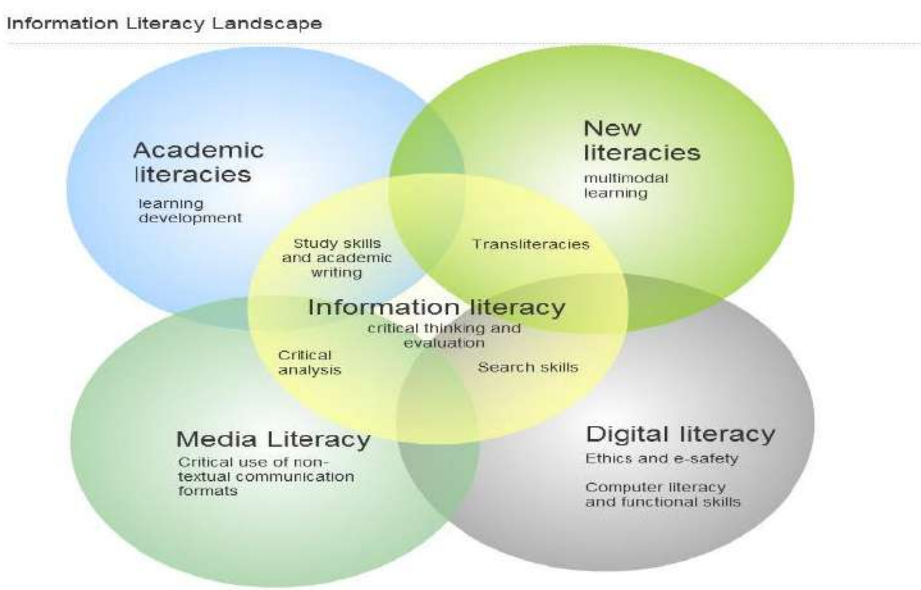
PROPER RECORD KEEPING FOR ENHANCEMENT OF INFORMATION LITERACY IN NIGERIAN HORTICULTURE

Adelowo E.O
Information and Documentation Department, National Horticultural Research Institute (NIHORT)
PMB 5432, Idi ishin Ibadan

ABSTRACT
Horticulture plays an important role in every area of human endeavor. Availability of information from research output contributes to increase in production and utilization of horticultural crops. Information literacy remains an issue to be given proper attention as low information literacy among farmers and other stakeholders can affect productivity due to low utilization of information. Proper record keeping of research output and information is vital in ensuring that farmers, policy makers and other stakeholders are abreast of latest technologies and breakthrough in horticultural crops production. On the other hand, there is need to increase visibility of research information from research institutes, Universities and private sectors in the areas of horticultural crops research. This will enhance visibility and information literacy among farmers, policy makers and other actors along the value chain.
Keywords: *Horticulture, information literacy, record keeping*

INTRODUCTION

Horticultural information availability and accessibility are important in ensuring food security and safety in Nigeria. Information is product of research and other human activities. Uptake of research information contributes significantly to food production, security, economic empowerment and improved livelihood. Information literacy is important in utilization horticultural information. Information literacy involves abilities to recognize, locate, evaluate and effective use of available information to meet various needs. Other requirement for information literacy include awareness and engagement with the digital world, usefulness of acquired information, articulation of acquired information, information use ethics, how to communicate info ration to other users and how to evaluate information for credibility and authority. (ALA, 2016) Information literacy is enhanced by knowledge acquisition. Sources of information and its landscape as shown in figure 1 play vital roles in information availability and utilization.



Source: Coonan and Jane (2014)

In enhancing information literacy, the role of record keeping cannot be over emphasized. Credibility of records goes a long way in supporting its relevance and trust by information users. The need for accurate records keeping and how records that are vital are managed in organization like research institute should be given adequate attention. Records keeping involve supervision and administration of digital or paper records to ensure availability and easy retrieval when needed (Kirvan, 2023). Records are materials which contain information which are created, executed or received, and further maintained as evidence and information by an organizations or persons. It can be used in pursuance of legal obligations or in the transaction of business. Horticultural research outputs can be termed as records covering agronomy, crop protection and utilization of products. Such records serve as basic tools for planning; monitoring and decision making that bring out efficiency and effectiveness in farmers, institutions and cooperate farming organizations. Horticultural Farming operations and decisions can be based on the available information carried out, processed, stored and retrieved when needed for daily decision making in research environment. Research institutions create records to support and provide evidence of their transaction in various formats either through paper based or electronic format.

Management and keeping of records in research institutions includes utilizations of information stored as records which serve as important resources to record keeping. Records management helps an organization get the costs and risks that can come with poorly managed records. This can improve crop yield and farmers productivity as they are abreast of latest information and technological breakthroughs n the areas of horticultural crops production. Proper record keeping has positive effect on workers' productivity and promotes proper agribusiness management Gomathy *et al*.,2022; Manteaw *et al.,* 2021). Therefore, research institutions must keep and manage vital records well; so that they can be used for day-to-day running of farming activities. Due to the importance of records in farming operations, there is need for proper management as tools for literacy among seekers of information in horticulture.

Research institutes must establish and cautiously manage and keep vital records by some levels of confidentiality, proper maintenance, security and preservation of such documents must be well managed for retrieval (Uwaifo, 2004., Akporhonor *et al.,* 2004). Retrieval of available information can be of great benefit to horticultural crop farmers. According to Igwokwe *et al.,* 2012, reading is an essential tool for lifelong learning and improvement. However, paper-based documentation in organizations such as Research institutes, polytechnics, colleges of educations and universities' hardcopies continue to be viewed as a factor affecting information availability, utilization and information literacy levels among users.

PROBLEMS OF RECORD KEEPING IN NIGERIA

According to (Afolabi 1999) record management practice in Nigeria has a number of problems. These include insufficient skilled and experienced record management personnel and possibly, low priority of record management in the scheme of things. Trained and qualified records managers should be in charge and handle records properly so as to end the loss and misplacement of vital records are not absorbed into the system. Lots of problems encountered in records keeping in research institutions which are mentioned above and others are lack of record manuals, and filling guidelines, difficulty in retrieval and lack of appreciation to staff and the management.

IMPROVING VISIBILITY TO ENHANCE HORTICULTURAL INFORMATION LITERACY

Research institute should see electronic records as means of organizing and keeping vital records. Staff should be adequately trained in the area of records and archival management. Records management policy should be set in place in all research institution so as to eradicate inefficiency of records keeping management. High premium should be placed on records that have enduring and evidential value. Poor management of records causes loss of correspondences and other useful information. Misplacement of vital documents useful for populating institutes data base and which are beneficial to farmers affects literacy level of horticultural information seekers. In a research carried out in NIHORT, over 60% of respondents were of the opinion that there is need to computerize the institute library as a means to enhance visibility and horticultural information literacy among stakeholders while >80% were not sure of the availability of useful horticultural materials in the library (Table 2) This may have affected the frequency of visit to the library as most library users visit the library Cooneman and Jane (2014), identified digital literacy as one of the factors affecting information literacy.

Table 1: Frequency and percentage views of respondents on effect of computerization on information literacy

Item	SD	D	NS	A	SA	U
Computerization of information will increase reliability	4 (3.3)	-	-	30 (25)	78 (65)	4.3
Awareness of valuable horticultural information in research library	2 (1.7)	1 (0.8)	100 (83.3)	-	17 (14.2)	3.2

Source: Field survey, 2017

Note SD: strongly disagree; D = Disagree; NS = not sure; A = Agree; SA= Strongly agree and U=undecided.

CONCLUSION

Due to the importance of information and its utilization for human development, there is need for proper horticultural crops record keeping as it is necessary in improving farmers efficiency in order to increase food security and environmental conservation.

ABSTRACT

Agro-morphological variations, earliness and fruit yield were evaluated in 20 tomato accessions at the National Horticultural Research Institute (NIHORT), Ibadan, Nigeria. Eleven elite tomato accessions (obtained from the World Vegetable Centre) and nine accessions (obtained from NIHORT) were evaluated. The study was conducted in a randomized complete block design with three replications. The tomato lines were transplanted to the field at 50cm x 50cm spacing. Plot size for each cultivar was 2m x 2.5m. The descriptors for tomato (IPGRI, 1996) was used to characterize the accessions. Data were collected on days to 50% flowering and fruiting, fruit set (%), and fruit yield. The result indicated high agro-morphological diversity among the cultivars. Three plant growth types were observed among the tomato accessions. Semi-determinate dominated with 60.87 % while determinate and indeterminate growth types were 17.39 % and 21.74 % respectively. Foliage density ranged from sparse to dense with most of the cultivars exhibiting intermediate foliage density (65.22 %). Fruit blossom end were flat (81%), indented (13.64%) and pointed (4.55%). Days to 50% flowering ranged between 27 in Ibadan Local to 40 in AVTO 0301while 50% fruiting ranged from 34 days in Ibadan Local to 45 days in AVTO 1219. Number of fruits and fruit weight per plant was significantly highest in Cherry 19 (261 fruits) and Ker-Ojik 22 (141 t/ha) respectively. The variations exhibited by these tomato accessions can be harnessed for selection and hybridization in tomato breeding programs.
