HORTSON Ogbomoso 2023

PROCEEDINGS OF THE 41st ANNUAL Conference

HORTICULTURAL SOCIETY OF NIGERIA (HORTSON)

Theme

Application of Science, Technology and Artificial Intelligence in Production and Practices of Horticulture

DATE

November 12 - 16, 2023

VENUE

LADOKE AKINTOLA UNIVERSITY OF TECHNOLOGY, OGBOMOSO

EDITORS

Akanbi, W.B., Olaniyi, J.O., Olabiyi, T.I., Olatunji, O.O., Ipinmoriti R.R., Adesina, J.M., Ajayi, E.O. and Ojo, O.O.

PROCEEDINGS
OF
41st ANNUAL CONFERENCE
OF
HORTICULTURAL SOCIETY OF NIGERIA (HORTSON)

OGBOMOSO 2023

HOSTED BY:

LADOKE AKINTOLA UNIVERSITY OF TECHNOLOGY (LAUTECH), OGBOMOSO, OYO STATE, NIGERIA

THEME

APPLICATION OF SCIENCE, TECHNOLOGY AND ARTIFICIAL INTELLIGENCE IN PRODUCTION AND PRACTICES OF HORTICULTURE

NOVEMBER 12 - 16, 2023

EDITORS

Akanbi, W.B., Olaniyi, J.O., Olabiyi, T.I., Olatunji, O.O. Ipinmoriti R.R., Adesina, J.M., Ajayi, E.O. and Ojo, O.O.

PROCEEDINGS OF 41ST ANNUAL CONFERENCE OF HORTICULTURAL SOCIETY OF NIGERIA (HORTSON) HELD ON NOVEMBER 12 – 16, 2023 AT THE GREAT HALL, LADOKE AKINTOLA UNIVERSITY OF TECHNOLOGY, OGBOMOSO, OYO STATE, NIGERIA

Publishers of the Nigerian Journal of Horticultural Science (NJHS)

A. Council Members of the

HORTICULTURAL SOCIETY OF NIGERIA (HORTSON)

1	Prof. R. R. Ipinmoroti	President in Council
2	Dr (Mrs) O. O. Idowu-Agida	Vice President 1
3	Dr. Abdul-Rafiu A. Monsur	Vice President 11
4	Dr. E. O. Ajayi	Secretary General
5	Dr. B.N. Okafor	Assistant Secretary 1
6	Mr. J. Raymond	Assistant Secretary 11
7	Dr (Mrs) S.Y. Yusuf	Treasurer
8	Dr. J. M. Adesina	P.R.O.
9	Dr (Mrs) B. O. Fagbola	Business Manager
10	Dr (Mrs) E.A. Adeyemi	Coordinator Fruits
11	Mr. U.M. Nasiru	Coordinator Ornamentals
12	Prof. A.A. Muhammad	Coordinator Vegetables
13	Prof. W. B. Akanbi	Editor –In- Chief (NJHS)
14	Dr. Usman Ibrahim	Ex-Officio I
15	Dr. O. O. Alamu	Ex-Officio II

B. LOCAL ORGANIZING COMMITTEE Executives

1.	Prof. W. B. Akanbi	Chairman
2.	Dr. O. O. Olatunji	Secretary
3.	Prof. J. O. Olaniyi	Treasurer

C. LOCAL ORGANIZING SUB-COMMITTEES

Technical and Review

1. **Prof. T. I. Olabiyi**
2. Prof. W. B. Akanbi
3. Dr. Olatunji O.O.
4. Dr. Ojo Olayinka

Finance

1. **Prof. J.O. Olaniyi**
2. Prof. B.A. Lawal
3. Prof W.B. Akanbi

Fund Raising

1. Prof. G. O. Adesina
2. Prof Olagunju
3. Dr. S. I. Adetumbi

Welfare & Protocol

1. Prof. (Mrs). E.A. Ewetola
2. Mrs. Akinde
3. Dr. Mrs R. F. Asafa
4. Mr E.A. Ojo
5. Dr. Olayioye A.
6. Mr I.A. Raji
7. Dr. Odewole
8. Dr. Shittu M.D.
9. Dr. Akintonde

..

Accommodation & Transport

1. Prof. O. A. Olaniran
2. Mr O.J. Gbadegesin
3. Mr E.O.Ajiboye
4. Mr Segun Omoleye
5. Mr Gbenga Adeleke
6. Mr E.A. Ojo

Exhibition

1. Prof. M.A. Azeez
2. Prof P.A. Babajide
3. Dr. I. O. Adesiyan
4. Dr Shittu M.D.

Field Trip

1. Prof K. A. Adelasoye
2. Mr E.A. Ojo
3. Dr Olayioye Adesanya
4. Dr Shittu M.D.

Publicity

1. Dr. Ojo Olayinka.
2. Dr. Olatunji O.O.
3. Mrs. Akinde
4. Odun Gbadegesin
5. Mr O.J. Ojo

Registration and Logistics

1. Prof. B. A. Lawal
2. Dr (Mrs) F.M. Owoade,
3. Dr. Akintonde
4. Dr. Olayioye Adesanya;
5. Mr. Raji Akintunde
6. Mr. Oladiran Ojo
7. Mr. Odun Gbadegesin
8. Dr Ojedokun
9. Dr. M.O. Ganiu

Technical

1. Prof. T. I. Olabiyi Chairman
2. Prof. W. B. Akanbi
3. Prof. O. S. Olabode
4. Prof. J. O. Olaniyi
5. Prof. R. R. Ipinmoroti
6. Dr. J. M. Adesina (PRO)
7. Dr. Ibrahim Usman (ABU, Zaria)
8. Dr. Abdul-Rafiu Monsur (NIHORT)
9. Dr. H. A. Akintoye (NIHORT)

PRESIDENTIAL ADDRESS AT THE OPENING CEREMONY OF THE 41ST ANNUAL CONFERENCE OF THE HORTICULTURAL SOCIETY OF NIGERIA (HORTSON) HELD AT THE LADOKE AKINTOLA UNIVERSITY OF TECHNOLOGY, OGBOMOSO, OYO STATE NIGERIA ON WEDNESDAY 15TH NOVEMBER, 2023

The Chairman of this occasion,
His Excellency, The Executive Governor of Oyo State,
Honourable Minister of Agriculture and Rural Development, Abuja,
Honourable Commissioners of Agriculture and Environment, Oyo State,
His Royal Highnesses here present,
The Vice Chancellor, LAUTECH, Ogbomoso,
The Chief Executives of Sponsoring Organizations,
Members of the Local Organising Committee, Ogbomoso 2023,
All Invited Guests and Fellows of HORTSON,
Distinguished Members of HORTSON,
Gentlemen of the Press,
Ladies and Gentlemen

I honourably welcome everyone to the 41st Annual Conference of this great Society, The Horticultural Society of Nigeria (HORTSON) holding here in LAUTECH, Ogbomoso, one of the ancient cities of Yoruba land, the land of valiant, and the second largest city in Oyo State (the Pacesetter State). I want to greatly appreciate our host, the Vice Chancellor **Professor Razaq Olatunde Rom Kalilu,** for his acceptance and support to host this Conference. This University is one of the top most ranked state Universities in Nigeria and unarguably, a nationally renowned Organic Agricultural practicing centre in Nigeria, As part of his support, the Vice Chancellor has provided the best of facilities on ground for a successful opening ceremony, this was in addition to other facilities for concurrent plenary sections during this conference. I want to use this opportunity to appreciate the entire University Management Staff, In-house Unions and particularly the Local Organizing Committee for working tirelessly in order to have a befitting conference.

The theme of this year's conference is **"Application of Science, Technology and Artificial Intelligence in Production and Practice of Horticulture".** This focuses on how to increase horticultural crops production in the midst of numerous challenges through the use of available research findings in Sciences, Technologies and Information Communication devices as tools. Horticultural trees and vegetable crops remain the surest solution to poverty eradication and food security and major means to improve the standard of living, income generation and foreign exchange earnings. Therefore, practicable knowledge of Science, Technology and Artificial Intelligence could be harnessed by individuals and government to enhance production under strict land tenure system. This will enhance cultivation, yield and income generation derivable from the production of horticultural crops.

Various government policies that could encourage and or mandate the adoption of Scientific and Technological recommendations as well as the use of ICT are needed in the areas of soil, crop managements, farmer security and easy access to credit facilities. It is my belief that this gathering of academia will come up with resolutions that will provide lasting solutions that will make our country not only secure for the citizenry but also to the farmers in particular with the sole aim to promote self-sufficiency in food production as well as increase in revenue generation. In order for this to become a reality, we have here today selected seasoned speakers for this year conference to do justice to the topic.

Let me state here that preparation towards the National Summit for all Horticulturists in Nigeria to review and set a draft document towards registration of the proposed Council for Regulation of Horticulture (CORHORT) in Nigeria is at its peak and necessary observation or information from members toward this could be sent to the council using info@hortson.org.ng. This will make horticulture a profession and enable production of horticultural crops that are safe for consumption by accredited bodies a reality.

In the last two years, the membership strength of the Society has increased and we appreciate the efforts of both the old and new members of the society on this, it has been a joint effort by all. However, we seek your continued support in the promoting of the society in our various institutions. The promise of the Council members is that, the HORTSON as a Society will continue to employ every available means to add value to each registered member, it is a promise that we shall keep. Therefore, we encourage everyone to share their academic research and publication challenges with the society because a problem share is a problem half solved.

As I stated in my first year speech as the PIC, the Nigerian Journal of Horticultural Science (NJHS) had enjoyed the full support from the Council. The number of issues per Volume has increased to four yearly. The Journal remains one of the most highly cited in the field of Agriculture in Nigeria today. I want to appreciate the Editorial team for this success. Some of the recent issues for the Volume 27 are here today for the purpose of launching. I am sure that many of our dignitaries will be generous towards considering the present high cost of production.

Fellow members of HORTSON, I want to appeal to every one of us that we should improve on our financial performance as registered members of the Society. The annual due is a must for all members. This is the major source of fund to run the Society. The insecurity in the country has affected attendance at our past annual conferences, and this had affected attendance and payment of annual dues. However, we appreciate the strong commitment of our Fellows, Associate and Student members, who despite the prevailing economic challenges, still find it necessary to be present at our conferences. Thank you all.

In conclusion, my appreciation goes to the entire Council members, the LOC Chairman and his team for their efforts at organising this 2023 Annual Conference. Ladies and Gentlemen, I wish to thank you all for your support and for finding time to attend this opening ceremony despite the economic challenges facing our country. My profound gratitude goes to our Host, The Vice chancellor, **Professor Razaq Olatunde Rom Kalilu**, for making this Conference a memorable one and to our distinguished Fellows of HORTSON for their present here today.

Thanks and God bless you all.

Long live the Horticultural Society of Nigeria

IPINMOROTI, R. Rotimi (PhD)
PRESIDENT-in-COUNCIL

**WELCOME ADDRESS BY THE ACTING VICE CHANCELLOR,
LADOKE AKINTOLA UNIVERSITY OF TECHNOLOGY, OGBOMOSO,
PROF R. O. ROM KALILU
AT THE 41ST ANNUAL CONFERENCE OF HORTICULTURAL SOCIETY OF NIGERIA
HELD AT LADOKE AKINTOLA UNIVERSITY OF TECHNOLOGY, OGBOMOSO, NIGERIA
ON WEDNESDAY 15 NOVEMEBR 2023**

Protocols

Your Excellency, the Executive Governor of Oyo State,
Visitor to the University and Chairman of this Occasion,
Honourable Commissioner for Agriculture,
Royal Majesties and Highnesses,
Vice Chancellors of other universities,
Principal Officers of this University,
Distinguished stake holders in Horticulture,
Distinguished ladies and gentlemen.

It is a great pleasure for me to welcome you all to the Ladoke Akintola University of Technology, Ogbomoso, a beautiful university set within the serene and peaceful land of the valiants whose other preoccupation is traditionally horticulture. It is also my privilege to welcome you to this year's conference of the Horticultural Society of Nigeria, the 41st in its series. The Horticultural Society of Nigeria, established in 1997, promotes the advancement and development of the science and art of Horticulture in Nigeria. Horticultural practices remain the surest solution to poverty eradication, food security and a major means to improve standard of living, income generation and foreign exchange earnings in Nigeria. The theme of this year's conference, "Application of Science, Technology and Artificial Intelligence in Production and Practice of Horticulture" cannot be more appropriate for a conference hosted by a university of technology, moreover by the prestigious Ladoke Akintola University of Technology, Ogbomoso. The University has been consistently rated high in world university rankings and has been consecutively adjudged to be the best state university in Nigeria for several years. It is currently the 7th overall best Nigerian university for research. This University has a lot to contribute to this theme and the studies of horticulture. The University is blessed with abundant cultivable lands and a very rich pool of remarkable scholars in diverse disciplines whose research orientations are technology based. The University is also into large scale production of horticultural crops like ginger, turmeric and lemon grass as well as cashew plants produced under organic conditions, and which placed the University on global recognition as the first certified organic horticultural crops producers in Nigeria. While wishing you fruitful deliberations, I want to assure you of this University's commitment to partner with diverse stakeholders in the horticultural sector to boost research and productions towards economic development and food security across the globe.

Thank you for your attention

KEYNOTE ADDRESS PRESENTED AT THE 41ST ANNUAL CONFERENCE OF THE HORTICULTURAL SOCIETY OF NIGERIA (HORTSON) HELD AT THE LADOKE AKINTOLA UNIVERSITY OF TECHNOLOGY, OGBOMOSO, OYO STATE NIGERIA ON WEDNESDAY 15TH NOVEMBER, 2023

TOPIC:
URBAN HORTICULTURAL TECHNOLOGY AS A VERITABLE STRATEGY IN ENHANCING FOOD SECURITY AND POVERTY ALLEVIATION

BY
Odunayo Clement ADEBOOYE,
PhD (Ibadan), Fellow UNU, Fellow DAAD, Fellow AvH
Vice-Chancellor, Osun State University, Osogbo

Preamble:
I want to express profound gratitude to the Executive Committee of the Horticultural Science Society of Nigeria (HORTSON) for inviting me to function as the Keynote Speaker at this 41st Annual Conference of the professional body. I particularly thank the Ag Vice-Chancellor of LAUTECH, Prof ROM Kalilou for allowing me entry into LAUTECH and for warmly welcoming me into this campus. I want to thank the generality of our association (HORTSON) for counting me worthy and for unanimously agreeing to my nomination to deliver this keynote to mark the commencement of our 41st Annual Conference and meeting holding here in Ogbomosho. This type of Lecture often offers policy institutions the opportunity to gain ideas for public policy formulation in order to drive regional and national development in the area of food security. My speech today will centre around the theme of this conference to catapult our nation-Nigeria to achieve food security. The Yoruba people say, "*Bi ounje ba ti kuro ninu ise, ise buse*". The same people also say, "*Oun ti a o je lagba oun ti a o se*". In their wisdom, the same people say, "*Ebi kii wo inu ki oro miran wo*". Satirically too, the Yoruba people say, "*Eni ebi n pa ko gbo yago*". The English also say, "*The three basic needs of human are Food, water and shelter*". The meaning is that food is the first unnegotiable option for human survival. Even in prison, where people are supposed to be serving some forms of punishment, food is provided to keep the inmate alive so that he can serve punishment. You can see how critical food is. This is the reason that we should start to interrogate the state of horticultural food production in Nigeria and thus place our interests correctly to develop and motivate the producer-the farmers, the food sellers-marketers and the value addition sectors-Processors. We should thank the eaters-Consumers…….. This is the reason that I will engage you in the next 30 minutes or so to chat with you on the topic, "**Urban Horticultural Technology as a Veritable Strategy in Enhancing Food Security and Poverty Alleviation"**

Introduction
Horticulture, the science and art of cultivating fruits (Pomology), vegetables (Olericulture), and ornamental plants (Floriculture), is undergoing a remarkable transformation in the face of advances in Science, Technology and Artificial Intelligence (AI). These advancements are not only shaping the future of horticulture but are also instrumental in addressing the pressing challenges of global food security, sustainability, poverty alleviation, climate change adaptation, resource use efficiency etc.

United Nations' Committee on World Food Security (2013) defined food security as when all people, at all times, have physical, social and economic access to sufficient, safe and nutritious food that meets their dietary needs and food preferences for an active and healthy life. But we have a shocker as documented in the Holy Bible Deuteronomy 15:11, "*the poor will never cease to be in the land*" and seems to be in direct contradiction to Deuteronomy 15:4, "*there will be no poor among you, since the LORD will surely bless you in the land which the LORD your God is giving you as an inheritance to possess*." Can food security as defined by the UN be a reality? By 2050, food demand is projected to increase by 59–98% in order to feed 9.7 billion people, of which 70% will be living in urban areas (United Nations Department of Economic and Social Affairs, 2019).

Saifaddin Galal (2023) in 2023 reported that nearly 12% of the world population in extreme poverty lived in Nigeria, considering the poverty threshold at US$1.90 a day. While the number of people living in extreme poverty in Africa was estimated to reach 422 million in 2025. With a fast-growing population of nearly 240 million, Nigeria is the leading country in Africa by number of inhabitants. For this reason, among others, the burden of unemployment has been prevalent over the years, leaving the labor dependency ratio forecast at 2.6% in 2022. In that year, the total labor force was estimated to increase to over 67 million. Together with the rising active population, the number of unemployed residents was also estimated to grow to reach over 63 million in 2021.

Overall, the unemployment rate in Nigeria has increased considerably, rising to 9% in 2020. Urbanization is an irreversible global trend, with more than half of the world's population now residing in cities. This rapid urban growth poses significant challenges, including ensuring food security for urban populations and addressing poverty, particularly in vulnerable urban communities. Urban horticultural technology has emerged as a promising strategy to tackle these challenges, offering a multitude of benefits. This paper discusses the role of urban horticultural technology in enhancing food security and poverty alleviation in urban and peri-urban areas. Over the recent years, urban farming has revealed its superiority over conventional farming (Keong and Mahkeswaran 2021). Conventional farming often adopts environmentally unsustainable practices, which can lead to deforestation, land degradation, environmental pollution, excessive water usage, and high carbon footprint (Clercq *et al.*, 2018). The drawbacks of conventional farming, along with the fast reduction of arable land, give rise to the development of urban farming – a practice of cultivating, processing, and distributing crops and livestock in urban areas (Mok *et al.*, 2020).

The current Urban farming techniques are:

1. Vertical farming: The concept of vertical farming is to farm up instead of farm out. Fish and vegetable crops in vertical farming are grown in vertically stacked layers on rooftops, building facades, or inside commercial or residential buildings, restaurants, grocery stores, greenhouses, warehouses, or shipping containers (Benke and Tomkins 2017)

2. Indoor farming: The method of growing plants and crops on a large or small scale entirely indoors and with the help of hydroponics and artificial light is known as Indoor Farming or Indoor gardening. Artificial light is required for providing the plant with nutrients and it also contributes to plant growth.

3. Hydroponics: It involves plants growing in soilless media where their roots are directly submerged in nutrient-rich solution (Jai *et al.*, 2018)

4. Aeroponics: It involves spraying nutrient-rich solution onto the plant roots periodically (Rahman *et al.*, 2018)

5. Aquaculture: entails farming of fish and shellfish in all kinds of water environments (Keong and Mahkeswaran 2021).

6. Aquaponics: combines aquaculture and hydroponics in a symbiotic closed-loop ecosystem. Fish excretes wastes in the form of ammonia. The ammonia is converted into nitrite and then nitrate by nitrifying bacteria. The nitrate-enriched water is pumped to the grow beds and provides natural fertilizer for the growth of plants. In return, the plants clean the water that flows back to the fish tanks (Alyssa *et al.*, 2019)

To explore the full potential and benefits of the urban farming techniques, new technological innovations are evolving such as:

1. Internet of Things (IoT)

It refers to an internet-connected network of multiple physical devices that can collect and share data with minimal human intervention (Kumar *et al.*, 2020). The global IoT platform market size is projected to hit USD 13.310 billion by the end of 2026, with a compound annual growth rate of 28.5% in 2021–2026 (Valuates Report 2020). Instant messaging software can be activated to send early warning alerts and notifications to farm operators so that immediate intervention can be done to prevent farm conditions from worsening (Li et. al., 2019). Multiple IoT-enabled farms can exchange information and interact with one another (Kodali and Valdas, 2018). IoT enables farm operators to remotely monitor their farm conditions in real time from anywhere at any time on any smart mobile devices (Sadiku *et al.*, 2020)

2. Automation

Agriculture involves multiple and repetitive operations, making automation a viable technology to improve urban farming processes (Keong and Mahkeswaran 2021). Hydroponics systems can be automated by deploying sensors to monitor environmental factors (e.g., air temperature, humidity, and light intensity). If any of these factors exceed the ideal conditions for crop growth, their corresponding actuators (e.g., air conditioners, ventilation fans, and grow lights) will automatically rectify the situation. Automating routine processes can significantly reduce manual labour. The implementation of fully automated farms can bring about entire farms managed by just a farm operator (Charania and Li 2020).

3. Artificial Intelligence (AI)

AI is a field of computer science that enables computers and machines to make decisions like human beings (Tian *et al.*, 2020). To make smart decisions independently, computers and machines need to be taught using machine learning (ML) algorithms; these algorithms can be broadly classified into four categories: supervised, unsupervised, semi-supervised, and reinforcement (Sarker 2021). Examples of common ML algorithms are linear regression, logistic regression, support vector machines, Naïve Bayes, decision trees, random forests, k-nearest neighbours, k-means clustering, and artificial neural networks. AI can analyze soil and water, as well as identify potential pests, weeds, and diseased plants so that proper irrigation, specific pesticides and fertilizers can be timely applied to plants that need treatments (Tian *et al*., 2020), hence cut down labour load on farm operators, decreasing yield loss and increasing farm productivity. Precise utilization of resources by AI helps lessen wastes and emissions in production (Mungai *et al*., 2019).

4. Robotics

Robotics is the unity of mechanical, electrical, and computer engineering to fabricate machines that can perform complex tasks based on pre-programmed instructions (Charania and Li 2020). Routine tasks, such as crop monitoring and watering, can be carried out by pre-programmed robots or drones. Required fertiliser or pesticide can be delivered to individual plants in a precise manner by robots. Drones are capable of sustained flight; they can provide a top view of rooftop farms, as well as a deterrence to pests (Sadiku et. al., 2020). Robots allow farm operators to monitor and manage farms without needing to move from their comfort. Tasks that pose hazards, such as handling chemicals and working at heights, can be easily managed by dispensable robots (Aisyah *et al*., 2019).

5. Blockchain

With the introduction of cryptocurrencies like Bitcoin, blockchain technology has elicited substantial attention from many industries. Moving away from a traditional centralised server, blockchain adopts a decentralised, open, cryptographically managed network of blocks to store information (Sadiku *et al*., 2020). Through blockchain, food can be traced back to the production farm, making food regulation more manageable and effective. Blockchain also provides an efficient tamper-resistant avenue to track the food journey through the supply chain, while keeping the consistency of product ownership and reducing the need for inefficient crop certifications. Other product information (e.g., batch number and expiry dates) can be stored; this addresses food safety, traceability, and quality, which in turn combat food fraud, safety recalls, and other supply chain inefficiencies (Mistry *et al*., 2020).

6. Digital Twins

A digital twin is a virtual representation of a physical system which uses simulation and AI to mirror system properties and behaviours in real time, embodying all statuses and information of the physical system. With digital twins, farm operators need not be physically at agricultural site to monitor, control, coordinate, and execute farm operations (Verdouw *et al.*, 2012). Virtual models of farm operating parameters such as energy and water consumption can guide farm operators in decision making, thereby maximizing yields while minimizing energy and water usage (Benis *et al*., 2017).

7. Renewable Energy

Solar energy and wind energy are two well-known clean and renewable energies (Campana *et al*., 2015). Both solar and wind energies can be utilized to power electrical equipment in the farms, for example, air blowers, water pumps, air conditioners, ventilation fans, and grow lights. Agrivoltaics combines crop cultivation and solar energy production with solar panels on the same land area. The shade provided by the panels lowers plant surface temperature and evaporation, decreasing plant drought stress and increasing plant biomass production (Barron-Gafford, *et al.*, 2019). At the same time, the plants reciprocate by keeping the panels cool and lowering panel heat stress (Keong and Mahkeswaran 2021).

8. Nanotechnology

Nanotechnology is the manipulation of nanomaterials with dimensions of less than 100 nanometres (Zhao *et al.*, 2020). Nanoencapsulated pesticides or fertilisers ensure that the optimal amount is administered to the plants, thus enhancing growth while lessening stress on the plants. Other benefits are increased germination success, improved root size and length, and enhanced photosynthetic and nitrogen metabolism activities (Agrawal *et al.*, 2014). Controlled environmental agriculture can be improved by using nanosensors to estimate crop harvest time, detect crop health, and determine microbial or chemical contamination on crops (Keong and Mahkeswaran, 2021).

Benefits of Urban horticultural technology

Local Food Production and Year-Round Availability

Urban horticultural technologies, such as vertical farming, hydroponics, and rooftop gardens, are instrumental in facilitating local food production within cities. By reducing the need for long-distance transportation, these methods minimize food losses and the associated environmental impact. Furthermore, controlled environments enable year-round cultivation of crops, ensuring a consistent food supply even in adverse weather conditions.

Space-Efficient Farming

Urban areas are often characterized by limited space, making efficient land use a necessity. Urban horticultural technology maximizes space utilization through innovative approaches. Rooftops, walls, and small plots can be transformed into productive gardens, effectively addressing the challenge of space constraints and enabling urban areas to meet the growing demand for fresh produce.

Diversification of Crops

A diverse diet is essential for good health. Urban horticultural technology supports the cultivation of a wide variety of crops, including fruits, vegetables, herbs, and even non-traditional crops. This diversification not only contributes to food security but also promotes a balanced diet.

Community Engagement and Job Creation

Urban agriculture is not only about growing food; it also fosters community participation and social cohesion. Community gardens and urban agriculture initiatives empower local residents, including marginalized communities, by providing employment opportunities in cultivation, maintenance, and distribution of produce.

Access to Fresh Produce and Reducing Food Deserts

Urban farming enhances access to fresh, nutritious, and locally grown produce, significantly improving the dietary quality of urban residents. In areas characterized by food deserts, where access to fresh and healthy food is limited, urban horticultural initiatives become a lifeline for better nutrition.

Resource Efficiency and Climate Resilience

Controlled urban horticultural technologies are resource-efficient. For example, hydroponics and aquaponics require less water compared to traditional agriculture. Moreover, the practices employed in urban farming enhance climate resilience by diversifying food sources and reducing the carbon footprint associated with long-distance food transport.

Waste Reduction and Empowerment

Urban horticultural technology can incorporate sustainable waste management practices. By composting and recycling organic waste, these initiatives reduce the overall waste generated by urban areas. Furthermore, they have the potential to empower vulnerable and underserved populations, offering training, resources, and economic opportunities for those who need them most.

Precision Agriculture and Smart Farming

Advances in science and technology is most pronounced in precision agriculture. Modern horticulturists are harnessing the power of remote sensing, imaging, and predictive analytics to optimize their farming practices. Satellites, drones, and ground-based sensors provide real-time data on crop health, growth, and water requirements. AI algorithms then analyze this data to offer insights into resource allocation, enabling farmers to make informed decisions. Predictive analytics, driven by AI, forecasts crop yields, identifies potential diseases, and recommends optimal harvest times. This technology allows for resource-efficient and environmentally sustainable practices.

The advent of smart farming has ushered in a new era of efficiency and automation. Network of sensors and actuators that monitor and control various environmental factors, such as temperature, humidity, and irrigation have also been innovated. Data collected from these sensors is then analyzed using AI, allowing for automated adjustments to optimize growing conditions. Moreover, automated systems, including robots and machinery, are capable of performing labor-intensive tasks such as planting, weeding, and harvesting. This automation not only reduces labor costs but also ensures precision and consistency in farming practices.

Advances in Plant Breeding

Science and technology have significantly impacted the field of plant breeding. Genomics, the study of an organism's entire genetic makeup, has empowered horticulturists to develop crop varieties that are resistant to diseases and more tolerant of changing climates. The rise of CRISPR-Cas9 gene-editing technology has taken this a step further by enabling precise modifications of plant genomes to enhance desirable traits. These innovations in plant breeding hold the promise of addressing food security concerns by creating crops that are resilient and productive in challenging environmental conditions.

Sustainability and Environmental Monitoring

A critical aspect of modern horticulture is sustainability. With the aid of AI, horticulturists are adopting sustainable practices that are eco-friendly and resource-efficient. Biological pest control, for example, is facilitated by AI monitoring systems that track pest populations and release beneficial insects precisely when needed, reducing the reliance on chemical pesticides. Additionally, water management is optimized through AI, ensuring that irrigation schedules are tailored to minimize water use and prevent wastage. AI also plays a pivotal role in climate control, particularly in greenhouses and indoor farming environments. These controlled environments provide ideal conditions for plant growth. AI algorithms can efficiently manage variables like temperature, humidity, and lighting to create the perfect microclimate for crops, ensuring optimal yields and resource efficiency.

Quality Control and Food Supply Chain

Quality control in horticulture is a critical aspect of ensuring that consumers receive the best produce. Computer vision, a technology driven by AI, assesses the quality and ripeness of fruits and vegetables. Automated sorting and grading systems, ensure that only top-quality produce reaches the market. Furthermore, in the food supply chain, AI is instrumental in predictive maintenance, which forecasts equipment maintenance needs, reducing downtime and ensuring the smooth operation of storage and transportation facilities. Additionally, blockchain technology, a distributed and tamper-proof ledger, enhances traceability and transparency in the supply chain. This reduces food spoilage and mitigates the risk of fraudulent practices.

The integration of science, technology, and AI in horticulture is nothing short of a revolution in the way we grow and distribute food. These innovations are essential for addressing the complex challenges of a growing global population, resource scarcity, and climate change. The application of precision agriculture, smart farming, sustainable practices, and advances in plant breeding are not only enhancing food security but are also promoting resource efficiency and environmental sustainability. The fusion of science, technology, and AI is propelling horticulture into a new era of productivity, sustainability, and resilience that will foster food security and poverty alleviation.

Urban horticultural technology is a transformative strategy for promoting food security and alleviating poverty in urban settings. By making the most of limited urban space, diversifying food production, creating jobs, and improving access to fresh produce, urban agriculture contributes to healthier and more sustainable cities. As urbanization continues, the integration of horticultural technology in urban planning becomes not just a choice but a necessity, ensuring that our cities are not only livable but also nourishing and inclusive for all.

Conclusion:

Distinguished ladies and gentlemen, we are all partners in progress to ensure that we help our nation to escape from the present bondage of inefficient and ineffective “food security strategy and poorly implemented policy on development of horticultural business in Nigeria”. The World Bank (2022) reported that Nigeria experienced its deepest recession in two decades, but growth resumed in 2021 as pandemic restrictions were eased and oil prices recovered to counter the economic shock. Nigeria, like other countries in Africa was highly vulnerable to the global economic disruption caused by COVID-19, particularly due to lock down of businesses and farms. Oil accounts for over 80% of exports, a third of banking sector credit, and half of government revenues. In 2021, 40% of Nigerians (83 million people) lived below the poverty line, while another 25% (53 million) were vulnerable. The number of Nigerians living below the international poverty line is expected to rise by 12 million in 2019–23, no thanks to the unpredictability of economic indices on a global scale and general gloomy economic outlook.

As a nation, our economic outlook remains highly uncertain because of the volatility in the oil sector and weaknesses in the financial sector. Even in the most favorable global context, the policy response of Nigeria’s authorities will be crucial to lay the foundation for a robust economy and food security through serious promotion of horticultural business. That policy recovery should be hinged on honest investment in agriculture, particularly horticultural technology. There is nothing that can replace food. Man must eat… Food must always be available for sale to everybody, whether they like it or not. Petrol can be replaced and you may be surprised to see very soon vehicles that will use water as fuel….. The only seriousness we can demonstrate as a nation is to focus on innovative food production through the development of urban horticultural crop technology because it is the only business that cannot and will never fail, for as long as the earth lives.

Distinguished guests, officers of the HORTSON, farmers and other stakeholders, I thank you for tolerating me and for listening.

LEAD PAPER PRESENTED AT THE 41ST ANNUAL CONFERENCE OF THE HORTICULTURAL SOCIETY OF NIGERIA (HORTSON) HELD AT THE LADOKE AKINTOLA UNIVERSITY OF TECHNOLOGY, OGBOMOSO, OYO STATE NIGERIA ON WEDNESDAY 15TH NOVEMBER, 2023

TOPIC: DEPLOYMENT OF ARTIFICIAL INTELLIGENCE IN HORTICULTURAL CROP PRODUCTION

BY
PROFESSOR GODWIN N. UDOM
FACULTY OF AGRICULTURE, UNIVERSITY OF UYO,
UYO, NIGERIA.

BACKGROUND

Horticulture holds significant importance in a country due to its economic, nutritional, and environmental contributions (Cyprian and Ndubisi, 2023). It encompasses the production of fruits, vegetables, flowers, and ornamental plants, which serve as essential components of a nation's food supply, export commodities, and beautification efforts (Jaskani and Khan, 2021). Horticulture plays a crucial role in ensuring food security and promoting healthy nutrition all over the world. The cultivation of fruits and vegetables provides a diverse range of essential vitamins, minerals, and dietary fiber, contributing to a balanced diet and improved public health. Moreover, the ornamental plants and flowers produced in horticulture contribute to aesthetic enhancement, tourism, and the cultural identity of a country. Despite its significance, horticultural crop production in many countries faces several challenges that hinder its full potential, such as limited access to modern agricultural practices and technologies, inadequate infrastructure and storage facilities, pest and disease management, climate variability, and water scarcity. Technology plays a crucial role in addressing the challenges faced in horticultural crop production.

Artificial Intelligence (AI) refers to the simulation of human intelligence in machines, enabling them to perform tasks that typically require human intelligence, such as perception, reasoning, problem-solving, learning, and language understanding. AI systems rely on algorithms, statistical models, and machine learning techniques to process and interpret information, adapt to new situations, and improve their performance through experience. By leveraging technological advancements, farmers can overcome these challenges and enhance productivity (Dinrifo *et al.,* 2022). With the advent of AI in agriculture, new technologies are being implemented to modernize and transform traditional methods of farming. This paper is aimed at identifying and highlighting how AI has been effectively deployed in horticultural production and how it can be further used.

OVERVIEW OF IMPLEMENTING AI TECHNOLOGIES IN HORTICULTURE PRODUCTION

AI technologies are revolutionizing horticulture production by enabling precision agriculture, crop monitoring, disease detection, automation, and data-driven decision-making. Integrating AI in horticulture improves resource management, enhances productivity, reduces environmental impact, and promotes sustainability. As AI continues to advance, horticulturists can leverage these technologies to optimize crop production, address challenges, and meet the increasing global demand for fresh and sustainable produce. Here are some key AI technologies and their applications in horticulture:

1. **Internet of Things (IoT) and Sensors**: IoT devices and sensors play a crucial role in collecting real-time data from the field. These sensors measure parameters such as soil moisture, temperature, humidity, light intensity, and nutrient levels. AI algorithms process this data to provide insights into optimal irrigation schedules, fertilization requirements, and environmental conditions for specific crops. By integrating IoT and AI, horticulturists can make data-driven decisions, ensure resource efficiency, and promote sustainable practices.
2. **Computer Vision and Imaging**: Computer vision technology enables the analysis of images and videos to extract valuable information about plant health, disease detection, and growth patterns. AI algorithms can identify and classify diseases, pests, and weeds based on visual cues, allowing for early intervention. Additionally, computer vision enables the assessment of crop quality, fruit ripeness, and yield estimation; facilitating informed harvesting decisions and post-harvest management.

3. **Robotics and Automation**: AI-powered robots and automated systems are transforming labor-intensive tasks in horticulture. Robots equipped with computer vision and machine learning can perform activities like planting, pruning, and harvesting with precision and efficiency. These technologies reduce the reliance on manual labor, alleviate labor shortages, and enhance productivity. Automated systems can also handle logistics, sorting, and packaging, streamlining the supply chain and reducing post-harvest losses.
4. **Machine Learning and Predictive Analytics**: Machine learning algorithms enable the analysis of large datasets to identify patterns, make predictions, and provide actionable insights. In horticulture, machine learning models can predict crop yields, optimize planting schedules, and recommend optimal nutrient management strategies. By analyzing historical data and environmental factors, AI can help horticulturists anticipate and adapt to changing conditions, mitigate risks, and optimize production processes.
5. **Decision Support Systems**: AI-powered decision support systems assist horticulturists in making informed decisions. These systems integrate data from various sources, including weather forecasts, market trends, and crop models; to provide recommendations on planting, harvesting, pest control, and resource allocation.

BENEFITS OF AI IN HORTICULTURE

1. **Field management:** Using high-definition images from airborne systems (drones or copters), real-time estimates can be made during the cultivation period by creating a field map and identifying spots where crops need water, fertilizer, or pesticides. This will sustain resource optimization to a great extent.
2. **Weather forecasting:** This is important in the horticulture industry as numerous intercultural operations depend on the weather. Machine Learning technology can be handy in using algorithms in connection with satellites to predict changing weather on a daily basis. These algorithms can also be used to predict crop health without contact with large fields. Machine learning also widens the scope of prediction and detection of pests and pathogens in the farmer’s field (Anonymous, 2019).
3. **Soil Health Analysis:** Soil health in terms of both moisture and nutrients is a basic need for horticultural crops. Nutrient and moisture-rich soils not only enhance yield but also increase fruit quality (Sennar, 2019). Both artificial intelligence and machine learning have the potential to build algorithms and sensors for detecting and quantifying moisture and nutrients in the soil. Robots may also be used to quantify soil nutrients, which may give predictive analysis for the recommended dose of fertilizer and irrigation.
4. **Agrochemical Production:** Horticultural crops require numerous synthetic chemicals, such as plant bioregulators, weedicides, pesticides, etc., for high production and quality. These chemicals have a tendency to remain in the soil and have plant-enhancing toxicity. Moreover, these chemicals enter the food chain, creating various metabolic ruptures. Machine learning with Big Data Analytics can be used to develop models that may help in the production of appropriate agrochemicals by capturing images of pathogens, weeds, and pests (Baruah, 2019).
5. **Post-Harvest Management:** Post-harvest processes such as cleaning, sorting, and grading can be done using Artificial Intelligence and Robots. Sensors can also be used in storage and warehouses to detect stored pests and pathogens. About 40% of horticultural produce is wasted as post-harvest loss. Machine learning and Digital Image Processing can be used to reduce such losses, which may enhance annual horticultural production (Kamilaris, 2018).

HORTICULTURAL PRODUCTION IN NIGERIA

Horticulture holds significant importance in Nigeria due to its economic, nutritional, and environmental contributions. It encompasses the production of fruits, vegetables, flowers, and ornamental plants, which serve as essential components of the nation's food supply, export commodities, and beautification efforts. Horticulture plays a crucial role in ensuring food security and promoting healthy nutrition in Nigeria. The ornamental plants and flowers produced in horticulture contribute to aesthetic enhancement, tourism, and the cultural identity of Nigeria. The cultivation of fruits and vegetables provides a diverse range of essential vitamins, minerals, and dietary fiber, contributing to a balanced diet and improved public health. Fruits and vegetables are among these crops that play a critical part in global horticultural production and exports.

Nigeria's export of fruits and vegetables has fluctuated substantially throughout the years (1970-2019). However, exports of fruits and vegetables from Nigeria were recently valued at 254,137.00 US dollars at the end of 2019 (Okorie and Nwachukwu, 2022). Horticultural crop production plays a vital role in

Nigeria's economy, contributing to the income improvement of rural communities and creating employment opportunities, particularly for youth and women. Despite its significance, horticultural crop production in Nigeria faces several challenges that hinder its full potential, such as; Limited access to modern agricultural practices and technologies, Inadequate infrastructure and storage facilities, Pest and disease management, Climate variability, and water scarcity. Technology plays a crucial role in addressing the challenges faced in horticultural crop production in Nigeria.

CASE STUDIES OF IMPLEMENTATION OF AI IN HORTICULTURAL CROP PRODUCTION

1. **Blue River Technology – Weed Control:** Controlling weeds is one of the top concerns for farmers, where an estimated 250 species of weeds have become resistant to herbicides. A California-based startup company developed a robot called “See & Spray” which reportedly leverages computer vision to monitor and precisely spray on weeds. Precision spraying can help prevent herbicide resistance. It precisely sprays fertilizers directly to the plant that needs it. This could save about 90% amount of herbicide that would be needed to spray in the entire field (Songthat, 2020).
2. **AI -Driver Less Tractor:** Driverless tractor has been introduced using ever-more sophisticated software coupled with off-the-shelf technology (sensors, radar, and GPS), the system which allows an operator working a combine to set the course of a driverless tractor. For the first time, Case IH and New Holland both introduced their new autonomous tractors at the 2016 Farm Progress Show (Songthat, 2020).
3. **FarmShots-Satellites for Monitoring Crop Health and Sustainability**: Based in Raleigh, North Carolina, FarmShots is another startup focused on analyzing agricultural data derived from images captured by satellites and drones. Specifically, the company aims to “detect diseases, pests, and poor plant nutrition on farms.” The company claims that its software can inform users exactly where fertilizer is needed and can reduce the amount of fertilizer used by nearly 40 percent. Hyperspectral imaging and 3D Laser scanning are capable of rapidly providing enhanced information and plant metrics across thousands of acres with the spatial resolution to delineate individual plots and/or plants and the temporal advantage of tracking changes throughout the growing cycle.
4. **Where - Satellites for Weather Prediction and Crop Sustainability**: ‘aWhere’, a Colorado-based company uses machine learning algorithms in connection with satellites to predict the weather, analyze crop sustainability, and evaluate farms for the presence of diseases and pests. The company provides its users with access to over a billion points of agronomic data on a daily basis. Data sources include temperature, precipitation, wind speed, and solar radiation, “along with comparisons to historic values for anywhere on the agricultural earth.”

Key Challenges and Limitations of AI in Horticulture

While AI offers great potential in horticulture, there are several technical challenges and limitations that need to be addressed. Here are some of the key challenges:

1. **Data Availability and Quality**: AI algorithms rely on large and diverse datasets for training and validation. However, acquiring high-quality horticultural data can be challenging due to various factors such as limited access to data, data privacy concerns, and data annotation requirements. Additionally, the availability of labeled datasets that cover a wide range of crops, diseases, and environmental conditions is often limited, making it difficult to develop accurate and robust models.
2. **Lack of Standardization**: There is a lack of standardized data formats, protocols, and platforms in horticulture, making it challenging to integrate data from different sources. Inconsistent data formats and variable data quality across different systems hinder the seamless exchange and analysis of data. Standardization efforts are necessary to facilitate data interoperability and improve the effectiveness of AI applications in horticulture.
3. **Adaptability to Diverse Crop Varieties and Growing Conditions**: Horticulture encompasses a wide range of crops, each with unique growth patterns, phenotypic characteristics, and environmental requirements. Developing AI models that can effectively adapt to different crop varieties and growing conditions is complex. Models trained on one crop may not generalize well to others, requiring significant efforts to customize and fine-tune AI algorithms for specific crops.
4. **Interpretability and Explainability**: AI models often operate as black boxes, making it challenging to interpret and explain their decisions. In horticulture, where decisions can have significant consequences on crop health and yield, it is crucial to understand the reasoning behind AI-generated recommendations. Ensuring transparency and interpretability of AI algorithms is necessary for building trust among growers and stakeholders.

5. **Limited Real-Time Decision-Making**: Some AI applications in horticulture, such as crop monitoring and disease detection, require real-time decision-making capabilities. However, the computational requirements and latency associated with training and deploying AI models can be a limitation. Real-time data processing, model deployment, and feedback loops pose technical challenges that need to be addressed to enable timely decision-making in horticultural operations.
6. **Cost and Infrastructure:** Implementing AI solutions in horticulture may require significant investments in hardware, software, and infrastructure. High-performance computing resources and storage capabilities are often necessary to handle large datasets and computationally intensive AI algorithms. The cost of acquiring and maintaining such infrastructure can be a barrier, particularly for small-scale growers or resource-constrained regions.

EMERGING TRENDS AND ADVANCEMENTS IN AI FOR HORTICULTURAL CROP PRODUCTION

1. **Advanced Sensing Technologies**: The integration of advanced sensing technologies, such as hyperspectral imaging, LiDAR, and multi-sensor fusion, holds great promise for enhancing AI applications in horticulture. These technologies can provide detailed information about plant physiology, nutrient status, and environmental conditions, enabling more accurate monitoring, diagnosis, and decision-making.
2. **Edge Computing and IoT:** The rise of edge computing and the Internet of Things (IoT) enables real-time data processing and analysis at the field level. By leveraging AI algorithms on edge devices, such as drones or field sensors, horticulturalists can gain immediate insights and make timely decisions, reducing dependence on centralized computing resources.
3. **Explainable and Transparent AI**: As AI becomes more prevalent in horticulture, the need for explainable and transparent AI models becomes crucial. Researchers are focusing on developing methods that enhance the interpretability of AI algorithms, allowing growers and stakeholders to understand the reasoning behind recommendations and decisions made by AI systems.

CONCLUSION

The deployment of Artificial Intelligence (AI) in horticulture offers significant opportunities to revolutionize crop production, resource management, and decision-making processes. Through the integration of advanced algorithms, sensing technologies, and data analysis techniques, AI can provide valuable insights and support in various aspects of horticultural crop production. The emerging trends and advancements in AI for horticulture, such as advanced sensing technologies, edge computing, and explainable AI, hold great promise for enhancing crop monitoring, disease detection, and autonomous operations. These technologies enable real-time data analysis, accurate decision-making, and improved resource allocation, leading to increased productivity and sustainability in horticultural systems. The potential benefits of AI in horticulture are vast. From enhanced crop productivity and precision management of pests and diseases to sustainable agriculture and climate resilience, AI has the potential to transform the industry and address key challenges faced by growers. However, it is important to acknowledge and address the technical challenges and limitations associated with AI deployment in horticulture. These challenges include data availability and quality, adaptability to diverse crop varieties, interpretability of AI models, real-time decision-making, and the cost of infrastructure.

LOOKING FORWARD

Further research in AI for horticulture should focus on developing comprehensive and adaptive AI models, precision management strategies, and decision support systems. Exploring the integration of AI with advanced sensing technologies, reinforcement learning, and climate modeling can unlock new possibilities for optimizing crop production, resource management, and sustainability.

ADOPTION OF HERBICIDE TECHNOLOGY IN CASSAVA WEEDS MANAGEMENT IN FEDERRAL COLLEGE OF EDUCATION, OKENE, KOGI STATE, NIGERIA

Abdullahi M. A.
Department of Agricultural Education, Federal College of Education, Okene, Kogi state,Nigeria

Corresponding author: ayatullah67@gmail.com 08032848660

Abstract
Cassava (Manihot esculenta Crantz) requires adequate and effective weed management, especially during the early development and establishment phase of the crop life for optimum yield and prolific productivity. In traditional Agriculture, manual weeding and such cultural practices as time planting, planting density, the use of vigorous cultivars, intercropping, cover cropping, minimal tillage, mulching, crop rotation etc. Studies have shown that use of herbicides in addition to these practices is necessary for optimal yields. Some recommended pre-emergence herbicides are Fluometuron, Diuron and Alachlor while full use of Glyphosate is recommended for post emergence. However, a combination of Diuron and Alachlor for pre-emergence, Glyphosphate in a variety of dosages according to soil characteristics, has been used successfully. It is however recommended to put shield on the sprayer while spraying to prevent damage of cassava crop plant.

***Keywords**: Active ingredients (ai), cassava, dosage, effects, emergence, recommendations,*

INTRODUCTION

Cassava (Manihot esculenta Crantz) otherwise called Tapioca, Arrow root or Manioc is a very important arable crop and a very good source of carbohydrate in the low latitude regions of the world (The tropics), especially in Africa and to some extent in Asia, in the Pacific and in the Latin America. It is a root/ tuber crop order of Ephorbiables, family of Euphorbiaceae, tribe Manihotae, genus Manihot and hence the species Manihot esculenta, which comprises of 7200 species (CIAT, 1990; IITA, 1999). It is established that Nigeria is the best producer of Cassava and unfortunately also the most important consumer of the crop in the world. Cassava is grown in and around the campus of Federal College of Education, Okene (Latitude 7^0 36'37.34"N, Longitude $6^0$15' 45.67"67^0 E and Altitude 1236 above sea level), Kogi state , Nigeria.

The direct impacts of tropical weeds on cassava on the field, competing with the crop for sunlight, water, nutrients and even space constitute a huge production problem. The invasion of weeds limits the productivity of cassava both in quantity and quality, and also negatively affects the producers and their families' economic life (Ogunwolu, 2004). Weed species hace adverse bearing on the yields and quality of cassava output and they are the number one enemy the farmer has to contend with to sustain profitable production or salvaging yield loss. (Smith *et al.*, 2007&Abdullahi, 2023). Cassava is purposely produced for the tuberescence starchy root storage as source of food and feed for man and livestock or as raw materials industrial use. It grows well between 30^o N and30^o S in areas where annual rainfall is greater than 500mm and average temperatures more than 20^o C (IITA, 1997; Onwueme, 1996 &CIAT, (1990). Nweke, (2004) observed that the length of cuttings and the parent plant source affect their germineability and ability to establish steadily in a given ecological settings. Global production of the crop was put at 160 million tonnes of fresh tubers in 1994 (Bruinsma, 2003).

Cassava production and weeds problems

Weeds infestation is the number one problem the farmer has to contend with if he means a profitable production (Smith & Akande, 2000). Many proficient cassava producers in the zone are toiling day and night to optionally produce the crop for himself, his family and immediate market, but their efforts are almost rendered wasteful by the infestation of unwanted flora of different species (Akobundu, 1987, 1988 and 1990). Weeds are undesired plants that voluntarily emerged or developed out of yesteryear cultivation in a crop field (Smith, 2004); they are plants adapted to disturbed or undisturbed habitats (Gorsi *et al.*, 1991) affecting the agricultural crops adversely by competing with them for light, nutrients, water and space.. Weed infestation is becoming more serious in the region because its development is favoured by high humidity, high average temperature and heavy rainfall (around 1900mm) per annum (Melifonwu, 1994) and regional edaphic variables which favours the species as does the arable crops.

Cassava production in the tropics is confronted with several problems of which weed competition is one of the most important. Weed species identified in cassava fields vary from location to location. However, the most common species of weeds found in cassava fields in most locations in and ar0und the campus of FCE, Okene include those enumerated in the table below:

Table 1: Occurrence and Abundance of weed flora in cassava fields in Federal College of Education, Okene.

Name of weed	Family	Lifecycle	Dem. Farm	Bsd. clinic	Staff quarter
*Ageratum convzoides*L.	Asteraceae	ABL	+++	+++	+++

Note: ABL=Annual Broadleaf, (+++) = very abundant, (++) = abundant, (+) = present but not abundant, (-) = not present at all. Those abundant have RIV up to 5%

Weeds management in the Cassava fields

Weed management entails every effort and strategy adopted to eliminate or decimate weed population in a field. This includes manual hand pulling, cropping cultural practices such as crop rotation, mulching and burning (Cultural); hoeing, slashing, mowing (Mechanical); use of other living organisms to drill the weeds to their bases (Biological). All these are laborious and less effective; and of importance to this write up, the use of herbicides or plant killers to kill the weeds (Chemical). The success of the use of different management strategies depends largely on a combination of principles and realistic approaches in cognisance of weed control and environmental safety. The principle of weed control is not necessarily the total elimination of weeds but importantly decimating the number to the minimal population so that much yield is not loss from a crop production function. This is not only necessary to check the menace of weeds but to also accomplish excellent environment for the crop and other cohabitants in the ecosystem, as much as ensuring profitable production with minimal cost. In cassava production, weed management is the task that gives the farmer many sleepless nights. It is laborious, time consuming, and wastages of human and material resources, (taking 50 -80% of total labour budget) with gambling hope of good marginal return (Zimdhal, 2013). The root crop is usually in the field for a very long time (8-15 months), they are usually planted at wide spacing (0.5-1m apart depending on variety) and thereby giving chance for more weeds infestation. Weed management in cassava compared to other arable crops in the humid tropics-home to cassava (Alumai *et al.*, 2010) is much more demanding. Weed control is far more difficult without herbicides even with the integrated pest management principles. Continuous zero tillage is therefore almost not possible in economic Cassava production business. The use of hoe and cutlass common with peasantry, need to be done many times to achieve minimum though excellent result in the field life of the crop. This is almost impossible because of other household or farming activities requirements and demands (Akobundu, 1970 & 1980; Melifonwu *et al.*, 2000). The ultimate option to effect adequate control of weeds for optimal successful production of cassava of good quality and high yields is the use of chemical to kill the weeds (Herbicides technology).

Adoption of Herbicide technology in cassava weeds management will help to increase productivity of cassava while minimizing the drudgery of manual hoeing, cost of labour and time wastages (Alimi &

Manyong, 2000). This management strategy however demands for wide consultation, education and sensitization of farmers and all the stakeholders. This becomes a necessity because of divergent opinions on the use of chemical substances on cassava fields. There are people with the opinion that herbicides should not be used on cassava field because it may add to the acidic contents of the tubers on formation or because of residual effects of chemicals on plants. Others think chemical can be used wisely and cautiously without necessarily endearing the crop to danger. Labrada *et al* (1994), suggested that herbicides are better used on cassava fields pre-emergence, in the process of stale bed preparation. This implies that after land clearing; early emerging weeds could be checked by spraying non selective herbicides before planting the cassava stems. Otherwise, the use of chemical herbicides post-emergence on cassava fields should be selective and done with caution (Onwueme, 1999, Abdullahi *et al*, 2017) and thereby preventing the chemical from getting in contact with the cassava plant, especially the root storage system (Melifonwu *et al.*, 2000).

Research on the use of herbicides to control weeds has been used successfully in Malaysia, Thailand and Indonesia (Howeler, 2000; Abdullahi *et al.*, 2017). The use of paraquat has been limited to research stations only in some African countries especially, Nigeria. In Malaysia, a mixture of 2 litres of alachlor and 2kg of fluometuron/ha is recommended for pre-emergence while 2litres/ha of paraquat are recommended for post emergence and pre harvest respectively (Tan, 1988, Tan *et al.*, 1995) In Lampung, Indonesia, a mixture of paraquat and diuron (3.75 l/ha) at 30 days after planting (post emergence) have been used successfully (Onweme, 1999; Abdullahi *et al.* 2017). The use of herbicides is more divergent in Thailand especially in CIAT research stations in Bangkok. Pre emergence application of 1.56kg a.i./ha of metolachlor with or without post emergence spraying of paraquat (0.5 kg a. i./ha) or with fluazifob-butyl (0.38kg a.i./ha) have been used on cassava fields successfully without residual effect. Spot treatment with paraquat (0.5kg a.i./ha) was also used in compliment of manual or tractiled weeding Zimdhal *et al.*, (1988). Application of metalochlor pre-emergence (2.4 l/ha) was used in South Vietnam and as an alternative for paraquat, glyphosphate (1.5kg a.i. /ha) was used post emergence to control weeds in cassava fields (Abdullahi *et al.*, 2017). It is good to note that, it is recommended in all cases, to use shield on the sprayer while spraying to prevent damage of the cassava crop plant. Their performance is very much influenced by a number of factors ranging from edaphic, climatic to the botanical nature of the weed flora as well as the dosage or rate of application of the herbicide (Melifonwu, 1994).

An experiment was conducted at the demonstration farm of the Agricultural Education department, Federal College of education, Okene, Nigeria. The soil at the site was sandy loam, with a pH of 6.5. Cassava cuttings were obtained from a local farm and planted at a spacing of 1 m x 1 m. The experiment was laid out in a randomized complete block design, with each treatment having three replications. The treatments were Paraquat (2.0 kg a.i./ha), Diuron (1.5 kg a.i./ha), Glyphosate (2.0 kg a.i./ha), and a control (no herbicide). The herbicides were applied at 6 weeks after planting (6WAP) using a knapsack sprayer. Data were collected on weed control efficacy, plant height, stem girth, leaf area, and yield. Diuron, Glyphosate, Round up and Alachlor were also used successfully in several fields in FCE,Okene and environs. The results showed that Glyphosate was the most effective herbicide, followed by Diuron and Paraquat. Glyphosate provided 100% weed control, while Diuron and Paraquat provided 80% and 60% weed control, respectively. Glyphosate also resulted in the highest plant height, stem girth, leaf area, and yield of cassava roots. The control had the lowest yield and quality of cassava roots. It is observed that the effectiveness of these herbicides depends on climatic and edaphic factors, weed flora, rate of herbicide applied, crop variety and management practices. (Akobundu, 1983; Aldrich, 1984; Onwueme, 1999). Herbicide application can provide the most effective and time – efficient method of managing weeds. Numerous herbicides are available that provide effective weed control and are selective in that grasses are not injured. Along with herbicide use is user responsibility and compliance with all product label requirements for herbicide handling

Conclusion

Herbicide technology in Cassava fields is imperatively the ultimate means of accomplishing weed management success in Cassava production, with less labour, time saving and result reassurance.70-80% successes of weed control has been recorded. The vulnerability, toxicity and environmental friendliness should be taken to cognizance at any point of herbicides usages in cassava fields and environs as the plant, the root and shoot systems are very sensitive to chemicals. It is the surest method of weeds control in large scale cassava production. The option of herbicide technology in cassava weed management is a viable alternative to traditional manual weeding. However, it requires proper training and adherence to safety precautions to avoid negative effects on human health and the environment. The adoption of herbicide technology in cassava weed management in Federal College of Education, Okene, Kogi State, Nigeria, has the potential to improve productivity, reduce labor costs, and improve the quality of cassava produced.

Recommendations

1. When using herbicides be mindful of proximity to water, trees, shrubs and other desirable vegetation. Herbicides are applied by banding, ringing round the crop stand or the spot spraying – where single nozzle application targeting individual plants, or broadcast spraying-multiple nozzles covering an entire area.
2. The use of Glyphosate is recommended for weed control in cassava fields. However, caution should be taken in the application of Glyphosate to avoid damage to non-target plants and the environment.
3. Whatever method is used calibration of spray equipment (gallons per acre spray output) is essential for accurate delivery and mixing calculations.
4. Estimating or guessing sprayer output can lead to misapplication which either injures non-target plants or results in failure to control the target weed species.
5. Pre-emergence chemicals are better used pre-planting of the propagules for expected germination success.
6. It is also recommended to put shield on the sprayer while spraying to prevent damage of cassava crop plant.

ABSTRACT
In Nigeria, the practice of managing honeybee colonies for deliberate pollination of established crops is very rare, resulting in complete underutilization and poor exploration of beekeeping, consequently, limiting the potential of large-scale commercial honey business in the country. Business models are important drivers of business commercialization without which value created from business opportunity and innovation cannot be captured. Consequently, descriptive features of National Horticultural Research Institute, NIHORT, Ibadan was used to provide the business model of NIHORT to establish specialty fields with particular crops to produce genuine honey. Value will be added to the honey through a quality test to bring it to international standard. The bottled honey will be branded with logo and QR-code to trace the source and sold in grocery stores.

Keywords: *Honeybee, Specialty honey, Business model, Pollination, Quality assurance.*

INTRODUCTION
The National Horticultural Research Institute (NIHORT), Ibadan, Nigeria is the Institute with mandate to conduct research into genetic improvement, production technologies, processing and marketing of fruits – citrus, mango, vegetables - melon, spices, and ornamental plants of nutritional and economic importance. Honeybee enhance the productivity of pollinated crops such as citrus, mango and melon, as was evident in the mean 6 fruits/plant, 19.9g seed weight and 90% seed viability compare with hand pollinated field of 1 fruits/plant, 5.7g seed weight and 10% seed viability (Kuti and Rovelo, 1992). Beekeeping in Nigeria is the practice of baiting hives to attract honeybee for the purpose of honey harvesting. Meanwhile, commercial beekeeping requires appropriate and adequate knowledge of honeybee's biology, integrated management of associated pests and diseases, provision of crops for pollination, application of modern equipment and tools for bee's management, honey processing and packaging and accessing potential and profitable markets with honey and hive products. Africa consumes more than three times the amount of honey it produces (Mattheus, 2019). Aside Ethiopia, Kenya, New Guinea, Papua and Tanzania who are self- sufficient in honey production and also produce most of the continent's honey, other large markets like Nigeria and South Africa are deficient in honeybee products (Mattheus, 2019, MyFarmbase Africa). In Nigeria, honey production is related to poor and ineffective collection and processing methods which results to inferior quality. Furthermore, honeybees are kept to forage on their own in the wild. The practice of managing honeybee colonies for deliberate pollination of established crops or gardens is very uncommon, resulting in complete underutilization and poor exploration of beekeeping, consequently, limiting the potential of large-scale commercial honey business in the country.

Business models provide the architecture for a firm to create and capture value out of an innovative idea (Teece, 2010), while an innovative idea or a technology do not represent any value until they are commercialized via a business model (Chesbrough, 2003; Schneider and Spieth, 2013). Business models help new businesses determine product types, labour availability, marketing strategies, distribution, delivery sales process, price strategies and customer payment methods. It is critical for business future growth. Inadequate preparation results in the business inability to anticipate future trends and challenges. Business models are important drivers of business commercialization without which value created from business opportunity and innovation cannot be captured. The discovery of business opportunities, innovations and technological developments in NIHORT beekeeping requires a business model to be commercialized. Therefore, this paper presents for the first time the business model to produce specialty honey through the planting of specialized crops for premium honey.

MATERIALS AND METHODS

A business model for commercial beekeeping is not yet in place in Nigeria. We used descriptive features of National Horticultural Research Institute (NIHORT), Ibadan to provide the business model of NIHORT considering the elements of the business model as provided in the business model canvas (Osterwalder and Pigneur, 2010). This reveals how NIHORT in the beekeeping value chain will create and appropriate in the new business models. SWOT analysis was applied according to the examination of the production capacity for specialty honey by NIHORT.

RESULTS AND DISCUSSION

Business Model for specialty honey in NIHORT

This business model is based on establishment of specialty fields with particular crops to produce genuine honey which will be stored in barrels. Value will be added to the honey through a quality test to bring it to international standard. The honey will be bottled then branded with logo and QR-code to trace the source and sold in grocery stores (Fig. 1).

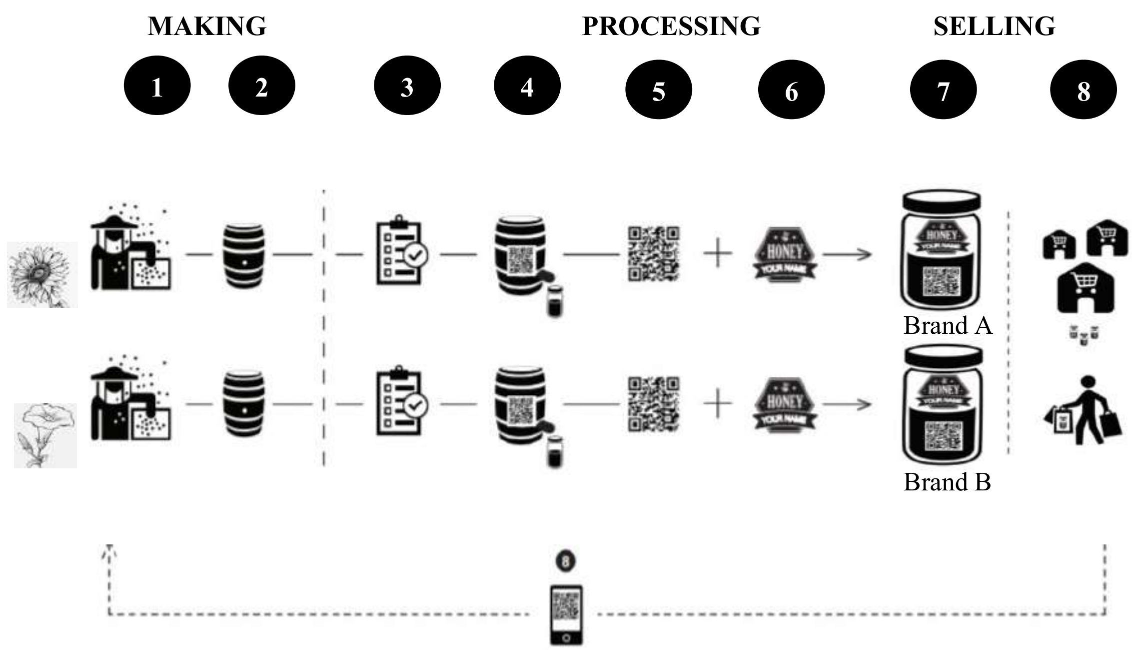

Figure 1. Business Model to produce specialty honey in NIHORT

Adapted from Single Spark 2014

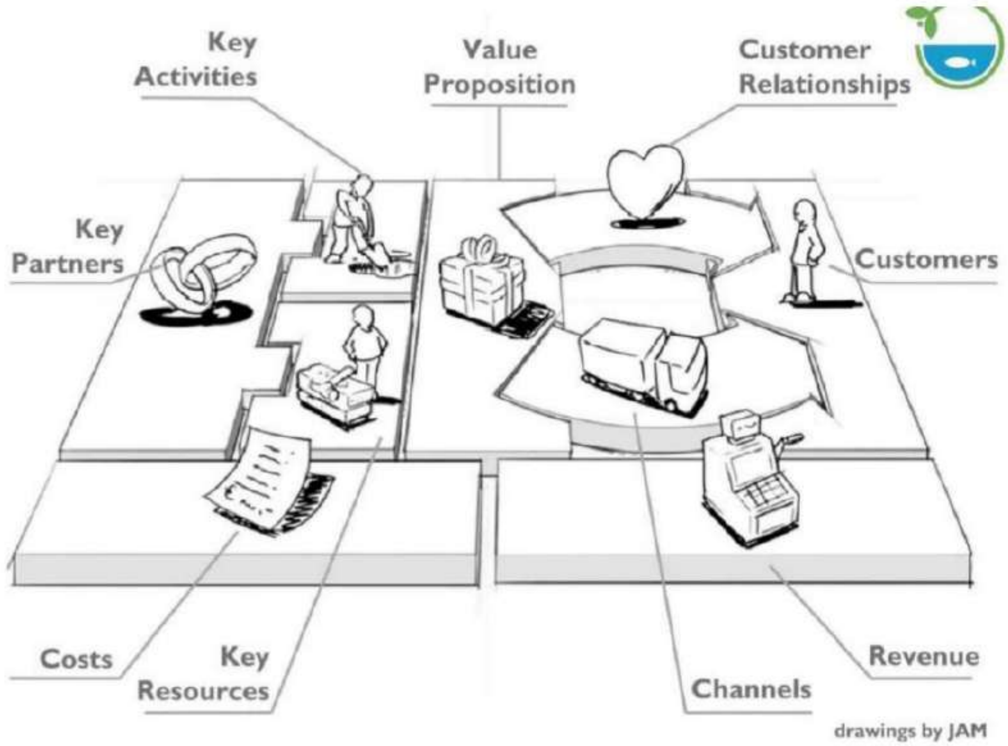
Business Model canvas for specialty honey in NIHORT

Business Model Canvas is a tool to create and analyze business models (Osterwalder and Pigneur, 2010). It consists of nine building blocks, each represented by a rectangle (Fig. 2). The nine blocks cover the three main areas of a business: desirability, viability and feasibility.

Desirability: This segment covering the value proposition, customer relationships, customers and channels exposes aspiration of customers to want the product.

Viability: This segment covering costs and revenue gives the worth of the product.

Feasibility: This segment covering key activities, key partners and key resources determines if the product can be delivered



Source: Mitja Kopina, 2015

KEY PARTNERS

These are the most important assets required to make the production of specialty honey business model work in NIHORT.

- Federal Ministry of Agriculture and Rural Development: Research is basically funded by the ministry supported by donor organizations.
- Bottles suppliers: NIHORT will develop partnership with bottle company for constant supply of different sizes of bottles.
- Grocery Stores: NIHORT will go into agreement with management of grocery stores on supply of honey to their stores.

KEY ACTIVITIES

These are the most important things NIHORT must do to make the production of specialty honey business model work

- Set up specialty fields: NIHORT will establish specialty fields with particular crops. Hives will be placed around the specialty field to pollinate the crops. This will guarantee the source of the honey.
- Set up clear track and trace system for honey: Every bottle of honey will have batch number and Quick Response (QR) code sticker. Consumer may scan the QR-code with mobile phone. The QR-code will be linked to a page on NIHORT web- site which will have information about the honey. Batch number can also be traced to a store.
- Build up a good and trustworthy brand: NIHORT will build brands that will be acceptable nationally and exportable.

- Discount at certain moments to old and new customers: NIHORT will give discounts to customers at Christmas, Easter, Ramadan and Eid Kabir.

KEY RESOURCES

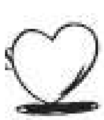
These are the most important assets required to make the production of specialty honey business model work in NIHORT

- Knowledge: NIHORT has expertise in modern commercial beekeeping, best management practice of honeybee and integrated pest management of honeybee pests and diseases.
- Quality assurance tools: Modern equipment will be available to check the moisture content and Brix Sugar Baume of honey.
- Modern honey extraction equipment: Health-conscious consumers want to be sure they buy hygienically processed honey, the modern honey extraction equipment will be available for the processing of the honey to prevent contamination assure health safety.
- Bottling machines with scale: Bottling machine will be used to fill bottles preventing contamination and scale to guarantee accurate measurement.
- Corking machine: This will be used to cork the bottles preventing spillage
- Labelling machine: This will be used to stick labels on the bottles
- Transport: This is required to distribute honey to grocery stores
- NIHORT marketing unit: customers can buy directly from NIHORT marketing unit

VALUE PROPOSITION

These are the bundle of products and services that create value for the customer of specialty honey

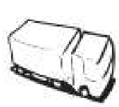
- Specialized honey: Consumers are weary of the genuineness of most available honey due to adulteration with sugar caramel or sugar cane caramel. The specialized will give an assurance of the source of the honey.
- Batch number and QR-code on the label: This will give consumers sense of trust and confidence in the honey
- Tamper proof package: This will further build the trust of consumers on the authenticity of the honey and quality assurance.
- Exclusive package for gifting/ souvenir: Customers can experience impressive and convenient package that will build high self-esteem.
- A day delivery for some areas: A convenient way of purchase without having to go to the grocery stores.



CUSTOMER RELATIONSHIPS

These are the types of relationships a NIHORT will establish with Customer of specialty honey

- Specialty honey: This will provide traceability of the honey
- Provide information about quality control of honey: This will give NIHORT trustable name.
- Provide information related to benefits of honey: This will make consumers to enjoy the honey
- Special promo for customers: This will give a sense of appreciation to customers

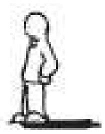


CHANNELS

This is how NIHORT will communicates with and reach its Customer to deliver specialty honey

- Web site: Information about the specialty honey and special promo will be made available on the web sites of NIHORT, and all the grocery stores to attract customers.

- Social media: Information about the specialty honey and promo will be circulated on different WhatsApp groups, Facebooks and Instagram of NIHORT and grocery stores to inform customers
- Jingles: NIHORT will create jingle to advertise the honey
- Live radio and television phone in interview: Honeybee expert will grant live radio and television phone in interview to create awareness about the honey and the promo.



CUSTOMER

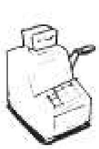
These are the different groups of people or organizations NIHORT aims to reach and serve.

- Neighbours: They will have opportunity to purchase honey at NIHORT marketing unit
- Event planners: They will have opportunity to book special branding of honey as souvenirs for different events
- Hoteliers: There will be an agreement for the production of one use pack for hoteliers
- Healthy life style enthusiast: People that do not take sugar

COST STRUCTURE

These are all costs incurred to operate a business model

- Specialty fields: This will involve the purchase and delivery of specialty seeds, cost of land preparation, planting and field maintenance all year round for continuous supply.
- Extraction machines: Cost of purchase and delivery of extraction machines.
- Bottling machines: Cost of purchase and delivery of bottling machines.
- Labelling machine: Cost of purchase and delivery of labelling machine to stick labels to bottles.
- Scales: Cost of purchase and delivery of scales for weighing the bottled honey.
- Crates: Cost of purchase and delivery of crates for packing the bottles.
- Bottles: Cost of purchase and delivery of bottles.
- Labels: Cost of production and delivery of labels.
- Transportation: cost of fueling and maintenance of vehicle used for distribution delivery of honey.
- Labor: Payment of manpower for different activities.



REVENUE STREAMS

This is the cash NIHORT will generate from each Customer (costs must be subtracted from revenues to create earnings).

Honey sale: Customers are willing to pay for hygienic packed honey in different weight and special packs for souvenirs.

SWOT analysis to evaluate the strengths, weaknesses, opportunities, and threats of specialty honey production: the case of NIHORT.

 STRENGTH	 WEAKNESS
• Expertise • Modern processing equipment • Quality assurance • Scarcity of un-contaminated honey	• Cumbersome accounting system • Non timely release of funds for expenses • Bureaucracies

• Scarcity of unadulterated honey • Easy quality track and trace system • Entrance to supermarkets	• Lack of policy on beekeeping/ documentation
 OPPORTUNITIES • Modern beekeeping training for those interested. • Collaboration with law makers for inclusion of training in constituency youth empowerment projects. • Organising Workshop for associations and organizations • Selling queens and nucleus colonies to beekeepers • Selling modern beekeeping equipment • Expanding business model to other NIHORT substations and part of the country	 THREATS • Delay in payment by supermarket • Labor strike/ unrest • Insecurity

CONCLUSION

The Business Model Canvas for the production of specialty honey by NIHORT for the first time will create value through establishment of specialty fields with particular crops to guarantee the source of the honey with precise track and trace system for consumer satisfaction, thus build up a noble and dependable honey brand in Nigeria.

ABSTRACT

Tomatotone (4-Chlorophenoxy acetic acid (4-CPA)) is a plant hormone used to enhance fruit setting and yield of tomato. The aim of the research is to investigate the efficacy of 4-chlorophenoxy acetic acid at different concentrations on yield of tomato. Field trials were therefore conducted during the rainy season of 2020 at two locations. The treatments consisted of four concentrations of 4-CPA (0, 50, 75 and 100 mgL^{-1} of distilled water). The experiment was laid out in a Randomized Complete Block Design and replicated three times. The data collected on yield and yield components were subjected to analysis of variance. The result showed that 4-CPA had significant effect on fruit length, fruit weight, marketable fruit yield and total fruit yield. Based on the findings of the study, it was suggested that farmers in the areas of study can be advised to grow tomato and apply100 mgL^{-1} of distilled water of 4-CPA for higher yield of the crop during rainy season.
Keywords: *Tomato, Tomatotone, Fruit, Yield and Components*

INTRODUCTION

Tomato was reported to have originated from around Peru and Ecuador from where it spreads to as far north as Mexico in pre-Colombian times. It was introduced into Europe from Mexico by the Spanish in 1523. Then from Europe it was carried across the pacific into south East Asia before 1650 (Srinavasan *et al*., 2010). Later it was introduced into West Africa in the 16th century by the Portuguese and it has since been regarded in temperate and tropical ranking next to potato in importance. In Nigeria, the main production area of tomatoes is the Northern part of the country, (latitude 8^0 – 13^0N) under irrigation during dry season between the months of September- March, when the temperatures are mild and humidity moderate. The rain fed production (June – September) is also important due to the fact that fresh tomato demand is all year round, but generally limited by high pests and disease that are prevalent under such humid and warm conditions (Grubben and Denton, 2004). Although tomato plants can be grown under a wide range of climatic conditions, they are extremely sensitive to hot and wet conditions, the type of weather that prevails in the summer and rainy season of tropical countries (Baliyan *et al.,* 2013).

However, tomato is adapted to wide range of climatic conditions from temperate to hot and humid tropical environment, with optimum temperature for growth in the range of 20 – 27^o C (Grubben and Denton, 2004). Moreover, marked prohibition of photosynthesis happens at temperatures above average, causing remarkable decrease in yield. Therefore, improved agronomic practices with potential for reducing the effect of high temperature and humidity for high yield of tomato especially during the wet and dry seasons should be investigated in order to meet up with the all year round demand of the crop. The agronomic practices with potential for reducing wet and heat effects on tomato especially during the dry/rainy seasons are reported to include; use of determinate varieties these are known to be better moisture conservers and also withstand adverse effect of heat, increase in plant population that could afford more shade to the developing fruit, mulching that could reduce evaporation and lower soil temperature. Several reports also indicated increased fruit size and fruit setting in tomato due to application of plant growth regulators such as 4-chlorophenoxy acetic acid (Tomatotone) and 2, 4-dichlorophenoxy acetic acid (2, 4-D). However, there is dearth of information on the effect of Tomatotone (4-chlorophenoxy acetic acid) on tomato production in Nigeria, as there was little or no study of such nature in the country. It is with all that in mind that the research was conceived with the aim of determining the effect of 4-Chlorophenoxy acetic acid (4-CPA) on yield of tomato under rain-fed condition.

MATERIALS AND METHODS

The research was conducted during the 2021 rainy seasons at two locations, Research and Teaching Farm of Faculty of Agriculture, Bayero University Kano (BUK) which lies on latitude 11^0 97' 98.6'' N and longitude 8^0 42' 03.7'' E and 475 m above the sea level and demonstration Farm of Audu Bako, College of Agriculture, Dambatta (DBT) which lies on latitude 11° 83' 40.3'' N and longitude 08° 10' 33.9'' E and 418 m above the sea level all within the Sudan Savanna Zone of Northern Nigeria. The treatments consisted four concentrations of 4-Chlorophenoxy acetic acid, (0, 50, 75 and 100 mgL^{-1} of distilled water). The experiment was replicated three times and laid out on a Randomized Complete Block Design. Seedlings of UC82B tomato variety were raised using seed beds until they were ready for transplanting at 6 weeks old. The area for the experiment was prepared by clearing, harrowing and ridging using a tractor mold board ridger. The area was then demarcated in to 27 main plots of 24 ridges that were 5 m long (24 x 0.75 x 5 m = $90m^2$). One meter (1m) alley was left between replications and between main plots. The seedlings raised in the nursery were transplanted at the age of 6 weeks after sowing on spacing of 60 x 75 cm, after establishment all agronomic management practices were carried out according to recommendation. The 4-CPA was applied after it was prepared by mixing 100 mg of 4-CPA powder L^{-1} of distilled water and two drops of baby shampoo were added to enhance stickiness of the 4-CPA on the flowers as recommended by (Baliyan *et al*., 2013). The mixtures were later applied to the flowers after few flowers had opened, about 1 ml per flower cluster was applied using hand held sprayer in the morning as from 8 am as recommended by Asian Vegetable Research and Development Center (AVRDC), (2001). Harvesting was done by hand picking at the time the fruits attained physiological maturity specifically when they were observed to changed colour from green to pink or reddish spanning four pickings. Data were collected from five tagged plants in the inner rows. The data were on: number of flowers clusters $plant^{-1}$, average fruit length (mm) $plant^{-1}$, average fruit weight (g) $plant^{-1}$, marketable fruit yield (t ha^{-1}), non-marketable fruit yield (t ha^{-1}) and total fruit yield (t ha^{-1}). The data collected were subjected to analysis of variance using Genstat (17^{th} Edition) and the means were separated using Fisher's Protected Least Significant Difference Test. The weather record during the study period was presented in Table 3.

RESULTS

Number of Flower Clusters $Plant^{-1}$

Table 1 shows the 4 – CPA effects on number of flower clusters $plant^{-1}$ during 2019 rainy season at BUK and Dambatta. At both location the result showed no significant difference among the 4-CPA concentrations on number of flower clusters $plant^{-1}$.

Fruit length (mm)

Fruit length of tomato as affected by 4-CPA concentrations during the 2019 rainy season at BUK and Dambatta is also shown in Table 1; the result obtained depicts that application of 4-CPA at different concentrations significantly affected fruit length of tomato at BUK, 75 and $100mgL^{-1}$ were at par but $100mgL^{-1}$ was significantly higher in fruit length than 0, and 50 mgL^{-1} 4-CPA concentrations which were statistically similar, while at Dambatta the result showed no significant difference among the 4-CPA concentrations on fruit length of the tomato.

Average Fruit Weight (g)

Also, Table 1 shows the fruit weight of tomato as affected by 4-CPA concentrations during 2019 rainy season at BUK and Dambatta. However, at BUK the result revealed significant effect of 4-CPA concentrations on the fruit weight, were 4-CPA concentrations of 50, 75 and 100 mgL^{-1} statistically at par with one another recorded significantly heavier fruits than the control, but at Dambatta the result shows that 75 and 100 mgL^{-1} statistically at par with one another recorded significantly heavier fruits than 50 and 0 mgL^{-1} statistically at par also.

Marketable Fruit Yield (t ha^{-1})

Table 2 revealed the Marketable fruit yield t ha^{-1} of tomato as affected by application of different concentrations of 4-CPA, the result indicated that at both locations, 100 and 75 mgL^{-1} 4-CPA concentrations were at par with one another but significantly higher in marketable fruit yield than 50 mgL^{-1} 4-CPA which was in turn higher than 0 mgL^{-1} which was the control.

Non-Marketable Fruit Yield (t ha^{-1})

Non-Marketable fruit yield t ha^{-1} of tomato as affected by 4-CPA concentrations; at BUK, 4-CPA concentration of 75 mgL^{-1} was significantly higher in non-marketable fruit yield than 4-CPA concentrations of 100, 50 and 0 mgL^{-1} which were at par with one another, while at Dambatta there was no significant difference among the 4-CPA concentrations.

Total Fruit Yield (t ha^{-1}) of Tomato

Table 2 also showed the total fruit yield (t ha^{-1}) of tomato as affected by 4-CPA application; the result indicated that at both location of the trial 4-CPA at 100 mgL^{-1} concentration was significantly higher in total fruit yield than 4-CPA concentrations of 75 and 50 mgL^{-1} which were statistically at par with one another but significantly higher than 0 mgL^{-1} concentration.

DISCUSSION

Effect of 4-CPA on Yield of Rain Fed Tomato

Plant growth enhancers can help address the challenges of feeding a growing world population and increasing food demand by improving crop yields in a sustainable way. They are usually found in small amounts throughout the plant. These substances are very important as they determine many different attributes of a plant. Plant hormones can be natural or synthetic. Plant hormones are also known as phytohormones. Thimann in 1948 coined the term "Phytohormone" The five major plant hormones are auxins, gibberellins, cytokinins, abscisic acid, and ethylene. (Hazra *et al*., 2007). The result of the study showed that application of 4-CPA significantly increase the total fruit yield of tomato at both locations, higher fruit yield was obtained with application of 100 mgL^{-1} 4-CPA. This could be attributed to the ability of the 4-CPA to enhance flower retention by the plant resulting to more fertilized flowers without much abscission and high fruit retention. This result was supported by the findings of Asian, Vegetable Research and Development Center (AVRDC, 2012), Nandwani *et al*. (2014), Ozguven (2000), Baliyan *et al*. (2013) and Lathiya & Sanjeev (2017) who reported that application of plant growth regulators has been shown to improve fruit setting in tomato, they further reported that sprays of hormone especially 4-chlorophenoxy acetic acid on flower cluster effectively increase the fruit set as well as fruit production. Also Karim *et al.* (2015) had shown that application of 4-CPA induced higher number of fruit set to some extent. It was further reported that application of plant growth regulators increased fruit set of summer tomato (Rahman *et al*., 2015). 4-CPA is also used in reducing pre-harvest fruit drop and resulting in increased number of fruits and yield in tomato crop. Alam and Khan (2002) reported that other plant growth regulators were also reported to increase fruit production and retention in tomato for example it was reported that application of Naphthalene Acetic Acid (NAA) at the time of flowering prevents pre-harvest flower abscission by increasing auxin concentration at this critical phase of reproductive development hence increasing yield. Meliha, Bengu and Kit (2006) reported that a number of studies have already established that external application of synthetic growth regulators and mineral nutrients are effective in increasing both yield and quality of crops including horticultural crops. They further revealed that the growth regulating substances used increased the number and size of fruits of tomato and their fresh and dry weights with 4-CPA being most effective.

CONCLUSION

Based on the findings of this study, it can be concluded that; there was significant and positive effect of 4-Chlorophenoxy acetic acid on yield and yield components of tomato during rainy season in which the result depicts application of 100 mgL^{-1} 4-CPA concentration recoded the highest fruit yield. Therefore, it can be suggested that farmers in the areas of study can be recommended to grow tomato (UC82B) variety and apply 4-CPA at 100 mgL^{-1} of distilled water in order to increase fruit yield of the crop during rainy season.

ABSTRACT
Adolescence marks a critical time for the establishment of healthy eating habits, as dietary beliefs and behaviors formed in this period can be maintained into adulthood. Therefore, the study aimed to identify the consumption patterns of food among adolescent students in Oyo State, using NIHORT-adopted secondary schools as a case study. Multi-stage sampling procedure was used to select 103 respondents. Data were collected using a questionnaire and was analyzed using descriptive statistics. The results showed that 70.9% of the students were still in their adolescent age between 11- 13 years old and they preferred empty-calorie foods over healthy options like fruits and vegetables. Snacks and sweets were consumed frequently (55.3% and 41.7% respectively), while vegetables and fruits were only consumed 1-3 times per week. Most students received only ≤₦200 per day, limiting their ability to buy healthier food options. This study found that, on average, students only eat vegetables and fruits once or twice a week, whereas snacks and sweets are consumed daily. The study also found that most students have a limited budget for food purchases, limiting their access to healthier options. The study recommends promoting more nutritious packed lunches from home and healthier snacks at school through nutrition education and policies to improve healthy dietary food intake.

INTRODUCTION

The health and wellbeing of children and adolescents is critical for achieving the Sustainable Development Goals, especially those related to poverty, health, education, and inequality reduction (WHO, 2017). The World Health Organization has emphasized the importance of adequate nutrition for enabling young people to enjoy good health while contributing to sustainable development (WHO, 2020). Proper nutrition during childhood and adolescence is essential for growth, development, preventing chronic diseases, and overall wellbeing. Adolescence is a critical period for establishing dietary behaviors that support current health, growth, and development as well as reducing the risk of chronic diseases later in life. The rapid physical, cognitive, and psychosocial changes that occur during the adolescent years create increased nutritional needs at a time of growing independence over food choices (Story, 2002). Inadequate or excessive intake of key nutrients during adolescence can negatively impact growth, bone mass development, menstrual health, mental health, dental health, and risk factors for conditions like iron deficiency anemia, eating disorders, obesity, and cardiovascular disease (Das *et al.,* 2017). Adopting healthy dietary patterns in adolescence characterized by nutrient-dense foods and beverages in moderation can support healthy maturation and reduce both short- and long-term disease risks (Salvo *et al.,* 2012). Adolescence marks a critical time for the establishment of healthy eating habits, as dietary beliefs and behaviors formed in this period can be maintained into adulthood (Hu et al., 2016). Studies show that Nigerian youth have an inadequate intake of nutrients needed for growth and development, including iron, iodine, and calcium (Ene-Obong *et al.,* 2018). Food habits adopted during adolescence tend to track into adulthood (Craigie *et al.,* 2011).

The impetus for this study was based on the observation that students are more inclined towards taking empty-calorie foods with little consideration for healthy foods, especially fruits and vegetables. This tends to predispose them to obesity, dental cavities, and other non-communicable diseases in later years. Although the prevalence of obesity is increasing worldwide, it is faster in developing countries due to declining levels of physical activity as well as nutrition transition characterized by a trend towards consumption of a diet high in fat, sugar, and refined foods low in fiber (Ogden *et al.,* 2014). Current evidence revealed a clear transition of increasing proportions of overweight/obesity in school-aged children in Sub-Saharan Africa, and a similar, but less prominent trend toward increasing proportions of obesity over time (Muthuri *et al,* 2014). This transition to higher proportions of overweight/obesity is similar to observed trends in developed countries. Therefore, assessing food and food-like consumption patterns among students in NIHORT-adopted secondary schools is a major concern to know the rate at which students in these adopted schools consume food, especially horticultural products, and also if NIHORT has been able to fill any gap in improving their nutrition on food consumed regularly.

Objectives

i. Describe the socio-economic characteristics of respondents in the study area;
ii. Ascertain student's frequency of consuming the selected categories of food;
iii. Identify reasons for consuming the selected categories of food by students;
iv. Evaluate constraints faced in the consumption of selected categories of food.

METHODOLOGY

The study was conducted in Ibadan, Oyo State, located on Latitude 8 00' North and Longitude 400' East of Greenwich Meridian. Oyo State covers approximately an area of 28,454 square kilometers. The population of this study consisted of JSS 2 students in NIHORT Adopted schools in Ibadan Ido Local Government. A multi-stage sampling procedure was used to select respondents for the study. In the first stage three secondary schools were purposively selected (Oba-Abass secondary school, Anwaru-Islam secondary school, and Baptist High school) which is because they are NIHORT adopted schools. In the second stage, a purposive selection of Junior Secondary School 2 class was selected which is because they have a long time to still be in school for further research and training. At the last stage, 20% of the students from the total population of level two junior secondary students (JSS2) students were selected given a total of 103 respondents. The data were collected with the aid of a questionnaire/ structured interview and analyzed using descriptive statistical tools. The descriptive statistics include means, frequency counts, and percentages.

RESULT AND DISCUSSION

Socio-Economic Characteristics of Respondents

The results in Table 1 revealed that the majority (70.9%) of the students were still in their adolescent age between 11- 13 years old, the average number of the respondents (50.5%) were male while 74.8% of the respondents were Yoruba. Also, 27.2% were 2nd born and 25.2% were 1st born respectively. The majority (54.4%) of the students' fathers were involved in other occupations aside from civil service, artisan, and trading, and also most of their mothers (40.8%) were involved in other occupations aside from civil service, artisan, and trading. It was also discovered that most (78.6%) of the parents had other sources of income apart from their major occupation, which implies that some parents might be able to provide more for their children in terms of feeding and pocket money. Majority (49.5%) of the respondents had a family size of 6-8 with an average of 6 people per household, indicating a relatively large family size considering the economic situation of the country. This may likely affect the purchasing power in terms of consumption of healthy nutritious food

Regarding food preferences at home, the most popular choice was "other" foods not listed (35%), followed by jollof rice and chicken (23.3%), and yam and egg (13.6%). Only small percentages preferred more nutritious options like vegetables (6.8%) and fruits (10.7%). In school, snacks were the top choice (38.8%), reflecting a desire for convenient, tasty foods, while few opted for vegetables (3.9%) or fruits (1.9%). The data on purchasing habits shows a similar preference for snacks, with 60.2% of students buying snacks at school. Only 19.4% purchased grains, 10.7% protein foods, and very few bought fruits or vegetables. This indicates that students are not purchasing well-balanced meals and snacks at school. In terms of money provided, most students received only 0-200 naira per day (63.1%), which limits their ability to buy healthier options. This finding connotes Wyse *et al.,* (2017) which suggests that students need sufficient financial resources to be able to purchase healthy food. The results suggest an opportunity to promote more nutritious packed lunches from home and healthier snacks at school through nutrition education and policies to improve healthy dietary food intake.

The Consumption Frequency of Food Categories

The result in Table 2 below shows the frequency of consumption of food categories. This revealed that Snacks and sweets are being consumed very frequently, with 55.3% and 41.7% of students respectively eating these daily. In contrast, vegetables and fruits are only consumed 1-3 times per week by most students. The high daily consumption of snacks and sweets aligns with the study of Bucher *et al*., (2016) which shows that snacks make up a large proportion of adolescents' daily food intake globally. Also, 35.0% of the respondents stated that they consume Grain/Cereals (Wheat, Rice, Maize, Oat, etc.) and 29.1% 27.2% of them affirmed that they consume Protein (Beans, Fish, Egg, etc.) 2-3 times per week. Consumption of Beverages is polarized, with 33.0% drinking them daily but 25.2% once or twice per week. Dairy foods is as well polarized with 31.1% intake daily, but 16.5% only weekly. Dairy is an important source of calcium and vitamin D. This implies that the students' dietary habits are poor and may have negative health implications (Molan, 2019). Their frequent snacking and low fruit/vegetable intake is especially concerning.

Table 2: The frequency of consumption of food categories (n=103)

Food categories	Once per week	2 times per week	3 times per week	4 times per week	Every day of the week
Grain/Cereals (Wheat, Rice, maize, Oat, etc.)	7 (6.8)	23(22.3)	36(35.0)	7 (6.8)	30 (29.1)
Protein (Beans, Fish, Egg, etc.)	8 (7.8)	30(29.1)	28(27.2)	20(19.4)	17 (16.5)
Beverages (Juice, Tea, soda, coffee, etc.)	26 (25.2)	26(25.2)	11(10.7)	6 (5.8)	34 (33.0)
Sweets (cookies, candies, chocolate, etc.)	16 (15.3)	22(21.4)	13(12.6)	9 (8.7)	43 (41.7)

Reasons for Consuming the Selected Food Categories by Students

The result in Table 3 provides insight into students' reasons for the consumption of selected food categories. The most commonly cited reasons were health benefits (96.1%), having a balanced diet (95.1%), proper growth and development (94.2%), and energy (98.1%), which connote the findings of Temple (2013). This indicates students are aware of the importance of nutrition for their health and growth. However, other factors reveal room for improvement. It is an indication that the students have the knowledge of the reasons for consumption of food but lack adequate knowledge about its application and inclusion in their dietary intake. Taste was a major driver (76.7%), which may explain preferences for snacks and sweets. Affordability (70.9%) and availability (80.6%) were also key, suggesting cost and access to healthy foods are barriers. Hunger (54.4%) may lead to less nutritious choices.

Constraints Faced in the Consumption of Selected Food Categories.

The result in Table 4 reveals some key constraints that may be limiting students' ability to consume a nutritious diet. The top constraints identified were food taste (82.5%), vendor hygiene (77.7%), and the environment where food is sold (77.7%). Between 24-33% rated these factors as very severe constraints. Cost also appears to be a major issue. Inadequate money was cited by 73.8%, with 32% calling it a very severe constraint. Food inflation was identified by 69.9%. This suggests students' limited funds may be forcing them to choose cheaper, less healthy options. Furthermore, 50.5% of the students attested that peer influence was a constraint which suggests mixed social norms related to healthy eating. Parents' economic status was also seen as a constraint with 64.1%. The result is consistent with the study of Akinyele *et al.,* (2021), which suggests that students may be hampered in their efforts to eat healthily due to a number of key constraints

Table 4: Constraints faced in the consumption of selected food categories (n=103)

Constraints	Yes	No	Very Severe	Severe	Not Severe	Mean	Ranking
Inadequate money	76 (73.8)	27 (26.2)	15 (14.6)	33 (32.0)	23 (22.3)	2.11	3rd
Social status of parents/Guardian	57 (55.3)	46 (44.6)	11 (10.7)	20 (19.4)	20 (19.4)	2.18	1st
The environment where food vendors sell	77 (74.8)	26 (25.2)	28 (27.2)	29 (28.2)	17 (16.5)	2.00	5th
Inflation (High cost of food)	72 (69.9)	31 (30.1)	19 (18.4)	30 (29.1)	21 (20.4)	2.00	5th
Peer influence	52 (50.5)	51 (49.5)	13 (12.6)	22 (21.4)	17 (16.5)	2.08	4th
Personal Hygiene of the vendor	80 (77.7)	23 (22.3)	28 (27.3)	34 (33.0)	8 (7.8)	1.71	10th
Food colour	79 (76.7)	24 (23.3)	28 (27.3)	28 (27.3)	11 (10.7)	1.75	9th
Food flavour	78 (75.7)	25 (24.3)	26 (25.2)	24 (23.3)	18 (17.5)	1.86	7th
Food taste	85 (82.5)	18 (17.5)	25 (24.3)	32 (31.1)	17 (16.5)	1.87	8th
The low economic status of parents	66 (64.1)	37 (35.9)	14 (13.6)	22 (21.4)	25 (24.3)	2.15	2nd

CONCLUSION

This study draws attention to the unhealthy eating habits of secondary school students in Oyo State, Nigeria, using the second-year students at NIHORT-adopted schools in Ibadan, Oyo State as a case study. On average, students only eat vegetables and fruits once or twice a week, whereas snacks and sweets are consumed daily. The study also found that most students have a limited budget for food purchases, limiting their access to healthier options. The results point to an opening for nutrition education and policies aimed at boosting healthy dietary food intake, such as encouraging more wholesome packed lunches from home and better school snacks.

MONTH OF COPPICING IN ENHANCEMENT OF CHUPON SURVIVAL, ESTABLISHMENT AND GROWTH PERFORMANCE OF CACAO (*Theobroma cacao* L) IN EDO STATE, NIGERIA

Adejobi, K.B., Adeosun, S.A., Famaye, A.O and Ayegboyin, K. O.

ABSTRACT

Most plantations in cocoa ecologies of Nigeria are old and rehabilitation of such cocoa farms through coppicing is inevitable. Therefore, investigation was carried out between 2017 and 2019 to evaluate coppicing at different months of the year on cocoa (Theobroma cacao L) chupons survival, establishment and growth performance in Cocoa Research Institute of Nigeria (CRIN), Uhonmora Station, Edo State. The months of coppicing considered as treatments were December 2017 to November 2018 while, data collection was terminated in May, 2019. The experiment was laid in Randomized Complete Block Design (RCBD) with three replications. Data were collected on chupon survival count, number of chupons , chupon height, chupon number of leaves, chupon diameter, leaf area and number of branches. Survival counts were carried out between 1 and 6 months after coppicing (MAC) across the coppicing periods. Data collected were subjected to analysis of variance (ANOVA) as well as descriptive statistics, and significant means were separated by Duncan Multiple Range Test (DMRT) ($P<0.05$). This study revealed that old cocoa trees coppiced in the months of March, April, June, September, October and December significantly ($P<0.05$) enhanced the survival count of regenerated chupons relative to other treatment months at one month after coppicing. Only cocoa plants coppiced in the month of April steadily maintained 100% survival count from the first month to the 6th month after coppicing. The cocoa coppiced in the months of April, generally recorded the highest success in all the growth parameters considered. Therefore, the month of April is recommended as the appropriate month to coppice old cocoa trees for the optimum growth performance of the generated chupons of cocoa in Uhonmora area of Edo-State, Nigeria.

***Keywords**: Chupon, coppicing, growth, old cocoa, rehabilitation, survival.*

INTRODUCTION

Cocoa was one of the main sources of income in Nigeria prior to independence. However, this changed following the exploration of crude oil in commercial quantities in the ’70s. Five decades later, oil has contributed more than agriculture to the nation’s foreign exchange earnings and as at the first quarter of 2022; the agriculture sector contributed just 4.96% to total trade, while the oil sector contributed 63.77% (ICCO, 2022). Over 50% of all exports in the 1970s and over 60% in 1980 were made up of cocoa. But during the 1990s, cocoa contribution steadily decreased, falling from 49 percent in 1989 to 22% in 1998. However, between 2015 and 2020, Nigeria was able to increase cocoa production by 25% to 250,000tons, compared to Cote d’Ivore, which had been able to increase production volume by 33% to 2,105,000 tons, and Cameroon, it increased by 32.7% to 280,000 tons (ICCO, 2022) while in Ghana, the Ghana Cocoa Board, despite the COVID-19 pandemic, reported a total production of 771,000 tons for the 2019/20 cocoa season as at November 2020, which was just 0.9% decline in cocoa production since 2015 (ICCO, 2022) . The cocoa production in Nigeria still remain low because most cocoa farms and farmers are aged, while the youths are not ready to farm because of the increasing insecurity in the farmlands, the cost of maintaining the existing cocoa farms is high, this is coupled with adverse effects of climate change, technological modernization and challenges in having access to finance.

Coppicing is one of the rehabilitation methods in cacao. It is the process of bringing unproductive cacao plants and plantations back to economic productivity or process of restoring yield by improved cultivation and management of existing mature trees. It is generally done by removal of the main stems of cacao trees (30 cm from cacao trees base) to encourage the regeneration of the canopy by chupon growth (Adejobi *et al*, 2014). It has been rightly observed by many authors that most plantations in cocoa ecologies of Nigeria are old, many are over 50 years of age, rehabilitation of such cocoa farms becomes inevitable if optimum yield is to be maintained (Olaiya, 2001; Olaiya *et al.,* 2003; Ogunlade *et al.,* 2017; Adebiyi *et al.,* 2021). Sheperd (1955) considered rehabilitation to be the restoration of the yields to the peak by systematic replacement of the inferior trees on a plantation. Low bean yield of about 400 kg/ha obtained in most cocoa plantations in Nigeria has been attributed to old age of the cocoa plantations and coupled with poor management practices. As it is applicable to all crops, there is a maximum age conditioned by varieties, soils, general plantation management, diseases, insects and other factors beyond which a plantation ceases to be of economic interest. Montgometry (1981) reported that optimalcocoa yields are achieved between 15 and 25 years of age; while Krung and Quartey-papafio (1964) after conducting cocoa survey throughout the growing regions of the world reported 30 to 40 years as the average economic life span of a cocoa tree. Olaiya (2001) suggested that apart from age consideration, a plot could be declared unproductive if the yield has declined to about the quarter of what is obtainable at the peak period (10 – 15 years), while Oduwole (2001) recommended the use of cost/benefit ratio of conducting rehabilitation.

Rehabilitation through coppicing and chuppon regeneration has been reported to improve growth and yield of cocoa (Olaiya, 2003). Odegbaro and Folarin (1974) had reported that budded and grafted F3 Amazon trees came into fruiting faster than the generated Amelonado trees and that by the sixth year, yield of F3 budded and grafted trees would have doubled that of the generated amelonado. However, there was no information on the months of the year that coppicing could be carried out for optimum performance. Therefore, this work was carried out to know the best month of the year to coppice cocoa trees for uptimum growth performance of generated cocoa chupons under field condition.

MATERIALS AND METHODS

Study area

Field experiment was carried out at the experimental farm of Cocoa Research Institute of Nigeria (CRIN), Uhonmora Substation in Edo State between 2017 and 2019, covering two consecutive rainy seasons and two dry seasons. The location lies between latitude 6'5N and longitude 5'50'E; a derived savanna zone of Nigeria. The rainfall is between 1000 – 1500 mm per annum. The maximum temperature ranges between 26 and 35 ^{0}C with average of about 30 ^{0}C; while minimum temperature ranges from 15 to 25 ^{0}C with average of 20 ^{0}C. Relative humidity is high during the rainy season; it ranges from 50 to 85% with average of 75%. However, there are seasonal variations in the values of relative humidity, which varies from 65 to 89% during the rainy season and 46 – 70 % during the dry season. The rainy season runs from April to October and characterized by heavy rain, low ambient temperature and high humidity; while the dry season is from November to March, is characterized with little or no rain, high ambient temperature and very low humidity.

Acquisition and preparation of experimental materials

About 50 x 30 m land area of old cacao plantation of fifty years was selected for the experiment. Plantain suckers used as shade crop for regenerated chupons were collected from experimental plots in the Station. Other materials used for the experiment were: Chain saw for cutting down of the cacao trunks, Long ruler for measurement of cacao coppicing height, vernier caliper for measuring the stem girth, red paint to paint the cut surfaces against pest and disease infestation and infection, respectively. The experiment was laid out with an average of 144 stands of cacao trees.

Treatments and experimental design

The field experiment had 4 trees randomly selected for each treatment, for a total of 48 and 144 cacao stands per block and experimental site respectively. The months of coppicing considered as treatments were: December, 2017 to November, 2018 twelve treatments. Two stands were eventually tagged per treatment for data collection. The experiment was laid in Randomized Complete Block Design with three replications and 144 plantain suckers were planted at 3 x 3m spacing as shade crop. The experiment was monitored for 22 months after coppicing.

Experimental lay-out, pegging and holing for plantain suckers were carried out before coppicing of tagged cocoa trees. The rehabilitation through coppicing was carried out on treatment and monthly basis by complete removal of the main stems of cocoa trees at 30 cm from the trunk base to encourage the regeneration of chupons, while the cut surface was painted with red paint contains red oxide to prevent infestation and infection of pest and disease. Chain saw was used to cut the trunk in a slant position at angle 45^O. Chupon growth commenced after a month of coppicing, which were left for 3 months in order to count the number of chupon per cacao trunk and the chupons were pruned to retain the 2 strong basal shoots which were allowed to develop to mature canopies.

Data collection and analysis

Data were collected on chupon survival count by visual count, chupon height using a meter rule from the ground surface to the tip of the main stem; chupon number of leaves. chupon diameter using vernier 'caliper at 30 cm above the ground level, leaf area (cm^2), and number of branches by visual counting. These growth parameters were taken monthly from 3 months after coppicing (3 MAC), while survival counts were carried out between 1 and 6 MAC. Data collected were statistically analyzed using analysis of variance (ANOVA) as well as descriptive statistics and significant mean differences were separated by Duncan Multiple Range Test (DMRT) ($P<0.05$).

RESULTS AND DISCUSSION

The results of the growth parameters on monthly basis (Tables 1-6) revealed that, coppicing old cocoa trees in the months of March, April, June, September, October and December significantly ($P<0.05$) enhanced better survival count of regenerated chupons relative to other treatments at one month after coppicing, but invariably, only cocoa plot coppiced in the month of April steadily maintained 100% survival count from the first month to the 6th month after coppicing (Table 1). This trend could be attributed to the fact that, by April, rain had just begin and nutrients, especially N, is steadily available in the soil. This might have aided healthier chupons generated and growth. The cocoa trees coppiced in January had the lowest chupon survival (Table 1). This might be attributed to the inherent dry spell of and hot weather conditions of that period which might have d led to scorching of most regenerated chupons. The month of January is the peak of dry season in the study area.

Table 2 showed that coppicing from January to December had between 3 – 15 chupons. Chileshe and Kitalyi (2002) observed that coppicing would enhance regrowth to produce many chupons and that the practice can help to improve the amount of leaves and branches. The cocoa trees coppiced in April significantly ($P<0.05$) enhanced number of chupon, chupon height, number of leaves per chupon relative to other months as treatments at 1MAC (Tables 2, 3 and 4). This trend continued for chupons height at 2, 3, 4, 5 and 6 MAC (Table 3). The highest number of chupons regrowth was recorded for the months of February and June (Table 2), however, there were some dieback across in all the months except for April (Table 1). The Cocoa coppiced in the month of April, generally recorded the highest growth parameter values probably because the coppicing was done at the onset of rain coupled with available soil nutrients. Low percentage of success in farmers' farm has been attributed to failure of farmers to follow due processes and good agricultural practices in coppiced cocoa plots (Adenikinju *et al.,* 1989; Olaiya, 2007; Akinnagbe, 2021). This might be as a result of choosing to coppice in the wrong month, as revealed in this study.

CONCLUSION AND RECOMMENDATION

This study revealed that cocoa rehabilitation through coppicing is a promising way of bringing old and unproductive cocoa plantation o economic productivity. That for coppicing to be successful, the timing and associated circumstances have to be considered painstakingly. Cocoa farmers in Nigeria therefore need being sensitized on rehabilitation through coppicing and the appropriate months of the year that coppicing can be carried out in the different regions and agro-ecologies of Nigeria, considering the prevalence of the climate change. Governments at all levels and non - governmental organizations should come to cocoa farmers' aid on this need. From the study, the month of April is the appropriate month to coppice old cocoa plantation for growth performance of cocoa trees in Uhonmora, area of Edo-State, Nigeria and is strongly advised to farmers in the area.

ACKNOWLEDGEMENT

The authors wish to acknowledge the Executive Director and Management of Cocoa Research Institute of Nigeria for the logistics support for this research.

Abstract
Tomato processing into value added products is crucial to mitigation of post-harvest losses, promotion of food security and household livelihood. The study evaluated effects of training on post-harvest handling and perception of stakeholders on the use of Raised-Platform Dryer for management of post-harvest loss in tomato. A random sampling technique was used to select 99 stakeholders out of the 160 trained in two local government areas of Nasarawa state. Data were collected with the aid of structured questionnaire and analyzed using descriptive statistics and probit regression. The result showed that most of the stakeholders were female (69.7%), with average age of 35 years and had secondary level of education (38.4%); and also, 59.6 percent were producing and processing tomatoes (59.6%). Findings revealed that 41% have adopted drying tomato with the aid of Raised-Platform Dryer. Majority of the stakeholders were of the opinion that the post-processing colour of the product developed was adequate (72.7%), and price offered for the product was commensurate (71.7%). The most important factors affecting the adoption of the Raised-Platform Dryer were size of tomato farm and years of experience in tomato production. The study recommends scaling out of the training to other areas of comparative advantage in tomato production to improve tomato handling, minimize post-harvest loss and promote production of hygienic product.
Keywords: *Tomato, Post-harvest losses, Handling, Raised drier, Nasarawa*

INTRODUCTION

Tomato (*Lycopercicon lycopercison*) is an important and outstanding vegetable due to its importance in daily diet (Babalola *et al*, 2010). Nigeria consumes an estimated 2.3 million tonnes of tomatoes annually with tomato consumption per capita standing at 12kg in 2016 (Helgilibrary, 2017). Lack of proper storage, packaging and processing are among the factors leading to post-harvest losses in the country (Bolarin and Bosa, 2015). Thus, domestic supply cannot meet domestic demand for fresh tomatoes which is estimated to be more than 2 million tonnes (demand) or $2.55 billion annually. The country supplement local demand for fresh tomatoes with #360 million (over 300,000 metric tonnes) of imported tomato paste annually. A lot of farmers have lost a substantial amount of revenue that should have accrued to them due to absence of storage and processing facilities in the country (Abass *et al*, 2018). Most farmers/processors use traditional methods of drying, especially drying tomatoes on bare ground (NIHORT, 2018). The National Horticultural Research Institute recently introduced a low cost Raised-Platform Dryer that may be used for drying tomato. Further to this the Institute organized training for tomato stakeholders at Nassarawa state to socialize the invention and build capacity on the use of the low-cost Raised-Platform Drier. The study therefore set out to profile the opinion of the stakeholders about the relevance and impact of the training, regarding post-harvest technique and management practices, skills, and adoptability.

METHODOLOGY

The study was carried out in Nasarawa State and the state is one of the North Central States of Nigeria. The state has thirteen local government areas and its capital is Lafia. A random sampling technique was employed to select 99 respondents from a total of 160 stakeholders earlier trained on tomato post-harvest handling and use of Raised-Platform Drier from Lafia and Obi Local Government Areas of Nasarawa South Senatorial District. Structured questionnaire was used to obtain information on opinion of the stakeholders about the usefulness of the training, appropriateness towards post-harvest technology and management practices, skills and adoptability of the technology introduced. Descriptive statistics and Probit regression was used to analyze data collected.

RESULTS AND DISCUSSION

Stakeholders' characteristics

Most of the stakeholders were female (69.7%), had secondary level of education (38.4%), married (57.6%) with mean age of 35.2±6.3. The respondents had average household size of 6.7. The average year of experience in tomato production and processing were 6.6 and 4.6 respectively. Majority of the respondents had farming as their major occupation (82.8%) and had been involved in tomato production and processing (59.6%); moreover, 73.7 percent and were members of cooperative society (73.7%) and have processed average of 780kg of tomato weekly during the peak season of tomato production (Table 1).

Perception of stakeholders on aspects of processing operations trained.

The most important aspect of the training involved washing (86%), followed by sorting (71%) and packaging in impermeable material (60%). Other important aspects of the training were drying on raised platform (54%) and cutting using plank (44%). Findings also revealed that most of the stakeholders adopted cutting tomato using plank (48%), drying their tomato using Raised-Platform Dryer to prevent product contamination (41%) and packaging in impermeable materials (36%) which is known to retain the red colour of the product. Additionally, 22% of the stakeholders had adopted sorting of tomato before processing while only 9% adopted washing before processing (Table 2).

Perception of the stakeholders on appropriateness of training and acceptability of product

Stakeholders were of the opinion that the range of equipment demonstrated during the training were adequate (66.7%), duration and content of the training (64.6%) were also adequate. Also, considered adequate was the quality of the product developed (54.5%) and knowledge disseminated by the facilitator (50.5%). Moreover, most of the stakeholders opined that colour of the product developed and the price being offered for the product developed were both acceptable (71.7%). In the same vein, the response of consumers to the product was acceptable by 63.6% of the stakeholders (Table 3).

Factors affecting adoption of the technology.

The result showed that factors that determine the likelihood of participants adopting the Raised-Platform Drier technology were years of tomato production and tomato farm size. Participants with higher scores in years of production were less likely to use the Raised-Platform Drier technology. This could be due to the fact that they were older in the business and used to the traditional way of tomato processing. However, increase in farm size increases the likelihood of adopting the Raised-Platform Drier technology ($p<0.001$). The result implies that participants with larger tomato farm size are more likely to adopt the sun drier technology. This is because larger farm size is expected to have larger yield/ output and may need to deploy technology to mitigate post-harvest loss. (Table 4).

CONCLUSION AND RECOMMENDATION

Most of the stakeholders trained were female had secondary level of education and were into tomato production and processing. Findings revealed that some of the stakeholders had as a fall-out to the training programme adopted the processes and the Raised-Platform technology recommended for tomato drying. Based on the findings from the study, it is recommended that the training should be extended to other areas of comparative advantages in tomato production to improve tomato post-harvest handling and processing and awareness creation on the importance of adequate post-harvest handling practices.

ABSTRACT
This study examined the production constraints and the prospects of coffee production in Nigeria. Desk research was carried out using past published literature. The research established the fact that coffee production has suffered setbacks in Nigeria over the years with production fluctuating from one year to the other. The fluctuation was attributed to factors such as old coffee trees, coffee plantation with little rehabilitation, poor finance or capital, climate change, problems associated with marketing and so on. The study, however, gave a high hope of coffee production in Nigeria if the subsector is revamped. It was recommended that coffee farmers in Nigeria should embark on rehabilitation or complete renovation of their coffee plantation to boost production. Cheap credits should also be made available to coffee farmers to purchase farm inputs and to cope with climate variability militating against coffee production in Nigeria.
Keywords: *Coffee production, Climate change, Plantation, Credits, Caffeine.*

INTRODUCTION

Some species of shrubs or trees of the genus *Coffea* are known to produce berries from which coffee is obtained. They are evergreen trees or shrubs which could grow up to 5 meters when not pruned. Coffee plants are native to Africa. However, the two major species of coffee commercially grown are *Coffee robusta* and *Coffee arabica* (Botanical Aspects, 2009). *Coffee arabica* was believed to have originated from Ethiopia while *coffee robusta* was traceable to Central African Republic. Coffee is cultivated or grown in over 70 countries, mostly in the Americas, the Indian subcontinent and Southeast Asia. However, Consumption of coffee mostly takes place in industrialized countries. Coffee is considered to be the most widely consumed hot beverage worldwide (Gichimu *et al,* 2010). Over 90 percent of coffee production takes place in developing countries mainly South America. Globally, Brazil is driving the coffee production and trade growth. The world coffee production experienced a growth rate of 6.4% in the year 2020 while Brazil's coffee production grew by 18.5% (ICO,2021). A significant revenue crop for many poor nations is coffee. It has also created several million jobs in many producing countries where more than nine million tons of green beans are produced annually (ICO, 2022). Coffee has become the main export and pillar for African countries like Uganda, Burundi, Rwanda, and Ethiopia as well as many Central American countries (Cousin, 1997). Small farm holders are the main actors along the coffee supply chain in many of the developing countries, including Nigeria.

The Health Benefits of Coffee

Coffee contains high quantity of B vitamins, niacin and riboflavin as well as magnesium. (Full Report, 2016). Coffee contains a psychoactive chemical which is caffeine. Caffeine is known for its stimulating effects *(Cappelletti et al*, 2015). According to a 2017 assessment of clinical trials, consuming three to four cups of coffee daily is generally safe at ordinary intake levels and is more likely to improve health outcomes than to have negative effects.

Objectives of the Study

This research work was carried out to determine the prospects and problems of coffee production in Nigeria. It could however be observed that the production of coffee in Nigeria is facing a downward trend despite the contribution of coffee export to the country's GDP and livelihoods for many families in the production and along the value chain. This study therefore finds it quite imperative to determine the problems associated with the downward trend in the production of coffee in Nigeria.

Justification for the Study

Coffee is considered to be a cash crop which serves as means of livelihoods or has created several million jobs in many producing countries where more than nine million tons of green beans are produced annually (ICO, 2022). Coffee also plays an important role in the balance of trade between developing and developed economies or countries since it is an important source of foreign exchange thereby contributing in different measures to each country's national income. However, according to ICO report 2009, coffee exports have been increasing. It has also been observed that the production of this valuable crop in Nigeria has been dwindling over the years. Since a lot of folks ranging from the producers (farmers) to processors, marketers, transporters and so on depend on coffee for their sustenance and livelihoods, there is however, the need to carry out scientific investigation as to the reasons for the dwindling production of this valuable crop in Nigeria.

METHODOLOGY

This research work adopted desk literature using findings from various past published literatures. The study areas were states where coffee is being produced in Nigeria. The study seeks to find out the constraints or problems bedeviling coffee production in Nigeria and the reduction in the production of this valuable crop.

Coffee Production Trend in Nigeria since Independence

Figure 1 below shows the production in tons of coffee in Nigeria from year 1961 to 2020. The annual production of coffee rose sharply from 1080 tons in 1961 to 5700 tons in 1964. But this production figure dropped sharply to 2700 tons in 1965 and since then the production of coffee in Nigeria has been fluctuating year after year until it gets to 1984 where it rose again sharply from 2520 tons in 1984 to 5700 tons in 1988. From 1988, it maintained a plateau shaped structure from 1988 to 1992 where it dropped sharply again to 2400 tons in 1993. However, from 1993, it started fluctuating in a downward trend until it reached the lowest level of 1000 tons in 2020. Generally, from the figure 2, it can be observed that there was an appreciable value in the quantity of coffee produced in Nigeria while from 1993, the coffee production continued to decrease drastically. Hence, there is a need for a quick intervention in the production of coffee in the country.

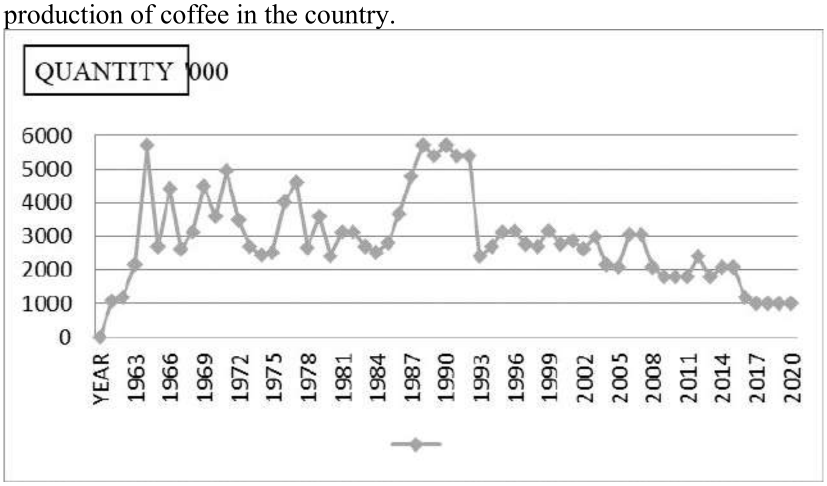

Figure 1: FAOSTAT, 2020

Production Constraints of Coffee in Nigeria

In Nigeria, the rise and fall of coffee production over the years are as a result of several factors among which are:

1) Moribund coffee trees: Majority of the coffee plants in Nigeria are already aged and have passed their fruitful ages. Most of these trees were planted some 40 years ago. Some of these coffee farms were actually acquired through family inheritance (Aderolu *et al.,* 2014).
2) Climate change: The devastating effects of climate change on crop production globally is alarming. Drought as a result of low level of rainfall and high temperature has negatively impacted coffee production in Nigeria. This is because drought negatively affects germination of seeds and inhibits photosynthesis as well as general growth of coffee trees (Bhutia *etal.*,2018).
3) Inadequate capital and poor access to credit: Access to credit at low interest rate goes a long way to increase coffee production. In other words, access to credits by small farm holders helps to procure capital assets and farm inputs which their savings alone cannot purchase. According to Kegode, (2005), research has shown that farmers have difficult access to financing, and borrowing has significant interest costs.
4) Marketing problems: According to Akinfenwa (2019), marketing problem is the most important challenge causing decline in coffee production in Nigeria which is attributable to inadequate

market information and poor pricing of coffee. Processed coffee beans are poorly priced in Nigeria as a result of low quality beans due to bad handling in various processing stages. This inevitably led to the refusal to buy most of the coffee beans produced in Nigeria in the international market due to it poor quality.

Prospect of Coffee Production in Nigeria

There is high hope of increased coffee production. This is achievable through the following:

1) It has been established that most coffee plants in Nigeria have become aged and surpassed their fruitful age. There is, however, a need to sensitize coffee farmers in Nigeria to embark on massive rehabilitation of their coffee farms so that the trees can rejuvenate and produce good yields. However, in situation where the coffee farms have gone beyond rehabilitation, the farmers can engage in complete replanting which means complete removal of old coffee trees and replanting with young and high yielding and disease resistance cultivars. This would go a long way to increased coffee production in the country.
2) The devastating effects of climate change and variability is real in Nigeria. The heat waves and low precipitation impact negatively on coffee trees. There is, however, the need to develop and adopt adaptation strategies for coffee trees. These include the development and adoption of drought resistance varieties. Also mulching of young seedlings and irrigation should be practiced.
3) Another factor to consider in revamping coffee production in Nigeria is the use of adequate farm inputs. For instance, correct application of recommended fertilizer at the appropriate time would inevitably increase coffee yield. The same applies to other farm inputs such as fungicide and other pesticides to control the incidence of coffee diseases and pests. However, these agrochemicals should be made available to farmers at subsidized rates.
4) Most of the coffee farmers in Nigeria are small farm holders with limited access to farm credits due to collateral issues and poor understanding of procedures to obtain loans. However, to boost coffee production in Nigeria, coffee farmers should be properly educated on the right procedures to follow in obtaining credits from financial institutions. Also, monetary policies should be tailored toward making cheap and quick loans available for agricultural productions especially coffee production.

CONCLUSION

Coffee production in Nigeria has suffered decline over the years in spite of the huge benefits derivable from its production in terms of foreign exchange to the country as well as being source of income to many farm families which depend on coffee farming as means of livelihoods. This is attributable to the various challenges faced by coffee farmers such as poor finance, moribund coffee trees, marketing problems, climate related issues and so on. It is, however, recommended that in order to revamp coffee subsector of the country's economy, the federal government as well as the necessary NGO's should take proactive steps in widening the scope of production of this crop as well as proffering solutions to the various marketing and other problems faced by coffee farmers in Nigeria.

ABSTRACT

Insect pest infestation is a major factor militating against cucumber production and farmers generally adopt synthetic insecticides for its management. A field trial was undertaken to evaluate the insecticidal potency of P. angulata + T. diversifolia for the management of Podagrica spp. insect pest of cucumber. The treatments consisted of aqueous leaf extracts of sole application of P. angulata, T. diversifolia, mixture of P. angulata + T. diversifolia and Cypermethrin as check; laid out in Randomized Complete Block Design and replicated three times. Data was collected on insect population before treatment application and 3 days after spraying of insecticides at 6, 7, 8, and 9 weeks after planting (WAP). Results obtained showed that the plant extracts exhibited effectiveness in reducing the insect population The order of effectiveness in decreasing sequence was found to be Cypermethrin > P. angulata + T. diversifolia, P. angulata and T. diversifolia crude extracts could be explored as promising insecticidal agents to provide valuable alternatives to chemical control of insect infestation on cucumber. Further study is recommended to determine the chemical constituents responsible for the plant insecticidal activity.

Keywords: *Aqueous extracts, insecticidal agents, insect infestation, Physalis angulata¸ Podagrica spp*

INTRODUCTION

Cucumber (*Cucumis sativus* L.) is an important vegetable and one of the most popular members of the Cucurbitaceae family (Lower and Edwards, 1986; Thoa, 1998) grown for its fruits, which are eaten either fresh or pickled in most countries (Lower and Edwards, 1986; Thoa, 1998). Cucumber is the fourth most important vegetable crop after tomato, cabbage and onion (Tatlioglu and Eguchi, 1998). In Nigeria, bulk production from northern Nigeria sustains demand from southern Nigeria, where these salad vegetables augment high intake of carbohydrate, hence high prices (Ayoola and Adeniran, 2006). Cucumber is susceptible to several chewing and sucking insect pests during the whole cultivation period and may cause damage to up to 80% (Rahman and Uddin, 2016) leading to great loss in quality and yield (Kaiser and Ernst, 2018). *Podagrica* spp is one of the most damaging insect pests causing the yield losses up to 30-100%, being polyphagous, adult stages are harmful to crop as they feed voraciously in leaf making irregular holes thus causing decline in the crop photosynthetic proficiency (Odebiyi, 1980). The insects correspondingly act as vectors of mosaic viral diseases (Fasunwon and Banjo, 2010). Thus, these major insect pests are becoming the foremost threat in cucumber cultivation and these might be one of the reasons for the lower yield and reasons why farmers are discouraged to cultivate the crop.

Farmers in Nigeria and other tropical countries exclusively depend on the use of synthetic insecticides to control the insect pest infestation in horticultural crops to considerably reduce yield losses. However, repetitive and constant uses of these toxic insecticides has some grave disadvantages. The injurious effects and increased cost–benefit ratio of synthetic insecticides have inspired scientists to advance substitutes to chemical control in insect pest management. Consequently, the focus has now been shifted in the direction of integrated pest management (IPM) such as the use of plant materials. Plants extracts may offer an alternative to the presently used conventional insecticides for the control of agriculturally important insect pests, as they constitute a rich source of bioactive chemicals compounds (Daoubi *et al*., 2005), that are practically an unexploited pool of insecticides that can be used as veritable substitutes for synthetic pesticides. Consequently, the present research was conceived to assess the effectiveness of *P. angulata* and *T. diversifolia* aqueous extracts as bio-insecticide against insect pests infesting cucumber.

MATERIALS AND METHODS

Experimental site

The study was conducted on a 15 m×10 m (150 m^2) area of land during the wet season of 2022 and at the Teaching and Research Farm, Faculty of Agricultural Technology, Rufus Giwa Polytechnic, Owo, Ondo State, Nigeria.

Collection and preparation of plant extracts

Physalis angulata and *Tithona diversifolia* were collected from different locations in Owo and its environs. The whole plants excluding the roots were washed with clean water to remove dirt and allowed to drain. Thereafter; 8 kg of the plant shoot and leaves was weighed using electronic balance and was pounded thoroughly using mortar and pestle to produce fine crushed materials. The pounded plant materials were in 10 litres of borehole water in plastic bucket for 24 hours, vigorously stirred to form a thorough mixture occasionally and filtered using muslin cloth ready for spray (Oparaeke, 2006). The procedure was repeated each week the spray operation was carried out.

Crop establishment and Field Layout

The field experiment laid out in Randomized Complete Block Design (RCBD) replicated three times per treatment consisting of five treatments namely: sole application of *P. angulata*, *T. diversifolia*, mixture of *P. angulata* + *T. diversifolia* crude aqueous extracts, synthetic insecticide (Lambda cyhalothrin) used as check to monitor the effectiveness of the plant extracts and control with no treatment (Adesina and Afolabi, 2014). The block size was 2m x 15m and each treatment was allocated to a plot of 3.7 × 2m and each plot size had three main and two discard rows (one on either side of the main rows). Each plot was separated by a 1.0 m wide border margin to check spray drift. Two seeds of market more cucumber variety were sown per hole at 60cm x 60cm spacing, which was later thinned to one vigorous stand; supplying was carried out a week after planting. Weeding was done as necessary but no fertilizer application was made.

The treatments were applied at 21 days after sowing (DAS) by preparing 10% concentration of the extracts from the stock solution, using Spray well 16 L Knapsack sprayer model under fairly calm weather condition to avoid drifting to adjacent plots. Subsequent application of the treatments was carried out at weekly intervals. Synthetic insecticide (Cypermethrin 25 EC) was applied at the rate of 0.25 kg active ingredient (a.i) per ha to serve as check to compare the efficacy of the plant extracts.

Data collection and statistical analysis

To assess the effect of the treatments on the *Podagrica* beetles counting of the insect was carried out early in the morning (6.00 – 7.00 am) daily (Adesina, 2013). Number of *Podagrica* spp was counted prior before treatment application, number of *Podagrica* spp third day post application of treatment and on five randomly selected plants per plot. Data collected were subjected to analysis of variance and treatment means were separated using Least Significant Difference at 5% probability level.

RESULTS

Effect of sole application and mixture of *Physalis angulata* and *Tithona diversifolia* aqueous extracts on *Podgrica* spp. Population at 6 WAP

The result in Table 1 shows *Podagrica spp.* population on okra before the application of the aqueous plant extracts treatments. *Podgrica* spp. population before spraying was slightly significantly different (P>0.05) in the plots assigned to the treatments evaluated. Though, plot assigned to be treated with *T. diversifolia* had the highest *Podagrica spp* population (2.46 insects/plant), while plot assigned to be sprayed with *P. angulata* and Cypermethrin had similar population respectively.

Sole application of *P. angulata* and *T. diversifolia* aqueous extracts and their mixture significantly influenced *Podgrica* spp. population at 7 WAP (Table 1). Highest population was found in control plots (2.31), least insect population was observed in the cucumber sprayed with cypermethrin and mixture of the extract (0.74) and was not significantly different from those observed from sole application of *P. angulata* extract (0.79). At the third day post application of the treatment after second spraying regime (7 WAP), insect population in control plot still remain the highest (1.99), followed by sole application of *T. diversifolia* (0.88) and *P. angulata* (0,86) which was not statistically different from each other. Cypermethrin and mixture of the extracts recorded the lowest (0.74) insect population. However, the insect population observed from both Cypermethrin and mixture of the extracts was not significantly different (Table 1).

Table 1: *Podagrica spp. infestation* at the commencement of treatment (6 WAP), 7 WAP and third day after spraying

Treatment	Pre spraying at 6 WAP	3rd day after 1st spraying	Insect population at 7 WAP	3rd day after 2nd spraying
Control	0.82c	0.74	2.31a	1.99a
P. angulata + *T. diversifolia*	0.85c	1.0	0.74c	0.74c
Cypermethrin	1.07b	0.85	0.74c	0.74c
T. diversifolia	2.46a	0.96	0.79c	0.88b
P. angulate	1.21b	1.0	0.86b	0.86b

Treatments with the same letter in column are not statistically significant different from each other.

Effect of sole application and mixture of *Physalis angulata* and *Tithona diversifolia* aqueous extracts on *Podgrica* spp. Population at 8 and 9 WAP

Result in Table 2, shows that application of *P. angulata* + *T. diversifolia* extract recorded the least *Podgrica* spp. population (0.92) T 8 WAP closely followed by a non-significant population observed in plots treated with Cypermethrin (0.94). Cucumber treated with sole application of *P. angulata* (0.99and *T. diversifolia* (0.86) extracts recorded significantly reduction in *Podgrica* spp. population compared to control. Similar trend was observed third day post treatment application as plant extracts and cypermethrin significantly caused a reduction in the insect population. Cypermethrin, sole and mixture of the extracts significantly suppressed the insect population in comparison with control at 9 WAP (Table 2). Non-significant difference was observed in the insect population from cucumbers in plots treated with Cypermethrin and *P. angulata* + *T. diversifolia* mixture. Third day after the fourth spraying regime, insect population recorded from plots treated with Cypermethrin, *P. angulata* + *T. diversifolia* mixture and sole application of *T. diversifolia* recorded statistically same number of insect population. However, this population was significantly different from what was obtainable from sole application of *P. angulata* and control.

Table 2: Insect population at 8 WAP and 3rd day after third spraying

Treatment	Insect population at 8 WAP	3rd day after 3rd spraying at 8 WAP	Insect population at 9 WAP	3rd day after 2nd spraying
Control	2.18	1.11	1.78	1.02
P. angulata + *T. diversifolia*	0.92	0.73	0.84	0.81
Cypermethrin	0.94	0.62	0.85	0.82
T. diversifolia	0.86	0.86	0.94	0.81
P. angulate	0.99	0.90	0.92	0.86

Treatments with the same letter in column are not statistically significant different from each other.

DISCUSSION

In Nigeria, cucumber cultivation has become a booming activity in urban and peri-urban cities these recent years. Unfortunately, insect pests are real problems for farmers because of the damage they cause and synthetic insecticides are most often used for the control of insect pests of cucumber. Because of the intensive and indiscriminate use of chemical pesticides, which has led to residual issues and the development of resistance to many common insecticides, there is a constant need for the search of environmentally benign insecticides from natural sources, particularly plants. Botanical insecticides contain compounds with properties that repel, deter or disrupt the growth, feeding or reproductive activities of insect pest on crops (Degri et al 2012). It can be inferred from the results of present investigation that the field evaluation of insecticides and biopesticides against insect infestation exerted variable efficacy in reducing the insect population. Though, the sole and combined application of the botanical extracts contributed in reducing the number of *Podgrica* spp. on treated cucumber. The mixture of *P. angulata* + *T. diversifolia* were relatively more effective against crops infestation compared to their sole application, therefore, seem to have potent insecticidal properties for checking *Podgrica* spp. infestation and population increase. This support the findings of Sapkota *et al.* (2010) who stated that application of mixture of leaf extract of many plants to be the most superior in terms of quality, size, yield and reduction in fruit infestation. Russel and Lane (1993) opined that plant extracts often consist of complex mixtures of bioactive constituent's plant metabolites may produce toxic effects if ingested leading to rejection of the host plant.

Cucumber plants in the plots sprayed with plant extracts were less invaded by insects and were at par with plots sprayed with synthetic insecticides. This study confirmed previous study by Adesina and Idoko (2013) who reported on the efficacy of *Chenopidium ambrosiodes* and *Spondia mobin* crude extracts in suppressing flea beetle infestation on okra plants. High effectiveness of Cypermethrin compared to crude aqueous extracts could be attributed to non-degradability of the active ingredient formulation that possesses immediate knock down effects on the target insects (Oladimeji and Kannike, 2010; Alao *et al.*, 2011). The organic products might have created a hostile environment for insects and a physical barrier to infestation, hindered feeding activities of the insects. These effects might be attributed to characteristic offensive odour perceived during application. The high infestation recorded in the control plot post treatment application is an indicative of the insect finding a refuge in the untreated cucumber to feed on the plant foliage.

CONCLUSION

The finding from this study confirmed that there is a vast array of plant materials with insecticidal properties that could be screened for reducing insect pest depredation to cucumber in the field. The utilization of *P. angulata* + *T. diversifolia* aqueous extracts mixture had positive toxicity impact in decreasing the rate of *Podagrica spp.* infestation which would ultimately reduce leave damages and increased cucumber fruit yield. Thus act as promising insecticidal agents as it compares favourably with Cypermethrin and they could provide valuable alternatives to synthetic insecticides in the integrated management of *Podagrica spp.* The effectiveness of the crude plant extracts and synthetic insecticides was found in the following order Cypermethrin > *P. angulata* + *T. diversifolia* > *P. angulata* > *T. diversifolia*. Therefore, resource-poor farmers are enjoined to adopt the utilization of mixture of *P. angulata* + *T. diversifolia* extracts to suppressed *Podagrica spp.* infestation and increase cucumber fruit yield. Further study is recommended to determine the extracts mode of actions and biochemical constituents responsible for the insecticidal activity of the plants.

ABSTRACT
Greenhouse technology is a technique for regulating the environmental factors for the benefit of the plants (bell pepper) under protective cultivation. The study aims to analyze of cost of production and profitability of bell pepper under a screen house production system. Data were obtained from farm records and operational system of a screen house production system in Akure north area of Ondo State. Data collated were obtained from 4 production cycles during the period the two years evaluated. Despite the initial high cost of investment, screen house productivity is high. Cost of inputs constituted 59% of the variable costs of production while labor cost constituted 29%. Production of bell pepper under screen house system resulted in high gross margin of approximately 81-86% depending on the level of productivity
Keywords: *Bell pepper, greenhouse, profitability, fertigation*

INTRODUCTION

Agricultural production system in Africa is faced with a myriad of problems including climate change, edaphic factor, ecological and biotic factors (pest and diseases). Majority of crop production system depends on natural or rainfed production system with consequent effect on yield limitation. To achieve competitive production, farmers must be able to manage their farms to mitigate the effect of those limiting factors that prevent their crops from attaining the potential yield as dictated by the genetic composition. The most limiting factor of production usually determine the crop performance. In the face of the current challenges with climate change, farmers can shift to more climate smart production system under controlled or partially controlled production system as in the case of greenhouse or screenhouse production systems often referred to as controlled atmosphere agriculture (CEA). Greenhouse crop production which is now a growing reality throughout the world according to FAO (2013) was explained by Mohammed and Dulamin (2021) as protected agriculture, one of the important and advanced production systems in terms of the use of scientific methods and technological equipment that ensure the provision of appropriate climatic conditions for the growth and development of the crop outside its normal niche and production times or seasons.

Capsicum (*Capsicum spp*) is an important vegetable cum spice crop grown in almost all parts of tropical and subtropical regions of the world (Reddy *et al*., 2022). Pepper is an annual vegetable crop which ranks next to potatoes and tomatoes in order of production. It belongs to the family *Solanaceae* and genus *Capsicum* which comprises 20-30 species. Pepper grows in most countries and covers 1.93million ha (FAOSTAT, 2022). Based on their culinary purposes and organoleptic features, pepper fruits are normally classified as two kinds: Bell pepper, a non-pungent, chunky sweet pepper type and Chilli pepper with pungent fruits (De, 2003). Sweet pepper (*Capsicum annum* L.), commercially known as bell pepper is an annual herb or shrub, 0.5-1.5m tall, erect and highly-branched crop with fruits harvested at green matured stage or at red and/or yellow ripened stage. It is rich in Vitamin A, Vitamin C and minerals like Calcium, Magnesium, Phosphorus and Potassium (Kelley and Boyhan, 2009).

Pepper is a crop grown extensively under rain-fed conditions with very high yields when the rainfall is about 600 to 1250 mm. The climatic changes will continue to exacerbate soil moisture and thermal stresses during the dry season with implications for crop performance (Tombesia *et al*., 2018, Agele, 2021). The inability to meet this moisture requirements has resulted in the adoption of irrigation to sustain plant growth. Adopting ways of increasing production of pepper has brought to the light the use of controlled environment (greenhouses, polyhouses etc.). Greenhouse is becoming a popular farming system among pepper farmers. Greenhouses increase crop yields by as much as two to five times as plants grown under open field conditions; the quality of the product is normally higher than open field and the incidence of pest and disease is reduced (Olatunji and Akeem, 2002). It can give manifold production of quality produce round the year from small landholdings, compared to the open field cultivation (Murthy *et al*. 2009; Rao *et al*. 2013).

With challenges experienced in the availability of vegetable crops especially pepper and tomatoes and the associated high price in the recent years, vegetable production in the southwestern part of Nigeria has increased. Ondo state has become a growing of hub of vegetable production in the Southwest Nigeria especially tomato and pepper. This is not only supporting the local market but marketers from Lagos, Edo and Delta states also source their fresh vegies from the state. However, majority of the tomatoes and pepper are produced under open field production system with some little supplemental irrigation in the dry season. The unstable pattern of the weather and climate change often results into losses when unexpected rain cessation occur. The use of protected cultivation or partially protected cultivation in the state is becoming visible in some part of the state but the adoption of such farming system is still low due to initial cost high cost of investment. The profitability of greenhouse farming depends on a number of factors, including the crops grown, the location of the greenhouse, the cost of construction and operation, and the market for the produce. In general, greenhouse farming can be more profitable than traditional field farming.

Crop Production in greenhouse or screen house is a capital intensive production technology that require substantial initial capital outlay / investment (Kumar *et al*., 2016, Prakash *et al.,* 2020). Peet *et al*., (2005) also asserted that greenhouse production is more expensive than producing the same crop in the open field. The most important factors determining costs are depreciation of the structure and equipment, labor, energy, and variable costs such as planting material, substrate, and fertilizer (Olatunji and Akeem). Despite the initial high capital outlay, the return on investment is high due to high productivity and opportunity of growing crops off season when the price will be high. The study was conducted with the aim of examining the cost components and profitability of growing bell pepper under a screen house production system in Akure, Ondo State.

METHODOLOGY

The study and data collection for the analysis were obtained from a screen house farm located in Akure sub-burb (coordinates: 7.266, 5.317). Akure is a cosmopolitan city located in the humid rainforest zone of Southwestern part of Nigeria. The operational system of the farm was monitored for a period of two years when production started. Data were collected regularly from the records of production and sales from the farm. The farm site where data were collected comprise of four production units of screen houses each measuring 10 x 30 m (300m^2). Data were obtained on cost of investment, cost of production, outputs and price for production cycle. Typically, 5 to 6 months are required for one crop cycle of bell pepper production in a screen house, and hence, two cropping cycles obtainable in a year. For this study, two years production records (four production cycles) were documented. Data used were actual data extracted on cost of investment (cost of fabrication and other components), cost of production (inputs, labor and other variable cost in the current price obtainable). Crop prices were averaged prices that were prevalent in the current season. Total revenues (gross income) were calculated per cycle of production for the number of production unit as the products of treatment yield and average price. Variable costs were the actual cost incurred in the production. Gross margin per cycle of production were calculated as the difference between gross income and total variable cost. In constructing the budget, no charges were included for land. Formulae for estimating economic indices used were:

1. Total Variable Cost (TVC) = Labor cost + Cost of inputs + other operating cost
2. Revenue = Average yield/kit x farm gate price (₦/kg)
3. Gross margin) = Total Revenue (TR) – Total variable Cost (TVC)

RESULTS AND DISCUSSION

Table 1 shows the cost of investment on infrastructure required for production under the screen house system. 79% of the cost is for fabrication of the main protected structure. An average of ₦3, 417,500 is invested per production unit. The variable cost comprising of the cost of inputs, labor cost and other operation cost averaged ₦513, 000 per production cycle of 5-6 month/cycle (Table 2). Cost of inputs constituted 56% of the variable cost while 29% of cost is spent on labor. The cost soluble fertilizers deployed in weekly fertigation constituted 31.8% of the variable cost while cost of plant protection chemicals (pesticides) constituted approximately 11.5%.

The yield obtained under the production system per unit of production (300sqm screen house unit) rages from 1500-2000 kg of marketable fruits of bell pepper per cycle depending on the plants response as affected by micro-climate fluctuation with season and management (irrigation, pest and other agronomic management practices). The gross margin per production unit, a portion of the business revenue left after direct cost are subtracted varies from ₦2, 186,500 to ₦3, 086,500). This translate to a gross margin of ₦4, 373,000 to ₦6, 086,500 per production in year (2 production cycle). The Gross margin expressed in percentage is approximately 81-86%. The gross margin increased with the productivity of the crop.

CONCLUSION

It is observed from the study that despite the higher cost of investment on screen house, cultivation of high value vegetable crops in this case, bell pepper is found profitable with high gross margin.

ABSTRACT
The field trial was conducted at Vegetable Research field of National Horticultural Research Institute, (NIHORT), Ibadan, Nigeria during the cropping season of the year 2019. The aim was to evaluate the agronomic and yield performance of 15 F_5 segregants of tomato selected from inter-specific crosses. These were laid out in a randomized complete block design with three replications using a spacing of 0.5m x 0.6m. The analysis of variance revealed significant differences for all the characters examined among the 15 F_5 segregants except for days to flowering, first day to fruiting and number of branches per plant which indicated sufficient variability for selection in future breeding plan. The earliest segregant was S15 while the latest was S8. The highest number of fruits per plant was recorded in S8 (78.75) whereas the least was observed in S10 (4.25). Segregant 8 had the heaviest fruit weight per plant (1,391 g) while the lightest weight was recorded in S10 (50.5g). Based on overall assessment, S1, S2, S3, S4, S6, S8, S11, S12, S13 and S15 were selected for advancement to F_6 generation for further selection and future release.
Keywords: *segregants, agronomic, yield, characters and selection*

INTRODUCTION

Tomato (*Solanum lycopersicum* **L.)** is one of the most important vegetable crops in Nigeria (FAO, 2010). Although, it is native to South America, it is produced and consumed all over the world (Arah, 2015). The red pigmentation in its fruit called lycopene is a vital anti-oxidant which helps in the fight against cancerous cells formation in human body and other health complications. It neutralizes the free radicals in the body (Bhowmik *et al*., 2012). It has been reported that African countries such as Nigeria and Angola have low yield of tomato production with 3.9 tons/ha and 2.7 tons/ha respectively when compared to European countries with over 400 tons/ha of tomato. Netherlands, Belgium and United Kingdom recorded 416.19 tons/ha, 507.04 tons/ha and 506.90 tons/ha respectively (FAO, 2016). Part of the cause of Africa's low production is attack of pests and diseases and poor post-harvest handling (Claudius *et al*., 2015). Hence, there is need for breeding improved varieties with resistance or tolerance to diseases of economic importance which would improve the yield of tomato production in Africa, especially in Nigeria. This study had started with breeding of improved tomato lines that are tolerant to *Fusarium* wilt disease and of high yield and good nutritional quality. In order to evaluate the agronomic and yield performance of the developed segregants, the research was conceived. The objectives of the study were therefore to determine the variations that exist among the 15 F_5 segregants of tomato with relation to yield and agronomic characters and to select the 10 top yielders with other related characters for further advancement in future breeding plan.

MATERIALS AND METHODS

Four moderately susceptible tomato landraces and four most tolerant landraces to *Fusarium* wilt disease were selected from screening experiment for resistance to *Fusarium* wilt disease at NIHORT, Ibadan. The list of names and codes of the tomato landraces and the hybrids used for selection of the segregants are presented in Table 1. The landraces were crossed using North-Carolina Design II at NIHORT screen house during the cropping season of the year 2016 to generate F_1. The F_1 generated were advanced to F_4 generation through selfing. Twenty-one (21) F_4 segregants selected based on yield and agronomic traits were advanced to F_5 generation. The experiment was laid out in a Randomized Complete Block Design (RCBD) with three replications using a spacing of 0.5m between plants and 0.6m within rows.

Data Collection

Data were collected on some agronomic and yield related characters viz: plant height (PH), number of leaves per plant (NLVSPP), number of branches per plant (NBPP), days to first flowering (DSFL), days to first fruit set (DSFR), number of fruits per cluster (NFCL), number of fruits per plant (NFPP) and fruit weight per plant (FWTP). The agronomic data were collected at 100% flowering while yield were recorded per harvest.

Data Analysis

The data collected were analysed using R-statistics, version 4.1.0.

RESULTS AND DISCUSSION

The analysis of variance revealed significant variations (P<0.5) for all the characters examined among the 15 F_5 segregants of tomato except for days to first flowering and days to first fruit set (Table 2). Variation is a good indicator for selection in any breeding programme. The variations observed in most of the agronomic and yield characters in this study indicated sufficient variability for breeder's selection and advancement in future breeding plan. Figure 1 presents the agronomic performance of 15 F_5 segregants of tomato while Figures 2 and 3 shows the number of fruits per plant and fruit weight per plant respectively.

In the present study, Segregant 11 recorded the tallest height (58.58 cm) while the shortest was observed in S8 (33.08 cm). The highest number of branches per plant was recorded in S15 (17.25 branches) while the least was observed in S8 (7 branches). The earliest segregant was S15 which flowered at 67 days while the latest (S8) flowered at 71 days after sowing. S8 had the highest number of fruits per plant (52.5) with the least recorded in S10 (4.25). The heaviest fruit weight was recorded in S8 (1,391g), followed by S13 (1,242.63g) while the lightest weight was observed in S10 (50.5g).

This is in conformity with the report of Haldavanekar *et al*., 2019 who worked on "Generation mean analysis of F_5 progenies of Brinjal (*Solanum melongena* L.). According to their findings, significant variations were observed in plant height, plant spread, number of secondary branches, number of leaves, days to first flowering, days to 50 % flowering, fruit length, fruit girth, number of harvest, harvesting span, number of fruits per plant, yield and per hectare yield except in number of primary branches per plant among 28 F_5 progenies. They concluded that, due to variations in these characters, they can be used to make selection for advancement of the brinjal progenies to F6 generation and 19 treatments were selected.

This study is also in agreement with the work of Gbadamosi *et al*., 2021 who studied Intra-specific crosses in tomato (*Solanum lycopersicum* L.) for improvement of fruit quality. According to their report, significant genotypic variations were reported for plant height, number of branches per plant, number of clusters per plant, number of fruits per cluster, number of fruits per plant, number of days to first flowering, number of days to first fruit set, fruit weight and pericarp thickness at 5 % level of probability for all parents used for the crosses.

CONCLUSION

In conclusion, the agronomic and yield characters observed in this study showed enough significant variations among 15 segregants of F_5 generations obtained from North Carolina Design II. Therefore, 10 top promising lines (S1, S2, S3, S4, S6, S8, S11, S12, S13, and S15) were selected for advancement to F_6 generation and future release.

ABSTRACT
A field experiment was conducted on a 24 months old juvenile sweet orange trees orchard to evaluate economic implication of the use of pumpkin (PK) at 1m x 0.5m + (Atrazine 250g/L + Metolachlor 250g/L) at 4L/ha (PK+P), Akidi (AK) at 50cm x 75cm + (Atrazine 250g/L + Metolachlor 250g/L) at 4L/ha (AK+AM), sawdust (SD) at 30t/ha and 4cm depth + glyphosate at 480g ai/L at 6L/ha (SD+GP), cassava peel (CP) at 30t/ha and 4cm depth + glyphosate at 480g ai/L at 6L/ha (CP+GP), (Atrazine 250g/L + Metolachlor 250g/L) at 4L/ha followed by glyphosate at 6L/ha (P+GP) and no weeding (NW) for weed control in juvenile sweet orange orchard at National Horticultural Research Institute (NIHORT). The spacing for Sweet orange was 5m x 5m, while the experiment was laid out in randomized complete block design in four replications. Data were collected on cost of input on cover crops, mulch materials and herbicide integration in sweet orange orchard as well as output at the prevailing market prices. Results revealed that highest cost of production was incurred in CP+GP compared to the combination of SD+GP, AK+AM, PK+AM and NW. Highest revenue of N108,640/ha was obtained in PK+AM. There were negative returns to investment in CP+GP, SD+GP, AM+GP and NW, while benefit to cost ratio was highest (2.4) in PK+AM. The study recommends use of cover crops with herbicide integration for weed management during juvenile stage of citrus due to improved weed suppression and generation of income that may be utilized to manage the orchard during the juvenile stage.
Keywords: *Sweet orange, juvenile orchards, weed management, economic analysis.*

INTRODUCTION

Integrated weed management practices are a system that combines more than one weed management methods at a reduced cost to obtain a level of weed suppression superior to that ordinarily obtained when one weed management method is used (Alamu 2019). The goal of integrated weed management is to optimize benefits and minimize liabilities associated with other weed control methods (Teasdale, 1996). Sustainable weed management employs both proactive and reactive measures to weed control (Sullivan, 2003) which farmers can afford, accept and practice with safety to land, water, crop and other resources. Weeds should be controlled by least expensive available technology that does not interfere with other phases of crop production or other human activities (Rana and Rana 2016). Any weed control measures should be used only when its results are expected to be more economically beneficial than without using any control measure. Farmers compare time and cost of weed control and usually select management tactics having the lowest cost. Therefore, choice of weed control inputs depends not only on its efficacy but also on its cost (Rana and Rana 2016).

There is little information on economics of weed control in sweet orange orchard. Previous empirical work on economics of weed management in Nigeria includes those of Osipitan et al, (2019). The authors analysed economics of weed management methods as influenced by row spacing in cowpea and found that pre-herbicide for weed management could help to optimize yield and increase profitability under a narrow spacing in cowpea cultivation. Samant and Prusty (2014) in India investigated effect of weed management on yield, economics and nutrient uptake in tomato and found that application of straw mulch was economically viable for control of weeds in case of labour scarcity with better nutrient uptake and maximum fruit yield and higher net profit. The present study therefore intends to fill the above gap by analyse the cost and benefits of the selected integrated weed management practices in order to recommended the most sustainable and profitable treatment to citrus producers during the juvenile stage of production.

MATERIALS AND METHODS

The experiment was carried out in an established sweet orange orchard with 24 months (2 years) old sweet orange trees at the National Horticultural Research Institute (NIHORT) Ibadan (07° 24'36.88" N, 003° 51' 16.05" E, 213 meters above sea level). Ibadan lies in the derived savannah of South west Nigeria. The area has a bimodal rainfall distribution which peaks in July and September. Treatment consisted of Cucurbita pepo + atrazine (250 g a.i/L + metolachlor 250 g a.i/L) at 4 L/ha (PK + P), Vigna sesquipedalis (Akidi) + atrazine (250 g a.i/L + metolachlor 250 g a.i/L) at 4 L/ha (AK + P), sawdust + glyphosate isopropylamine salt (480 g a.i/L) at 6 L/ha (SD + GP), cassava peel + glyphosate (isopropylamine salt 480 g a.i/L) at 6 L/ha (CP + GP), metolachlor followed by glyphosate (P + GP) and no weeding (NW) as control. These treatments were applied at the beginning of each cropping year, while the duration of the experiment was two years. The plot size was 10m x 10m, while the spacing for sweet orange seedlings was 5m x 5m within and between rows, with total land area of 2400 m2. The experimental design was a randomized complete block design (RCBD) in four replications. Economic analysis of the performance of sweet orange with the cover crops, mulch materials and herbicide integration treatments were carried out using gross margin analysis, benefit to cost ratio and rate of return to investment.

Gross Margin = TR - TVC

TR = Total Revenue

TVC = Total Variable Cost

BCR = TR/TVC

BCR = Benefit to Cost Ratio

BCR > 1 = Viability of the business

BCR = 1 is breakeven point

BCR < 1 = business not viable.

Gross margin and BCR were computed for each treatment using the prevailing price in the study area. The BCR was used to examine the viability of the investment.

RESULTS AND DISCUSSION

Estimated cost of Production and revenue with the integrated weed control strategies in juvenile sweet orange orchard during the cropping year.

The cost of production of sweet orange as influenced by integrated weed management strategies is presented in Table 1. At first year, with the mulch materials and herbicide treatments plots, highest total variable cost of N95,400/ha was recorded in sweet orange plots mulched with CP + GP, followed by SD + GP (N49,400/ha). Atrazine 250g/L + Metolachlor 250g/L (AK + P) recorded higher total cost of N45,600/ha compared to PK + P (N44,900/ha) with the use of the cover crops. Combination of Atrazine and Metolachlor recorded lower costs compared to the mulch materials and cover crops. Succinctly, costs of production were higher in mulch materials with herbicide integration compared to the cover crops and herbicide integration plots. This may be attributable to the cost of obtaining cassava peel and sawdust, most especially the cost of transporting the materials. There were returns from the cover crops during the cropping season. The highest total revenue of N108,640/ha was obtained from pumpkin plots while N69,600/ha was obtained from Akidi plots. There was no revenue from cassava peel, sawdust and herbicide integration plots.

The results of the gross margin analysis indicated a total of N63,740/ha from the sweet orange + PK + P plots. Alamu et al., (2022) reported that highest gross margin of N106,000/ha was recorded from sweet orange plots interplanted with sweetpotato compared to pumpkin and egusi melon plots. A total of N24,000/ha was also realized from sweet orange + AK + P during the cropping year. There were negative returns in CP + GP, SD + GP, P + GP and the NW plots. Highest negative returns were obtained in CP + GP (95,400/ha) followed by SD + GP plots (49,400/ha), while the least negative returns were recorded for P + GP plots (38,000/ha). This is similar to the report of Alamu et al., (2022).

CONCLUSION AND RECOMMENDATION

This study revealed that alternative use of cover crops, mulch materials integrated with herbicide could reduce the cost of production by reducing the weed pressure and increase economic returns to the farmers.

PROFITABILITY AND ECONOMIC ANALYSIS OF PINEAPPLE-BASED INTERCROPPING SYSTEM IN SOUTH-WEST NIGERIA

Ajayi A. J* and Ajayi G. O.
. Department of Crop Production Technology, Federal College of Agriculture, Akure.

Corresponding author: ajayiaj@yahoo.com

ABSTRACT
In this study, the economic and profitability of pineapple-pepper-cowpea based intercropping system in Akure was evaluated. The experiments evaluated the impact of time of introduction of one of the component crops, cowpea into the intercropping system on the intercrop. Sowing of cowpea into pineapple-pepper intercrop was done at the time of transplanting pepper seedlings into pineapple, at 3, 6 and 9 weeks after transplanting (WAT) pepper seedlings into pineapple. Sole crops of the crop components were also established. The cost of production and returns from each crop combination were aggregated. Economic returns and profitability indices showed that sole pineapple and pineapple-pepper-cowpea intercrop were profitable. Pineapple-pepper intercrop without cowpea and sole pineapple appeared as the preferred options based on their slightly higher net benefits. However, delayed sowing of cowpea into pineapple-pepper intercrop ensures the spread and diversification of produce and income to the farmer in addition to immediate satisfaction of food need of the farmer's family.
Keywords: *pineapple, cost benefit ratio, intercropping, profitability, income diversification*

INTRODUCTION
Pineapple (Ananas comosus (L.) Merrill) is an important tropical fruit characterized by initial slow growth during establishment phase and long gestation period from planting to flowering and fruiting. The lack of immediate returns on investment in a sole pineapple enterprise during the first year of cropping and challenges associated with management of the wide spaces between the rows of pineapple pose a lot of challenges to farmers. However, pineapple intercropping provides an opportunity for resource constraint farmers to optimize their production by growing short duration food crops with pineapple in order to get income more quickly (Uriza et al., 2005). This will improve crop diversity, spreads of labor and their economic profitability. Introduction of Peppers (*Capsicum spp*), a short-term perennial crop within the rows of pineapple during the establishment phase can be practiced to maximize utilization of farm resources. The introduction of another short duration crop such as cowpea (Vigna unguiculata) can further extend the utilization of resources (space, light and water). However, the productivity of the components of the intercropping and the effectiveness of resource utilization will depend on timing and scheduling of the growth phases in which the component crops interact on the field and the seasons. It is imperative to adjust cropping pattern and the timing of introduction of component crops into the pineapple-pepper intercropping system especially the timing of cowpea introduction in order to minimize competition among component crops. The choice of intercrop combination to adopt is the decision of the farmer which may be based economic profitability in addition to other perceived benefits such as internal insurance from crop failure obtained from crop diversity and steady and continuous flow of income. The aim of this paper) is to evaluate the economic and profitability of pineapple-pepper based intercropping system when cowpea is introduced at various intervals.

METHODOLOGY
The economic and profitability of pineapple-pepper-cowpea based intercropping system of experiment an conducted at the Experimental Station of the Federal College of Agriculture Akure, Nigeria between 2014 and 2015 was evaluated. The experiment comprised of four dates of sowing cowpea into pineapple-pepper intercrops namely: sowing of cowpea at the time of transplanting pepper seedlings into pineapple, sowing at 3, 6 and 9 weeks after transplanting (WAT) pepper seedlings into pineapple, pineapple-pepper intercrop without cowpea and the sole crops of pineapple, pepper and cowpea. The cost of production and returns from each crop combination based on one cycle of production were aggregated. A number economic analysis tools were used to evaluate the different treatments. These include: partial budget analysis, benefit to cost ratio, rate of return on investment and profit margin. Crop enterprise budget were

developed for each treatment. Crop prices and operational cost used in the budgets were averaged prices that were prevalent in the study area during the cropping seasons. Total revenues were calculated annually as the products of treatment yield and average price. Variable costs were the actual cost incurred in the production. Net benefits per hectare were calculated as the difference between total revenue and total cost. In constructing the budget, no charges were included for land.

Formulae for estimating economic indices

1. Total Variable Cost (TVC) = Labor cost + Cost of inputs + Transportation/handling
2. Total Cost (TC) = Total Variable Cost (TVC) + Fixed Cost (FC)
3. Gross return/revenue = Average yield/ha x farm gate price (N/kg)
4. Net Benefit (NB) = Total Revenue (TR) – Total Cost (TC)
5. Rate of Return on Investment (RORI) = Net Benefit (NB)
   Total Cost (TC)
6. Benefit to Cost Ratio (BCR) = Total revenue (TR)
   Total Cost (TC)
7. Profit Margin (%) = Net Benefit (NB)
   Total Revenue (TR)

RESULTS

Analysis of economic returns

Gross Returns from intercropping treatment combinations

The Gross Returns of each component crops in the intercropping treatment in relation to the cost of production are presented in Fig. 1. The figure show the trends reduction in the gross returns from pineapple fruits associated with intercropping with cowpea and pepper. The magnitude of reduction in Gross Return recorded for pineapple was minimal when cowpea was introduced at the time of transplanting pepper into pineapple compared with those delayed. The returns from pepper however increased progressively with delayed sowing of cowpea into pineapple-pepper intercrop while returns from cowpea declined with the delay in sowing cowpea.

Budgetary analysis

Tables 1 show the enterprise budget of the different crop enterprises in the experiments. Table 3 shows the summary of economic returns under the different treatments. Positive Net Benefits were obtained except for sole pepper and cowpea with negative net benefits. The lowest Net Benefits (N959, 961) was obtained among the intercropped plots when cowpea was introduced at the time of transplanting pepper into pineapple. Negative net benefits were obtained for pepper and cowpea. Table 2 presents the benefit to cost ratio (BCR) which were in general greater than 1 except for sole pepper and cowpea. The highest BCR (1.91) which was obtained from pineapple-pepper intercrop alone (no cowpea) was not different from BCR (1.90) for sole pineapple. Benefit cost ratio is greater than one (BCR>1) indicates efficient production of crop combination while BCR < 1 indicates an inefficient production. The introduction of cowpea into the pineapple-pepper intercrop tends to reduce the BCR. The BCR > 1 is indicative of efficient production from such crop combination. That is high returns are made as profit for every unit amount invested. BCR value of 1.91 and 1.86 for plots with pineapple-pepper alone and plot with cowpea introduced into pineapple-pepper intercrop at 6 WAP means that for every N1 spent on the enterprise N0.91 and N0.86 were returned as profit respectively. The rate of return on money invested in the crop enterprise follows the same trend as benefit to cost ratio. It is an indication of profitability of an enterprise; it shows the percentage of return on every unit of investment in the enterprise. Moderate profit margins were returned from economic evaluation of the production experiment.

DISCUSSION

Analysis of economic returns

The high slight reduction in the Net Benefit obtained when cowpea was introduced into pepper during the time of transplanting pepper into pineapple resulted from competition experienced by pepper and pineapple from cowpea which grow vigorously and partially shaded them at early stage. Increasing magnitude of Net Benefits followed the trend of increase in the yield of pepper recorded with the delayed sowing of cowpea since higher yield of pepper was obtained with delayed sowing of cowpea. Generally, the higher Net Benefit was obtained could be adduced to higher yield recorded for pineapple. This might have resulted from lower competition and recovery growth after other component crops has completed their growth cycle and subsequent higher yield that follows.

Positive and high rate of return is always desirable in any enterprise. Enterprise with negative net benefit (net loss), RORI and PM should not be undertaken. The profitability ratios such as BCR, RORI and PM indicates that the intercropping of pineapple and pepper with cowpea introduced at later stage of development are all profitable. Olubode *et. al*., (2012a, 2012b) reported profitability of pawpaw-okra and pawpaw-okra-cucumber intercrop. The rates are indicative of profitability of pineapple enterprise and its intercropping combination. In research involving interplanting pineapple with hot jalapeno pepper, dry beans, corn and tomato, Uriza et al., (2002) reported that the benefit/cost ratio was best for pineapple intercrop than when they were alone. Balasubramanian and Sekayange (1990) while citing Zandstra (1979) reported that utilizing different mechanisms in cultural manipulations could assist to maximize profit in intercropping system.

CONCLUSION AND RECOMMENDATIONS

Economic returns and profitability indices showed that sole pineapple and pineapple-pepper-cowpea intercrop were profitable. The performances were just slightly above that of intercropping involving introduction of cowpea into pineapple-pepper intercrop at 6 WAP. Pineapple-pepper intercrop without cowpea and sole pineapple appeared as the preferred options based on their slightly higher net benefits. However, delayed sowing of cowpea into pineapple-pepper intercrop especially by 6 weeks enhanced utilization of growth resources in addition to diversified produce obtained and can be practiced by farmers. Diversity is a form of internal insurance to ensure steady and continuous flow of income and prevention of crop failure that might be associated with mono-cropping. This includes the diversified sources of income and farm products from the farm, spread or distribution of income to the farmer in addition to immediate satisfaction of food need of the farmer's family and the possibility of farmers making high returns from the short duration annual crops such as pepper and cowpea intercropped at the early stage of the establishment of pineapple. This might help to offset initial cost of maintenance because most farmers are resource constrained. The appropriate time to introduce the cowpea is important. Early sowing of cowpea was more detrimental to the other component crops especially pepper. Hence, when the introduction of cowpea into pineapple-pepper intercrop is desired, cowpea should be introduced as from six weeks after transplanting pepper into the mixture

Based on the findings of the study, it can be recommended to pineapple farmers to introduce pepper into the spaces between the rows of pineapple as soon as the pineapple field is planted. Nevertheless, sowing of cowpea should be delayed up to six weeks after transplanting pepper. This practice will expand income base from the minor component crops (pepper and cowpea) while the main crop (pineapple) is getting established.

ABSTRACT
The research study aimed to evaluate the fertility status of the soils using fertility indicators and soil nutrient index. The findings showed that the soil samples had a slightly acidic soil reaction. The organic carbon content ranged from low to medium levels, varying from 0.80 to 9.20 g/kg. Similarly, the total nitrogen and available phosphorous contents were in the low range, with values ranging from 0.10 to 1.15 g/kg and 2.98 to 5.95 mg/kg, respectively. The soil nutrient index value (NIV) calculated for soil organic carbon, total nitrogen, available phosphorus, extractable magnesium, and extractable potassium indicated a low category, with a value less than 1.67. The NIV for pH and extractable calcium content fell into the medium category, with values of 1.71 and 1.72, respectively. The study recommends the utilization of both organic manure and inorganic fertilizers to enhance the fertility status of the soil.
Keywords: *Organic carbon, Fertility, Minerals and Nutrient index,*

INTRODUCTION
The productivity of crops in sub-Saharan Africa is hindered by poor soil fertility, primarily due to inadequate soil nutrient management strategies (Mugo *et al*., 2020). Continuous cultivation without proper nutrient replenishment leads to nutrient deficiencies, as crops extract large amounts of essential nutrients from the soil. Assessing soil fertility is crucial for sustainable nutrient management, as it allows for the measurement of available nutrients and estimation of the soil's capacity to supply nutrients to crops. Soil fertility plays a vital role in determining crop yield and productivity, and nutrient deficiencies are major obstacles to soil sustainability and productivity (Kumar *et al*., 2013). However, there is limited information on soil fertility and nutrient analysis in the garden soils of the Institute for Agricultural Research (IAR) in Zaria. Therefore, this study aims to fill this knowledge gap by investigating the fertility status of the garden soils to provide appropriate fertilizer recommendations and promote sustainable agricultural development. Conducting soil testing and nutrient analysis will provide valuable information for strategic planning and enhance cultivation practices, particularly for horticultural crops. By understanding the nutrient availability in the garden soils, this research will contribute to maximizing crop yields and maintaining optimal soil fertility over time.

METHODOLOGY
The Study area
The present study was carried out at the Botanical Garden of Institute for Agricultural Research (IAR) Samaru, Kaduna State of Nigeria Experiment site is located on 11° 10.37.0'N latitude and 7° 37.88.1'E longitudes with an altitudinal 698 m above the sea level in the northern guinea savanna ecological zone of Nigeria. The climate is characterized as sub humid tropical region with two distinct wet and dry seasons The botanical gardens grow different fruits and agriculture crops in 6.41 hectare area. The garden has several hybrid fruit trees: guava, mango, cashew, grape vine, pawpaw, coconut, apple, oil palm, jack fruit, avocado pear, custard apple, kola nut, cocoa, coffee, orange, banana, among others. The garden is well laid out and bifurcated for the nursery and permanent plots for specific tree species.
Field Observation

Two profile pits were randomly dug within the garden and a total of seven (7) soil samples were collected from the pedogenic horizons for soil characterization. Bulk soil samples were also collected from each genetic horizon for laboratory analysis.

Laboratory analysis

Bulk soil samples collected from each genetic horizon were air dried, ground and sieved to remove materials greater than 2 mm in diameter. The less than 2 mm separates were used for laboratory analysis. Soil reaction (pH) was determined in water in a 1:2.5 soil solution ratio, using a Pye Unicam model 290 MK pH meter (Agbenin, 2005). The acid dichromate wet oxidation method of Walkley and Black as described by Nelson and Sommers (1986) was used in the determination of organic carbon. Total nitrogen was determined by the Macro Kjedahl method (Bremmer and Mulvaney, 1982). Available phosphorus was determined by the Bray-1 method as described by Bray and Kurtz (1945). Exchangeable bases (Ca, Mg and K) and cation exchange capacity (CEC) were determined by neutral (pH 7.0) ammonium acetate (NH_4OAc) solution as described by Anderson and Ingram (1993). Base saturation (BS) was calculated by dividing the sum exchangeable bases (Ca, Mg, K and Na) by the CEC as follows:

$$BS = \frac{Sum\ of\ exchangeable\ bases}{CEC} X100$$

Nutrient index

Nutrient index value is a measure of nutrient supplying capacity of soil to plants (Amara *et al*., 2017). The nutrient availability Index was calculated based on the Federal Ministry of Agriculture and Rural Development, (2012) fertility rating chart (Table 1). An index refined by (Kumar *et al.,* 2013; Amara *et al*., 2017) was used to compare soil fertility levels in the garden.

$$Nutrient\ index = \frac{(1 * X) + (2 * Y) + (3 * Z)}{Total\ Number\ of\ Samples}$$

Where X is the No. of samples in the lower category

Y is the No. of samples in the medium category

Z is the No. of samples in the High category

The nutrient index value 1.67 to 2.33 is considered as medium. The NIV less than 1.67 is considered as low and greater than 2.33 is as high. The NIV is evaluated for pH, OC, Total N, Available P, exchangeable K, Ca and Mg.

RESULTS AND DISCUSSION

Fertility status of Soils at IAR Horticultural Garden

Soil pH is the single most factor affecting soil nutrients due to its effects on availability of essential plant nutrients (Mugo *et al*., 2020; Sachan and Krishna., 2021). The pH of the soil samples in salt medium ranged from 4.60 to 5.90 (Table 2) similarly, the pH in a natural medium ranged from 5.70 to 6.40. This shows a low acidic soil reaction (pH) The pH range of soil are within the range of plant available nutrient which implied that nutrients are likely to be available for crop uptake (Aliyu 2023). The organic carbon content of soil samples examined province ranged between 0.80 and 9.20 g/kg. (Table 2). Low organic carbon status of the soil could be due to degradation of plant parts, litter, crop, and animal residues via the mineralization process (Aliyu, 2023). Nitrogen is an essential nutrient for plants and ranged between 0.10 and 1.15 g/kg (Table 2). This indicates the low status of nitrogen. The available phosphorus in soil samples ranged between 2.98 and 5.95 mg/kg (Table 2). This indicates the low status of the available phosphorus. The range may be attributed to variations in soil pH and organic matter content, (Shobayo *et al*., 2019). The exchangeable calcium of the analysed soil samples varied from 0.80 - 1.80 cmol/kg (Table 2), this indicates low to medium exchangeable calcium. Calcium content of soils depends upon the parent material and weathering status of the soil (Prasad and Shivay, 2020). The exchangeable magnesium of soils of the analysed soil samples from 0.20-0.50 cmol/kg (Table 2) indicating its low. The available Potassium of the analysed soil samples varied from 0.12-0.27 cmol/kg (Table 2). This indicates low to medium status of the available potassium. Low to medium extractable potassium in the farm might be due to the optimum application of potash as well as less loss of potassium ions from the soil (Aliyu, 2023). The cation exchange capacity (CEC) of soils of the analysed soil samples ranged from 5.70-9.60 cmol/kg (Table 2) indicating a moderate CEC. The moderate CEC of the soils could be attributed to nature of the clay minerals having mixed mineralogy (Shobayo *et al*., 2019). Moderate CEC implies that moderate plant nutrient will be retained. Base saturation in the garden soils was rated low, it fell within the range of 19.24 to 37.85 %. FAO (1999) reported that soils with base saturation of > 50 %

are regarded as fertile soils while soils with less than 50 % were regarded as not fertile soils. Based on this therefore, the soils are generally not fertile.

Nutrient Status of Soil in IAR horticultural Garden

The soil samples nutrient values were rated using the soil nutrient rating chart. The results are presented in Table 3. The NIV calculated for pH measured in water (1.72) and exchangeable calcium (1.74) were greater than 1.65 thus classified in the medium category. The NIV calculated for pH measured in salt, organic carbon, available nitrogen, exchangeable magnesium, and potassium content were in the low category with values of 1.00, 1.00, 1.00, 1.00, 1.00 and 1.29, respectively.

CONCLUSION

This study evaluated soil fertility status of soil using nutrient index method at IAR Horticultural Garden with low content of organic carbon, Total nitrogen, available phosphorus. Low to medium extractable calcium and potassium and moderate cation exchange capacity. The nutrient index varies from low to medium. Given the depleted state of plant nutrient in the garden, this study recommends management practices such as manure or compost incorporation, crop residue retention, green manuring, urea application, and potash.

ABSTRACTS
*Importance of turfgrass in the environment cannot be overemphasized and its essence is in the quality, which can be affected by seasons. Therefore, this study was conducted to determine the effect of seasonal variation on quality parameters (colour, density, texture, and vigour) of some selected turfgrasses (*Axonopus compressus, Cynodon dactylon, *and* Paspalum vaginatum*) in Akure for the 2018/2019 and 2019/2020 season. Data were analyzed using Microsoft Excel and results were presented graphically using bar and line charts. Results indicated variations among the turfgrass species for quality parameters across seasons. Generally, the variations were directly proportional to the rainfall patterns in both seasons. This implies that moisture determines the quality of turfgrasses. Consistently,* P. Vaginatum *performed best in all the quality parameters evaluated in both seasons due to its possession of underground stem (rhizome), and thus recommended as an excellent turfgrass specie.*
Keywords: *rainfall, seasonality, turfgrass, turf quality*

INTRODUCTION

Turfgrasses are the primary vegetative covers for lawns found in airports, athletic fields, cemeteries, commercial buildings, golf courses, home, schools, recreation parks and gardens. Apart from typical usage for recreation and aesthetic facilities, turfgrasses also provide a valuable environmental function by preventing soil erosion from wind and rain, reducing runoff from rainfall, improving soil absorption of and infiltration of water, fire abatement and other beneficial environmental impacts (Chawla *et al*., 2018). In Nigeria, there is a growing increase in the use of turgrasses for its aesthetic value around residential, public, stadia and commercial buildings (Agufugo and Iyi, 2023). Climatic factors are key determinants to turf production processes; solar radiation, rainfall and temperature fluctuations lead to water shortage, altering soil moisture content, pest and disease occurrence that restrict turf growth (Oerke *et al*., 2012; Gommes *et al*., 2010). Rainfall is undoubtedly one of the most important climatic variables. It has far-reaching influences in agricultural production, the crucial role rainfall plays in crop production includes the supply of moisture to the soil to activate crop growth, the replenishment of water in rivers to make irrigation possible through seepage and percolation, and building of underground water resources which are later tapped by wells in drier areas (Tiamiyu *et al*., 2018).
The essence of turf is in its quality. Visual qualities are actually founded on functional qualities and the functional quality of a turfgrass is determined solely by its vegetative plant part and its growth and development (Gobilik *et al*. 2013). Turf respond differently to seasonal variation thereby affecting their qualities. Hence, identifying turf species that can have consistent quality across season is very essential. Important turf qualities include; colour, texture, density, flatness and growth habit of turf.
The objective of the research work is to determine the effect of seasonal variation on turf quality parameters such colour, density, texture and vigour.

MATERIALS AND METHODS

The experiment was conducted at the field of The Federal University of Technology, Akure in southwest Nigeria. Field establishment of the experiment was carried out from May 2018 and repeated the following year 2019. The experiment comprised three species of turfgrass: *Axonopus compressus* (Carpet grass), *Cynodon dactylon* (Bahama grass), and *Paspalum vaginatum* (Portharcourt grass) as test crops replicated three times in a Randomized Complete Block Design and grown for two season. Carefully stripped sprigs of the three turfgrass species, of 10 cm long were planted at spacing of 10 x 10 cm in each experimental plot according to the randomization. Data on Turf quality parameters such as; turf colour, turf density, turf vigour and turf texture were collected every month. Monthly data on precipitation of the two seasons were obtained throughout the duration of the experiments. Turfgrass quality was assessed by a visual score based on a 1 - 9 scale, as used in the National Turfgrass Evaluation Program in the USA. The lowest level (1) defines very poor turf quality while the highest level (9) indicates outstanding turf quality, a rating of 6 is considered minimally acceptable (Morris, 2002). Microsoft Excel was used to analyze the data and the results displayed in bar and line charts.

RESULTS AND DISCUSSION

The quality of a turf is a function of its utility, appearance and favourable characteristic according to its intended use (Turgeon, 2008). Quality of turf is related to function and subjective requirement (Weicko, 2006). Turf quality is a synthetic index evaluated by visual observations and it highlights the quality of turf. The most common way of assessing turfgrass quality is a visual rating system that is based on the turfgrass evaluator's judgement. Turf species respond differently to seasonal variation thereby affecting their quality (density, texture, growth habit, flatness, vigour, color and homogeneity). Hence, identifying turf species that can have consistent quality across season is very essential. In this study variations were observed among the species for quality parameters such as colour, texture, density and vigour across seasons. These variations could be attributed to differences among the turf species. This is in line with the findings of Severmutlu *et al.*, 2012 where variations were observed among different turf species in Turkey across seasons.

Colour is a measure of light reflected by turfgrass (Turgeon, 1980). It is a useful indicator of general condition of plant and influenced by weather, fertilization, disease, nutrient deficiency, cultural practices like mowing quality. In addition, green is a colour of chlorophyll and thus it indicates chlorophyll concentration and grass health (Mangiafico and Guillard, 2005). The colour variation across the turf species for the 2018/2019 and 2019/2020 seasons are presented in Figures 1 and 2. There was high variation among the different species of turfgrass with regard to turf colour scores in different seasons and years. At two months after planting (July) during the course of the two seasons, all species achieved a minimum acceptable turf colour rating of 6, however, declines were observed during the dry season except for the month of November in the 2019/2020 season. This decline in colour can be attributed to low soil moisture due to shortage of rain during the dry season (Figure 1). All species in the 2018/2019 growing season reached their ideal turf colour at 2 MAP (July), with the exception of *A. compressus*, which did so at 3 MAP (August). All species achieved a pretty consistent turf colour in the 2019/2020 growing season between 4 MAP (September) and 6 MAP (November). *P. vaginatum* had the best colour rating in both seasons, this could be seen vividly in the 2018/2019 season.

Turf density is a measure of number of aerial shoots per unit area (Turgeon, 2008). It can vary with genotypic, natural environmental and cultural factors (Bell, 2011). High density (dense) is the requirement for turf density, as the fundamental function of grass is to cover the ground (Janakiram and Namita, 2014). High density contributes to high visual quality of turf stands and help them withstand trampling. Variations observed in turf density of various turf species for the two growing seasons 2018/2019 and 2019/2020 could be attributed to differences in their branching ability. At 2 MAP (July), all turf species across the two growing seasons attained an appropriate turf density rating of 6 (Figures 3 and 4). *A. compressus* reached its optimal density in 3 MAP (August) in the 2018/2019 growth season, while *C. dactylon* and *P. vaginatum* did so at 1 MAP (June). From 6 MAP (November) to 8 MAP (January), a dramatic decrease in density was seen for all species. With the exception of *C. dactylon*, all turf species reached their optimal density during the 2019/2020 growing season at 4 MAP (September). In the 2018/2019 growing season, *P. vaginatum* gave the highest turf density while *C. dactylon* was the best performing in 2019/2020. This variation is attributed to differences in climatic condition in both seasons.

Fine texture is the requirement for texture to permit high speed ball movement and to create a nice feeling for feet, depending on turf field usage and personal preference (Han and Huckabay, 2008). Costea *et al*. (2012) reported that texture of turf is being influenced by the species that are composing the turf. Generally, *A. compressus* had the least texture quality, this can be attributed to the broad leaves of *A. compressus*, and the result is in agreement with the work of Roshni and Shiv (2017). The variation in texture of different turf species for the 2018/2019 and 2019/2020 growing seasons are shown in Figures 5 and 6. Turf species in both growing seasons attained acceptable turf texture rating of 6 at 2 MAP (July). All turf species attained optimum texture at 3 MAP (August) except for *C. dactylon* which does so at 2 MAP (July) in the 2018/2019 growing season. Optimum texture was obtained at 3 MAP (August) for all turf species in the 2019/2020 growing season.

The variation in vigour of different turf species for the 2018/2019 and 2019/2020 growing seasons are presented in Figures 7 and 8 respectively. All turf species attained acceptable vigour at 2 MAP (July). All species in the 2018/2019 growing season attained optimum vigour at 2 MAP (July) with the exception of *A. compressus* which did so at 3 MAP (August). In 2019/2020 growing season, all turf species attained optimum vigour at 3 MAP (August). *A. compressus* had the least vigour in both seasons, this is due to the fact that the turf where planted in open field and *A. compresus* is of shade loving type.

CONCLUSION

The turfgrass species varied for quality parameters throughout seasons. The variations were directly related to the timing of both seasons' rainfall. This suggests that moisture influences turfgrass quality. Among the studied species, *P. vaginatum* performed best in all turf qualities parameters, this can be attributed the possession of rhizome which serves as food reservoir in this species. Therefore, it can be recommended as the best turf quality parameters such colour, density, texture and vigour.

ABSTRACT
One of the primary challenges faced by cashew farmers in the nursery is weed control. This study determined the effects of different periods of hand weeding on the growth of cashew seedlings raised in nursery polythene bags. The 3 month experiment was set up in a nursery. The treatments were weed-free (WF), weedy check (WC), weeding once per week (1W), weeding once in 2 weeks (2W), weeding once in 3 weeks (3W) and weeding once in 4 weeks (4W) were replicated three times. Morphological data were collected and emerging weeds were identified. The result showed that WC (2.8) had the least seedling vigour and was also significantly different from WF (4.8), 1W (4.7), 2W (4.8), 3W (4.7) and 4W (4.8). Weed infestation affected cashew seedling growth negatively in the nursery.
***Keywords**: Weeds, Cashew Seedlings, Nursery, Weeding.*

INTRODUCTION

Cashew (*Anacardium occidentale* L) plays a vital role in Nigeria's agriculture sector and significantly contributes to the country's economy (Olukunle, 2022). It is a prominent non-oil export crop, generating substantial revenue and contributing to foreign exchange earnings (Ogunwolu *et al*., 2020). The export of cashew nuts provides income for numerous individuals involved in cultivation, processing, and trading. Cashew trees are primarily propagated through seeds, which are planted in nursery beds, nursery polythene bags, or directly in the field (Essien, *et al*., 2021). Raising cashew seedlings in polythene bags is a common practice among cashew farmers. One of the primary challenges faced in the nursery is weed control (Yu and Marble, 2022). Due to favourable conditions, such as well-drained and moist potting soil, newly potted plants are extremely susceptible to weed infection (Norcini, *et al*., 2010). Weed infestation in nurseries can lead to intense competition for vital resources such as water, nutrients, and light. Weeds compete with cashew seedlings for these resources which adversely affects their growth and development. Weeds have the potential to cause nutrient deficiencies and hinder the growth of cashew plants due to their competition with seedlings. Additionally, weeds can act as hosts for insects or pathogens, increasing the risk of infestation or disease transmission to the cashew plants.

It is crucial to implement timely and appropriate weed management practices to minimize the negative effects of weed infestation on cashew seedlings. Manual weeding, mulching, and regular monitoring are recommended as effective weed control measures in cashew nurseries. By adopting proper weed management practices, cashew farmers can ensure healthier, facilitating their successful establishment and subsequent growth in the field. The objective of this study was to determine the effects of different periods of hand weeding on the growth of cashew seedlings in the nursery.

MATERIALS AND METHOD

The three-month experiment was set up in a nursery at Akinyele Local Government Area, Ibadan, Oyo State, Nigeria. The experimental design was a complete randomized block design (CRD) replicated three times. The treatments were weed-free (WF), weedy check (WC), weeding once per week (1W), once in 2 weeks (2W), once in 3 weeks (3W) and once in 4 weeks (4W). Medium cashew nut biotype sown at 4 cm depth was used in this experiment. The seedlings were raised in a 2 mm sieved topsoil-filled polythene bag size 25 by 12.5 cm. Watering of the seedlings was carried out every two days. The polythene bags were perforated at the base to allow drainage t. Five seedlings were used per treatment making a total number of 30 seedlings per replication and 90 seedlings for the 3 replications. The initial soil sample was taken for the analysis of the physicochemical properties. . From one month after sowing, morphological data such as plant height, stem diameter, number of leaves and leaf area were recorded every two weeks. General seedling vigour was observed at three months after sowing using a vigour scale (5-Excellent, 4-Good, 3-Average, 2-Below average and 1-Poor) (Olasan *et al*., (2018). The weeds observed were also identified and recorded. Data were analyzed using Analysis of Variance (ANOVA) with the aid of GenStat statistical software and treatment means were compared using Least Significant Difference (LSD) at a 5% probability level.

RESULTS AND DISCUSSION

Table 1 highlights some of the weed species identified growing along with the cashew seedlings within the nursery polythene bags. The following weed species were identified, *Talinum triangulare, Tridax procumbens, Laportea aestuans, Spigelia antelmia* and *Chromolaena odorata which are all broad-leaf weeds and Eragrostis tremula* was the only grass weed identified. It is important to note that topsoils used in nurseries carry weed seeds from the source location and germinated with the cashew seedlings. These weeds are tropical weeds (Agyakwa and Akobundu, 1998) and they have been observed to be highly competitive with crop plants. The physical and chemical properties of the soil before planting is shown in Table. . The soil was sandy clay loam and acidic with a pH of 4.36. Egbe *et al* (1989) reported the critical level of some essential plant nutrients that must be available in the soil for raising cashew. The critical level reported for nitrogen (N) was 1g/kg, phosphorus (P) to be 3.7mg/kg, potassium to be 0.12cmol/kg and Organic Carbon (OC) to be 8.7g/kg. In reference to the report of Egbe *et al*. (1989), the N content of the soil used wass low (0.36 g/kg), OC was also low (1.74 g/kg) while available P (5.13 mg/kg) and K (1.01 cmol/kg) were high.

At 3 months after sowing (MAS), the cashew seedlings in the nursery morphologically responded differently to the weeding treatments imposed as shown in Table 3. None of the treatments significantly influenced cashew seedling height. A similar result was also observed by Garau *et al*., (2008) in their study on the effect of weeds on *Eucalyptus globulus* seedlings. However, WC still had the least seedling height of 25.5cm. Seedlings that were weeded monthly (4W) had the tallest height of 29cm followed by 3W (27.6cm), WF (27.4cm), 2W (27.2cm) and 1W (25.9cm). Table 3 further revealed that WC (18.8) developed the highest number of leaves among the treatments and was significantly different from 4W (11.5) and 2W (13.7) but not significantly different from WF (14), 1W (17.2) and 3W (13.7). Trimble, (2021) reported plants can remodify their morphology to gain a competitive advantage by growing more leaves to monopolize the limited resources within their environment. None of the treatments significantly influenced cashew seedling stem diameter (Table 3). WC (5.5 mm) and WF (5.5 mm) had the same stem diameter while 3W (5.1 mm) had the least. As shown in the leaf area column on the table, cashew seedlings were influenced by the treatments. WC (31.39 cm^2) had the least leaf area of all the treatments. This implies that WC produced the smallest leaves of all the treatments despite producing more leaves. Deen, (2003), also observed a reduction in the leaf area of *Triticum aestivum* (Wheat) under a competitive condition with *Lolium rigidum* grass weed. However, only 4W (45.77cm^2) and 3W (43.56 cm^2) produced significantly larger leaf area than WC (31.39 cm^2). Still in Table 3, notable difference in cashew seedling vigour was observed among the treatments. WC (2.8) had the least seeding vigour compared with the other treatments. This implies that weeds growing along with cashew seedlings in the polythene bags negatively impacted the general seedling vigour.

CONCLUSION

In conclusion, weeds generally affected the morphological appearance or vigour of the cashew seedlings negatively. This is at a disadvantage to cashew farmers as poor seedlings command poor market value and also cause poor survival rate of seedlings when transferred to the field. To minimize the additional cost incurred on weeding, a monthly periodic weeding can be maintained in the nursery without adversely affecting the growth of cashew seedlings.

ABSTRACT

The prevalence of micronutrient especially vitamin A deficiency has increased tremendously due to poor dietary intake. Hence, there is need to address this problem with pro-vitamin rich foods. Pumpkin which has high carotenoid content is a good candidate for alleviating vitamin A deficiency. The effects of boiling and steaming on the carotenoid contents in the pulp of two pumpkin varieties (Orangetti and Connecticut field) obtained from National Horticultural Research Institute farm around July 2023 was modeled and optimized. The pumpkin pulp was steamed and boiled for varying time between 0 to 6 minutes, and total carotenoid content was determined on it. The result showed that the carotenoid content decreased for variety 1 (Orangetti) after treatment from 13.79 to 7.94 µg/g while the second variety increased after treatment from 8.79 to 29.40 µg/g. Central composite design of response surface methodology was used as statistical indicator with boiling and steaming time (0-6 minutes) serving as independent variables. As indicated by p-values that of 0.01 and 0.02, both boiling and variety had a significant impact on the carotenoid content of pumpkin pulp. However, steaming had no significant impact on the carotenoid content. The optimization result revealed that Connecticut field was the most desirable with 28.511 % of carotenoid by steaming at 2.6 minutes and boiling for 6 minutes. This study deduced that the application of heat to pumpkin improved the carotenoid content compared to the raw form.

INTRODUCTION

Micronutrient malnutrition, particularly vitamin A deficiency, affects about three billion people worldwide (Pritwani and Mathur, 2017). Vitamin A Deficiency (VAD) has afflicted around 5.2 million preschool-aged children and 9.8 million pregnant women, primarily in sub-Saharan Africa according to the World Health Organization (WHO) (Ohanenye *et al.*, 2021). Vitamin A is required for adequate vision, epithelial tissue integrity, and a wide range of other metabolic processes (Pritwani and Mathur, 2017). According to studies from developing countries, pro-vitamin A-rich foods account for up to 80% of dietary vitamin A intake (Cardoso *et al.* (2009);Van den Berg *et al.* (2000). Vitamin A is available in the form of pro-vitamin A carotenoids, which are pigments generated by many plants and found in green, orange, and yellow plant tissues. Most fruits and vegetables contain carotenoids and encouraging their injection daily can serve as a good potential in tackling VAD. According to the report of Pritwani and Mathur (2017), vegetables that are excellent sources of carotenoids include but not limited to carrots, green pepper, spinach, sweet potato, and pumpkin.

Pumpkin also referred to as squash exist in the family of Cucurbitaceae, genus Cucurbita (Shamsuri and Ahmad, 2019). It is widely grown throughout the tropical and subtropical countries. The most common species of pumpkin are C. maxima, C. pepo, and C. moschata (Lucia Maria Jaeger *et al.*, 2012). The flesh of the fruit is distinguished by its hard outer cover with characteristic yellow to orange colour which indicates the presence of carotenoids, with firm texture and flavour (Chuwa *et al.*, 2022). Rodriguez *et al.* (2018) reported that the fruit is abundant in minerals such as potassium, calcium, phosphorus, ß-carotene (which can be converted to vitamin A), dietary fibre, and lycopene. Vegetables are eaten in either raw or cooked form. Research has shown that most nutrients in fresh vegetables are preserved in the raw condition, however any degree of cooking leads in partial loss of nutrients and significant changes in its sensory properties. Some researchers have conducted studies on the effects of different cooking methods on pumpkin (Shamsuri and Ahmad (2019);Lotfy *et al.* (2017). However, studies focused on modeling and optimization of cooking methods on the total carotenoid content of pumpkin is very hard to come by. Therefore, this study modeled and optimized the effects of boiling and steaming on the total carotenoid content of two varieties of pumpkin using response surface methodology (RSM).

Variety 1 (Orangetti)

Variety 2 (Connecticut field)

MATERIALS AND METHODS

Sample preparation

Two pumpkin varieties (Orangetti and Connecticut field) cultivated and harvested at the same time were obtained from the Research farm of National Horticultural Research Institute, Ibadan, Oyo State. Fresh samples were washed and peeled to remove the outer skin. The seeds were removed and the pulp was cut into smaller sizes and divided into eight portions to increase the surface area and in order to facilitate the treatment process i.e. boiling and steaming. For boiling, 20 g of the sample was randomly selected from the lot and was immersed in boiling water at 100°C for 0 to 6 minutes based on the experimental design while steaming was conducted by placing 20 g of the sample above boiling water in a steamer with lid for varying time between 0 to 6 minutes.

Determination of total carotenoid

The total carotenoid content of the pumpkin was determined according to the method of Lucia Maria Jaeger *et al.* (2012) with little modification. This was done by weighing 0.5 g of the mashed sample into a 20 ml test tube and 5 ml of cold acetone was added and mixed to form a paste, and the mixture was continuously shaken until it became colourless. The extract was then transferred into a 100 ml separating funnel of containing 8 ml of n-hexane, and the acetone was separated by slowly adding water to avoid the development of an emulsion, and the aqueous phase was discarded. The technique was repeated until there was no more remaining solvent. The procedure was repeated until no residual solvent remained. Then the extract was transferred to a 50 ml volumetric flask containing 3 g of anhydrous sodium sulfate and the volume was made up to its full volume by adding n-hexane and read at 450 nm with a UV-visible spectrophotometer (T80 series UV-visible double beam spectrophotometer).

$$\text{Carotenoid content } (\mu g/g) = \frac{A \times V(ml) \times 10^4}{A^{\%}{}_{1cm} \times P}$$

Where A=Absorbance; V=Total extract volume; P=sample weight; $A^{\%}{}_{1cm}$=2560 (ß-carotene Extinction coefficient in n-hexane).

Experimental design and statistical analysis

The experimental design used in this study was the central composite design of response surface methodology; with three independent variables; in which two are numeric (boiling (0-6 minutes) and steaming (0-6 minutes), and one categorical factor (varieties). A total of 18 experimental runs was generated using Windows design expert version 13. Table 1 below give the details of the experimental runs and the treatment combinations considered for each of the run. The data obtained for the corresponding carotenoid content responses for each of the run was then subjected to multiple regression analysis. This was done by fitting the data into polynomial models whose fitness was verified using R^2 (coefficient of determination) and the corresponding p-value.

RESULTS AND DISCUSSION

The carotenoid content of the pumpkin pulp decreased after steaming and boiling for Orangetti from 13.79 % to 7.94 %. While for Connecticut field, the carotenoid content increased upon steaming and boiling from 8.79 % to 29.40 % as shown in table 1 below.

Table 1: Experimental runs, treatment combinations, and carotenoid content of the two varieties of pumpkin pulp.

Runs Variety 1	Factor 1 A: Steaming (minutes)	Factor 2 B: Boiling (minutes)	Carotenoid content (µg/g) Mean ± S.D	Runs Variety 2	Factor 1 A: Steaming (minutes)	Factor 2 B: Boiling (minutes)	Carotenoid content (µg/g) Mean ± S.D
1	0	0	13.79±0.51	**10**	0	0	8.79±0.16
2	6	0	10.38±0.92	**11**	6	0	21.29±0.10
3	0	6	8.92±0.75	**12**	0	6	24.06±0.13
4	6	6	12.86±0.80	**13**	6	6	22.34±0.13
5	0	3	10.00±0.47	**14**	0	3	17.17±0.57
6	6	3	11.46±0.67	**15**	6	3	19.25±0.06
7	3	0	7.94±0.13	**16**	3	0	8.96±0.24
8	3	6	10.60±0.82	**17**	3	6	29.40±0.41
9	3	3	9.40±0.35	**18**	3	3	20.23±0.25

As shown in the table below, the p-value of the model is 0.0215 which is less than 0.005, indicating that the model is significant. Due to the p-values above 0.05, steaming (A) is not a significant factor while boiling (B) and variety (C) is a significant factor. However, the interaction between AB and AC are not significant, while BC and ABC are significant. This implies that both boiling, and variety affects the carotenoid content no matter the treatment time of exposure while steaming does not influence the carotenoid content. The model's F-value of 5.76 obtained implies that the model is significant, and it is a good fit for predicting the responses. An R^2 value of 0.91 indicates that the model is a good predictor for the data.

Table 2: Analysis of variance table for carotenoid responses.

Source	F-value	p-value
Model	5.76	0.0215
A-Steaming	1.79	0.2292
B-Boiling	11.16	0.0156
C-Variety	9.42	0.0220
AB	0.5769	0.4763
AC	0.9630	0.3643
BC	10.83	0.0166
ABC	5.69	0.0544

Model equation for carotenoid content of the pumpkin

$12.85130-1.78426S-0.905741B+0.204259SB+0.213580S^2+0.051358B^2$ …….Equation 1

$7.07889+2.37426S+3.05500B-0.395185SB-0.079074S^2+0.028704B^2$ ……....Equation 2

The model equation above can be used to predict the value of carotenoid content in the pumpkin as steaming and boiling time varies.

The Figure 1 below shows the interaction of steaming (A) and boiling (B) time with the varieties on the carotenoid content of pumpkin respectively. The two undotted lines denotes the first (Orangetti) and second variety (Connecticut field) respectively. It can be observed that for the first variety (Orangetti), between 0-6 minutes the carotenoid content is constant and falls around 10 for both steaming and boiling i.e., the carotenoid content remains constant between that time ranges. While for the second variety (Connecticut field), the carotenoid content shows an increasing trend for steaming and boiling from 0-6 minutes. Though, boiling exhibited a more increasing trend than steaming. It can also be observed that the second variety has better carotenoid content than the first variety. According to Hwang *et al.* (2012), thermal treatment improves carotenoid availability. Similar findings were reported by Shamsuri and Ahmad (2019). Cooking methods degrade food matrices and loosen carotene-binding fibers. This may result in nutritional loss, but it may also improve bioavailability and enhance carotene content (Fernández-García *et al.*, 2012).

A B

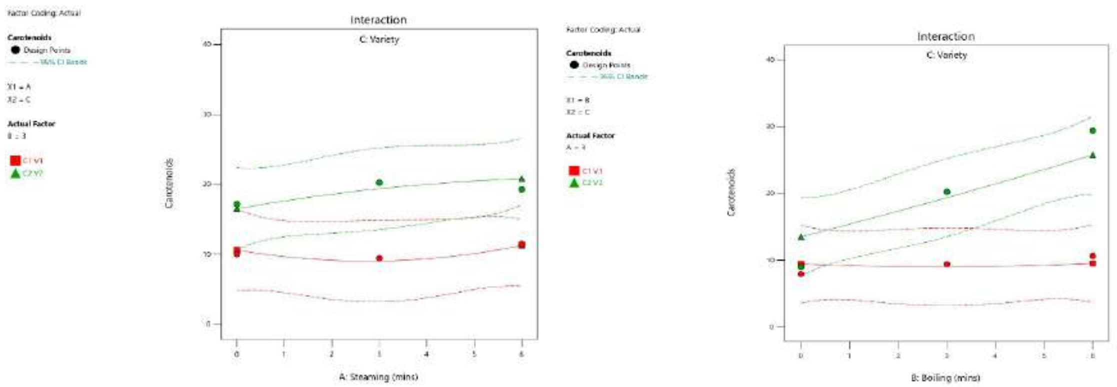

Figure 1: graph illustrating the interaction of steaming (A) and boiling (B) on the carotenoid content of pumpkin.

Optimization of the carotenoid content of pumpkin based on varied treatments

The optimization result generated 19 outputs and only 5 of the optimum desirable output were considered. The most desirable output to obtain 28.511 % of carotenoid was in second variety (Connecticut field) by steaming at 2.6 minutes and boiling for 6 minutes.

CONCLUSION

In conclusion, boiling, and time used has a substantial influence on the carotenoid content of the pumpkin varieties. However, steaming has no significant impact. The second variety (Connecticut field) was the best in terms of availability of carotene, steaming and boiling within 6 minutes can be used to enhance carotenoid bioavailability. Therefore, the inclusion of pumpkin in the diets of both children and elderly ones is recommended.

ABSTRACT
Understanding interrelationships among various agronomic traits is vital to plan an effective production program in pearl millet/ cowpea intercropping. Field experiments were conducted in 2015 and 2016 rainy seasons at the Teaching and Research Farm of the Department of Crop Production, University of Maiduguri, Maiduguri (11⁰47N; 12⁰16E) to determine the correlation effect on growth and yield traits of pearl millet varieties (Pennisetum glaucum) (L.) R. Br.) intercropped with cowpea (Cowpea Vigna unguiculata (L.) Walp) varieties. The treatments consisted of pearl millet varieties: ZATIP, SOSAT-C-88 and LACRI-9702-IC and cowpea varieties: Borno Brown and SAMPEA 11. The experimental design was Split-Split plot with the pearl millet varieties allocated to the main plots and cowpea varieties assigned to the sub-plots in 1:1 alternate row arrangement, and replicated three times. The parameters collected for pearl millet were plant height, number of leaves/plant, number of tillers/plant, leaf area, number of days to 50% flowering, grain yield/ plant, number of panicles/plant, panicle length, panicle diameter, panicle weight, 1000 grain weight, harvest index and straw yield/plant, while length of branches, number of branches, pod yield/plant, grain yield/hectare, 100 seed weight and fodder yield/hectare were determined for the cowpea component. The results showed that in 2015, 2016 and the combined mean, linear relationships among agronomic parameters of millet revealed that, grain yield/ hectare increased significantly with increase in leaf area, number of leaves/plant, number of tillers/plant, plant height, number of panicles/plant, number of grains/panicle, grain yield/plant, panicle length, panicle diameter and harvest index. Also, in cowpea number of leaf branches at harvest was positively correlated with number of pods per plant, grain yield/ha and fodder yield/ha. Length of branches was positively associated with number of pods per plant, pod per plant, grain yield/ ha and fodder yield/ hectare.
Keywords*: interrelationship, correlation, association, grains, positive*

INTRODUCTION

Cropping systems that carry with them species diversity are seen by agro ecologists and nature conservators, as having the greatest potential of imparting balancing effect on natural ecosystems, since they mimic natural crop communities with in-built processes and mechanisms that exhibit association resistance to withstand ravages of diseases and pests (Trendbath, 2006). Agro ecologist like Micheal and Talbot (2013) opined that investigating such system with a view of improving their biological efficiencies is not only agronomically desirable, but morally sensible. Intercropping is a popular traditional cropping system in the tropical part of the world. It is a practice used by famers for increasing crop yield, crop diversity and stability of crop production. For the fact that the climatic conditions in the tropics are favorable for crop production during much of the year, cropping patterns are numerous in the region. Farmers therefore, choose the one suited to their micro ecological conditions, dietary needs, management level and economic disposition. Under this system, the number of days the land is idle is greatly minimized. According to Trenbath (2001), environmental factors dictate the farming practices, since crop productivity is not only a function of the variety potential of the crops, but also the total environment in which the crops are grown. The total environment has aerial environment (defined in terms of solar radiation, temperature, precipitation, cloudiness, winds etc.) and soil environment as sub-components. The interaction of these components dictates the farming system of a given agro-climatic region by setting broad limits to land patterns and duration. The sahel with annual rainfall of 300 – 600 mm and 60 – 100 days growing season is the main area of production of pearl millet. In the Sudan

Savanna with 600 – 800 mm rainfall and a growing season of 100 – 150 days millet is intercropped with sorghum, maize, cowpea or groundnut (ICRISAT, 2013). In Nigeria 5.2 million hectares are cultivated with a total production of 6.4 million metric tonnes. Mean yield in Nigeria is 1462 kg/ ha (FAO, 2017).

Little was known on the chemistry that intricately govern the competition of same or different varieties of crops raised together before the works of De Wit (1960), Donald (1993), Trenbath (2001). But now several researchers have focused their research lights on the dynamics of this phenomenon. Two types of inter stand or neighbourhood effects influence various mixture performance, namely competition and complimentarity. **Competition**: This is said to occur when component crops compete for light, nutrients, water, CO_2 and other growth factors when they are in limited supply (Gomez and Gomez, 2007). **Complementarity**: The effects of one component on the other which enhance growth and productivity as opposed to competition (Gomez and Gomez, 2007). Thus in complimentarity, crops appear not to compete when they share a habitat (Trenbath, 2001). When each component of the mixture competes equally for growth resources as in pure cultures, the yields that would have been obtained is called the 'expected yield' (De Wit, 1960; Trenbath, 2001). Under this theoretical situation, inter specific competition equals intra-specific competition. Where both crops yields are reduced such that their yield fall short of the mean mixture yield, then we have **inhibitive competition (**De Wit, 1960). He further identified **compensatory competition** as that where increase in yield of one component results in proportional decrease in yield of a second member. The member commanding a large share of growth resources is the **aggressor** or **dominant**, while the lesser competitive is the **subordinate** or **dominated** (De Wit, 1960; Huxley and Miangu, 2009). Of recent, Vandermeer (2010) proposed two useful principles of competition which give insights into the mechanism of mixture advantages. These are **competitive production principle** and **environmental modification principle**. In the former, inter specific competition is sufficiently weak to give the intercrop an advantage, while in the latter, the environment of one or both species is altered through the presence of a second species. Adetiloye (2007) observed that neighbourhood effects are caused by competition for light, water, soil nutrients and alleged allelopathy. While competition between mixture components leads to yield compensation or even mutual inhibition such that mixture yields deviate slightly from mid-pure yield, complimentarity is the desirable situation of appreciable tolerance displayed by both members Bassi and Dugje (2016).

The fact that growing crops in mixtures ensure better land use efficiency is no longer disputable. But the dynamics of the intercrop over-yielding, especially the main source of gains in the mixtures is an aspect that many scientists report contrasting findings. But generally planting early maturing varieties and slow growing crops together seems to be an agreeable arrangement leading to intercrop over-yielding. Also important are the relative statures and size of different crops, growth cycles and seasonal period available for growth (Parish, 2005).

MATERIALS AND METHODS

The experiment was conducted during 2015 and 2016 rain-fed cropping seasons at the Teaching and Research Farm, Department of Crop Production Faculty of Agriculture, University of Maiduguri. The experimental site was located between latitude $11^0 47^1$N and $56\ 00^1$N, and longitude $03^0 12^1$ and 16^0E and altitude of 345 m above sea level, in the northern fringes of the Sudan savanna belt of Nigeria. Seeds of pearl millet and cowpea varieties were obtained from the seed multiplication Unit of Borno State Agricultural Development Programme, Maiduguri and Crop Division of Lake Chad Research Institute, Maiduguri respectively. The treatments consisted of three improved pearl millet varieties: (ZATIP, SOSAT-C-88 and LACRI-9702-IC) intercropped with two cowpea varieties: (Borno Brown and SAMPEA 11). The pearl millet was grown at (3) three plants/stand, while the cowpea were grown at 2 plants/stand (Dugje *et al*.,2009). experimental design was split-split plot with pearl millet varieties assigned to the main-plot and cowpea varieties assigned to the sub-plot, which were replicated three times. The sub-plot size was 3.0 x 5.0 m (15.0 m^2). An alley of 2.0 m was allowed between the replicates, while 1.0 m and 0.50 m alley was allowed between the main plots and sub-plot, respectively.

The land was harrowed with tractor driven disc, after which the plots were laid out and leveled before sowing. Seeds were treated with a pre-planting fungicides Apron Star (42 WS) Anaso *et al* (1998) at the rate of 5 g of chemical per kilogram of seeds. Following land preparation and leveling, the experimental micro individual plots (5m x 3m) were bounded at the edges to minimize run in and run-off. The pearl millet varieties were sown at 90 cm x 50 cm on 5th July each year while each cowpea variety was intercropped into the pearl millet at a distance 45cm from the pearl millet row and 50cm within the row at each sowing dates. The pearl millet and the cowpea intercrops were sown in 1:1 alternate row arrangement.

Fertilizer was applied by band placement at the recommended rate of 60 kg N, 30 kg P_2O_5 and 30 kg K_2O/ha (FPDD, 2002) in 2 split doses. The first dose of 30:30:30 was applied at 2 weeks after sowing (WAS), using NPK (15:15:15). The second dose of 30 kg N/hectare was applied at 6 weeks after sowing using Urea (46%N). For the legumes 50 kg P_2O_5/hectare was applied to the sole plots and the legume componet in the intercrop using single super phosphate (18% P_2O_5) one week after sowing. The same fertilizer rates and methods were applied each year. Insecticide spray for insect pest control in cowpea was done thrice at 30, 45 and 60 days after sowing each year in 2015 and 2016. The insecticide used was Cypermethrin + dimethoate (Sherpar Plus) with active ingredient of 30grams/litre + 250grams/litre. at the rate of 1 litre/hectare The sprayings were conducted using Knapsack sprayer in the evenings during the two years.

Statistical Analysis

Pearson correlation coefficient was used to estimate the relationships between yield and the crops relate traits using Discovery Edition- 3rd software (Genstat, 2007). Differences between treatments means were compared using possible linear correlation coefficients to determine the degree of association among the agronomic trats of pearl millet on one hand and that of cowpea on the other.

RESULTS

The response of pearl millet varieties intercropped with cowpea varieties in 2015 showed that, plant height was positively associated with number of leaves/ plant at harvest (r=0.78*), grain yield/ hectare (r= 0.95*) and straw yield per plant (r= 0.81*) (Table 1). Millet number of leaves/ plant at harvest was positively correlated with harvest index (r=0.92*) and straw yield (r=0.85*). Similarly, number of tillers/plant was positively correlated with number of panicle per plant (r=0.83*), grain yield per plant (r=0.95*), grain yield/ha (r=0.99**), panicle diameter (r=0.93*) and straw yield/plant (r=0.75*). Also, leaf area at harvest was positively associated with number of grains per panicle (r=0.91*), grain yield per plant (r=0.89*), grain yield/ha (r=0.93*), panicle diameter (r=0.69*), panicle weight (r=0.65*) and straw yield/plant (r=0.94*). Number of grains per panicle was positively correlated with grain yield per hectare (r=0.91*), panicle diameter (r=0.97**) and straw yield per plant (r=0.76*), Similarly, number of panicles per plant was positively associated with grain yield per plant (r= 0.88*) and grain yield per hectare (r=0.79*). Harvest index was positively correlated with grain yield per plant (r=0.90*) and grain yield per hectare (r=0.99**) (Table 1). Grain yield per plant was positively associated with panicle diameter (r=0.92*), panicle weight (r=0.85*) and straw yield per plant (r=0.77*). There was no significant linear correlation among the other agronomic traits observed during the 2015 cropping season.

The effect of intercropping pearl millet and cowpea variety on linear relationships among agronomic traits of pearl millet in 2016 are presented in (Table 2). The results showed that, there was significant linear association between millet plant height at harvest with harvest index (r=0.94*) and straw yield (r=0.92*). Number of leaves at harvest was positively associated with grain yield per hectare (0.97**) and straw yield per plant (r=0.75*). The results further revealed that, millet leaf area at harvest was positively associated with number of grains per panicle (r=0.96*), grain yield per plant (r= 0.89*) and grain yield per hectare (r=0.99**) and panicle diameter (r= 0.75*) (Table 2).

The results showed that, there was significant linear association between millet plant height at harvest with harvest index (r=0.94*) and straw yield (r=0.92*). Number of leaves at harvest was positively associated with grain yield per hectare (0.97**) and straw yield per plant (r=0.75*). The results further revealed that, millet leaf area at harvest was positively associated with number of grains per panicle (r=0.96*), grain yield per plant (r= 0.89*) and grain yield per hectare (r=0.99**) and panicle diameter (r= 0.75*). There was significant correlation between number of grains per panicle and grain yield per plant (r=0.78*), grain yield per hectare (r=0.82*) and panicle diameter (r=0.88*) (Table 2). Number of panicles per plant was positively associated with grain yield per plant (r=0.98**) and grain yield per hectare (r=0.96*). Grain yield per hectare was positively associated with millet panicle diameter (r=0.92*), panicle weight (r=0.84*) and straw yield per plant (r=0.87*). Also, panicle diameter was significantly associated with straw yield per plant (r=0.69*) in 2016 cropping season (Table 2). There was no significant correlation among the other agronomic traits observed in 2016 cropping season.

The effect of intercropping pearl millet variety with cowpea variety on interrelationships among agronomic traits of pearl millet for the combined mean of 2015 and 2016 cropping seasons showed that, there was positive linear correlation among agronomic traits of pearl millet intercropped between the plant height at harvest and millet grain yield per plant (r=0.84*), grain yield per hectare (r=0.93*).

and straw yield per plant (r=0.76*)(Table 3). Number of leaves per plant at harvest was positively correlated with number of grains per panicle (r=0.91*), grain yield per plant (r=0.98**), grain yield per hectare (r=0.90*) and straw yield per plant (r= 0.63*). The effect of intercropping on pearl millet variety in combined mean showed that, millet leaf area at harvest was significantly correlated with number of grains per panicle (r=0.79*), grain yield per plant (r=0.87*), grain yield per hectare (r=0.96*), panicle diameter (r=89*) and straw yield (r= 0.70*), while grain yield per hectare was significantly correlated with panicle diameter (r=0.75*) and straw yield (r=0.81*). There was no significant linear correlation among the other agronomic traits determined for the combined mean (Table 3).

Interrelationships among Cowpea Variety Agronomic Traits

The response of cowpea varieties to intercropping with pearl millet varieties in 2015 cropping season showed that, there was significant linear correlation between plant height at harvest and fodder yield/ha (r=0.96*) (Table 4). Similarly, number of leaf branches at harvest was positively associated with number of pod per plant (r=0.99**), pod yield per plant (r=0.86*), grain yield/ ha (r=0.94*) and fodder yield/ ha (r=0.86*). Length of branches at harvest was positively correlated with number of pod per plant (r=0.93*) and pod yield per plant (r=0.80*), grain yield/ ha (r= 0.95*) as well fodder yield / ha (r=0.99**) (Table 4). There was significant linear correlation between number of pods per plant, pod yield per plant (r=0.81*) and grain yield / ha (r=0.90*). Pod yield per plant was positively associated with grain yield / ha (r=0.88*) and fodder yield / ha (r= 0.91*). No significant linear correlation was observed among the other agronomic traits determined for the cowpea component (Table 4).

The effect of intercropping pearl millet varieties on cowpea varieties on cowpea agronomic traits showed that, plant height at harvest was positively associated with pod yield per plant (r= 0.81*) and fodder yield/ ha (r=0.69*) (Table 5). However, number of branches at harvest was positively associated with number of pods per plant (r=0.89*), pod yield per plant (r=0.70*), grain yield/ ha (r=0.92*) and fodder yield/ ha (r=0.97**). Length of branches at harvest was positively associated with number of pods per plant (r=0.79*), grain yield/ ha (r=0.89*) and fodder yield/ ha (r=0.67*). Similarly, number of pods per plant was positively associated with pod yield per plant (r=0.72*) and grain yield/ ha (r=0.86*), while pod yield per plant was positively correlated with grain yield/ ha (r=0.90*) and fodder yield/ ha (r=0.84*). No significant linear correlation was observed among the other agronomic traits determined for the cowpea components during the 2016 cropping season (Table 5).

The effect of intercropping pearl millet + cowpea variety on cowpea traits for the combined mean showed that, there was positive correlation between the plant height at harvest and fodder yield/ ha (r=0.86*) (Table 6). Number of leaf branches at harvest was positively correlated with number of pods per plant (r=0.92 *), pod per plant (r=0.83*), grain yield/ ha (r=0.94*) and fodder yield/ ha (r=0.77*). Length of branches at harvest was positively associated with number of pods per plant (r=0.99**), pod per plant (0.77*), grain yield/ ha (r=0.98**) and also fodder yield/ ha (r=0.91*). Number of pods per plant was significantly associated with grain yield/ ha (r=0.90*) and fodder yield/ ha (r=0.89*). No significant correlation was observed among the other agronomic traits of the cowpea for the combined mean.

DISCUSSION

The linear relationship among agronomic traits of pearl millet varieties intercropped with cowpea indicated that most of the growth characters studied had significant and positive linear correlation with grain yield. Similarly, most of the yield components studied had significant and positive

correlation with grain yield. These suggests that the characters contributed positively towards the yield of pearl millet. The positive linear relationships among grain yield/ hectare, grain yield /plant, harvest index, leaf area, number of grains/panicle, number of leaves/plant and number of panicles /plant were the major determinants of the superior grain yield. Changhani and Odo (2005) reported that higher values of grain yield indicate successful capture of growth resources early during the season. In similar findings by Dugje and Odo (2006a), reported that leaf area index, effective grain filling duration and number of grains are positive contributors towards increase in grain yield of pearl millet.
The linear relationships revealed that all agronomic traits of cowpea contributed positively to both plant and plot yield. There was simultaneous increase in plant height, length and number of branches with increase in grain and fodder yield/hectare. This also suggests that the growth traits contributed positively towards the yield of cowpea in the combined mean. The greater plant height and numbers of branches of cowpea in association with pearl millet is an indication of competition for light. Okigbo and Greenland, (1978), reported enhanced transmission of light to shorter crop for longer period before canopy closure of the main crop. The sparse canopy of these short pearl millet varieties allow more light penetration and subsequent interception by the cowpea understory. These complementary relationships imply minimum competition in the system. Olufajo and Singh (2008) reported enhanced transmission of light to shorter crop for longer period before canopy closure of the main crop enhanced the growth component of the crop system. The significant grain yield of cowpea variety relative to could be associated with its higher number of branches and longer branches, which promoted number of pods per plant.

CONCLUSION AND RECOMMENDATION

The correlation matrix of the varieties in two – cropping season and the combined mean showed that any increase in such character as number of leaf, leaf area, length of branches, number of branches will result to a corresponding increase in total grain yield of the pearl millet and cowpea varieties. Based on the result from the correlation analysis selecting of any pearl millet and cowpea varieties with higher leaf area and number of tillers, panicle diameter, panicle weight, longer length and number of branches, higher pods and grain yield/ hectare is the best for intercropping system.

UNDER-UTILIZATION OF PINEAPPLE AND ORANGE GENERATED WASTE: BIOACTIVE COMPOSITION, ANTIOXIDANT ACTIVITIES AND REVENUE GENERATING POTENTIALS

Raphael D.O.[1*], Ademoyegun O.T.[1], Mustapha B.O.[1], Ahmed R.S.[1]
[1]National Horticultural Research Institute, P.M.B. 5432, Idi-Ishin, Ibadan, Nigeria.

ABSTRACT
Pineapple and orange waste contributes substantially to food loss and waste generated globally at processing and consumption stages, they also constitute 29-40% and 50-55% of fresh fruit weight respectively and are often discarded despite observed nutraceutical and therapeutic values. The objective of this research was to analyze bioactive composition, antioxidant activities and provide recommendations for improving and facilitating orange and pineapple waste processing at domestic and industrial level. Highest free radical scavenging activity was observed in pineapple peel (46.93% and 52.14%) for ABTS and DPPH assays respectively. Higher total phenolic content was observed in orange peel and core as compared to pineapple waste. Concentrations of total phenol, total flavonoid and DPPH for pineapple waste were significantly different. This study faulted slow acceptance and adoption of research findings from researchers by food processing industries as a major factor affecting revenue generation and perspective of populace towards fruit generated waste.
Keywords: *Bioactive composition, food loss and waste, orange waste, pineapple waste, revenue generation*

INTRODUCTION

Pineapple (*Ananas comosus*) and orange (*Citrus sinensis*) are widely grown and consumed fruits the world over with estimated annual production of 25.4 million metric tons (Hikal et al., 2021) and 54.3 million tons (Mahato et al., 2019) respectively. Sub-Saharan Africa accounted for an estimated 21% food loss and waste on farm during harvest, storage, transport, wholesale and processing levels (FAO, 2022). Waste to wealth initiative has driven scientist and enthusiast alike to seek innovative ways of processing food waste into re-usable and marketable goods such as pineapple peel wine (Zhang et al., 2020). However, despite research findings and breakthroughs in areas of value addition for food waste, food processing industries has been particularly slow in accepting and adopting these findings. Horticultural fruits are characterized by relatively short shelf life as compare to cereal and tuber crops, they contribute significantly to global challenge of food loss and waste generated at processing and consumption stages. Pineapple peel constitutes 29-40% (w/w) (Zhang et al., 2020) while orange waste constitutes 50-55% (w/w) of fresh fruit (Suri et al., 2022). This implies that an equivalent 7.37 million metric tons of pineapple and 27.15 million tons of orange is wasted annually. As such the aim of this research is to analyze bioactive composition, antioxidant activities and provide recommendations for improving and facilitating orange and pineapple waste processing at domestic and industrial level.

MATERIALS AND METHODS

Total phenolic content

Total phenolic content was determined using method by (Patil et al., 2015).

Total flavonoid content

This was determined using method adopted by (Kumar et al., 2008).

Antioxidant activity using ABTS+ (2,2-azino-bis-(3-ethylbenzothiazoline-6-sulfonic acid))

ABTS (2,2-azino-bis-(3-ethylbenzothiazoline-6-sulfonic acid)) radical scavenging activity was conducted according to method adopted by (Dudonné et al., 2009).

$$\%\ \mathbf{Scavenging} = ((Ac - As)/Ac)\ X\ 100$$

Ac = Absorbance of control As = Absorbance of sample

Free radical scavenging using DPPH assay

Antioxidant activity using 2,2-diphenyl-1-picryhydrazyl (DPPH) assay was done according to method by (Naveen Kumar et al., 2013).

$$\% \text{ Scavenging} = ((Ac - As)/Ac)\ X\ 100$$

Ac = Absorbance of control As = Absorbance of sample

Statistical analysis

Data was analyzed using statistical package for social science (SPSS) to perform one-way analysis of variance (ANOVA) to identify significant differences at a 95% confidence interval level.

RESULT

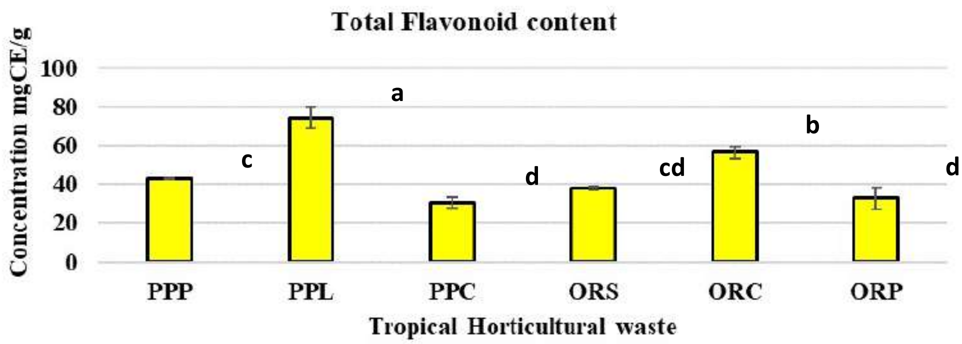

Figure 1: Total flavonoid concentration of pineapple and orange fruit waste.

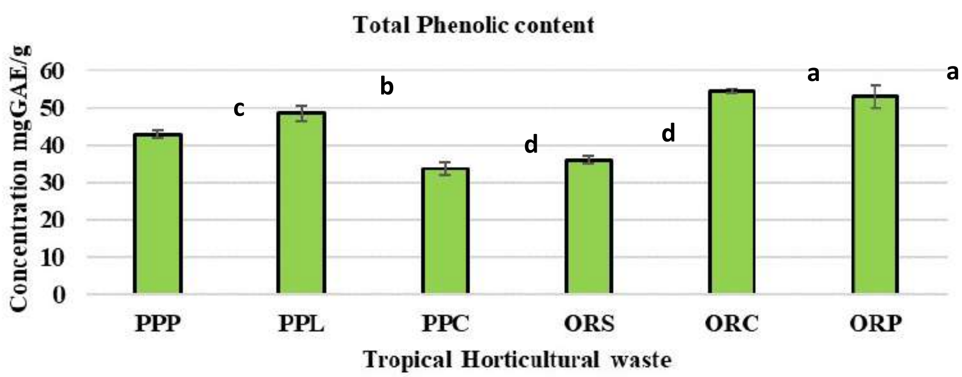

Figure 2: Total phenolic concentration of pineapple and orange fruit waste.

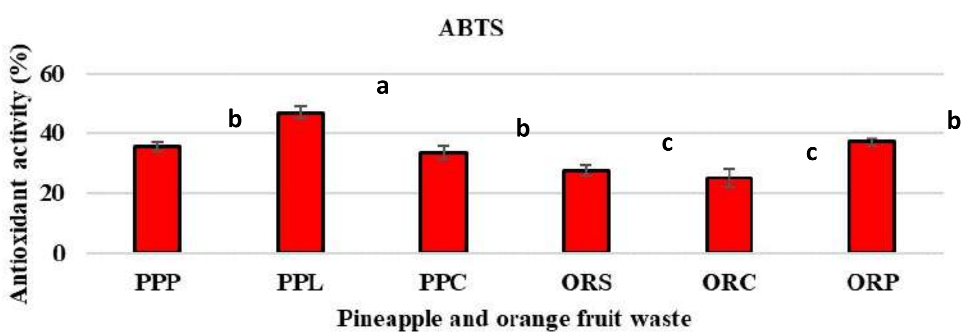

Figure 3: Antioxidant activity of pineapple and orange fruit waste using ABTS+ assay.

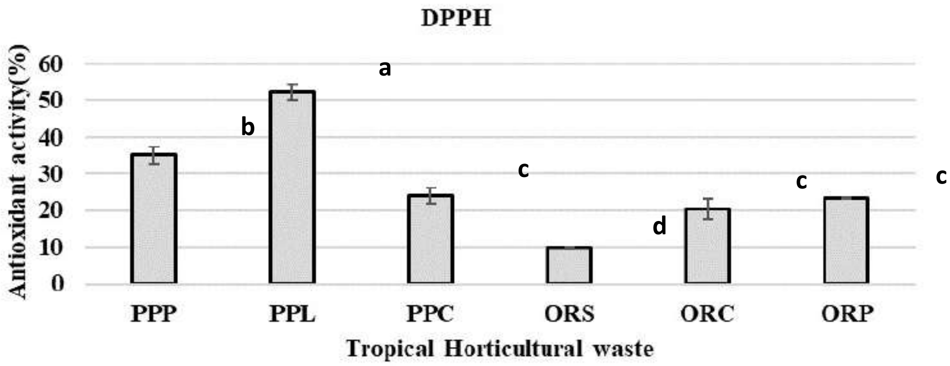

Figure 4: Antioxidant activity of pineapple and orange fruit waste using DPPH Assay.
KEY: TFC= Total flavonoid content, TPC= Total phenolic content, PPP= Pineapple pulp, PPL= Pineapple peel, PPC= Pineapple core, ORS= Orange seed, ORP= Orange peel, ORC= Orange core, DPPH= 2,2-diphenyl-1-picryhydrazyl and ABTS= 2,2-azino-bis-(3-ethylbenzothiazoline-6-sulfonic acid)

DISCUSSION

Highest free radical inhibition 46.93% and 52.14% was observed in Pineapple peel (PPL) for ABTS and DPPH assays respectively as compared to orange generated waste. Higher concentration of total flavonoid, total phenolic content, and antioxidant activities were also observed in pineapple peel as compared to pineapple core and is in accordance with deduction by Lasunon *et al.* (2022). Significant difference was observed in total phenolic and total flavonoid concentrations of pineapple peel, seed and core. Highest concentration of flavonoid were also observed in peels of pineapple as compared to other waste generated from parts of pineapple and orange while orange waste particularly peel and core showed higher phenolic concentration as compared to pineapple generated waste. Findings of this research highlights the bioactive and antioxidant benefits of pineapple and orange waste. As such, incorporation of pineapple and orange waste is encouraged during food processing to maximize their nutraceutical and therapeutic values. Findings by Wu & Shiau (2015) indicates that varying the particle size of pineapple peel fiber can be used to alter the rheology of dough as desired.
These findings are applicable in other fiber rich fruits such as orange (Akubor et al., 2023) towards improving physical condition, overall acceptability, shelf-life and reducing cost of production for cakes, snacks, bread and other areas of food processing where dough is applicable. Incorporating waste from orange and pineapple as supplement, primary or secondary raw material in food processing is highly recommended.

CONCLUSION

Despite increased awareness on nutritional and therapeutic benefits of different fruit waste, its utilization has been particularly low. The path of revenue generation through value addition of horticultural waste is still relatively unchartered as such, there is need for higher adoption of research findings on waste utilization by food processing industries as this would significantly increase the demand for fruit waste leading to increased revenue generation, reduced unit cost of production, and also encourage populace to see and accept parts of fruits such as seeds, peels, pomace and core as fruit parts of immense value and not waste.

ABSTRACT
Bryophyllum pinnatum is very rich in phytochemicals useful for human health as well as serve as ornamental plant. The role of iron ethylenediaminetetraacetic acid and Myo-inositol for rapid micropropagation B. pinnatum was investigated. Leaf explants of B. pinnatum were surfaced sterilized and cultured on Murashige and Skoog basal media with FeEDTA complex (MS) or without FeEDTA complex (MS-FeEDTA), and without Myo-inositol (MS-MI) in a completely randomised design (CRD) in triplicates. The leaf explants were monitored for colour changes until 21 days after culture (DAC). The results showed that leaf explants cultured on MS supplemented with FeEDTA complex had greenish leaves when compared to MS without FeEDTA complex, and MS without Myo-inositol with stunted leaves. All micropropagated B. pinnatum on MS media acclimatized successfully. The addition of micronutrient (FeEDTA complex) and vitamin (Myo-inositol) to micropropagation media is therefore necessary for plant growth and development.
Keywords: *Bryophyllum pinnatum, medicinal plants, micronutrients, plant growth hormones, plant tissue culture, vitamins*

INTRODUCTION

Bryophyllum pinnatum also known as *Kalanchoe pinnatum* belongs to the family Crassulaceae. It is a perennial herb commonly called Air plant in English language but is also known as Divine herb, Wonder of the world and Mexican love plant (Pattewar, 2012). The plant originated from Madagascar and has been found to thrive in temperate regions of the world such as in Asia, Australia and New Zealand (Latif *et al.*, 2019). It is a very useful medicinal and ornamental plant species having all parts from shoot to root utilized globally. Quazi *et al.* (2011) reported the use of the leaf extracts in treatment/management of various diseases such as chicken pox, epilepsy, rheumatoid arthritis, psychiatric disorders and abdominal-related disorders (Sadhana *et al.*, 2017). Pharmacologically, it has been reported to possess antibacterial, antimicrobial, antifungal, anti-inflammatory, analgesic, antihypertensive, anti-cancer, antioxidant and antidiabetic properties (Latif *et al.*, 2019). It is also indicated in prevention of premature labour in pregnant women in Southeast Nigeria (Gupta *et al.*, 2016). Rapid micropropagation allows for quick selection of cultivars showing desirable traits of interest. The nutritional medium can be carefully determined with optimum key elements and composition. Due to its relatively partial solubility, Iron III (Fe^{3+}) is being used in chelated forms as ethylenediaminetetraacetic acid (Fe-EDTA) in micropropagation medium (Nikulina *et al.*, 2020). Iron is introduced into the medium in its hydrated sulphate form ($FeSO_4.7H_2O$) in a mixture with sodium ethylenediaminotetraacetic acid (Na_2EDTA) in the following equation;

$$FeSO_4.7H_2O \quad + \quad C_{10}H_{14}N_2Na_2O_8 \longrightarrow C_{10}H_{12}FeN_2O_8 + Na_2SO_4 + 8H_2O$$

The purpose of the study was therefore to evaluate the importance of Iron ethylenediaminetetraacetic acid (FeEDTA Complex) and myo-inositol in micropropagation of *Bryophyllum pinnatum*.

MATERIALS AND METHODS

Media composition and preparation

Murashige and Skoog (1962) media composition (MS) or without FeEDTA complex i.e. Stock group III (MS-FeEDTA) and Myo-inositol were used for the experiment as shown in Table I following the methods of Esuola and Olusoji (2021). The media also consists of 3% table sugar as carbohydrate and energy source and 10 mg L^{-1} Ascorbic Acid. The pH of the medium was adjusted to 5.8 with few drops of NaOH and HCl. The medium was solidified with 0.7% purified agar tissue culture grade and melted in a microwave oven. The medium (20 ml each) was dispensed into 50 ml baby food jars and autoclaved at 121ºC for 15 min.

Plant Materials

Bryophyllum pinnatum young leaves were collected from fully grown plants at the Floriculture Garden, National Horticultural Research Institute (NIHORT), Ibadan, Nigeria.

Explants surface sterilization

The young leaf pieces were subjected to surface sterilisation steps by first washing under running tap water with few drops of detergent for 1 hour in food jars. Each leaf was sectioned into about 4-6 pieces, each section was about 1 cm long and used as explants. The explants were transferred to the laminar flow chamber and following aseptic conditions they were washed with 70 % Ethanol for 5 min, followed by washing with 3 % of sodium hypochlorite (3.5 v/v) for 10 min with few drops of detergent. Finally, the explants were rinsed thoroughly three times with sterile double distilled water.

Growth culture conditions

The sterilized leaf explants (20 explants per treatment) were dissected to about 1 cm each using sterilised scalpel and blade holder. The explants were each placed into the sterile medium in the baby food jars. The culture tubes were sealed using parafilms and incubated in the growth room at the temperature of 25ºC $\pm$ 2ºC with fluorescent tubes providing light. Morphological changes on the leaf colour changes were observed 21 days after culture (DAC).

RESULTS AND DISCUSSION

B. pinnatum leaf explants regenerates well in the (MS) medium, as well as proliferates well in the plant growth hormone supplemented medium (Fig. 1A and Fig. 2A). The leaves were greenish in this medium. Esuola and Olusoji, 2021 recently observed a similar leaf colour changes in MS media supplemented with iron complex and suggested a possible ability of the plant to photosynthesize in this medium and compared to media with iron complex. It was also observed that media without iron complex did not support a good plant morphology as most of the plants had stunted growth (Fig. 1B and Fig. 1C). Hence, addition of iron complex and Myo-inositol are vital agents to support the plant growth during micropropagation procedures. All the plants acclimatized successfully in the humidity chamber after the micropropagation steps (Fig. 2D).

CONCLUSION

Bryophylum pinnatum could be used as a model crop for plant tissue culture investigations, as the plant can easily grow in test tubes using the leaf explants. This research has paved ways to understand the importance of iron complex and Myo-inositol as well as macro- and micro- nutrients for in vitro micropropagation of horticultural crops.

ACKNOWLEDGEMENTS

The Management of the National Horticultural Research Institute (NIHORT) Ibadan and staff of Biotechnology Research Unit, NIHORT, Ibadan, Nigeria are appreciated for providing enabling environment for the investigation.

ABSTRACT
Fumonisin are mycotoxins recently reported from horticultural crops and pose as serious health threats to humans and animals. Fumonisin was first isolated from Fusarium verticilloides which is responsible for fusarium ear rot in maize and thereafter, it was isolated from other fungi such as Aspergillus niger. Fumonisin can be detected from crop plants by high performance liquid chromatography (HPLC) and mass spectrometry (MS). Fumonisin prevalence is relatively high in humid and hot weather conditions, thus leading to decrease yield and quality of horticultural crops. The implications of fumonisin to human health and horticultural crops are hereby highlighted. This will assist conscious research efforts for the preventive measures of fumonisin producing plant pathogens in horticultural crops.
Keywords: *Fumonisin, Fusarium verticillioides, High performance liquid chromatography (HPLC), mycotoxin, vegetables*

INTRODUCTION

Contamination caused by fumonisin is one of the major mycotoxins found in plant crops which adversely affected human and animal health as well as causes substantial economic losses (Li *et al*., 2023). According to the experts of Food and Agriculture Organisation (FAO) of the United Nations, an estimation of 25% of the world's food crops are lost each year as a result of mycotoxin contamination, with the *Fusarium* species significantly contributing to food contamination (Waskiewicz *et al*., 2012). Fumonisin are a class of toxic secondary metabolites which are synthesized by several *Fusarium* species. Fumonisin are stable to heat and are also water soluble type of mycotoxin (Mostrom, 2016). In 1988, the first isolation and characterization of fumonisin which is a food borne carcinogen that naturally occur in maize was performed in South Africa (Marasas, 1995). The mycotoxin, fumonisin B1 and B2 were isolated from the cultures of *F. verticillioides* MRC 826 at the programme on Mycotoxin and Experimental Carcinogenesis of the Medical Research Council in Tygerberg in South Africa, this isolate was reported to be responsible for the outbreak of equine leukoencephalomalacia (ELEM) in South Africa in 1970, causing porcine pulmonary edema (PPE) syndrome in pig and liver cancer in rats (Marasas, 2001). Fumonisin are insoluble in non-polar solvents but soluble in polar solvents such as water and aqueous solutions of methanol and acetonitrile. Its pure compound is a white, hydroscopic powder that can dissolve in water (in which it is unstable), acetonitrile-water (in which it is stable) or methanol (Waskiewicz, 2012). The importance of fumonisin in horticultural crop, health, as well as its chemical structures are hereby highlighted to insights to its occurrence in major food crops and create awareness for future research.

Microorganisms producing fumonisin

Fumonisin was discovered as a mycotoxin produced mainly by *Fusarium monilifome* and *Fusarium proliferatum*, *Fusarium verticilloides* in maize (Keller *et al*., 1997, Voss *et al*., 2006). Also, the fungus *Gibberella fujikuroi* produces fumonisin B1 (FB1) which are structurally related mycotoxins (Won-Bo Shim, 1999). *Aspergillus nigri* also has been discovered to produce fumonisin but in this case fumonisin B2 [FB2] (Frisvad, 2007). A major producer of fumonisin which is a fungal pathogen *Fusarium verticilloides* of maize produces mycotoxin that negatively affect human and animal health (Brown *et al*., 2007).

Fumonisin in fruits and vegetables

Fumonisin has been seen to affect banana peel as a result of reactive oxygen species of which its imbalance leads to oxidative stress in banana peels leading to increase in fumonisin production in *F. proliferatum* in banana (Xie *et al*., 2023). Fumonisin mycotoxins were found in the African vegetable, morogo; also, different fumonisin producing species such as *Fusarium verticillioides*, *F. proliferatum* and some others were isolated from morogo vegetable (Van der Walt *et al*, 2006), this is so because the vegetable, morogo grows as a weed within the corn farm and so, it could be contaminated by the maize plant with *Fusarium* species producing fumonisin (Bezuidenhout *et al*., 2006). Fumonisin has also been discovered in dates, dried vine fruits, figs when they are infected with *Aspergillus niger* using reversed-plase high performance liquid chromatography/electrospray ionization-ion trap mass spectrometry (RP-HPLC/ESI-ITMS) (Varga *et al*., 2010). Tomato, tobacco, wheat among others have also been discovered to contain B1fumonisin, a secondary metabolite of *Fusarium* species found in these plants (Iqbal *et al*., 2023). *Aspergillus nigri* isolated from onions also produce fumonisin in onions (Massi *et al*., 2021). Interestingly, some horticultural crops have been found to be useful against fumonisin producing pathogens, such as turmeric, which works as an antioxidant for the protection of the liver in chicken (Galli *et al*., 2002). Also, cabbage has been discovered to give protection against fumonisin B1 (Abdual-shahid, 2013). Rosemary (*Rosemarinus officinalis L.*) essential oil (REO) had strong antifungal properties against *Fusarium verticillioides*, it has inhibitory and reducing effect on fumonisin and ergosterol production (Bomfim *et al*., 2015). Clove (*Syzygium aromaticus*) has proven to reduce fungal infections such as that of *Fusarium graminearum* and it is a potential preservative in the postharvest management. Bay leaf essential oil also shows antifungal effects but not as efficient as clove essential oil (Santamarina *et al*., 2016).

Fumonisin in health

The mycotoxin, fumonisin, has affected human and animal health. Initially, the fungus *Aspergillus niger* was discovered to be the producer of the carcinogenic fumonisin B2 (Frisvad *et al*., 2007) in vegetables. Fumonisin has been categorised by International Agency for Research on Cancer (IARC) as group 2B carcinogen and that the consumption of any food that contains this mycotoxin will lead to different sicknesses in both man and animal (Ahangarkani *et al*., 2014). Fumonisin can be detected in urine especially when people or animals are exposed to high concentration of fumonisin (Turner *et al*., 1999). It has also been discovered in breast milk (Mesfin, 2023). It is assumed that high concentration of fumonisin leads to neural tube defect (NTD) which is a birth defect of the brain and spinal cord since it causes equine leukoencephalomalacia (Voss and Riley, 2013). Apart from being a likely carcinogen in human, fumonisin B1 (FB1) has been identified to be toxic to the nervous system, liver and kidney in animals (Stockmann-Juvala and Savolainen, 2008). Fumonisin B1 is a non-genotoxic carcinogen which causes tumours by inducing atrophy, apoptotic necrosis and consequent regeneration (Dragan *et al*., 2001). Prenatal exposure to fumonisin can cause inflammation in strained muscles such as in the heart, and skeletal muscles of wistar rat (Tomaszewska *et al*. 2023). When feed contaminated with fumonisin and aflatoxin are eaten they lead to adversely affected process of growth in nursery pigs (Deng *et al*. 2023). Histological lesions in the liver of chicks have also been discovered as a result of their consumption of feed contaminated with fumonisin (Weibking *et al*., 1993).

Structure and chemical characterization of fumonisin

The fungus *Fusarium verticillioides* which infects maize plants produces mycotoxins formed from polyketide known as fumonisin (Bojja *et al*., 2004). Fumonisin B1 with the molecular formula $C_{34}H_{59}O_{15}$ has two of its polyhydroxy side group esterified with propane tricarboxylic acid (Pitt, 2014). Fumonisin has structure similar to that of spingolipid's sphingoid base backbone (Pitt, 2014). The most common fumonisin forms are the B forms and C forms (which are similar to B forms but only differing in the absence of the terminal methyl group) have been discovered in maize (Pitt, 2014) [Fig. 1]. The A and P forms also have been isolated from pure fungal cultures, but are very rare (Pitt, 2014) [Fig. 1]. Fumonisin B1 (which makes up to 80% of the total fumonisin content in *Fusarium verticillioides* cultures) has the empirical formula of $C_{34}H_{59}NO_{15}$; this mycotoxin happens to be a diester of propane-1,2,3-tricarboxylic acid and 2-amino-12,16-dimethyl-3,5,10,14,15-pentahydroeicosane (WaÅkiewicz, 2012).

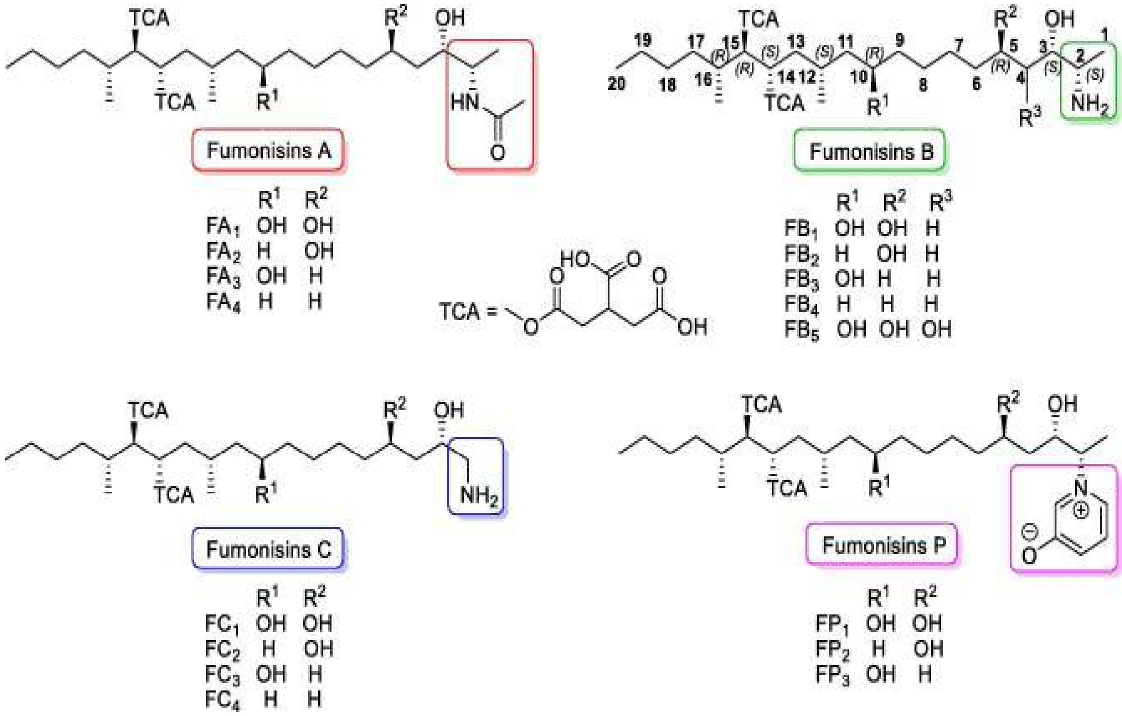

Figure 1: Different structures of fumonisin (Ocampo-Acuna *et al*., 2023).

CONCLUSION

Fumonisin is a mycotoxin have been detected in some important horticultural crops and is a leading cause of human and animal diseases. Therefore, more research work should be done on how to reduce fumonisin producing pathogens of horticultural crops for a healthier world.

ABSTRACT
In vitro germination technique helps in achieving clean, healthy, fast growing, and nutritious plants. Sweet orange (Citrus sinensis) is a major source of vitamin C, sufficient amount of folacin, calcium, potassium, thiamine, niacin and magnesium. The aim of the research was to develop a protocol for in vitro germination of Citrus sinensis seeds using media with and without hormone supplements. The result indicates that citrus seeds that was scarified before inoculation performed better than citrus seeds that were unscarified before inoculation. Control media supported the germination rate than media susplemented with hormones. The number of roots, shoot/height, and leaves when observed in media without hormones performed better than the media with hormone. Contamination rate was low in the control media than the media with hormone. In conclusion, citrus seeds in vitro germination is achievable when the seeds are scarified prior to inoculation in the media without hormone supplements.
Keywords: *Citrus sinensis, plant growth hormones, micro propagation, scarification, germination,*

INTRODUCTION

Citrus species are among the most commercial fruit crops of the world, cultivated in more than 100 countries (Barlass and Skene, 1999). Citrus is widely grown In Nigeria and many other tropical and subtropical regions (Piccinelli *et al*., 2008). Citrus ranks after banana as the world second fruit crop with more than 108 million tons (FAO Statistics 2006). Sweet orange (*Citrus sinensis* L. Osbeck) commonly called orange is a member of this family and a major source of vitamins, especially vitamin C, sufficient amount of folacin, calcium, potassium, thiamine, niacin and magnesium (Angew, 2007). Citrus fruits are also known for their fine flavor, nutritional quality and medicinal value (Ani and Abel 2018). According to UN 2007 data, India is the largest producer of lemons and limes in the world and ranks sixth in the production of citrus fruits. Citrus fruits are mainly produced in coastal areas of numerous countries as well as in the Mediterranean region. *Citrus sinensis* is a member of family Rutaceae, commonly known as navel orange, sweet orange and Malta in Uttarakh and, India (Christman, 2003). *C. sinensis* is a small evergreen tree having 7.5 m height and sometimes reached up to 15 m. Many biologically active, non-nutrient compounds found in citrus fruits such as antioxidants (Tripoli et al., 2007), soluble and insoluble dietary fibres (Ejaz et al., 2006) known to be helpful in reducing the risk for cancers (Elangovan et al., 1994). Many chronic diseases like arthritis; obesity (Walton et Al., 1945) and coronary heart disease (Crowell, 1999). A single orange is said to have about 170 phytonutrients and over 60 flavonoids with anti-tumor, anti-inflammatory, blood clot inhibiting and antioxidant properties (Etebu and Nwauzoma, 2014). Due to high vitamin C content and antioxidant potential of *C. sinensis*, it is consumed worldwide, therefore, considered as one of the major commercial fruit crops of the world (Kiong et al., 2008).
However, the cultivation of *C. sinensis* is difficult due to slow growth, short storage life (Mukhtar *et al*., 2005) Further, citrus stands among difficult to root crops (Usman et al., 2005) and their seeds have a very short life because they are injured by drying during storage and thus, lose their viability (Johnston, 1968; Ali and Mirza, 2006). This study aimed to develop a protocol for in-vitro germination of *C. sinensis*.

MATERIALS AND METHODS

Plant material and explant preparation

Sweet oranges were obtained from the National Horticultural Research Institute, Ibadan, Oyo State. The seeds were extracted by removing the pulp adhering to the seeds. The seeds were washed with running tap water. Seeds were then subjected to floating test as described by Pandey and Tamta (2013), healthy and viable seeds were selected and washed with a few drops of tween 20, a laboratory detergent, for 1 hr; followed by five times rinsing in distilled water. The seeds were dipped in 70% ethanol for 5 min followed by three times rinsing in autoclave distilled water. The seeds were also dipped in 10% hypochlorox for 10 min followed by three times rinsing in autoclave distilled water. Afterwards they were placed in the laminar flowhood for inoculation. Four seeds were scarified to compare the growth rate between the non-scarified.

Culture media

Control Media: The nutrient medium consisted of Murashige and Skoog (MS; Murashige and Skoog, 1962) 2.215 g fortified with 15 g sucrose, myo-inositol is 0.0625 g, having pH adjusted to 5.8 with 1 N NaOH and solidified with 1 g phytagel. The prepared media were autoclaved (in 1.05 Kg cm^{-2}, 121°C for 20 min).

Media with Hormones: The nutrient medium consisted of Murashige and Skoog (MS; Murashige and Skoog, 1962) 2.215 g fortified with 15 g sucrose, myo-inositol 0.0625 g, Ascorbic acid 2.5ml, BAP 2ml, NAA 0.9ml. The pH was adjusted to 5.8 with 1 N NaOH or HCl and solidified with 1 g phytagel. The prepared media were autoclaved (1.05 Kg cm^{-2}, 121°C for 20 min).

RESULTS AND DISCUSSION

From our results in Table 1 and Figure 1 above, 50 citrus seeds each were inoculated into two separate media with different constituents (Control media and Hormone media). 25 of the citrus seeds of each media were scarified and the remaining 25 citrus seeds were not scarified. In the control media, the scarified 25 citrus seeds germinated while the remaining non scarified citrus seeds did not germinate as a result of the thick shell. These indicated that scarification of seeds helps in proper in vitro germination of citrus seeds. In the media containing hormones, 10 citrus seeds out of the 25 scarified citrus seeds germinated while the remaining 40 citrus seeds did not germinate. These indicate that control media supports citrus in vitro germination when compared with media suspended with hormones. The average number of rooting in the control media is 3 while that of the hormone supplemented media is 1. The average number of shooting/height for the control media is 1/3cm while for the hormone supplemented media is 0. The average number of leaves in the control media is 3 while for the hormone supplemented media is 0. The number of contaminated plants for the control media is 5 while for the control media is 8. The control media did much better than the media supplemented with hormones. Our result is the same with in vitro germination of *Telfairia occidentalis* which does not support addition of hormones (Akinyemi and Esuola, 2012).

Table 1: In vitro germinated *Citrus sinensis* at 21 days after treatment in the control and hormone supplemented media

Parameters	Control media	Hormone media
Number of seeds inoculated	50	50
Number of seeds scarified	25	25
Number of seeds non-scarified	25	25
Number of seeds germinated	25	10
Number of seeds not germinated	25	40
Average number of root/seedling	3	1
Average number of shoot/height	1/3cm	0
Average number of leaves	3	0
Number of contaminated plants	5	8

Figure 1: In vitro germinated citrus seeds at 21 days after inoculation in the control media.

CONCLUSION

In conclusion, media without hormones and prior seeds scarification support in vitro citrus seed germination compared to the media with hormones and un-scarified seeds.

ACKNOWLEGMENT

The Management of NIHORT and staff of the Biotechnology Research Unit are hereby appreciated.

IMPACT OF OIL EXPLORATION ON SOIL, CLIMATE, COCOA BEANS PRODUCTION AND NIGERIA REVENUE: A REVIEW

*** Fagbami, O. and Olasoji H.O.**
Cocoa research institute of Nigeria Ibadan

*Corresponding author: fagbamisamuel@yahoo.com

ABSTRACT
This paper review negative impact of crude oil exploration on soil, climate, cocoa bean production and Nigeria revenue. Reports showed that oil contributes about 80% foreign exchange earnings and mining causes continuous contamination of soil and climate change through oil spillage and gas flaring. Data on oil contaminated soil of 5, 10, and 20 year physico-chemical properties shows that mean pH value and TOC content were 8.02, 8.07, 8.68 and 2.46%, 3.31%, 4.56% higher than 7.86 and 2.13% of uncontaminated sites respectively while TN and TP contents of 1.17, 0.67, 0.84 g kg−1 and 0.37, 0.32, 0.26 g kg−1 respectively of the sites were significantly lower than 1.26 g kg−1 and 0.36 g kg−1 respectively in control sites. Available land and value of exported crops particularly cocoa bean further reduce through GHG emissions couple with failure of government policies from $611.800 in 2016 to $510, 825 in 2020 while oil revenue remain unstable. This review emphasized the comparative advantage which Nigeria has in cocoa cultivation as well as possible revenue from beans export through establishment of management programme that prevent soil contamination and air pollution.
Keywords: *Cocoa beans, Crude oil, foreign earnings, soil contamination, climate*

INTRODUCTION

The discovery of crude oil in 1956 changed Nigeria from being agrarian economy and oil became major export commodity and main source of foreign earnings. Nigeria has turned to oil revenue dependent nation and overall oil contribution to the economy grew from an insignificant 0.1% to about 80% since 1970 (Ibama and Eyenghe, 2015). The oil exploration has helped Nigeria in terms of infrastructural development but has adversely affected the climate and soil. It was estimated that above 7.0 billion cubic metres per year of natural gas is released into atmosphere through crude oil mining (GGFR, 2021) while soil and water contamination occurred through oil spillage from pipeline leakage, oil tanker accident and waste from refineries. Wang et al., (2010) report on physico-chemical properties of 5, 10 and 20 year-old crude oil contaminated soil increase mean pH and Total Organic Carboncontent (TOC) of oil wells sites were 8.02, 8.07, 8.68 and 2.46%, 3.31%, 4.56%, higher than 7.86 and 2.13% in uncontaminated sites respectively. Total Nitrogen (TN) were 1.17, 0.67, and 0.84 g kg−1 while Total Phosphorus (TP) were 0.37, 0.32 and 0.26 g kg−1) contents in polluted sites significantly ($p<0.05$) lower than (1.26 g kg−1 and 0.36 g kg−1 respectively) control sites. Also, Udoh and Chukwu, 2014 and Onwuka, *et al*., 2021 reports on pH, OC, N and P content of oil contaminated soil in Nigeria showed that these results may be from increase in soil residual hydrocarbon.

The rich soil resources and good climate weather condition in Nigeria before oil exploration made agriculture a source of employment to about 70% of the population, provide raw materials for industries, income for farmers and foreign exchange earnings from crops such as groundnut, cocoa, kola, sorghum, cotton, oil palm and others. Cocoa bean and by product contributed about 90% to Nigeria GDP in the 60s but this has decline gradually to about 0.13% in 2022 (Sekumade 2009; Punchng.com, 9 July 2023). The increase in foreign earning from sales of crude oil shift off focus from agricultural products and cocoa production in particular and reduced market trading as well as income from sales of cocoa (Table 1). Nigeria produced average of about 350 metric tonnes of cocoa beans in the 60s up to 70s but decreased to the range of 250-280 tonnes currently, which place it in the fifth position among Africa countries (Punchng.com, 2022). The reported decrease in cocoa production attributed to crude oil discovery was further linked to continuous depletion of soil nutrient through continuous pod harvest without fertilizer input coupled with failure of government policy among other factors such as inadequate storage facilities and migration of labour needed for harvesting and beans processing to the city (Ogunlade *et al.,* 2012) reduces quantity and quality of cocoa beans produce (Idowu *et al.,* 2007). Also, changes in weather condition through oil exploration has been reported to increase risk of crop pest and diseases which is one of major factors responsible for low quantity and quality of cocoa beans produced (FAO 2021, ICCO, 2015). Report by Orisajo and Dongo (2005) confirmed that pests and diseases are responsible for poor quality beans from the field and during storage. Therefore, government need to play major role in mitigating effect of oil exploration on climate, soil and insect pests infestation which will increase cocoa beans quantity and quality as well as revenue accrue from it sales.

Effects of oil discovery and dangling price on Nigeria revenue

Establishment of new industries and increase in the production of agricultural goods were experienced between 1950s and 60s because of greater attention given to farming. The story changed following the discovery of crude oil which becomes the major export commodity replacing agriculture as the main source of foreign earning (Sylvester Okotie 2018). Consequently, there was sudden decrease in agricultural produce such as rubber, sugar cane, kola and cocoa beans used as raw materials. This manifested in inadequate supply or non-availability of the produce and high market price which resulted to increase importation of the produce as materials to feed our industries. This has gradually brought setback to the operation of some and the total closure of many industries. This has remained irreversible because petroleum exploration continue to gain better backing of the government as their primary source of foreign exchange earnings (Fadipe *et al*., 2012, Adeogun *et al*., 2013). The high price of goods and services produced in Nigeria coupled with continuous and unpredictable fall in oil price per barrel has reduced the standard of living of the citizens. As a major exporter, Nigeria oil revenue (Table 2) remains unstable and tends often to fall as reflected in government budget estimation since the year 2014. Furthermore, the reduction in price and revenue derivable from oil for Nigeria and other countries has continued to decline with increasing advocacy for a shift to renewable energy due to negative effect of fossil fuel emission on climate. The gradual adoption as a means to mitigate effect on climate has reduced though minimal the demand for crude oil. Hence, increase in adoption will make oil price and Nigeria revenue to become more unstable.

Use of renewable energy to mitigate climate change and soil contamination caused by oil exploration

Oil spillage has increased through oil exploration and effects include destruction of farm land, reduction of crop produce, fish and other wildlife, pollution of sources of drinking and irrigation water such as stream, ponds, well, rivers and lakes (Ojimba, 2011). The negative effects of oil on soil chemical composition, structure and texture reduces fertility and available land for cultivation (Anna Klamerus-Iwan *et al*., 2015). Ojimba, (2011) reported increase in poverty level of farmers, especially cocoa farmer in the oil producing state due to soil contamination through oil spillage and air pollution by gas flaring with conclusion that oil exploration reduced income and impoverished farmer. Changes in the average weather condition further increases as a result of emission of greenhouse gases (such as CO_2, CH_4, O_3 etc) when using by-product of crude oil as sources of energy. These gases absorb heat, raise temperature of the ecosystem and reduce the quantity of radiation that is release to the outer space from the earth. The effects of these changes have been observed in rainfall pattern, temperature, relative humidity, sea level and insect pest infestation which affect cocoa production when it stands beyond recommended range (Table 4). There have been several campaigns on need and ways to mitigate climate change with emphasis on reduction of greenhouse gas (GHG) through adoption of alternative energy. Alternative Renewable Energy (ARE) comes from natural sources such as wind, biomass, water, and sun. This has become part of climate change program with focus on improving world economy, human standard of living and welfare (Finance and Development, 2019). The success of ARE in countries such China and Germany (Aparupa Pani, 2022) has placed it at the forefront in the process of mitigating effect of climate change. This has minimal effect on oil consumption and marketing but greatly benefit ecosystem through reduction in the quantity of carbon emission. As knowledge on ARE technology advances, oil price will continue to fall because supply of the commodity will meet gradual decrease in demand and would lead to reduction in exploration, soil contamination, air pollution as well as countries accrue revenue.

Prospect of cocoa production through government policy

It has been revealed that Nigeria has a high comparative advantage in soil and climatic requirement for cocoa production (Table 4). This has been reflected on quantity of cocoa beans and other cocoa product exported yearly compared to other crops (Table 3) and as such become necessary that government step up efforts in ensuring yield increase through rehabilitation of old cocoa plantations, establishment of new ones and clean-up of contaminated soil. Also, activities that encourage farmers to adopt new production, harvesting and processing technique through coordinated programmes of various agency of government to surpass the present export quantity and improve quality that will earn more foreign exchange to reduce dependent on oil revenue are important. Compared to other agricultural produce, cocoa beans have contributed larger percentage of revenue per quarter in 2020 to 2022 (Table 3), supporting economic growth of Nigeria. Cilas and Bastide, (2020), Ogunlade et al., (2012) and Orisajo and Dongo (2005) report among other findings decline in cocoa yield and ascribe this to depletion in soil nutrient, soil contamination, air pollution, insect pest infestation and migration of labour to city which are associated to increase oil exploration. Therefore, programmes that will protect the environment and encourage youth to stay in rural areas to take up farming business especially cocoa cultivation should be adopted through policies and act of government agencies and commissions such as ADP, FADAMA, NCDC etc. Report of Kenfack Essougong *et al.,* (2020) and Attipoe et al., (2020) revealed a positive relationship between cocoa output, soil fertility management, labour and farmer access to finance. Therefore, government institution should work on policy intervention gear towards management of soil in oil and non-oil producing states, provision of credit facility as well as educating farmer on the need for application of research findings on soil-water pollution and contamination remediation as well as adoption of scientific recommendations against insect pest infestation and improve soil fertility so as to increase cocoa production. Finally, guided scientific recommendations that will increase income generation from cocoa export, contribute to grow Nigerian economy and reduce its overdependence on oil export should be worked on.

CONCLUSION

Cocoa as agricultural product contributed significantly to Nigeria revenue and has been identified as major product among commodity of foreign exchange from non-oil export. There is need for policies toward adoption of recommendations on various good agricultural practices, soil contamination and air pollution management to increase cocoa bean production which will reduce effect of crude oil unstable price on Nigeria economy and exploration on air and soil. Therefore, it will be a great achievement, if government could sustain existing and as well make new policies that eliminate constrains in cocoa production to achieve higher yield and revenue.

ABSTRACT

A field trial to evaluate the growth of Cocoa intercropped with Coconut was conducted in Cocoa Research Institute of Nigeria (CRIN) Headquarters, Idi-Ayunre, Ibadan, Oyo State between 2019 and 2022. There were four treatments comprising Cocoa sole, Cocoa/plantain, Cocoa/coconut and Cocoa/coconut/plantain intercrop. The experimental design was Randomized Complete Block (RCBD) replicated three times. Data were collected on plant height (cm), stem diameter (cm) and leaf area (cm^2) of cacao. The data were analysed with analysis of variance ($P \leq 0.05$). Result obtained showed that cocoa/plantain was significantly higher than all other treatments in all the growth parameters considered, and closely followed by cocoa/coconut; then cocoa sole, with cocoa/plantain/coconut giving the least performance. Therefore, cocoa/coconut intercrop could be recommended to cocoa farmers in Southwest Nigeria to increase their revenue generation when coconut starts bearing fruit instead of sole planting of cocoa.

INTRODUCTION

The cacao (*Theobroma cacao L*) is a native to the undergrowth of the Amazon forest (Wood and Lass, 1985). Since its introduction in West Africa, farmers have grown cacao under shade trees in order to create light conditions that are similar to those found in native forest (Besse, 1972; Boni, 1985). To obtain these light conditions, several techniques have been developed: under managed natural forest, under natural re-growth or under artificial shade (Besse, 1972; Keli *et al*., 2005). Intercropping is a common agricultural practice in the tropics. It has been reported to increase crop diversity, biological stability of the ecosystem and labour efficiency (Okigbo *et al*., 1975; Osei-Bonsu *et al*., 2002), and that inter-cropping can stabilize socio-economic conditions and alleviate poverty. However, Famaye *et al.* (2014) had reported that small-scale farmers are more concerned with profitability, food security, labour availability and agronomic sustainability than with forest conservation and the loss of biodiversity. Some authors have described the physiological, environmental and economic values of trees in cacao growing systems (Famaye *et al*., 2003; Schroth *et al*., 2004). They quote benefits such as shade for cacao; soil fertility maintenance by recycling nutrients in the soil; biodiversity conservation; protection against drought, bush fire and insect attacks; and additional income through sales of timber species, fuel wood and non-wood forest products.

Cocoa cultivation in Nigeria is currently threatened by the gradual disappearance of the forest. Thus, cocoa growers, which traditionally used forest galleries as a precedent for planting, are now facing difficulties to plant cacao in new lands and need to rejuvenate the current plantations with planting and replanting techniques adapted to this shortage of forest. At the same time, the cocoa farms are getting older as 70% of the plantations age between 11 and 30 years (Aguilar *et al*., 2005). Faced with the deterioration of the plantations, some producers have decided to replant, with considerable difficulties, on previous non-forest land (Assiri, 2008; 2010a). Given these recent cultural practices under light shade, researchers need to assess farmers' innovative intercropping practices (Assiri, 2008; 2010b). Agronomic practices in simplified orchards combining cacao and fruits trees such as coconut have been little documented in the literature. Most studies brought out the concomitant importance of mineral nutrition and way that shade trees filter incident light (Beer, 1998; Somariba and Beer, 2011), but little has yet been reported about the growth of cacao under cacao/coconut intercrop. Although, several species of trees can be used in the same plot of cacao, but the type of associations and planting densities vary greatly (Aguilar *et al*., 2005; Assiri and Koko, 2009).

However, in Nigeria, intercropping in cocoa is usually carried out with arable crops to provide food and income to the farmer before cacao start bearing pod and it is done at juvenile stage between 1-3 years before cacao closes canopy (Famaye, 2013). Similarly, in Nigeria, cacao has been conveniently intercropped with oil palm, kola and citrus (Famaye *et al*., 2003). Should the price of cocoa fall, the income of small holder farmers would still be safe-guided because of the accompanying crops intercropped with it.
Intercropping cocoa with coconut and palm trees is a commons practice in South East Asia (Famaye, 2013). Mature cocoa plantation can also be intercropped with coconut as a way to increase diversity, income, and reduce environmental degradation. However, this has not been practiced in Nigeria. Therefore, the objective of this study was to evaluate the vegetative growth in cocoa intercropping with coconut in Southwest Nigeria.

MATERIALS AND METHODS

This study was carried out in Cocoa Research Institute of Nigeria (CRIN) Headquarters, Idi-Ayunre, Ibadan, Oyo State, Nigeria. Idi-Ayunre (7°25'N, 3°24'E) is an alfisol in the tropical rainforest region of Nigeria. The plantain materials (suckers) were purchased from a plantain farmer. Cocoa seedlings were obtained from CRIN nursery. Coconut seedlings were obtained from coconut nursery farmers in Calabar, Cross River State. The experiment had four treatments; cocoa sole (control), cocoa/plantain (plantain check), cocoa/coconut, and cocoa/plantain/coconut. The experiment was laid out in Randomized Complete Block Design (RCBD) replicated three times. In data collection, parameters considered were physical and chemical properties of the soil at the beginning of the experiment, as well as morphological parameters (plant height, stem diameter and leaf area) of cacao. The data obtained was subjected to statistical analysis of variance and LSD was used to separate the means that were significant.

RESULTS AND DISCUSSION

Result of the physical and chemical properties of the study location at the beginning of the experiment is shown in Table 1. Texturally, the soil was sandy loam belonging to Onigambari series and an Alfisol (Soil Survey Staff, 1999). The site was considered suitable for cocoa production. Tables 2, 3 and 4 show the results of plant height, stem diameter and leaf area, respectively. There were not much significant differences between the treatments on the morphological parameters in the first 3 and 6 months of transplanting. However, from 9 months there were significant ($P<0.05$) differences among the intercrops. The least plant height, stem diameter and leaf area were recorded in cocoa/coconut/plantain. This could have been due to much competition for light at upper surface and nutrient at the root sphere. This agrees with earlier report of Famaye (2000) on effect of shade regimes on growth and nutrient uptake of seedling and matured tree of coffee species in Nigeria. The results equally showed a significant ($P<0.05$) higher increase in growth parameters of cacao in cocoa/plantain, closely followed by cocoa/coconut compared to cocoa/plantain/coconut and the sole cocoa. This agrees with earlier information that intercropping cocoa with coconut and palm trees was a common practice in South East Asia (Famaye, 2013). This result was also in consonance with earlier work of Famaye *et al.* (2014) that reported good growth performance of cocoa seedlings in the nursery at Ibadan, Nigeria.

Table 1: Soil physical and chemical properties of the experimental site at the beginning of the experiment

Soil properties	Idi-Ayunre (Ibadan)

Mean	134.74	151.83	214.58	262.43	275.08	287.06	302.85	322.81
LSD($P \leq 0.05$)	5.72	5.05	15.51	28.59	22.19	12.27	20.06	28.43

CONCLUSSION

The morphological growth results show that cocoa/coconut is second to cocoa/plantain in performance and both were superior to cocoa sole and cocoa/plantain/coconut treatments. It was also concluded in the trial that the two crops, cocoa and coconut are compatible when grown on the same piece of land as they did not show any deleterious effect on their respective growth when intercropped together. Therefore, it could be concluded that cocoa/coconut intercrop as well as cocoa/plantain could be recommended to cocoa farmers instead of sole cocoa planting. This would increase the revenue base of the farmers when coconut and plantain would start bearing fruit from the intercrop as against only cocoa beans harvestable from sole cocoa planting.

ABSTRACT
This study investigated the extent of adoption of solar dryers in Nigeria, using farmers and processors in Osun state, as a case study. This study also evaluated the impact of socioeconomic factors on the level of adoption of solar dryers as well as the major drawbacks and interests attributed to its use. The study adopted the convenience sampling approach and selected survey respondents from the major towns in Osun; using a structured questionnaire and analysed data obtained using both descriptive and inferential statistics. The findings indicated that the level of adoption of solar dryers for drying biomaterials is low with 80.6% and 8.5% blaming it on lack of awareness and high initial cost respectively. Age, education, and income level positively correlated ($p < 0.05$) with solar dryer awareness level. Factors mitigating the use of solar dryers in Osun state include the high cost of maintenance, low technological knowledge and the problem of low capacity. The farmers and processors showed a high level of interest (89.9%) in the adoption of solar dryers. This study, therefore, recommends that researchers should pay more attention to awareness of solar dryer use demonstrations to enhance its adoption in Nigeria.

INTRODUCTION

In countries like Nigeria, where sunlight is abundant, and the supply of electricity is inconsistent, the use of solar energy has helped farmers reduce post-harvest losses considerably and as well minimise energy costs needed to preserve their products (Olujobi, 2020). Most farmers in the country however rely on the open sun-drying method which has been proven to result in quality losses of processed biomaterials (Udomkun et al., 2020). According to Meléndez-Martínez et al. (2022), exposure to dust, pests, UV photo-bleaching, and fluctuating drying air conditions experienced when the method is used leads to some chemical and biochemical degradation in the quality of products being dried. Additionally, the high level of contamination attributed to the method also renders most food products dried unfit for the export markets, making it challenging for processors to exploit and utilize the full potential of their products for international markets (African Union Commission, 2019).

Solar dryers have emerged as one of the promising and sustainable drying technologies for agricultural products globally (Goel et al., 2023). Solar dryers were designed to minimise most of the drawbacks attributed to the use of conventional open-sun drying methods. They have been designed to utilize the energy from the sun as part of the full heat source for the controlled drying of biomaterials while simultaneously protecting products from rain, insects, birds, and rodents (Chavan et al., 2021; Gorjian et al., 2021). In spite of the many advantages solar dryers have over open-sun drying, the two drying methods are still faced with the problem of reduced efficiency when solar energy is unavailable (Prakash and Kumar, 2017). Hence, researchers and professionals have spent decades developing solar dryers with improved drying efficiency in cases where solar energy is unavailable (Adnouni *et al.*, 2021; Muhumuza *et al.*, 2018).

The evolution of solar-drying technology over the last few decades began with simple designs in the mid-20th century and gradually progressed to passive solar dryers that utilized natural convection (Prakash and Kumar, 2017). In recent times, solar dryers have now been designed with fans, alternative heat sources, integration with other renewable energy systems, and advanced control systems incorporating sensors for enhanced performance, making it a sustainable and efficient solution for agricultural drying needs (Ortiz-Rodríguez *et al*., 2022). However, despite the research efforts to improve the performance of solar dryers, their use among farmers in Nigeria is hard to come by and seldom reported in the literature.

A study conducted by Okala *et al*. in 2011 as well as the study by Ayeni et al. in 2021 established that the practical use of solar dryers is absent in Nigeria. As of the moment, little to nothing has been reported on the subject; making it necessary to conduct a more recent study to track the level of solar dryer adoption in Nigeria; especially in Osun State where the supply of solar energy is readily available and agricultural activities are highly explored (Giwa *et al.*, 2017). This study was therefore aimed at investigating the extent of the adoption of solar dryers in Nigeria, using Osun State farmers and processors as a case study. the objectives of the study revolved around investigating the level of awareness, barriers, and interest of Osun state farmers in the use of solar dryers. The study also explored the impact of socioeconomic factors on the level of awareness of solar dryers among the farmers and processors in the state. Findings from this study will enhance the understanding of how solar dryer designs could be tailored towards addressing the drying needs of farmers and processors in Nigeria.

METHODOLOGY

This study adopted a positivist research philosophy and used the deductive approach of Saunders et al. (2009) to guide the investigation. The study area is located between latitudes 707.5' and 7010'N and longitudes 4032.5' and 4032'E, which lies in the southwestern part of Nigeria and covers several towns, including Osogbo, Ede, Ife, Gbongan, Ilesha, and Ikire in Osun State, Nigeria (Rauf and Fahm, 2022). Following the method of Kungu *et al.* (2017), a cross-sectional survey of farmers was conducted in the study area using a structured questionnaire as the primary data collection tool. This study acquired data utilising the convenience sampling strategy; where farmers and processors, were recruited for the study in a free manner (Atkins, 2014), and a total of 100 respondents were targeted through an online survey approach. This study contacted potential respondents with informed consent and approval to use the information obtained through the study for educational purposes.

The survey tool was administered using the Google form platform and the participants were contacted through administrators of major social media groups created for Osun State farmers and processors. The questionnaires were designed in English and structured into five sections, including respondents' biographic information, their degree of awareness about solar dryers, the extent of usage of solar dryers among farmers, issues impeding the adoption of solar dryers in the state as well as their level of interest in future adoption. To confirm the credibility of the data obtained, the internal consistency of the data was verified using Cronbach's Alpha reliability test of SPSS, with a reliability threshold of 0.7 chosen as the benchmark for validity.

Through the use of SPSS software version 26, the survey results were analysed using descriptive statistics such as frequency, and percentage; as well as inferential statistics like Pearson correlation to determine the relationship between socio-economic factors (which include age, level of education, and monthly income) and some cogent survey parameters indicating the extent of awareness of solar dryers in Osun State

RESULTS AND DISCUSSION

A total of 87 responses were obtained for the study however 20.69% of the responses were considered invalid as the responses were either obtained from respondents who are not farmers or processors or those who do not carry out their farming/processing activities within the study area. Therefore, a total of 69 responses were selected as valid for the research; with 68.12% of the responses obtained from farmers with 31.88% obtained from processors. As presented in Table 2, for all survey responses, the Cronbach's Alpha values ranged from 0.714 to 0.781, with an overall value of 0.785 indicating that the data has good internal consistency and are reliable (Alhayani et al., 2021).

(i) Demographic Information of Osun State Farmers

Table 2 presents the demographic distribution of the survey respondents. Careful examination of the age distribution reveals that most of the farmers and processors in Osun State are between the ages of 31 and 40, indicating that they are youthful and energetic. As further presented in the table, about 60.9% of the responders were males, revealing that males are more active in agricultural activities in Osun State than women. According to the information obtained for the religion, Muslims were more active in farming/processing activities than Christians. A total of 62.3% of the respondents were married indicating that most involved in agricultural practices in the location are not single. Finally, the majority of the farmers have monthly income levels of either between 100 and 150 thousand Naira or less than fifty thousand Naira, which indicates that based on level of income, Osun state farmers and processors can be categorised as either low- or medium-income farmers and processors. At the time the survey was completed the official exchange rate of dollar to Naira is 435. Since 60.9% of the farmers/processors earn below eight Dollars in a day (maximum of 100 thousand monthly) with a family size of not less than four on average as reported by Onya et al. (2019), one can conclude that most of the farmers are living below the poverty line as they have access to less than 2.15 Dollars poverty line per person per day threshold (Jolliffe et al., 2022).

(ii) Solar dryers and the extent of their adoption among farmers/processors in Osun state

The two prominent sources of solar dryers in Nigeria include local fabrication, and importation from overseas (Akinboro *et al.*, 2012) were explored. While 70.22% of the respondents are unaware of the sources of solar dryers used in Osun state, only 29.79% of the respondents have some level of information regarding the sources and 29.79% selected local fabrication as the primary source. As opinionated by Olorunnisola (2021), one may suspect the high cost of importation as a coagent factor responsible for the high adoption of locally fabricated solar dryers. Additionally, despite the majority of the respondents (63.8%) having no idea what solar dryers are, about 17% of respondents identified tent solar dryers as familiar and easier to come by than the other types (direct (10.6%) and mixed-mode together with indirect (8.5%)) in the state. This therefore indicates that while tent solar dryers are the most common in the state direct solar dryers are also common, with indirect and mixed mode types perceived as very rare.

While solar dryers can be used for drying many types of agricultural products, in Osun state, solar dryers are used for some selected agricultural products. While most of the respondents have never seen solar dryers being used in the state, 9.9% of the respondents indicated that cocoa beans are often dried in solar dryers in Osun State. Furthermore, 4.3%, 2.9%, and 2.8% of respondents identified corn, beans, and fish respectively as being commonly dried in solar dryers in the location. Some other products seldomly dried in solar dryers in Osun state as deduced through the survey are cashew, cassava, and melon. okra and grains; whereas, 25.3% of responses show that solar dryers are rarely used for drying ginger and pepper in the state.

Owing to the information obtained through the responses only 15.9% of the respondents have seen solar dryers being used within the state, whereas, only 8.7% have used solar dryers in the state. This result thus establishes that the use of solar dryers in Nigeria is no longer absent as previously reported by Okala et al. (2011) and Ayeni et al. (2021), however, comparing this to the report of Matavel et al. (2022), the level of its adoption among farmers/processors in Nigeria is still low compared to Mozambique, with 65% level of adoption. Furthermore, the information presented in Figure 1 gives the possible reason for the low level of adoption of solar dryers in the location. While 12.8% of the respondents do not know why solar dryers are not adopted by farmers, 76.6% of the respondents blamed the low adoption on a lack of awareness of its use. Nevertheless, 10.6% of the respondents claimed that farmers do not use solar dryers because it is too expensive for them. Based on this deduction, it can be inferred that the level of adoption of solar dryers is still low in Nigeria. This finding is in line with the report of Ayeni et al. (2021) which established that there is poor awareness about solar dryers and this poor awareness is the reason for the low level of its adoption among spice farmers.

(iii) The impact of socioeconomic factors on the level of adoption of solar dryers in Osun state

Table 3 details the outcome of Pearson correlation analysis among some coagent survey parameters. As presented in the table, the Age of Osun state farmers had a negative correlation with hearing about solar dryers, using solar dryers, and seeing solar dryers. This result implies that the higher the age of the Osun state farmers, the lower the likelihood of being aware of solar dryers. The correlation between age and likelihood of hearing about solar dryers and seeing solar dryers are however significant; whereas, a weaker correlation was obtained for the likelihood of using solar dryers. This shows that while age significantly influences the likelihood of seeing or hearing about solar dryers, it does not have any significant effect on the likelihood of using solar dryers. The study conducted by Benard et al. (2018) linked the age of farmers in Tanzania to their level of awareness about solar dryers and the result shows some levels of agreement with the findings made through this study indicating that younger farmers are more enlightened about solar dryer use than the older ones.

Additionally, the level of education of Osun state farmers had a positive correlation with the likelihood of hearing, seeing, and using solar dryers before. This result implies that the higher the number of years of education of Osun state farmers, the higher the possibility that they are aware of what solar dryer is and how it works. The result however shows no significance in the correlation between education and the three variables. Hence, one can say that the level of education of Osun state farmers does not significantly impact their level of awareness about solar dryer use and operation.

Furthermore, the income of Osun state farmers had a positive linear relationship with whether the farmers have heard of, seen, or used solar dryers before. The correlation value of 0.891 recorded for the likelihood of seeing solar dryers indicates that the higher the monthly income of farmers, the higher the likelihood that they might have seen solar dryers before. The result shows that as the income of farmers goes from below 50 thousand to 200 thousand Naira monthly, so also their levels of awareness of solar dryers increase.

(iii) The major drawbacks attributed to the use of solar dryers in Osun state and the level of interest of farmers in solar dryers' adoption.

Based on the responses obtained from the survey participants who are familiar with the use of solar dryers, the factors mitigating the use of solar dryers in Osun state are the high cost of maintenance, high frequency of the need for maintenance, high initial cost, low technological knowledge and the problem of low capacity. These findings are thus in line with the report of Giwa et al. (2017) which highlighted problems such as incentives and financing, research and development, as some of the additional problems confronting the maximal exploration of solar dryers in Nigeria. The level of interest in the adoption of solar dryers among the population considered was as high as 89.9 % of the total responses, which is significantly higher ($p<0.05$) than those who seemed uninterested in its use. This indicates that a very large fraction of farmers and processors are open to the adoption of novel solar drying technology in the study area. His finding is in line with the deduction of Matavel et al. (2022), which indicated that 100% of commercial rural farmers in the population surveyed in Mozambique indicated an interest in the adoption of solar dryers.

CONCLUSION

The aim of this study was to determine how widely solar dryers are adopted in Nigeria; using Osun state's farmers/processors as a case study. All solar dryers found in the state were locally fabricated and they have a low degree of adoption and usage with factors such as lack of awareness and high initial cost identified as the bane for low adoption. Age, education, and income level strongly correlated with solar dryer awareness level. Factors mitigating the usage of solar dryers in Osun state include expensive cost of maintenance, insufficient technological expertise and the problem of low capacity. The farmers and processors exhibited a high degree of interest (89.9%) in the implementation of solar dryers. Therefore, this study suggests that additional time be devoted to raising awareness and holding local demonstrations of the usage of solar dryers.

FUNDING ORGANIZATIONS

This research was co-funded by the International Foundation for Science (IFS) and the Committee on Scientific and Technological Cooperation (COMSTECH) under the grant (number: IFS- I3-E-6579-1).

EFFECTS OF TEMPERATURE VARIATIONS ON KOLANUT PRODUCTION IN NIGERIA

Ibe, O. and Adeyemi, E.A.
Cocoa Research Institute of Nigeria (CRIN), Ibadan.

Corresponding author: ibe_xcel@yahoo.com

ABSTRACT
Kola, a tree crop cultivated in Nigeria is faced with low nut yield due to climate change effects. Data of 61 years (1961 – 2021) from FAOSTAT was used to measure area cultivated (ha), yield (kg/ha) and yearly temperature (^{0}C). The data were analysed using least squares regression. Results revealed 895.3kg/ha average yield from157,673.7 ha. Temperature trend showed 18.0 % decrease in 11 years and 82.0 % increase in 50 years. There was 0.0200^{o}C annual temperature increase and 0.0007^{o}C decrease at $R^2$of 0.6380 and 0.0014 respectively. The temperature decrease resulted to increased kola yield by 5.5kg/ha while its increase decreased yield by 7.8kg/ha with R^2 of 0.8302 and 0.3532 respectively. This indicated a direct correlation (0.057) between kola yield and temperature decrease, but an inverse correlation (-0.641) with increase in temperature. Yield in kolanut could be enhanced when ambient temperature is controlled through good agricultural activities that mitigate climate change
Keywords: *Climate change, FAOSTAT, kolanut, temperature variations, yield*

INTRODUCTION

Kola, a tropical African genus of the family Sterculiaceae, comprises about one hundred and twenty five species. Kola species are evergreen, mostly small or moderately sized trees although a few grow to 25 metres. It is mostly produced in Africa and is cultivated to a large degree in Nigeria, but also in Ghana, Ivory Coast, Brazil and the West Indian Islands (Opeke, 1987). Annual production from these countries alone is in excess of 250,000 tons, while the world production is about 300,000 tons (Brickell *et. al*., 2002). A number of species are widely cultivated in tropical countries, especially in Africa. The most commonly used are *Cola. verticillata*, *C. acuminate* (P. Beav) Schott and Endl., and *C. nitida* (vent) schott and Endl, with the latter two having the greatest economic importance. While *C. acuminata* bears seeds containing 3–6 cotyledons, *C. nitida* produces seeds with 2 cotyledons only (Adeleye *et. al*., 2015). The plants are grown purposely for their nuts which are widely consumed in West Africa as stimulants and also used in traditional ceremonies; it is depicted as an object of life that brings peace and progress in African society (Odo *et. al*., 2023).

C. nitida, referred to as “the true kola of commerce” has featured in the internal trade of West Africa for a number of centuries. It is widely cultivated in the tropical rainforest of West and Central Africa and is found as perennial tree in Nigeria, Angola, Liberia, Gambia, Togo, Republic of Benin, Sierra-Leone, Tanzania, Ghana, Mozambique, Gabon and Cote d’Ivoire (Akinola *et. al*., 2020; Aduama-Larbi *et. al*., 2022). Nigeria accounts for 55% of the total world production of kolanuts in 2020 (Wikipedia). It has industrial usage in production of soft drinks as well as flavouring agent in food industry (Asogwa *et. al*., 2006, Nyadanu *et. al*., 2020). It could also be used in jam and jelly production because of its high pectin content. Furthermore, due to the high potassium content of the kola nut testa, it has been suggested as a possible ingredient for making fertilizers (Olubamiwa *et. al,*. 2002). As stated by Asogwa *et. al.,* (2006), other local uses of kola are as follows: (1) it provides some essential materials for cloth dying; (2) the pod bark, when mixed with some ingredients, are used in traditional medicine to reduce labour pains; (3) the bark is used in treating swellings and fresh wounds; (4) the roots provide excellent chewing sticks for cleansing the teeth and the wood is used in local carvings, coach work and boat building. However, About 50% of the existing kola trees especially in Western Nigeria yield insignificant produce (Asogwa *et. al*., 2006) which among other factors has been attributed to climate change (Akinfenwa, 2018). The study is therefore aimed at determining the effects of temperature on kolanut yield and proposing climate mitigation measures towards optimizing its yield.

MATERIALS AND METHODS

Data on area harvested (ha), yield (kg/ha) and temperature (^{O}C) in Nigeria was sourced from the database of Food and Agricultural Organisation Corporate Statistical Database (FAOSTAT); the duration was 61 years (1961 - 2021). The data were analysed using least squares regression.

The least squares line method uses a straight line

$Y = a + bx$

to approximate the given set of data, (x_1,y_1), (x_2,y_2), … , (x_n,y_n), where $n \geq 2$

Where 'a' stands for the intercept and 'b' stands for the slope; x and y are the variables. The slope is equivalent to variation in kolanut yield and temperatures per year (Kadioglu, 1997). Correlation analysis was used to measure the association between the variables.

RESULTS AND DISCUSSION

Temperature variations and kola yield

The surface temperature of Nigeria increased by a range of 0.0004 – 1.4367 ^{0}C with a mean value of 0.7333 ^{0}C while the decrease ranged from 0.0136 - 0.4743 ^{o}C with a mean value of 0.1710 ^{o}C in the 61 years of consideration (Table 1).

Table 1: Kolanut cumulative yield as influenced by temperature variations in 61 years

Variables	Yield as temperature increases		Yield as temperature decreases	
	Temperature (^{0}C)	Yield (kg/ha)	Temperature (^{0}C)	Yield (kg/ha)
Minimum	0.0004	536.6	0.0136	896.8
Maximum	1.4367	1364.6	0.4743	1076.9
Mean	0.7333	881.9	0.1710	956.1
Standard deviation	0.3918	184.7	0.1380	47.6
Correlation analysis	-0.641		0.057	

The maximum kolanut yield per hectare during temperature increase was 1364.6 kg while the minimum yield was 536.6 kg with the mean yield of 881.9 kg. During the decrease in temperature, 1076.9 kg and 896.8 kg were the maximum and minimum yield respectively with the mean yield of 956.1 kg as shown in Table 1. The differential of 77 % between the mean temperature increase and decrease is an indicator of global warming with its attendant effects on mean kolanut yield as reported by Akinnagbe and Ikusika (2016). Kolanut yield was 1.7 % higher during the periods of temperature decrease than at the periods of increase in temperature implying that a decrease in temperature enhanced kolanut yield. This is buttressed by the correlation analysis which showed an inverse relationship (-0.641) between kolanut yield and temperature increase but a direct relationship (0.057) between both variables. In the 61 years under consideration, the yield of kolanut as affected by the rate of temperature increase and decrease is as shown in figures 1 and 2 respectively

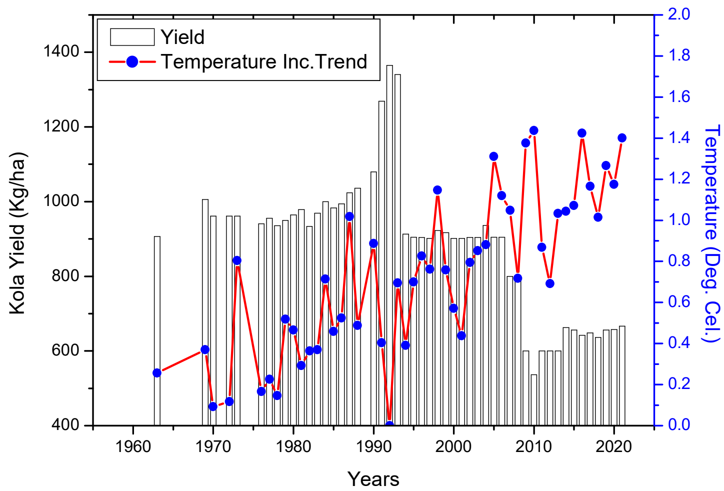

Figure 1: Kolanut yield at the rate of temperature increase

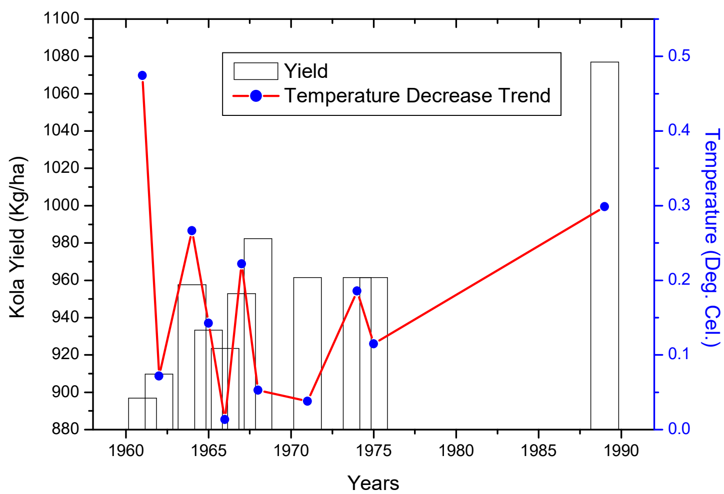

Figure 2: Kolanut yield at the rate of temperature decrease

Regression analysis of kolanut yield trend

The regression analysis showed the trend in kolanut yield during the periods of temperature variations. In 11 years, temperature decreased by 0.0007 ^{0}C per annum with a corresponding annual 5.452 kg/ha kolanut yield increase while in 50 years, temperature increased by 0.02 ^{0}C per annum and the kolanut yield decreased by 7.84 kg/ha per annum (Figures 3 and 4). In 11 years, the overall temperature decrease and corresponding kolanut yields were 0.0077 ^{0}C and 86.24 kg/ha respectively while in 50 years of temperature increase by 1.0 ^{0}C, the kolanut yield decreased by 392.0 kg/ha.

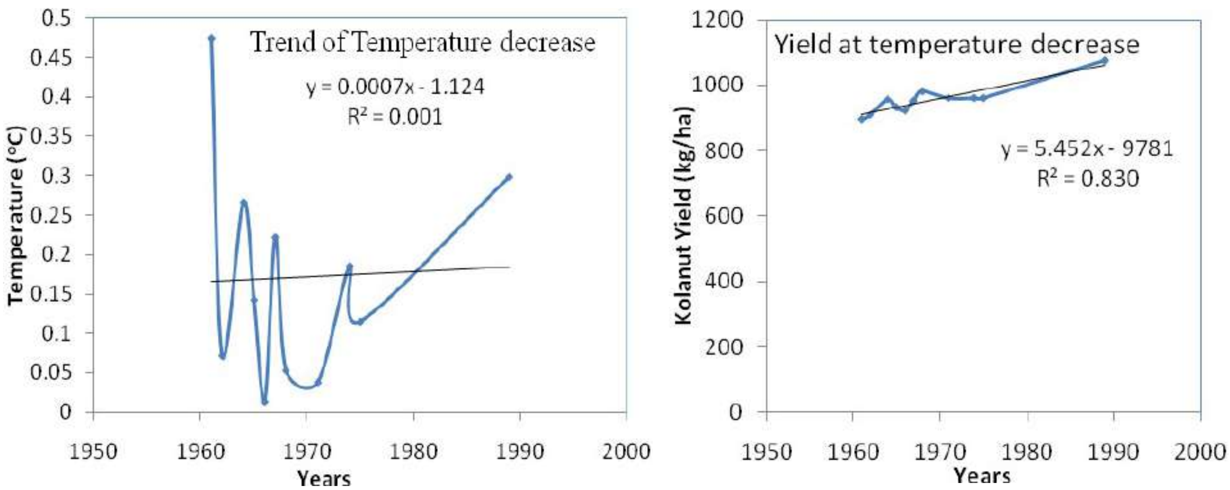

Figure 3: Relationship between annual temperature decrease and kolanut yield

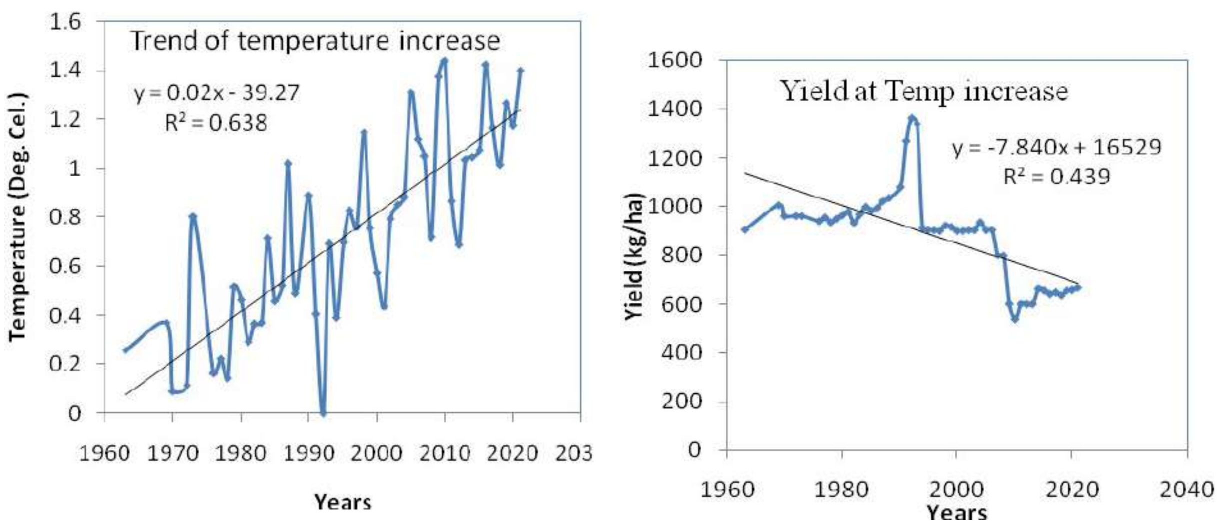

Figure 4: Relationship between annual temperature incr

The corresponding regression coefficients (R^2) in temperature variations were 0.0014 and 0.638 while the values in kolanut yield were 0.830 and 0.439 for temperature decrease and increase respectively. It becomes imperative therefore to control the ambient temperature in Nigeria through mitigation of anthropogenic activities, in order to enhance the yield of kolanut in a sustainable manner. This could be realised by enacting Government policies that encourage aforestation practices such as the planting of economic tree crops like cashew that thrives in various agro-ecologies in Nigeria. Planting of timber trees like teak and mahogany should also be encouraged and sustained. Indiscriminate felling of trees and bush burning should be prohibited.

CONCLUSION

The study has shown that decrease in ambient temperature resulted in increased kolanut yield and vice versa. Consequently, policies and measures that promote green practices which lead to a controlled temperature in Nigeria should be encouraged.

SOIL FERTILITY EVALUATION FOR CASHEW PRODUCTION AT IYAPO FARM ESTATE, OFFA, KWARA STATE

Ibiremo, O.S; Ogunlade, M.O; Iloyanomon, C.I and Ogbeide, C.E
Cocoa Research Institute of Nigeria, P. M. B 5244, Ibadan, Nigeria.

Corresponding author: femiibiremo@yahoo.com

ABSTRACT
Cashew (Anacardium occidentale L) is an important commodity crop with great potential as a foreign exchange earner. It is grown principally for it nuts and apple and is a hardy crop which is adapted to a wide range of agro-ecologies. As result of increased in the price of cashew nuts globally, many people developed interest in the cultivation of the crop. The Management of Iyapo farms Limited in its desire to key into this sector requested the technical assistance of Cocoa Research Institute of Nigeria (CRIN) to carry out soil fertility evaluation of the 50 hectares of land proposed for establishment of cashew. The farm was divided into three main sections (A, B and C) based on topography and four land use types (water logged, cassava plot, previously cultivated land and excavated land). section A was parallel to River Oyun followed by section B in the middle of the farm, while the last section C ran parallel to the road from Ijagbo town. The land use types were scattered within the three blocks. The water logged area was however confined only to section A which was close to river Oyun. Soil samples were collected at soil depths of 0-20 cm and 20-40 cm and at a distance of 20 m apart. The soil collected was put in nylon bags and properly labelled. Soil samples collected were air dried, passed through 2 mm sieve and analyzed for some of its physical and chemical properties. In section A, total soil nitrogen at 0-40cm soil depth ranged between 0.07g/kg to 0.18g/kg with a mean value of 0.11 g/kg soil while mean soil available phosphorus at 0-40cm soil depth was 3.16mg/kg. The exchangeable potassium content across 0-40cm soil depth ranged between 0.09cmol/kg to 0.35 cmol/kg with a mean value of 0.25 cmol/kg and 0.19cmol/kg for 0-20 cm and 20-40cm soil depth respectively. In section B, nitrogen across the various soil depths ranged between 0.04 g/kg to 0.12 g/kg with nitrogen content of the soil decreasing with increasing soil depth. This falls below the soil critical level of 1 g/kg required for cashew and was grossly inadequate to meet nitrogen need for cashew. There is need for nutrient supplementation as Nitrogen fertilizer is required to meet the nitrogen needs of the cashew. Similarly, phosphorus was also inadequate across the soil depths with a range of 2.47 mg/kg to 4.51 mg/kg across the various soil depth and a mean value of 3.24 mg/kg and 2.65 mg/kg for 0-20cm and 20-40cm soil depths respectively. This was below the soil critical value of 3.7 mg/kg. There is therefore need to apply phosphorus fertilizer to boost cashew productivity. Soil exchangeable potassium was adequate across the various soil depths with a range of 0.13 to 0.20 cmol/kg and a mean value of 0.18 cmol/kg and 0.16 cmol/kg for 0-20cm and 20-40cm soil depths respectively. There is no need for potassium fertilizer application. The results above indicated that sections A, B and C require 180kg/ha of urea and 31.5 kg of Single Super Phosphate (SSP). The cassava plot and previously cropped bare land requires 189 kg/ha urea and 9.9 kg/ha SSP, while the excavated land requires 194.2 kg urea 25.8 kg SSP and 32.28 kg MOP. Cashew should not be grown on the water-logged section.
Key words: *Cashew, Soil fertility, nutrient management, fertilizer, yield*

INTRODUCTION

Cashew is an important commodity crop with great potentials as foreign earner and source of industrial raw materials with the prospect of becoming a major commercial tree crop in Nigeria. Cashew as a result of its wide adaptation is often grown in very poor soils and this has affected its survival and establishment (Opeke, 2005; Topper, *et al*.2001). Cashew is a commodity crop of international recognition for its numerous importance, food security, foreign exchange earnings, and afforestation with its roles in mitigating the adverse effects of climate change. It is a hardy crop which survives where most tree crops cannot thrive (Ohler, 1979). Hence, it is cultivated in a variety of ecological zones of Nigeria which connotes a wide variety of soil. It is often grown on poor soils and this has affected its survival and adaptability. Cashew nuts production has the potential of increase in Nigeria if available resources are adequate annexed. Particularly important is the financial resources needed to boost cultivation and perform marketing functions that can further facilitate cashew production couple with appropriate record keeping for sustainability. Cashew nuts are among the healthiest and most popular nuts in the world and regular consumption can contribute to the reduction of risks of cardiovascular diseases (MTP 15). The cashew apple is edible fruit rich in vitamin C, sugars and contains considerable amount of tannins (35%, less in the yellow) and minerals, mainly calcium, iron and phosphorous. The fruit can be improved on for consumption and trade by removing the undesirable tannins and processing the apples into value-added products, such as juices, syrups, canned fruits, pickles, jams, chutneys, candy and coffee. The nuts are also processed for other value-added products.

Cashew however grows optimally with corresponding economic returns under ideal soil condition and proper management. Good soil management is a criterion for good quality and high yield of both cashew nuts and apples. This is however lacking in cashew production in Nigeria. Some of the components of good soil management include proper site selection and use of fertilizer. Proper site selection is critical in cashew production because it's a long term investment and this site should have deep soil (1-1.5 m), well drained with steady and continuous supply of nutrients.

Iyapo farm is interested in establishing about 50 hectares of cashew. Soil fertility evaluation is crucial to ensure appropriate recommendation of soil management practice to enhance establishment and yield of cashew. The objective of this work is to carry out soil fertility assessment of Iyapo farm for cashew cultivation.

MATERIALS AND METHODS

Study Site

Kwara State is located between latitude 7°N and longitude 3°E and 7°E. It is geographically located at the Southern border of River Niger and in the Southern guinea savanna. The average annual rainfall in the State is 1202.4mm with two peaks in July and September and a dry spell in August, known as August break. The rainfall starts in late April and ends in October. The Average monthly temperature are fairly constant. However, February, March and April are the hottest months, while June to September has lowest maximum temperature which coincides with the peak of the dry and wet seasons respectively (Ogunwale *et al,* 1999).

Parent materials

Kwara State has two distinct geologies. The soils were formed from basement complex rocks metamorphic and igneous rocks) which is about 95% and sedimentary rock along the Niger River bank which is about 5% of the total area. The metamorphic rocks include biotite gneiss, quartizite, augite gneiss and grantitic gnesis. The intrusive pegmatite and vein quarz (Lawal, 1977).

The farm is located at Ijagbo, Oyun Local Government area near Offa Kwara State. It is on latitude 8° 13.44^1N, longitude 0040 43.501^1 and 36.5 metres above sea level. The 49.547 hectares' farm which is located in the Southern Guinea Zone is bounded by River Oyun, a citrus farm, farm house and a road from Ijagbo at the four boundaries. The farm consisted of scattered locust bean trees, oil palm trees and a few cashew stands. Part of the farm was presently cultivated with cassava, while some had been previously cropped with maize. There was evidence of sand mining in the excavated lands while excavation of the top soil had been carried out.

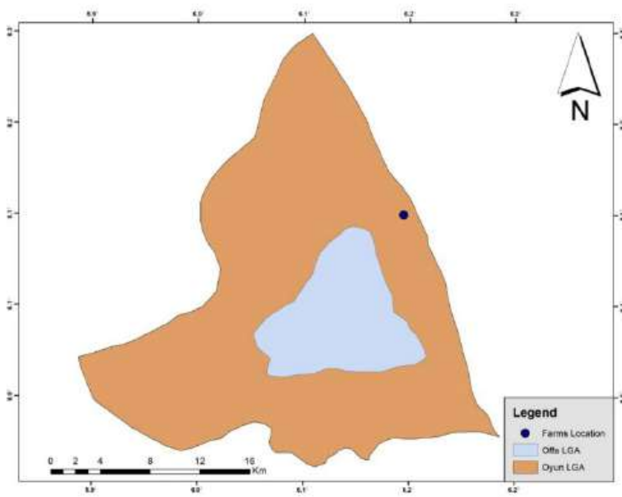

Figure 1: Map of Kwara State showing the location of Iyapo farm

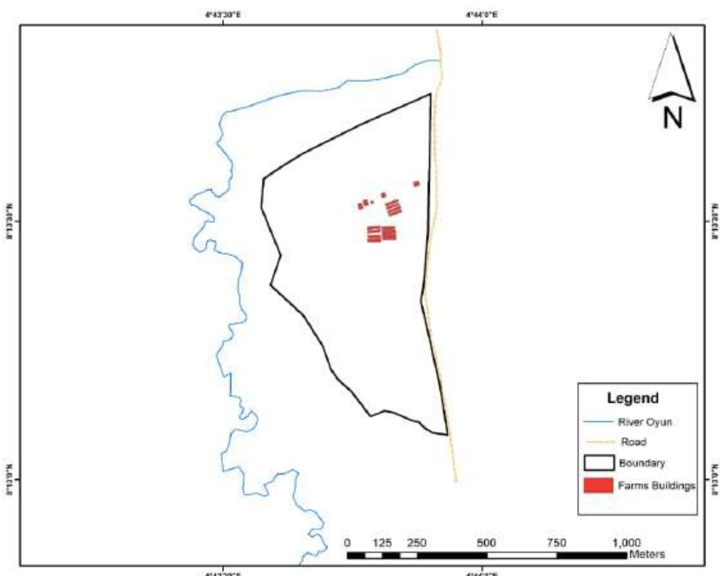

Figure 2: Map of Iyapo farm in Kwara State, Nigeria

METHODOLOGY

Field soil sampling

The farm sampled was divided into three main sections (A, B and C) based on topography and four land use types (water logged, cassava plot, previously cultivated land and excavated land). Section A was parallel to River Oyun followed by section B in the middle of the farm while the last section C ran parallel to the road from Ijagbo. The land use types were scattered within the three blocks. However, the water logged area was confined only to section A which was close to river Oyun. Soil samples were collected at the depth of 0-20cm and 20-40cm and at a distance of 20m apart. The observation spots were selected in such a way that biased points like anthills and rocky spots were avoided. The soil collected were put in nylon bags and properly labelled.

Laboratory analysis

The soil samples collected were bulked to form composite samples, air dried passed through 2mm sieve and analysed for some of its physical and chemical properties. Particle size was determined by Bouyoucos hydrometer methods; soil pH was measured in 1:1 soil - water ratio using the EDT BA350 digital pH meter while organic carbon was determined by the wet digestion dichromate acid-oxidation method. Total N was determined using Kjeldahl digestion method and available P by Bray P1 method. Exchangeable cations (Ca^{2+}, Mg^{2+}, K^+ and Na^+) were extracted with 1 N ammonium acetate (NH_4OAc) buffered at pH 7.0 (Thomas,1982). Exchangeable K and Na in the extracts were read through the Jenway flame photometer (model PFP7) and Ca and Mg were read on Atomic Absorption Spectrophotometer (AAS) Buck Scientific 200A model. Exchangeable acidity was extracted with 1 N KCl and determined by titration with 0.05 N NaOH using phenolphthalein indicator (Mclean, 1965) while the effective cation exchange capacity (ECEC) was by summation method and percent base saturation was calculated as follows:

$$\% \text{ Base saturation} = \frac{\text{Exchangeable bases}}{\text{ECEC}} \times \frac{100}{1}$$

The fertilizer computation was based on the chemical properties of the top soil (0-20cm) taking into consideration that both lateral and creeping roots are housed at this soil depth.

RESULTS AND DISCUSSION

Soil physical and chemical characteristics

Section A

Soil physical and chemical characteristics of block A is shown on (Table 1). Sand content of the 0-20cm and 20-40cm soil depth ranged between 662g/kg to 762.4 g/kg and 602.4g/kg to 742.4g/kg respectively, with a mean value of 682.4g/kg. Sand content decreased with increasing soil depth. Silt content of the top 0-2cm soil depth ranged between 72.8g/kg to 232.8g/kg with a mean value of 160.8g/kg. The silt content of 20-40cm soil depth ranged between 112.8 to 252.8 g/kg, with a mean value of 172.8 g/kg. Silt content increased with increasing soil depth. Clay content of the soil decreased with increasing soil depth. Clay at the top 0-20cm soil depth ranged between 124.8g/kg to 164.8g/kg with a mean value of 151.8g/kg. Clay in 20-40cm soil depth also ranged between 144.8g/kg to 168.8g/kg with mean value of 149.1g/kg. The textural class of the soil is sandy loam. Despite the high sand content of the soil, cashew thrives well on this soil because cashew is hardy and adapt to dry environment (Ohler, 1979). The soil is slightly acidic with soil pH increasing with increasing soil depth. At the top 0-20cm soil depth, soil pH ranged between 6.19-6.66 with a mean value of 6.54. Cashew thrives well in soil of pH of 5-7.7. The soil pH is therefore favourable for cashew production.
Soil organic carbon content in the top 0-20cm soil depth ranged between 16.2g/kg to 28.8g/kg with a mean value of 19.7g/kg. Organic carbon at 20-40cm soil depth also ranged between 10.1g/kg to 22.7g/kg with a mean value of 15.35 g/kg and organic carbon content decreased with increasing soil depth. Soil organic carbon content was medium and was sufficient to sustain cashew production. Total soil nitrogen in the top 0-20cm soil depth ranged between 0.07g/kg to 0.18g/kg with a mean value of 0.1 g/kg soil. While total N in 20-40cm soil depth ranged between 0.07g/kg to 0.16g/kg with a mean value of 0.12g/kg. This is highly inadequate for cashew production, as this value is well below the soil critical value of 1g/kg (Egbe *et al*, 1989) required for cashew production. There is therefore urgent need to apply nitrogen fertilizer. Soil available phosphorus decreased with increasing soil depth. Soil available phosphorus in the top (0-20cm) soil depth ranged between 2.82g/kg to 3.47mg/kg with a mean value of 3.22mg/kg. Similarly, available phosphorus at 20-40cm soil depth ranged between 1.78mg/kg to 4.08mg/kg with a mean value of 2.62mg/kg. Mean soil available phosphorus in the top 0-20cm soil depth was below the soil critical level of 3.7mg/kg, phosphorus level than the critical soil. Phosphorus level all other locations had values. At 20-40cm soil depth, soil available phosphorus also fell below the soil critical phosphorus level with a ranged of 0.09 mg/kg to 0.16mg/kg and a mean value of 2.62 mg/kg. There is need for application of phosphorus fertilizer. Mean exchangeable potassium content across 0-40cm soil depth ranged between 0.09cmol/kg to 0.35 cmol/kg with a mean value of 0.25 cmol/kg and 0.19cmol/kg for 0-20 cm and 20-40cm soil depth respectively. This is above the soil critical potassium level of 0.12 cmol/kg soil required for cashew production. There is therefore no need for potassium fertilizer application. Exchangeable calcium across the various soil depth was high ranging between 4.82 cmol/kg to 7.43 cmol/kg with a mean value of 6.69 cmol/kg and 5.91 cmol/kg for 0-20cm and 20-40cm soil depth respectively. Calcium content of the soil was adequate for cashew production as soil exchangeable calcium content was well above the soil critical calcium value of 0.8 cmol/kg soil. There is therefore no need for calcium

fertilizer application. Similarly, soil exchangeable magnesium across the various soil depth ranged between 0.84 cmol/kg to 1.38 cmol/kg with mean value of 1.12 cmol/kg at 0-20cm and 20-40cm soil depth. Soil exchangeable magnesium was adequate for cashew production as it was well above the 0.08 cmol/kg soil recommended for cashew production. Exchangeable acidity ranged between 0.18cmol/kg to 0.76cmol/kg in the top 0-20cm soil depth with a mean value of 0.28cmol/kg. Exchangeable acidity of 20-40cm soil depth also ranged between 0.40 cmol/kg to 0.68 cmol/kg with a mean value of 0.51 cmol/kg soil.

Section B

The sand in the top 0-20cm soil depth ranged from 762.4 g/kg to 802.4 g/kg with a mean value of 782.4 g/kg. In the 20-40cm soil depth, sand content ranged between 742.4g/kg to 782.4g/kg with a mean value of 767.4 g/kg, with sand content decreasing with increasing soil depth (Table 2). Silt in the 0-20cm soil depth ranged between 32.8-112.8g/kg with a mean value of 82.5 g/kg. Similarly, silt in 20-40cm soil depth ranged between 32.8g/kg to 92.8 g/kg with a mean value of 77.8 g/kg, with silt content increasing with increasing soil depth. Clay content across the 0-40cm soil depth ranged between 124g/kg to 224.8 g/kg with a mean value of 134.8 g/kg and 154.8 g/kg for 0-20cm and 20-40cm soil depth respectively. The textural class of the soil is loamy sand. This is ideal for cashew production. Soil pH content across the various soil depth ranged between 6.24-6.68 with a mean value of 6.51 at 0-20cm soil depth and 6.57 at 20-40cm soil depth. The soil is slightly acidic and okay for cashew production as it falls within the pH range recommended for cashew production. Soil organic carbon at the top 0-20cm soil depth ranged between 7 g/kg with a mean value of 18.6 g/kg. Soil in the 20-40cm soil depth ranged between 3.2 g/kg to 10.5g/kg with a mean value of 7.38 g/kg. Soil organic carbon content decreased with increasing soil depth. Organic carbon in the top 0-20cm was sufficient to sustain cashew production. However, at the lower 20-40cm soil depth soil organic carbon was insufficient. There may be need to apply organic fertilizer in subsequent years to enhance the organic carbon content of the soil. Nitrogen across the various soil depths ranged between 0.04 g/kg to 0.12 g/kg with nitrogen content of the soil decreasing with increasing soil depth. This falls below the soil critical level of 1 g/kg required for cashew and was grossly inadequate to meet nitrogen need for cashew. There is therefore need for nutrient supplementation as fertilizer to meet the nitrogen needs of cashew. Phosphorus was also inadequate across the soil depth with a range of 2.47 mg/kg to 4.51 mg/kg across the various soil depth and a mean value of 3.24 mg/kg and 2.65 mg/kg for 0-20cm and 20-40cm soil depth respectively. This was below the soil critical value of 3.7 mg/kg. There is therefore need to apply phosphorus fertilizer to boost cashew productivity. Soil exchangeable potassium was adequate across the various soil depth with a range of 0.13 to 0.20 cmol/kg and a mean value of 0.18 cmol/kg and 0.16 cmol/kg for 0-20cm and 20-40cm soil depth respectively. There is therefore no need for potassium fertilizer application. Soil exchangeable calcium and magnesium were also adequate. Soil exchangeable calcium had a mean value of 5.54 cmol/kg and 5.59 cmol/kg in 0-20cm and 20-40cm soil depth respectively. This was well above the soil critical level of 0.8 cmol/kg required for cashew. Similarly, exchangeable magnesium content ranged between 0.80 cmol/kg soil and 0.94 cmol/kg soil with mean value of 0.95 cmol/kg and 0.93 cmol/kg for 0-20cm and 20-40cm soil depth respectively. This was also well above the soil critical value of 0.08 cmol/kg soil required for cashew production. Mean exchangeable acidity was 0.61 cmol/kg and 0.56 cmol/kg for 0-20cm and 20-40cm soil depth respectively. This was also adequate for cashew production.

Section C

The mean sand, silt and clay at the top soil (0-20cm) was 772.6, 97.8 and 129.8 g/kg soil respectively while the mean sand, silt and clay at the sub soil was 747.4, 102.8 and 149.8 g/kg soil respectively (Table 3). The soil has a very high sand fraction both at the top and sub- soil. Although the sand fraction at the top soil decreased by 3.2% at the sub-soil while the silt and clay both increased by 5% and 15% respectively. The clay soil content is below 300 g/kg soil which can be considered low and the possibility of water deficit during the dry season is there. However, cashew has ability to adapt to dry environment more than many other tree crops as soon as it survives the first two years of establishment. It is still expected that with good agronomic practices, cashew will still establish despite the level of sand in the farm.

The pH of the soil at both depth was 6.46 and thus falls within the acceptable range of 5.50 to 6.50 for cashew cultivation. Hence, there is no need for any form of adjustment through liming. The average organic carbon and total N at the top soil (0-20cm) was 12.38 and 0.12 g/kg while at the sub soil (20-40cm), the mean was 12.57 and 0.10 g/kg soil respectively. This shows that the organic carbon and the total N at the top soil were higher than the values obtained at the sub soil, the values were however moderate for good cashew cultivation. This gives the possibility of using N- fertilizer particularly of organic origin so that the soil will not be acidified if inorganic N source is used like urea and other acidifying fertilizers. The mean available P at both depth was 4.03mg/kg soil. The value is moderate for cashew production as this could fall below 3.7 mg/kg. There is need for routine management of the P through the use of natural rock phosphate (Sokoto rock phosphate) but if this is not available, single super phosphate could also be used as recommended in the findings of Ibiremo *et.al* (2005).

Similarly, the level of exchangeable K across the depth was 0.22 cmol/kg soils. The mean exchangeable cashew at the top soil was 6.68 cmol/kg soil while at the subsoil was 6.52 cmol/kg soil. The value of exchangeable calcium at the top soil decreased by 2.4% when compared with the value of exchangeable magnesium that was 1.03 cmol/kg soil which is moderate. The Ca/Mg ratio was 6.38. This value maintains the normal relationship provided for productive soil. This indicates that the soil matrix maintains a proper balance and hence there is no likelihood of nutrient imbalance in the soil. It is instructive that there is no need for adjustment in the content of the soil total N, available P and exchangeable potassium. These three major nutrients give the direction for the productivity of soil when pH is within the appropriate range of 5.50 to 7.50.

The mean value of N across the two soil depths was 0.11g/kg. This value is below the soil critical value of 1g/kg. The average value of soil available P of 4 mg/kg soil is higher than the soil critical value of 3.7 mg/kg soil. Similarly, the value of K was above the soil critical value for cashew production. Hence, there is no need for P and K fertilizers as at now. However, nitrogen fertilizer will be required for optimum production.

Table 4: Physical and chemical properties of water logged cassava plots previously cultivated and excavated land at Iyapo farm in Offa, Kwara State.

Table 5: Fertilizer recommendation for different land use types in Iyapo farm

Land Use Types	N, P and K Required					
Fertilizer Recommendation						
		N kg/ha	P_2O_5 (Kg/ha)	K_2O(Kg/ha)		
Sections A, B and C	82.8	5.6	-	180	31.50	-
Cassava farm and previously cultivated bared land	84.78	1.97	-	189	9.9	-
Excavated land	87.4	5.10	22.97	194.2	25.8	38.28

The sand content of the waterlogged area of the farm which occupied about 1/32 of the farm land (1.56 hectares) was lower than the other land use types - cassava, previously cultivated and excavated land. This might be due to washing away by erosion and the portion of the top soil was higher in sand content. Clay +silt content of the water- logged surface soil (0-20cm) was higher than other land use types. This might be the reason for more water retention which led to water logging because of poor drainage. The water logged portion was situated in the section area of the farm parallel to the major stream at the boundary of the farm. Exchangeable Ca and Mg contents were adequate for cashew in the water - logged area of the farm. The total nitrogen, available phosphorus and exchangeable potassium content were slightly below the amount required by cashew. Fertilizer will be required to supply the deficient N, P and K in that portion of the land.

Cassava plot on the land

The sand content of the top soil of the cassava plot was higher than water-logged and excavated portion of the land. The pH was slightly acidic. All the major nutrients except nitrogen were adequate and slightly above the amount required for cashew. There will be need for supplementation with nitrogen fertilizers.

Cultivated soil

The previously cultivated bare soil portion of the land had lesser amount of available P, exchangeable K and Mg in the top soil compared to the sub soil. This might be due to leaching and or run off. Total nitrogen and phosphorus in the previously cultivated bare land were low and below the critical values required by cashew. This implies that nitrogen and phosphorus fertilizers will be applied.

Excavated land

Total nitrogen, available phosphorus and exchangeable potassium were slightly below the critical nutrient values required by cashew in the excavated land. Exchangeable calcium and magnesium content of the soils were adequate and grossly above the critical values required. N, P and K fertilizer will be required for application on cashew to be planted on excavated land.

CONCLUSION

The soil fertility evaluation of the 49.56 hectares of land proposed for the establishment of cashew by the farm. The farm was divided into three main blocks (A, B and C) based on topography and four land use types (water-logged, cassava plot, previously cultivated land and excavated land). Block A was parallel to River Oyun followed by Block B in the middle of the farm, while the last block C ran parallel to the road from Ijagbo. Soil samples were collected at soil depth of 0-20cm and 20-40cm and at a distance of 20m apart. The soil collected was put in nylon bags and properly labelled. Soil samples collected were air dried, passed through 2 mm sieve and analyzed for some of its physical and chemical properties. In the various land use types, section (A, B and C) requires 180 kg/ha of urea and 31.5 kg of Single Super phosphate (SSP) for optimum productivity. Application of fertilizers improved growth and nut yield of cashew (ComCashew , 2018).The cassava plot and previously cropped bare land require 189 kg/ha urea and 9.9 kg/ha SSP, while the excavated land requires 194.2 kg urea 25.8 kg SSP and 32.28 kg MOP as showed in Table 5 below. Cashew should not be grown on the water-logged section because cashew will not thrive well there.

ABSTRACT
Telfairia occidentalis (fluted pumpkin) is an important indigenous vegetable in Nigeria. It is mostly grown and consumed in the Southern part of the country because of it is rich in nutrients and minerals which are important in fighting hidden hunger. The study was conducted to assess the differences in the nutrient composition of ugu plant based on different sex type expression in ugu, Seeds of ugu were extracted from the pod and pre-nursed in sawdust, the seedlings were later transferred at four weeks after sowing to well-prepared field using a completely randomized design with three replications. Fresh leaves were harvested at flowering from identified male and female vines for nutrient analysis. Results revealed significant variations (p < 0.05) for the measured nutrient constituents suggesting that the either of the sexes possess useful alleles for recombination. The iron content recorded in female was higher (9.83mg/100g) than in male (9.6mg/100g) both still fall within the recommended dietary allowance (RDA). The result provides evidences that leaves from both sexes can be consumed for improved diet and that both sexes possess useful genes that can further be exploited to develop improved ugu with increased nutrient content.
Keywords*: Hidden hunger, indigenous vegetable, sex type, nutrient, ugu*

INTRODUCTION

The tropical fluted pumpkin is a dioecious and perennial plant belonging to the family of Cucurbitaceae and is characterized by broad lobed greenish leaves commonly referred to as *U*gu. The shrub grows into either a male or female plant; the sex differences are only identifiable after flowering. While the female plant which produces big fruits containing the seeds has broad and succulent leaves; the male plant only produces flowers and smaller leaves. The stems of the female plant are usually big and strong while that of the male plants are tiny. Farmers usually harvest the male plant for leaves while the female plant are left on the field for productions of seeds for the next planting season. However, consumers prefer the female leaves for culinary uses because of its succulent texture and broadness of the leaves (Ajibade et al 2006). Majority of the studies conducted on sex of ugu had been on morphological basis of identification for production and yield ration (Aremu and Adewale 2012, Akoroda and Adejoro1990, Emebri and Nwufo, 1996). Adequate consumption of leafy vegetables has been reported as an important means of fighting hunger and malnutrition, ensuring food security and generating income for farmers. Fluted pumpkin has been associated with several healing properties for treating and alleviating certain diseases and illnesses. It can also be used for making soaps as well as for preparing local spices known as ogiri. Considering that the leaf of *T. occidentals* constitutes a major part of diet and herbal remedies for populations in West Africa, this study seeks to compare the proximate, phytochemical, antioxidant, antinutrients, vitamin and mineral composition of the female and male plant in order to generate useful information for consumers and to generate evidence to support selection for desired sex expression in ugu.

MATERIALS AND METHODS

Plant material

The ugu pod was bought from Ojoo market in Ibadan. The seeds were sown in sawdust in nursery trays in the screen house. The seedlings were transplanted to a well-prepared vegetable research field (N07.40130; E003.84905; 178.06m above sea level) four weeks after sowing in the nursery in the year 2020. The seedlings were planted at a spacing of 1m x 1m using a completely randomized design

(RCBD) with three replications. Vines were tagged separately with regards to the sex type expressed by the flower. Harvested fresh leaf samples were collected from tagged vines and taken to the Product Development Laboratory of the National Horticultural Research Institute for nutrient analysis.

Preparation of leaves

The leaves were first sorted to remove any infested parts; they were then washed under running water to remove dirts and drained off in a perforated plastic basket. The leaves were dried using a hot air food dehydrator at 50^0C. They were ground into powdery form and kept in an airtight container in a refrigerator for further analyses.

Proximate and antioxidant analysis: The Vitamin C content, moisture content and % ash according to standard methods of the Association of Official Analytical Chemists (AOAC, 2005). Moisture content was determined by weighing 50g portion of each sample to constant weight using a vacuum oven at 70^oC for 24 hours. Moisture content was taken as the difference in weight between the initial sample and the dried sample.

Determination of mineral composition

The sample was investigated for elemental composition by using atomic absorption spectrophotometer (AAS- Bulk Scientific model AVG 211) after an acid digestion. Appropriate working standard solution was prepared for each element. The calibration curves were obtained for concentration versus absorbance. The data were statistically analyzed by using fitting of straight line by least square method. Laboratory procedures for the preparation and determination of micronutrients were used as outlined by Shah et al. (2009) for plant samples.

Determination of Proximate Composition

Proximate composition was determined according to the methods described by AOAC (2005). Briefly, protein content was determined using the Kjedahl method. To determine moisture, 5g of samples was placed in a crucible and the crucible in an oven at 100^0C until constant weight was obtained. The moisture content was calculated by finding the percentage loss in weight between the initial and final weight of samples. The fat content was determined using a Soxhlet extractor. The residue left after the extraction of oil using Soxhlet was used for fibre determination. The fat-free material was boiled and washed severally. The resulting residue was ash and the quantity of ash noted. Ash was determined by calculating the percentage loss in weight of 2g of samples in a crucible placed in a muffle furnace at 600^0C for 2 hours. Carbohydrates were determined by difference. Standard procedures were followed for the determination of other measured nutrients.

Data analysis: Data generated were subjected to statistical analysis using SAS version 9.4. Results were expressed as mean of triplicate determinations and statistical significance accepted at 5% probability level.

RESULTS AND DISCUSSION

Result in Table 1 revealed significant variations ($p < 0.05$) in the composition of measured nutrient constituents as differentiated by the sex types. Protein is an important part of human diet as it is responsible for growth and replacement of worn-out tissues. The amount of crude protein in both male and female ranged between 18 – 21% respectively in this study (Table 2). This result is somewhat closer to the findings of Arowosegbe et al. (2015) and Orole et al. (2020) but far from the findings of Mohd et al. (2016) which reported 56% and Adeyeye and Omolayo (2011) which reported 35.4%. The crude fiber content for male and female in this study (1.9 % - 2.0%) was lower to that reported by Orole et al (2020) which reported 8.0 – 9.0% for male and female respectively. Calcium is needed for strong bone formation and skeletal build up. The amount of Calcium is higher in the male ugu (33.2mg/100g) than in the female (32.4mg/100g) which is contrary to the result by Orole et al (2020) which reported higher Calcium in female ugu. Iron is an important constituent of haemoglobin responsible for the transport of oxygen from one part of the body to another while is a trace mineral element meaning that it is needed in small amounts and yet it is a major player in the creation of DNA growth cells, building proteins, healing damaged tissue and supporting a healthy immune system. Iron content was higher in female (9.8mg/100g) while zinc content was higher in the male ugu (0.8mg/100g). Values obtained for iron in this study fall within the recommended dietary allowance (RDA) of 8mg – 18mg/100g.

Male and female ugu contain important phytochemicals. Flavonoids possess a number of medicinal benefits, including anticancer, antioxidant, anti-inflammatory, and antiviral properties. They also have neuroprotective and cardio-protective effects. Flavonoid was higher in the male ugu (210.5mg/100g) which is higher than what was reported by Orole et al. (2020). Antioxidants create protective effects by neutralizing free radicals produced in the course of normal catabolic and anabolic processes within the cells. They act through hindering oxidative damage by bonding free radicals thus inactivating the radicals, antioxidants reduce inflammation and support healthy aging process (Yimer et al., 2023). Total antioxidant activity was higher in the male ugu (823.8mg/100g) than the female ugu. Chlorophyll is a rich source of vitamins including Vitamins A, C, E and K, as well as antioxidants and minerals such as Magnesium, Iron and Calcium. In this study, Chlorophyll A/B in the male ugu (17.50). This may due to the fact that the male ugu does not produce pod like the female where there is high demand for assimilate partitioning for the pod, the male plant thus retains all the trapped chlorophyll in the leaves (Pérez-Llorca and Sanchez, 2019; Sun et al., 2022).

CONCLUSION

The result of this study revealed that both sexes of ugu are reservoirs of healthy minerals and phytochemicals needed for healthy nutrition and well-being. This suggests that the ugu vegetable can be further improved for increased nutrient composition along the sex types. Improved male ugu with increased nutritive value will contribute useful alleles in cross combination to produce better progenies.

ABSTRACT
This study aimed to compare the effects of the screen house method of cultivation and open-field cultivation systems on the crown size and performance of two varieties of lettuce. The experiment was a 2x2 factorial scheme arranged in a randomized complete block design (RCBD) involving two methods of cultivation and two lettuce varieties. The results showed that the cultivation system significantly affected crown size and yield of both lettuce varieties. Protected cropping resulted in a higher polar and equatorial crown size and yield compared to the open field cultivation while the leafy lettuce variety had a larger crown size and yield compared to the head variety under both cultivation systems. These findings suggest that protected cropping is the most efficient cultivation system for growing lettuce, with leafy lettuce variety producing higher yield and crown size. It is recommended that farmers and horticulturists use protected cropping for growing lettuce, and should consider the appropriate lettuce variety for the desired yield and crown size.
Keywords: *Cultivation methods, lettuce varieties, Crown size, Yield.*

INTRODUCTION

Lettuce (*Lactuca sativa L.*) is one of the most popular vegetables worldwide and is consumed in large quantities due to its high nutritional value. In addition, it is widely cultivated for its edible leaves that are rich in vitamins and minerals (Kumar *et al*., 2016). In south western Nigeria, lettuce farming provides a source of income for farmers and also satisfies the growing demand for fresh vegetables in the region (Mukaila *et al.,* 2022). The cultivation of lettuce in many tropical and sub-tropical countries. Nigeria inclusive is still largely limited to the wet season, as dry season cultivation requires a lot of irrigation, which is expensive and often unavailable to smallholder farmers (Awazi *et al.,* 2022). The performance of lettuce is influenced by many factors, such as variety, cultivation system, and environmental conditions. One of the key factors affecting lettuce growth and yield is the crown size, which is the diameter of the main stem at the soil level (Islam *et al*., 2021; Fahmy and El-Shahawy, 2018). Crown size is an important growth parameter as it determines the number of leaves that can be harvested, which directly influences the yield of the crop. (Rathore and Singh, 2019). Production practices of different varieties of lettuce is dominated by two groups of varieties, namely the crisp head and the loose-leaf types (Fahmy and El-Shahawy, 2018). The crisp head group includes varieties such as Great Lakes and Grand Rapids, while the loose-leaf group includes varieties such as Salad bowl and Black-seeded Simpson. These two groups of lettuce varieties have different growth habits and are adapted to different climatic conditions. The loose-leaf varieties are easier to cultivate and have a shorter growing period, making them suitable for dry season cultivation.

On the other hand, the crisp head varieties require a longer growing period and are more sensitive to environmental stress, making them more suitable for wet season cultivation (Myers, 2017). Screen house systems of lettuce cultivation involve the use of protective structures to shield the crop from environmental stresses such as extreme temperatures, excessive rain or wind, pests and diseases (Aroune and Haj Sassi, 2019). Studies have shown that screen house systems provide an ideal environment for lettuce cultivation, promoting speedy growth and minimizing yield loss caused by environmental fluctuations (Petropoulou *et al*., 2023). Screen house systems have also been reported to provide better control of pests and diseases, resulting in better yield and quality of lettuce (Wang*et* *al*., 2023). However, the high initial investment in construction and maintenance and increased energy costs for heating, cooling, and ventilation (Barbosa *et al.,* 2015) limits its practices among local farmers in Nigeria. Conventional (open) systems, on the other hand, involve cultivation of lettuce in the open field without any protective structures. This system relies on natural conditions for plant growth, including temperature, rainfall, and sunshine (Alam and Agarwal, 2018). However, open systems have limited control over pests and diseases, leading to significant yield loss (Ashraf *et al.,* 2018).

MATERIAL AND METHODS

Site Description

The experiment was conducted at the screen house in the Department of Agricultural Technology, Federal Polytechnic, Ado-Ekiti (Latitude 7.61^{0}N and 5.23^{0}E) between April and October, 2017. The soil in the area was sandy loam, which is an ideal soil for lettuce.

Establishment of *Lactuca sativa*

Treatments consisted of two methods of cultivation, namely, the Screen House System (SHS) and the Open Field System (OFS) where lettuce seedlings were planted in an open environment. The two varieties of lettuce considered for this study were the crisp head variety (CHV) and the loose-leaf variety (LLV). These two groups of lettuce varieties have different growth habits and are adapted to different climatic conditions. The experiment was a 2x2 factorial scheme arranged in a randomized complete block design (RCBD) involving the following treatments:

i. The Screen House System (SHS) + The loose leafy variety (LLV)
ii. The Screen House system (SHS) + The crisp head variety (CHV)
iii. The Open Field system (OFS) + The loose leafy variety (LLV)
iv. The Open Field system (OFS) + The crisp head variety (CHV)

There were five beds replicated four times to make a total of 20 beds for both trials. Planting was carried out in the screen house between April and June 2017 while the field trial was carried out between August and October, of the same year using the same experimental design. The seedlings were raised in a well prepared seed bed of loose pliable good tilt soil. The dimension of the nursery seed bed was (3mx2m). Watering was done twice a day for a period of three weeks. Transplanting was done when the seedlings were three weeks old at a spacing of 0.3mx0.3m on a raised seed bed. For the screen house trial, a drip irrigation system was installed immediately after transplanting. Drip lines were aligned parallel in every row. Irrigation was usually applied two hours every day from 7:00am to 9:00am every morning while the field trial was subjected to the natural rainfall condition throughout the duration of the experiment. Manual hoe weeding was done every 2 weeks to control weeds and allow for soil aeration until harvesting.

Data Collection

Three plants were randomly selected in each plot for observation on growth parameters (plant height; number of leaves, stem girth) while yield (fruit dry and fresh weight per plant and total fresh fruit yield per hectare) was recorded for the whole plot and converted to yield per hectare by extrapolation. Lettuces were harvested when the head was full and compact at about 30 days after transplanting. In addition, the crown size (polar and equatorial length) was measured.

RESULTS AND DISCUSSION

The effect of different methods of cultivation on crown size development and performance of two varieties of lettuce is presented in Table 3. The result shows that the screen house method (SHS) of cultivation recorded significantly higher values for most of the measured growth and yield characters. The result also shows that the loose leafy head (LLH) variety was significantly better than the Crisp head variety (CHV). Under the screen house method of cultivation, LLH recorded significantly better values for plant height (66.41cm over CSH, 57.03cm), with a lower value being recorded for CHV under the open field condition (OFC). Similar result was recorded for, number of leaves, (40.62 over CSH, 35.91), fruit weight, (228.95g over CSH, 187.43g), and total fresh fruit yield (19.03t/ha, over CSH, 15.65t/ha). In addition, the polar and equatorial crown size was significantly larger under the screen house system (SHS) for LLH than CHV under (OFS).

The results showed that crown size and yield of both lettuce varieties was significantly affected by the cultivation system. Protected cropping resulted in a higher crown size and yield compared to the open field cultivation. The leafy lettuce variety had a larger crown size and yield compared to the crisp head variety under both cultivation systems. Protected structure served as protection of crop from rain, wind and extreme temperatures, (Gerona *et al* 2015, Rogers *et al.,* 2013) which explained the increase in production. Another contributing factor to higher yield efficiency in the protected system is reduced soil borne disease infection and insect pests infestation (Rathore *et al.,* 2019). Foliage diseases could be controlled or eliminated through protected cultivation. The results suggest that protected cropping is the most efficient cultivation system for growing lettuce, and loose leafy lettuce variety is more suitable for higher yield and crown size.

CONCLUSION AND RECOMMENDATIONS

The study shows that the protected cropping system increased crown size and enhanced yield. In addition, the system produced healthier plants with reduced incidence of diseases. It could be a great asset in the enhancement and sustainability of lettuce production in preventing further damage on crops when compared to the open field system which is characterized by excessive rainfall and wind. Leafy-type lettuce when grown inside the protected shelters produced larger crown size compared to plants grown under open field condition.

ABSTRACT

A field experiment was carried out on the effects of different tillage practices in combination with poultry manure rates on the production of Turmeric (Curcuma longa L.) at the Teaching and Research Farm, School of Agriculture and Agricultural Technology, Imo State Polytechnic, Omuma. The experiment was arranged in a spilt plot Design fitted into a Randomized Completely Block Design (RCBD) replicated four (4) times. The treatments include three (3) tillage practices (Bed, Flat and Ridge) and three poultry manure rates (0t, 5t and 10t/ha). Data were collected on plant height, number of leaves/plant at 4,8,12 and 16 weeks after planting while yield values were determined at harvest (thirty six (36) weeks after planting). Analysis of variance (ANOVA) showed that ridge tillage practice + poultry manure at the rate of 10t/ha produced the highest rhizome yield (26.84t/ha). and Dry matter yield (19.29t/ha) which were significantly different from other treatments. Vegetative growth was influenced positively by the ridge tillage practice + poultry manure applied at the rate of 10t/ha throughout the experimental period. However, lowest rhizome and dry matter yields as well as lower vegetative growth were observed at flat tillage practice + 0t/ha (control) treatment. Therefore, ridge tillage practice + poultry manure at 10t/ha is recommended for Turmeric production in the study area.

Keywords: *Curcuma longa, tillage practice, poultry manure, Turmeric.*

INTRODUCTION

Turmeric (*Curcuma longa L*) is a ginger that belongs to the family *Zingiberaceae*. It originated from south East Asia and grows in Bangladesh in about 16.06 thousand hectares with annual production of 41.50t/ha (BBS, 2009). It is an ancient most valuable sacred spices of Bangladesh that contains appreciable quantities of proteins (6.3%), lipids (5.1%) carbohydrates (69.4%), and fibre (2.6%). It is a horticultural root crop that is important not only as a spice, cosmetics but also as a medicinal plant worldwide (Herman and Martin, 1991; Osawa *et al.*, 1995; Hossain *et al.,* 2005; Nakamura *et al*, 1998). In Nigeria, it is mostly cultivated in homestead garden in about 19 states, given different names according to locality (Olojede *et al.*, 2005) (Not included in your reference list). Tropical soils are fragile in nature. In view of this, Integrated Soil Management is necessary for sustaining high crop yield. One of the practices that can moderate the organic matter and sustain productivity is appropriate tillage practice and use of organic manures. Avwundiogba, 2000, Oman, 2007, postulated that water holding capacity in the soil showed that soil was high in the tilled soil. Poultry manure is used as an organic fertilizer for soils low in nitrogen having the highest amount of Nitrogen and Potassium (Adams *et al.,* 2004). Due to the importance of Turmeric in the study area, it was necessary to adopt a strategy that will enhance its sustainable productivity. Therefore, the objective of this study was to evaluate the effects of tillage practices and poultry manure rates on the production of Turmeric (*Curcuma longa L.*) in Owerri, Imo state, Nigeria.

MATERIALS AND METHODS

The experiment was conducted at the Teaching and Research Farm, School of Agriculture and Agricultural Technology, Imo state Polytechnic, Omuma situated between latitude $05^{0}17^{1}$N and longitude $06^{0}54^{1}$ (NIMET, 2015). It has a minimum and maximum temperature of 28 – 32^{0}C, mean annual rainfall of 2500mm and a relative humidity of 89.5%. The area is in the Tropical humid rainforest zone of South East Nigeria. Before and after the experiment, soil sample with 0-25cm was collected at different points at the experimental site which were air dried and bulked for the analysis of physical and chemical properties. The land was cleared manually and marked out in plots. Thereafter, seed bed preparations measuring 3m x 3m were made. 3 tillage practices namely: bed, flat and ridge and 3 rates of poultry manure: 0t, 5t and 10t/ha formed the treatments. The experiment was arranged in a split plot Design replicated 4 times. Each replication is made up of six (6) plots making a total of twenty-four (24) plots in the experiment. Seeds of turmeric variety NCL INVRI obtained from Natural Roots Research Institute (NRCRI), Umudike were planted at a spacing of 50cm x 45cm. Poultry manure was applied at two (2) weeks after planting using band placement method. Data were collected on plant height, number of leaves/plant at 4,8,12 and 16 weeks after planting while yield values (rhizome and dry matter) were determined at harvest thirty six (36) weeks after planting. All data collected were subjected to analysis of variance (ANOVA) for Split Plot Design using SAS package, (1990) while treatment means were separated using Duncan's Multiple Range Test (DMRT).

RESULTS

Soil physico-chemical properties

The results of the pre-planting and post planting soil analysis are presented in Table 1

The effect of different tillage practices and poultry manure rates on plant height

The effect of different tillage practices in combination with poultry manure rates on the plant height of Turmeric (*Curcuma longa L)* is presented in Table 2. At 2 weeks after planting (WAP), Ridge tillage practice + 10t/ha poultry manure gave the highest mean plant height of 3.10cm for Turmeric plant. This was closely followed by a plant height of 2.77cm obtained using Ridge tillage practice + 5t/ha poultry manure during the same period which did not differ significantly ($P<0.05$) from each other. The plant that did not receive any poultry manure in both tillage practices gave the lowest mean plant height of 1.7 and 1.04cm respectively which were statistically ($P<0.05$) the same. The highest plant height (9.42cm) was obtained at Ridge tillage practice + 10t/ha poultry manure at 8 WAP which differed significantly ($P<0.05$) from other treatments. The lowest plant height (3.99cm) was recorded at flat + 0t/ha during the experiment.

The effect of different tillage practices and poultry manure rates on number of leaves/plant

The highest rates of poultry manure in combination with ridge tillage practice produced the greatest number of leaves per plant of Turmeric and this was significantly different from other treatments. At 2 WAP, ridge + 10t/ha poultry manure produced 3.50 leaves, which were statistically the same with the value obtained while using ridge + 5t/ha poultry manure during the experiment. The greatest number of leaves per plant (7.76) of Turmeric was obtained at 8 WAP using ridge + 10t/ha poultry manure which was statistically different ($P<0.55$) from other treatments. This was closely followed by a value of 6.21 leaves obtained using Bed + 10t/ha poultry manure. The least number of leaves per plant (4.63) was recorded for flat + 0t/ha which were statistically similar with the value of 4.69 leaves obtained using Bed + 0t/ha poultry manure throughout the experimental period (Table 3).

The effect of different tillage practices and poultry manure rates on rhizome yield

The rhizome yield of Turmeric (*Curcuma longa* L) at harvest is presented in Table 4. Ridge tillage practice + 10t/ha poultry manure produced the highest rhizome yield of 26.84t/ha. This was closely followed by a rhizome yield of 20.2t/ha obtained using Ridge tillage + 5+/ha poultry manure. The result however indicated a significantly difference ($P< 0.05$) among the treatments. Flat tillage practice + 0t/ha produced the lowest rhizome yield of 12.8t/ha in the experiment. Flat + 0t/ha poultry manure produced a rhizome yield of 14.81t/ha which is statistically similar with the yield of 14.75t/ha obtained using Bed + 0t/ha poultry manure.

The effect of different tillage practices and poultry manure rates on dry matter yield

A similar trend was observed in the dry matter yield of Turmeric. Highest levels of poultry manure in combination with ridge tillage practice produced the highest dry matter yield. Ridge tillage practice + 10t/ha produced the highest dry matter yield of 19.25t/ha which differed significantly ($P<0.05$) from other treatments. Flat tillage practice + 0t/ha poultry manure (control) gave the lowest dry matter yield of 6.4t/ha (Table 5).

DISCUSSION

The yield, dry matter and vegetative growth of Turmeric were significantly influenced with the application of poultry manure at a higher rate in combination with tillage practices. The plants grown on ridge tillage practice and highest rate of poultry manure had the tallest plant height, number of leave per plant, dry matter and rhizome yield. Previous investigation reported the influence of tillage practice on the yield of tuber crops. The experiment further explained that ridge tillage practice performed better when compared to flat and bed tillage practice. Ihenacho *et al.,* (2014) postulated that turmeric crop planted on ridge tillage performed better than those planted on bed and flat tillage practices in terms of plant height, number of leaves, number of days to 50% flowering, rhizome yield and dry matter yield. The greater performance of the plant grown on ridge may be attributed to the ability of the tilled soil to provide better space for the plant root to anchor and establish well which in turn resulted to better root development. Buschiazzo *et al.* (1998) stated that good tillage results to greater shoot development. Bankole and Ojeniyi, (2005), Agbede (2006) had earlier reported higher bulk density for zero tillage compared with tilled soils in south West Nigeria. (Is this report in agreement with or negates your experiment?) This implies that the higher the bulk density, the lower the crop yield as this resulted to the lower yield of the crop planted on the flat tillage practice. The significant improvement as recorded in the application of poultry manure is due to the fact that organic manure improved soil fertility which influenced yield of Turmeric. Manhas and Grill (2010) reported that the application of farm yard manure increased the growth, dry matter and quality of Turmeric. This is in agreement with Agbede and Adekiya (2011) who observed that poultry manure are effective source of nutrient for tuber crops like sweet potato. They further reiterated that poultry manure improved nutrient availability in the soil and improved physical conditions leading to significant improvement in nutrient status, growth and tuber yield of sweet potato.

CONCLUSION

The yield performance of Turmeric *(Curcuma longa L)* grown under different tillage practices and poultry manure rates indicated that ridge tillage + 10t/ha poultry manure produced the highest yield of rhizome and other vegetative growth investigated in the experiment. Lowest yields were constantly observed from the plants grown on flat tillage practices and 0t/ha poultry manure (control).

ABSTRACT
This paper provides an overview of the importance of trees in combating the effects of climate change on the environment. It highlights the role of trees as carbon sinks and emphasizes their ability to absorb carbon dioxide and mitigate global warming. The paper also discusses the significance of forests and agroforestry in climate mitigation strategies, emphasizing their potential to sequester carbon and promote biodiversity. Furthermore, it highlights the role of trees in protecting soil, improving air quality, and providing habitat for wildlife. The paper presents an overview of the benefits of trees in addressing climate change and emphasizes the urgency of tree planting and forest restoration as effective measures for environmental protection.
Keywords: *Trees; Climate Change; Environmental Protection; Carbon Sinks.*

INTRODUCTION

Trees have amassed a great deal of attention recently as one of the most significant nature-based solutions to protect all of humanity from Climate Change (Mukul *et al.,* 2020). Planting trees is a simple and cost-effective solution to combating climate change (Anabaraonye, 2022). As one of the greatest carbon sinks on the planet, trees play a significant role in balancing the rise of atmospheric carbon due to anthropogenic activities (Bastin, 2019). Climate change encompasses more than just the increase in global temperatures; it also contributes to the occurrence of more frequent and severe natural disasters such as droughts, floods, forest fires, and other extreme weather events. These changes in climatic conditions have wide-ranging impacts on ecosystems, human populations, and infrastructure. Trees play a crucial role in mitigating the possibility of such disasters (Keenan, 2015). For example, when there are strong winds from storms, trees can help reduce the force with which they rip through the landscape. The environmental benefits of planting trees are immense and far-reaching, ranging from improved air quality to conserving biodiversity. Trees absorb odours and pollutant gases and filter particulates out of the air by trapping them on their leaves and bark (Makovníková *et al*, 2022).

Zomer *et al*. (2022) suggest a gradual transition from current practices i.e., increasing tree cover by no more than 10% in regions that are currently below the median tree cover for their individual bioclimatic or ecological zone. These restrictions guarantee that change will only occur when planting trees is ecologically and possibly also economically and socially feasible. The objective of this paper is to present a review of the significance of trees in combating the effects of climate change on the environment. The world's total forest area is 4.06 billion hectares (ha), accounting for 31% of the total land area (FAO, 2020). According to the IPCC (2018) increasing the total area of forests, woods, and wooded savannas by 9% by the year 2030 may absorb 25% of the atmospheric carbon needed to comply with 1.5°C pathways on land. In practice, this requires planting 350 million hectares (Mha) of new forest or an area about the size of India. Researchers have discovered that the planet has over 3.5 million square miles (9 million square kilometres) to spare for trees after excluding cities and agricultural areas from the study. Such newly planted trees might reduce atmospheric carbon (a component of the greenhouse gas carbon dioxide) by roughly 25%, bringing it to levels not seen in almost a century (Geggel, 2019).

Climate Change

Climate change which tends to be used interchangeably with global warming refers to the rise in the average temperature of the earth over time, as recorded through the years at least 30 years, due to the accumulation of additional carbon dioxide and other greenhouse gases (GHGs) in the atmosphere. According to the Intergovernmental Panel on Climate Change (IPCC) assessment, of 2022, atmospheric concentrations of greenhouse gases, such as Methane (CH_4), carbon dioxide (CO_2), and Nitrous Oxide (N_2O) have risen to unprecedented levels during the previous several centuries (Abbass *et al.* 2022). These gases absorb and confine heat, leading to a gradual increase in temperature (Farmer and Cook, 2013). Climate change classification is based on an analysis of extensive and persistent alterations in temperature and precipitation patterns, along with other factors such as atmospheric pressure and humidity levels.

Because of this, measures to restore forests around the world have been recommended to sequester carbon and combat the impacts of climate change (IPCC, 2018). Scientists investigating climate change have advanced past the basic concept of global warming and are currently working to come up with strategies on how people can adapt to rising temperatures and their repercussions (UCS, 2021). There is an urgent call for understanding the climate and doing everything possible to mitigate its warming (IPCC, 2018).

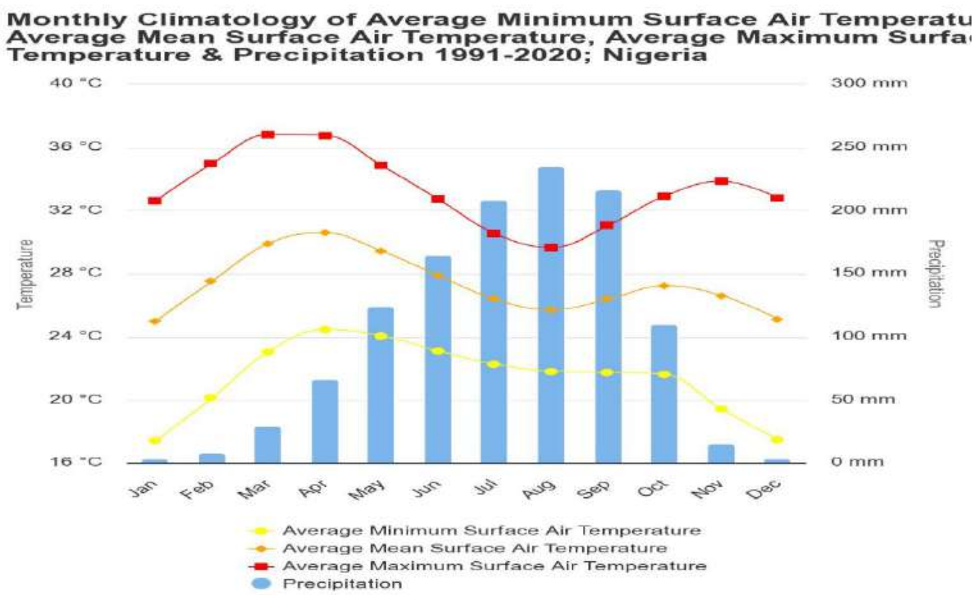
CARBON SEQUESTRATION- TREES AS THE ULTIMATE CARBON CAPTURE AND STORAGE



Carbon sequestration is the process of capturing and storing carbon dioxide (CO_2) from the atmosphere, typically through natural or artificial means, to mitigate the effects of climate change. Carbon sequestration aims to reduce the amount of greenhouse gases in the atmosphere, thereby slowing down the rate of global warming (IPCC, 2018). The various methods of carbon sequestration are;

- Geological Carbon Sequestration- injecting carbon dioxide into underground geological formations.
- Carbon Capture and Utilization (CCU)- capturing CO_2 emissions from industrial processes and using them for various purposes.
- Carbon Capture and Storage (CCS)- capturing CO_2 emissions from industrial processes and storing them permanently underground.

Natural Carbon Sequestration: This occurs through the natural processes of photosynthesis and ocean uptake, where plants and trees absorb carbon dioxide during photosynthesis and store it in biomass, and the oceans absorb CO_2 from the atmosphere and store it in the form of dissolved carbon. (Global CSS Institute, 2021). Terrestrial systems, particularly trees and plants, are an important natural carbon store, with a worldwide estimate of 638 Gt, 44% of which is stored in plant biomass. Carbon stock varies according to forest type. While tropical forests retain an average of 303 tons of carbon ha^{-1}, temperate and boreal forests maintain 66 and 44 tons of carbon ha^{-1}, respectively (Aweh *et al*, 2023). According to Schmidt *et al.* (2011), the largest levels of carbon stock are found in young forests, and as forests mature, they become less abundant. Carbon stock refers to the amount of carbon that is absorbed by growing vegetation and stored in wood, other biomass, and soil organic matter (Mukul *et al,* 2020).

Adeyemi and Adeleke (2020) noted that *Pinus caribaea and Gmelina arborea* plantations had more net total biomass and carbon stock of the forest types in Omo Forest Reserve, Ogun State, Nigeria with an estimate of 35.78 ± 2.73 tons/ha and 18.96 ± 1.82 tons/ha. Aweh *et al*. (2023) observed that areas with lower tree cover loss had a higher level of biomass carbon stock than areas with higher tree cover loss in Edo State, Nigeria. These studies further buttress the significance of trees for carbon sequestration to combat Climate Change.

FOREST RESTORATION, AGROFORESTRY AND REFORESTATION: CLIMATE MITIGATION STRATEGY

Forests and trees have a great capacity to mitigate climate change. The approximate potential is influenced by elements including tree kind and location, management techniques, and climatic variables in the area (Safford, 2013; Keenan, 2015 FAO, 2018). According to Aweh *et al.* (2023), forests and other ecosystems account for the majority of land-based mitigation, with a cost-effective potential of about 50%. While natural forests had the highest levels of biodiversity, preliminary findings presented during the workshops revealed that agroforestry landscapes supported higher species richness for trees, birds, mammals, and insects than arable mono-crops, grassland, and other land use categories (Abbass *et al.,* 2022). However, by planting trees in farms and pastures, a network of trees could be built, reducing emissions and at the same time encouraging forest restoration and agroforestry.

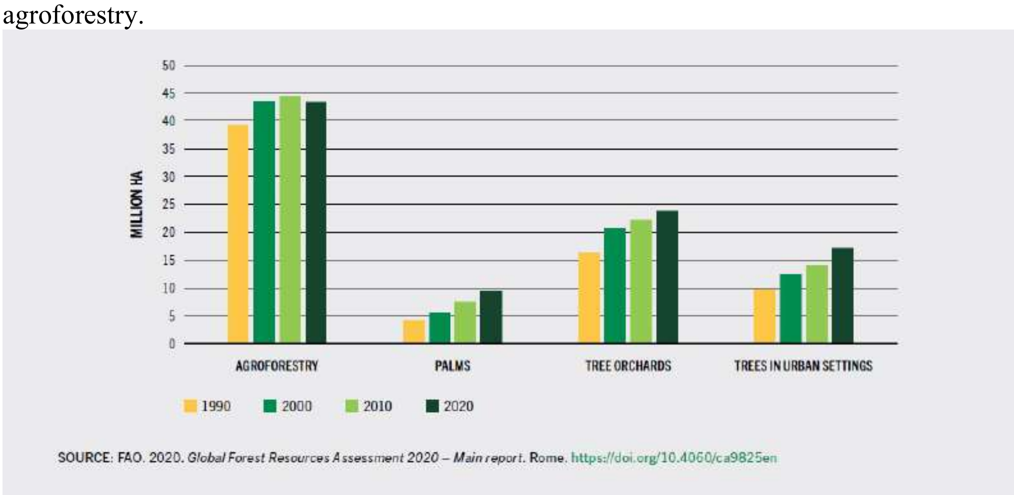


Figure 2: Global Area of other lands with Tree Cover 1990-2020

Simelton *et al.,* 2021 explored concerns pertinent to agroforestry interventions to support livestock keeping in East Africa, where most portions of the region are predicted to become drier due to climate change impacts in the hydrological cycle in the next decades. These interventions included the planting of predominantly exotic fodder trees (Maybeck *et al*, 2021).

Coffee-based agroforestry system (age, planting density)	Ref No	Est ton C/ha	Estimated C (tCO2-eq/ha)
Monoculture Arabica coffee, 10 yr, ~6200 trees/ha	Mulia *et al.* 2020		~18
Coffee 7yo, 750 trees/ha Macadamia 5 yo, 100 trees/ha Jackfruit 4 yo, 30 trees/ha Mix: Peach, longan, plum 2 yo, 170 trees/ha	6	5.5	20
Coffee 7yo, 2000 trees/ha plum 20 yo 75 trees/ha mango 4yo, 50 trees/ha peach 2yo, 40 trees/ha	5 5	12.5 21.2	46 78
Coffee 4yo, 1460 trees/ha *D. indica* 9yo, 50 trees/ha Mix: mango, peach, pear 3 yo, 45 trees/ha	4 4	11.6 22.4	43 82
Coffee 20 yo 85 trees/ha *D. indica 20* yo, 20 trees/ha Peach 10-20yo, 115 tree/ha Mix: pomelo, mango, pear 20 yo 55 trees/ha	8	14.0	51
Coffee 13 yo, 1110 trees/ha Longan 26 yo, 170 trees/ha Plum 22 yo, 135 trees/ha Pomelo 10 yo, 50 trees/ha Mix: mango, jackfruit, guava, starfruit, 3 yo, 140 trees/ha	7	67.5	248
Coffee 10 yo, 3110 trees/ha Longan 30 yo, 330 trees/ha Plum 19 yo, 270 trees/ha Mix: pomelo, mango, litchi, guava, peach 3 yo, 440 trees/ha	9 9	46.3 83.4	170 306

Simelton *et al*.(2021) discovered that among Vietnamese coffee farmers, households adopting coffee agroforestry had more diverse revenue sources and were economically more resilient than those producing coffee monoculture. The findings also show that farmers generally thought about coffee-tree interactions, which are crucial entry points for switching from intensive to organic production. In this case, trees' roles in maximizing shade and legumes' roles in nitrogen fixation are crucial for serving as a climate mitigation strategy (Dobbie *et al.,* 2020).

TREES PROTECT THE SOIL AND PROMOTE HEALTHY SOIL

Soil erosion is one of the impacts of Climate change, causing nutrient weathering and fertility loss as well as altering soil structure and texture, affecting plant nutrition and development and negatively affecting the productivity and sustainability of natural and agricultural ecosystems. Precipitation which has been altered by climate change also is the most important climatic element regulating soil erosion and sediment transport (Cao *et al.,* 2020). Maintaining soil health and productivity is crucial as demands for food production and global population growth increase. The use of trees through agroforestry presents a promising chance to capture and store carbon in the soil that is lost as a result of increased agricultural productivity, intensive tillage, and fertilizer use (Fahad *et al.*, 2022). Integration of trees in cropland can help in maintaining the soil's physio-biochemical properties. Trees litter and pruning biomass improves soil fertility through the release of nutrients into the soil by mineralization. The trees improve soil health through the maintenance or increase of soil organic matter through carbon fixation in photosynthesis and its transfer via litter and root decay. This improves soil biodiversity by providing a specific habitat, refugia for epigenetic species, microclimate variety, buffering action, soil wetness, and humidity which is altered by changing climate (Beliveau *et al.,* 2017).

IMPROVED AIR QUALITY

The World Health Organization (WHO, 2018) has estimated that climate change is responsible for approximately 2% of global deaths each year. This figure is based on a range of different factors, including the direct impact of extreme weather events, as well as the indirect effects of climate change on things like air quality and water availability. The medical journal, The Lancet 2021 published a report that estimated that climate change was responsible for seven million deaths worldwide in 2018, or approximately 12.5% of all deaths. Of these deaths, around 2.4 million were attributable to ambient air pollution, which is exacerbated by climate change. The presence of trees has a noteworthy influence on the quality of air. They can absorb harmful substances like carbon monoxide, sulphur dioxide, and nitrogen oxides from the surroundings, thereby reducing air pollution and enhancing the overall well-being of communities (Nowak *et al.,* 2014; Kardan *et al.*, 2015).

Urban localities are particularly susceptible to elevated levels of air pollution due to heavy traffic and industrial activities. However, by planting trees in cities, it is possible to alleviate the impact of air pollution by trapping harmful particles in the air (Escodedo *et al.,* 2011; Kardan *et al.*, 2015). Zhang *et al.* (2019) stated that trees not only absorb pollutants but also release oxygen, which contributes to improving air quality by producing fresh and breathable air. Additionally, trees can alleviate the heat island effect in urban areas, which is the temperature rise caused by human activities. By providing shade and cooling, trees can decrease the demand for air conditioning, resulting in reduced energy usage and greenhouse gas emissions. Trees contribute significantly to maintaining healthy air quality not only in cities and urban areas but also in rural regions.

BIODIVERSITY AND HABITAT FOR WILDLIFE.

Biodiversity is one of the world's most significant casualties of Climate Change which has led to a rapidly rising species extinction. The rate and degree of Climate are changing the suitable habitat ranges of marine, freshwater, and terrestrial living organisms (Abbass *et al.,* 2022). The majority of Earth's terrestrial biodiversity and its three components - ecosystem, species, and genetic diversity - are found in forests. Trees are the foundations of forest ecosystems, and many of the world's 60,000 tree species also play a vital role in woodlands and agricultural landscapes. Forests are home to around 80% of amphibian species, 75% of bird species, and 68% of mammal species (FAO, 2022). Tropical forests are arguably the most significant biomes on the planet, accounting for one-third of land-surface productivity and evapotranspiration, and are estimated to host over half of all global terrestrial biodiversity (Malhi, 2012; Malhi *et al.*, 2014) and home to around 60% of all vascular plants (FAO, 2022). The sustainability of ecosystems is impacted by changes in general temperature regimes in a variety of ways, including variance in species' relative abundance, range shifts, variations in activity timing, and usage of microhabitats (Abbas *et al,* 2022). Biodiversity is equally susceptible to the other effects of climate change, such as rising temperatures, droughts, and invading pest species.

CONCLUSION

Even when trees are planted quickly, their impacts take time to influence. It may take decades for young forests to reach their full potential in terms of growth and development. To avert the effects of climate change, it is necessary to maintain the existing forests, look into alternate climate solutions, and progressively lessen reliance on fossil fuels. By strategically planting trees, there is a general improvement in quality of life, and increased socioeconomic benefits for the immediate community. Trees offer several additional advantages, including reducing noise pollution, aesthetic benefits, shielding us from harmful ultraviolet radiation, and promoting better health thereby reducing stress levels.

ABSTRACT
The experiment was conducted in the Postharvest Laboratory of Federal College or Horticulture Dadin-kowa. Gombe State to evaluate the effect of three levels of Gibberellic acid (5g, 10g and 15g) and dipping time (5 minutes, 10 minutes and 15 minutes) on the postharvest quality of mango fruits under ambient temperature condition. The experiment was laid out in completely randomized design (CRD) factorially combined and replicated three times. Data collected on fruit weight loss, fruit decay, marketable fruits and skin colour change were analysed using analysis of variance and means separated at 5% level of probability. Results obtained showed that 10g of GA_3 for 5 minutes reduced fruit weight loss (23.3%) after 15 days of storage. Similarly, fruit decay was affected by concentration of 10g of GA_3 dipped for 15 minutes (33.3%). Fruits treated with 15g GA_3 dipped for 5 minutes was more superior in marketable fruits and skin colour change at the end of the storage period. Based on this finding, GA_3 at concentration of 10g/L and 15g/L and dipping period of 5 minutes should be adopted for better mango storage.

INRODUCTION

Mango (*Mangfera indica* L.), is a tropical fruit and contains vitamins, mineral and fibre which are essential to human health and export market (Sethi, *et al,* 2011). Mango is classified as climacteric fruit and shows rapid deterioration after harvest due to ripening and senescence. The fruit is considered king of fruits due to its attractive colour, aroma and jelly pulp, but it is highly perishable in nature. Several environmental conditions, higher moisture content, soft textures of fruits and susceptibility to various pathogenic infections are the limiting factors to its shelf life. In this regard, postharvest life of mango is important to consumer's acceptability and marketing (Zhong, *et al.,* 2006; and Chien, *et al.,* 2007).

Application of postharvest treatments which have non-toxic mode of action, with negligible residue, safe on humans, animals and environment has been reported to prolong the storage life of apricots (Fan, *et al.,* 2000), banana (Jansasithorn *et al.,* 2006) and delayed firmness, TSS and TA on sapodilla (Zhong *et al.,* 2006). The use of different plant growth regulators like Gibberellic Acid (GA_3) and BA were seen as highly significant in respect of prolonging the shelf life of bananas (Sultana *et al.,* 2012). Vargas and Lopez (2011) reported the delaying of ripening in Cavendish banana by 3–4 days is achieved through the application of GA_3 at concentrations ranging from 50-250 mg/L Osman and Abu-Goukh (2008) reported that Gibberellic acid treatment (100 ppm) by dipping the fruit whole showed the highest shelf life than by dipping tip only and control where an association of whole fruit dipping with sealed film liners showed superior results.

Although several efforts have been conducted to prolong the shelf life of mango fruits using different levels of gibberellic acid, the result had not been encouraging possibly the dipping period have not been fully explored. The need to employ the use of different concentrations for various dipping periods that are more promising should therefore be experimented. The objective of this study is to determine the appropriate concentration of GA_3 and dipping period for prolonging the quality and shelf life of mango fruits in storage.

MATERIALS AND METHODS

The experiment was conducted in the Postharvest Laboratory of Federal College or Horticulture Dadin-kowa. Gombe State, Nigeria. Freshly harvested mango fruits of uniform size and maturity were purchased from the farmer's field and brought to the laboratory. The fruits were washed in clean running water and allowed to dry before subjecting them to various treatments.

Preparation and Application of the Chemicals

To prepare the treatments, 5g, 10g, and 15g of GA_3 was dissolved in 1000 ml of distilled water. Five mango fruits were submerged into each of the prepared solutions for 5, 10 and 15 minutes respectively and removed, allowed to dry and kept in plastic baskets of 20 cm x 30 cm x 50 cm at room temperatures (35^{o} c) for observation.

Experimental Design

The experiment was laid out in a completely randomized design (CRD), with four levels of GA_3 (0g, 5g, 10g and 15g) and three dipping periods (5 minutes, 10 minutes and 15 minutes) factorially combined. The treatments were replicated three times giving a total of 12 treatment combinations.

Data Collection

Data were collected on fruit weight loss, fruit decay, marketable fruits, skin colour and chemical composition expressed in percentages.

Data Analysis

The data collected was subjected to the analysis of variance (ANOVA) using Gestat statistical package version 10. Mean comparisons was made using least significant difference (LSD) at $P< 0.05$ level of probability.

RESULTS AND DISCUSSION

Effect of Gibberellic Acid and Dipping Period on Percentage Weight Loss of Mango Fruits

The result of the combined effect of GA_3 and dipping period on percentage fruit weight loss of mango is presented in Table 1. The results showed that there were no significant variations among the treatments in all the storage periods of 15 days. There was however gradual increase in weight loss as the storage period increased irrespective of the treatments. The results showed that the highest weight loss (12.1%, 26.6%, 29.3% and 38.1%) at 6, 9, 12 and 15 days respectively was recorded in the control treatment while the least percentage weight loss (10.7%, 16.1%, 20.0% and 23.3%) was in fruits treated with combination of 10g of GA_3, dipped for 5 minutes. Archana and Sivachandiran (2015) found out that a higher concentration of GA_3 results in lower physiological weight loss and vice-versa. Tapas (2016) observed that Gibberellic acid dipping at 150 ppm resulted in the lowest weight loss during storage compared to the other treatments. Similarly, Le (2021) found out that different dipping times would generate different thickness of the film layer resulting in variations of water vapor leakage rate and fruit respiration. This result however, shows that dipping period did not have significant effect on fruit weight loss, hence it is not in agreement with their findings.

Effect of Gibberellic Acid and Dipping Period on Percentage Decay of Mango Fruits

The results of the percentage decay of mango fruits is presented in Table 2. The results obtained showed no significant variations among the treatments, even though they are statistically similar. It also shows that the decay loss increased with the increase in period of storage in all the treatments. The highest fruit decay was observed in the control treatment (55.5% and 73.3%) at 12th and 15th days of storage respectively. Generally, the results showed that 5g GA_3 was not as much effective as other treatments in preventing fruit decay irrespective of the dipping periods. However, fruit dipped in 10g of GA_3 for 15 minutes had the least (0.0%, 0.0%, 6.7%, 20.0% and 33.3%) fruit decay throughout the storage period. The result is in accordance with the findings of Sembok *et al.* (2016), Sahithya *et al.* (2015), Tourky *et al.* (2014) and Archana and Sivachandiran (2015). Archana and Shivachandiran (2015) observed the four different concentrations of GA_3 (250 ppm, 350 ppm, 500 ppm and 750 ppm) to obtain qualitative and quantitative data for analyzing the shelf life in Kathali banana where they observed more shelf life in 500 ppm and 750 ppm treated banana by 4 and 5 days.

Effect of GA_3 and Dipping Period on Percentage Marketable of Mango fruits

The result of the effect of GA_3 and dipping period on marketable mango fruits is presented in Table 3. The results obtained shows that there were no significant differences among the treatment combinations however, there was gradual decrease in the marketable fruits as the storage period increased regardless of the treatment. Highest and significant effect (83.3% and 53.3%) on marketability percentage of fruits was recorded in concentration of 15g GA_3 dipped for 5 minutes, which was at par with 5g GA_3 dipped for 10 minutes (80.0% and 53.3%) treated fruits. Conversely, combination of 5g and 5 minutes had the least (53.3% and 33.3%) percentage marketable fruits at 9 and 12 days respectively, which is however comparable with the control treatment. Similar results were found by Sundaram (2013) lower marketability losses are recorded in GA_3 than uncoated fruits. Kumar and Nath (1993) stated that marketable fruits were noted to be higher in GA_3 coated fruits of banana than fruits dipped in salycilic acid. Plant growth regulator improves the marketability of fruits for a longer period (Pareek *et al.,* 2009).

The effect of GA_3 and dipping period in the skin colour rating of mango fruits is given in Table 3. The result showed that there was no significant variation in all the days of storage except at 9 days. Skin colour score generally progressed during the storage period of mango fruits irrespective of treatments. The result further showed a delay in colour change with GA_3 15 g dipped for 5 minutes (1.33, 2.53 and 3.33) for 3, 6 and 9 days respectively as compared to control and other treatments. The highest colour change was however, observed in 15g + 10 minutes treated mango fruits (3.80 and 4.20) at 9 and 12 days respectively. Similar result was observed by Tapas (2016) where peel color become marketable only after 15 days in 150 ppm GA_3 treated which might be due to control in ethylene level and respiratory activity. Cytokinins inhibit the degradation of chlorophyll and a similar effect can be seen from Gibberellins (Shrestha, 2010). This finding suggests that higher concentration of GA_3 at 15g dipped for 5 minutes might delay colour change in mango fruits stored for 9 days due to the effect of gibberellins.

Table 3: Combined Effect of GA_3 and Dipping Period on Percentage Marketable and Skin Colour of Mango Fruit

Treatment	Marketable		Skin Colour		
	9 DAS	12 DAS	3 DAS	6 DAS	9 DAS
5mg + 5m	53.3	33.3	2.20	3.33	3.93
10g + 5m	76.7	43.3	1.80	3.13	3.87

P<F	0.451	0.252	0.120	0.276	0.007
L.S	NS	NS	NS	NS	*
LSD	27.83	33.23	0.943	0.8359	0.3894

Key: DAS = Days After Storage, L.S. = Level of Significance, L.S.D. = Least Significant Difference

CONCLUSION

The study indicates that different concentrations of GA_3 and dipping periods significantly affect the quality of mango fruits stored under room temperature. Also, combination of GA_3 at 10g and 5 minutes' dip significantly reduced fruit weight loss and decay while 15 g + 5 minutes was superior in retaining skin colour and higher marketability of mango fruits. Based on the results obtained, higher concentrations of GA_3 and lower dipping period influenced fruit quality stored under ambient temperature conditions.

ABSTRACT
Field experiments were conducted during the cropping seasons of 2022 at the Teaching and Research Farm of the Faculty of Agriculture, Nasarawa State University, Keffi Shabu-Lafia Campus and at the National Cereals Research Institute Baddegi Niger state, Kusotachi experimental site to study the influence of planting method, weed management and timing application on growth and yield on rice. The experiment was a 2 x 6 x 2 factorial combination of two planting methods (pregerminated seeds and transplanting), six methods of weed control (Weedy check, Hoe weeding at 3 and 6 WAS, cyhalofop-butyl + MCPA, quinclorac + pyrazosulfuron-ethyl, MCPA 2 chloro 4 diphenoic acid, pretilachlor + pyribenzoxim) and two timing (Lafia and Badeggi) laid out in a Randomized Complete Block Design (RCBD) with three replications. Planting method was assigned to main plot, location was allocated to the sub plot and weed management was assigned to the sub-sub plot. The results obtained in both locations showed that, the plots with weed management had higher growth and yield of rice than the weedy check. . The highest leave area index was recorded in Lafia location while seed per panicle have the highest record in Lafia location while Badeggi location recorded the highest number of panicles per plant, number of seeds per panicle and highest grain yield.The use of Transplanting method gave the maximum leaf area index, yield and yield attributes of rice. Plots with weed management had higher growth and yield of rice than the weedy check. However the application of MCPA performed better than the other weed management.Therefore, it is recommended that farmers should adopt the integration of transplanting method of planting rice with early and late applications of MCPA in both locations for improved growth; yield and yield of rice.

INTRODUCTION

Rice (*Oryza sativa L)* constitutes major staple foods in many parts of the world. It supply more of carbohydrates, proteins, fats and also minerals vital needed for survival and healthy life (Ejebe, 2013). In Nigeria, the demand for rice assumed a regular increase for the past decades compared to sorghum and millet which fluctuate annually. Rice demand annually in Nigeria was estimated to about 5 million metric tons while local production around 2.21 million metric tons and about 2.79 million metric tons imported to bridge the gaps (NRDS, 2009). The time required for harvesting, transplanting, weeding and other management practices is much higher during rice cultivation. Thus, to reduce the cost of cultivation, shifting from traditionally practiced of transplanting to dibbling method of rice cultivation could easy planting method of rice (Dendup *et al.,* 2018). Transplanting is the most common method of planting rice, while dibbling and broadcasting are reported to be picking-up gradually (Gill *et al*., 2014). Akhgari *et al*. (2011) defined dibbling (direct seeding) of rice as the process of establishing a rice crop from seeds sown in the field rather than by transplanting rice seedlings from the nursery, it assist rice farmers to have a reduced production cost.

Weed being one of major pests in agriculture, having ability to compete with crops for nutrients through rapid growth and development. Hence, good weed management program is essential throughout the growing period of crops to overcome various types of weeds challenges (Neog *et al.,* 2015). Manual control of weeds is not a quick method thus, requires lot of time and labour. Cates, A.H. (1969), the period required for weeds to be hand pull thus, have the ability to compete with the growing crop and reduced yields. Although, hoe weeding and hand weeding have similar disadvantages. It is, however a faster means of weed management. It can be carried out at an earlier stage in the growth cycle of rice crop, and is more effective when weeds within the row are removed by hand at the same time. In addition it has proved more effective to other mechanical methods of weed control. Both hand and hoe weeding are suitable only for use on small farms. Other methods of weed control must be used on larger areas (De Datta *et ai.,* 1973). Herbicides offer easy, economical and quick control of weeds if applied in proper dose and at proper stage of crop growth (Bhullar *et al.,* 2018). Among all measures taking in rice weed control, chemical weed control is commonly used to overcome weeds infestation and it is reliable, easy, quick, time saving, and cost effective.

There is no or little attention given by the rice growers in Nigeria on the use of metsulforun methyl, cyhalofop-butyl + MCPA, quinclorac pyrazosulfuron-ethyl, MCPA 2 chloro 4 diphenoic acid, pretilachlor + pyribenzoxim herbicides in controlling of weed in rice production due to paucity of information about the herbicides. However, this study is aiming at evaluating the effects of these herbicides application under various timing (early and late) and planting methods (pre-germinated seed and transplanting) on rice production. The objective of this study therefore is to determine the effect of location, planting methods and weed management on weed control, growth and yield of lowland rice.

MATERIALS AND METHODS

The field experiment was conducted at two locations during 2023 cropping seasons at the Teaching and Research Farm (Latitude 08.33^{0}N, Longitude 08.33^{0}E) of the Faculty of Agriculture, Shabu-Lafia Campus, Nasarawa State University Keffi, Nasarawa State, Jayeoba, 2013. And at National Cereals Research Institute (NCRI) Baddeji, Niger State at experimental site Kusotachi latitude 9°3'24.58"N, Longitude 6°8'36.31"E) Ojohomon *et al*., 2006. The experiment is a 2 x 6 x 2 factorial combination of two planting methods (Dibbling and transplanting), six methods of weed control (Weedy check, Hoe weeding at 3 and 6 WAS, cyhalofop-butyl + MCPA, quinclorac + pyrazosulfuron-ethyl, MCPA 2 chloro 4 diphenoic acid, pretilachlor + pyribenzoxim) and two location (Lafia and Badeggi) arranged in a randomized complete block design (RCBD) replicated three times. The gross plot size was 3 m x 4 m (12 m^2) while the net plot size was 1.5 m x 4m (6 m^2).

The field was cleared using a land preparation herbicide (Glyphosate a.i 360g/L) at 3 L/ha. The soil was ploughed and the site was marked into plots and replications. One meter unplanted boarder were maintained between plots, while 0.5 m unplanted boarder was maintained between each replication. The nursery was prepared in dry soil conditions on 3 by 4 m wide seed bed, was filled with top most soil to a height of 10 cm level. A layer of half burned paddy husk was distributed on the nursery bed to facilitate uprooting. 80 kg/ha of seed was used for the sowing covered with mulch, watering the beds at regular basis (morning and evening). Transplanting of vigorous healthy seedlings where done after 14-21days of germination. Five pre-germinated seeds were sown (direct seeding) and thinned to two plants per stand. For transplanting method, 14-21 days old seedlings were transplanted from nursery bed to permanent field. One seedling per hole at a space of 20 cm by 20cm between and within the plant where maintained. Same plant spacing for transplanting was maintained for pre-germinated seed planting methods. Seed rate of 80 kg/ha where used for pre-germinated seeds while 40 kg/ha for transplanting. Fertilizer application wasdone using side placement in all the plots at the rate of 46 kg P_2O_5/ha and 64 kg N /ha. Phosphorus in the form of single super phosphate (SSP) was applied at the time of sowing and transplanting. Whereas, N in the form of UREA was applied in three splits (one third during sowing and transplanting and the remaining two third was apply in two splits at 4 and 8 WAS

The following data was collected at appropriate crop phenology. Data was taken from the five randomly selected tagged plants during growth period at 4, 6, 8, 10 and 12 WAS. The leave area index was calculated as sum of the leaf area divided by unit area as described by Yoshida (1981). Numbers of panicle per plants from the five tagged plants was counted and the mean recorded. The Numbers of seeds per panicle taken from the main tiller of each tagged plant was counted at maturity stage separately after harvesting. The net plot where harvested manually, grain collected, dried to 13.5% moisture content, and weight recorded. This was determined by weighing grains from the net plot, divided by net area and multiply by 10,000.

$$\text{Grain yield} = \frac{\text{Seed yield per net plot}}{\text{Net plot area}} \times 10{,}000$$

The data collected where subjected to analysis of variances (ANOVA) using Statistics software while Least Significant Difference (LSD) was used to separate treatment means at 5 % level of probability.

RESULTS AND DISCUSSION

The effect of location, planting method and weed control on leaf area index of rice at 4-12 WAS as presented in (Table 1) below show location had a significant effect on leaf area index at 6 and 12 WAS respectively. The Lafia location consistently produced the highest leaf area index than Badeggi location which consistently produced the lowest leaf area index. Planting method also had a significant effect on leaf area index throughout the sampling periods of the study. The use of Transplanting method consistently recorded the highest leaf area index than dibbling method which consistently produced the lowest leaf area index. Weed control affected leaf area index significantly at each sampling times of the study. At 4 WAS, the use of 2 HW at (3 + 6 WAS) produced significantly highest leaf area index than all the other weed controls compared with late application of Pretilachlor + Pyribenzoxium which recorded the lowest leaf area index. At 6 WAS, early application of Pretilachlor + Pyribenzoxium significantly produced the highest leaf area index than all the other weed controls compared with the weedy check which recorded the lowest leaf area. But that was not the case at 8 WAS, were early application of Metsulforun methyl produced significantly highest leaf area index than all the other weed controls compared with the weedy check which had the lowest leaf area index. At 10 WAS, early and late applications of MCPA significantly produced statistically similar highest leaf area index than all the weed controls compared with the weedy check which recorded the lowest leaf area index. At 12 WAS, early application of Metsulforun methyl; early and late application of MCPA significantly produced similar highest leaf area index than all the other weed controls compared with the weedy check which recorded the lowest leaf area index in this study.

The interaction between location, planting method and weed control on leaf area index of rice at 10 WAS was significant on (Table 2) below. The combinations of Lafia location, transplanting method with early and late applications of MCPA produced statistically similar highest leaf area index than all the other combinations compared with the combination of Badeggi location, dibbling method and weedy check which produced the lowest leaf area index in this study. The effect of location, planting method and weed management on number of panicles per plant and number of seeds per panicle as presented below on (Table 3). Lafia location significantly produced highest number of seeds per panicle than Badeggi location which recorded the lowest number of panicles per plant and lowest number of seeds per panicle. Planting method affected number of panicles per plant and number of seeds per panicle. The use of transplanting method significantly produced highest number of panicles per plant and highest number of seeds per panicle than dibbling method which produced the lowest values of the parameters.

Weed control had a significant effect on number of panicles per plant and number of seeds per panicle. Application of early Metsulforun methyl; early Cyhalofop butyl + MCPA and late application of MCPA significantly produced similar highest number of panicles per plant than all the other weed controls compared with the weedy check which produced the lowest number of panicles per plant statistically similar with early application of MCPA. The use of 2 HW at (3 + 6 WAS) and late application of Cyhalofop butyl + MCPA significantly produced similar highest number of seeds per panicle than all the other weed controls compared with early and late applications of Pretilachlor + Pyribenzoxium which recorded statistically similar number of seeds per panicle. The effect of location, planting method and weed control on grain yield, indicate that, location affected grain yield significantly. Badeggi location significantly recorded the highest grain yield than Lafia location which recorded the lowest grain yield. Planting method also had a significant effect on grain yield. The use of transplanting method significantly produced the highest grain yield than the use of dibbling method which recorded the lowest grain yield in both locations. Weed control significantly affected grain yield. Early and late applications of MCPA significantly produced similar highest grain yield than all the other weed controls compared with the weedy check which recorded the lowest grain yield.

DISCUSSION

The constantly leave area index observed during sampling period with lafia location having the highest leave area index and badeggi location recording the highest grain yield. This is in line with Andrew (2014) and Yosida *et al.,* 2010, who observed an efficient photosynthetic process in crop, good soil fertility and better utilization of fertilizer applied to crop, could be attributed to widest leave area thus contributed to crop growth and yield in the different location of this study. A significantly increase that produce the highest number of panicle, highest number of seed per panicle and highest grain yield in transplanting method in badeggi location. Is in line with Berhanu (2015). who reported an increase in spikelet number of panicle which was attributed to adequate nutrient availability and ease of light penetration even to the older leave which was due to a better spacing. Mobasser *et al.,* 2010 also reported an increase in grain yield due to higher number of panicles produce by 120 plants as compared to 20 plants.

The lowest growth, yield and yield attributes of rice recorded in the weedy check plot could be attributed to poor interception of light as well as lesser nutrient availability to rice plant that resulted in poor photosynthesis and photochemical energy supply which negatively affected the translocation of photosynthesis to the developing grains. This finding is in conformity with the work of Manisankar et al. (2021) who reported that unweeded control obtained significantly lower number of yield attributes and yield of rice due to poor interception of light as well as lesser nutrient availability to rice plant that resulted in poor photosynthesis and photochemical energy supply which ultimately affected the translocation of photosynthesis to the developing grains. Parthipan and Subramanian (2013) reported that unweeded control registered lower yield and straw yield of rice due to severe crop weed competition during throughout crop growth period.

CONCLUSION

It is concluded from the results of this study that, Lafia location recorded the highest leaf area index while Badeggi location recorded the highest number of panicles per plant, number of seeds per panicle and highest grain yield. The use of Transplanting method gave the highest leaf area index, yield and yield attributes of rice. Plots with weed management had higher growth and yield of rice than the weedy check. However, the application of MCPA performed better than the other herbicides tested in this study.

EFFECTS OF SPENT ENGINE OIL ON THE GROWTH AND HERBAGE YIELD OF AMARANTH (*Amaranthus hybridus* L.) BIOREMEDIATED WITH LIQUID ORGANIC FERTILIZERS

Law-Ogbomo, K. E., Osaigbovo, A. U. and Sani, D. O
Department of Crop Science, Faculty of Agriculture, University of Benin, Benin City, Nigeria

Corresponding author: edomwonyi.law-ogbomo@uniben.edu

ABSTRACT
This trial is focused on the potential of liquid organic fertilizer as bioremediant for spent engine oil polluted soils conducted in the Screen House, Department of Crop Science, Faculty of Agriculture, University of Benin, Nigeria. This study involved three concentrations of spent engine oil pollution (0, 5 and 10 % w/w, spent engine oil in 10 kg soil) and four liquid organic fertilizers types (water (control), cattle dung, poultry manure and rabbit manure) laid out in a 3 x 4 factorial arrangement and fitted into completely randomized design (CRD) with three replications. Data were collected on plant height, stem girth, number of leaves and leaf area at two, four, six and eight weeks after sowing, both fresh and dry yield were estimated at six weeks after sowing. Soil analysis showed that Soil pH was significantly ($p<0.05$) reduced with increase in spent engine oil pollution. However, organic carbon and Heavy metals (Cr. Cd and Pb) concentration increased with increasing concentration of spent engine oil pollution. Soil pollution adversely affected plant height, number of leaves, leaf area, stem girth and herbage yield. Growth and herbage yield were significantly ($p<0.05$) higher in liquid organic fertilizer amended spent engine oil polluted soil than with soils without amendment. The highest herbage yield (13.30 t ha^{-1}) was obtained from unpolluted soil. Rabbit manure amended plants had the highest fresh herbage (12.49 t ha^{-1}) which was similar with liquid poultry manure treated plant yield (12.21 t ha^{-1}). Spent engine oil unpolluted soil supplied with rabbit manure had the herbage yield of 20.49 t ha^{-1}. However, poultry and rabbit manures had similar dry weight values. Hence poultry and rabbit manures are thereby suggested for the bioremediation of spent engine oil polluted soils.
***Keywords**: Bioremediation, growth, herbage yield, liquid organic fertilizers, spent engine oil.*

INTRODUCTION
Spent engine oil is used motor oil collected from mechanical automobile workshops and industrial source like hydraulics oil, turbine oil, process oil and metal working fluids (Oluaboji and Ogunwale, 2008). It is usually obtained after servicing and subsequent drawing out from automobile and generator engines (Sharifi *et al,* 2007). Spent engine oil is a mixture of different chemical including petroleum hydrocarbons, lubricant additives, decomposition products and heavy metal that come from engine parts as they wear away (Wang *et al.,* 2000). The physical, chemical and microbiological properties of soil polluted with petroleum hydrocarbons, undergo various changes, the changes in soil due to contamination with petroleum derived substances can lead to water and oxygen deficit (Odjegba and Sadiq, 2002). Soil contamination with spent engine oil lead to significant reduction of soil moisture content which subsequently increase retardation in plant growth considerably. It causes damage to different parts of the plant that are vital for its well-being and survival and hence obstructs development and growth (Appiah-Adjei *et al.*, 2016). Leaves of plants affected by the pollution tend to dehydrate and show a general sign of chlorosis, indicating water deficiency (Udo and Fayemi, 2004).
The reduction in photosynthetic rate results in the decreased rate of growth, which leads to the reduction of leaf sizes (Boyd and Murray, 1982). Spent Engine oil delay germination by inducing stress, inhibiting

water and nutrients uptake by the root of the plant, hence causing deficiency to other parts of the plant (Appiah-Adjei *et al*., 2016). Bioremediation is a collective, phenomenon involving processes that use biological systems to either restore or clean-up contaminated sites. It aims to reduce or bring down pollutant levels up to understandable, nontoxic, or acceptable levels (Kumar *et al,* 2015). Organic fertilizers act as means of bioremediation by degrading the oil and improving the physical properties of soils which leads to increased agronomic parameters of such soil (Mbah *et al*., 2009). More so, the use of Organic fertilizers like cattle dung and poultry droppings for bioremediation is cost effective because it also serve as source of manure thus reducing the cost of using inorganic fertilizer (Essien *et al.,* 2015). This study is thus aimed to determine the effect of spent engine oil on the growth and yield of *Amaranthus hvdridus* bioremediated with liquid organic fertilizers.

MATERIALS AND METHOD

This experiment was conducted between April and June 2021 and 2022 in the screen house 1 of the Department of Crop Science, Faculty of Agriculture, University of Benin, Nigeria (Lat 6" 20' 1.32" N Long. 5° 36' 0.53" E). Benin-City lies in the forest zone of South Western Nigeria with an altitude of 86m above sea level. Top soil was obtained from Capitol in the University of Benin, Seeds of *Amaranthus hybridus* used for this study were purchased from a local farmer in Benin City. Spent engine oil was obtained from a motor mechanic workshop at Uwelu, Benin City, Poultry and rabbit droppings were obtained from the University of Benin Farm project and Cattle dung from the cattle market at Uselu, Benin City.

General procedure and experimental design

Ten (10) kg samples of top soil was weighed and contaminated with 0, 5 (64ml) and 10 % (128ml) levels of spent engine oil with each of the contamination levels watered with ordinary water, liquid cattle dung fertilizer, liquid poultry manure and liquid rabbit manure in a 3 x 4 factorial layout making it a total of twelve treatments combinations and replicated three times in a completely randomizes design (CRD). An analysis was conducted to determine the physical and chemical properties of the soil and liquid organic manure using standard laboratory procedures. The liquid manure was prepared by immersing 5 g of already cured manure tied inside a jute bag inclusion of stone into 15 litres of water and left for three days. On the third day, the liquid manure was sieved and diluted with three times it's volume of fresh water. *Amaranthus hybridus* seeds were sown directly in the soil and thinned to three plants per bucket at two weeks after sowing (WAS). The buckets used for the experiment were perforated on the sides to prevent water logging and nutrient run off, the liquid fertilizer used for watering was intermitted weekly with fresh water.

The data collection started two weeks after sowing and continued at two weeks interval until the six weeks after sowing. The parameters recorded were plant height, number of leaves per plant, stem girth and leaf area. Number of leaves was counted manually, the Stem girth, leaf length, leaf width and plant height was measured with a calibrated tape rule. The leaf area was calculated by multiplying the leaf length, leaf width and a correction factor of 0.65 for *Amaranth* (Marshal, 1968). At 6 WAS, the plants were harvested, the fresh weight was measured with a mechanical scale and dry weight with an electrical sensitive scale after oven drying at 60° C to a constant to a weight. Data collected were subjected to analysis of variance (ANOVA) after finding the mean of the data collected between the two cropping seasons using GENSTAT statistical package. Differences among treatment means were separated using the Least Significance Difference (LSD) test at 0.05 level of probability.

RESULTS

Effect of spent engine oil on soil chemical and physical properties

The soil analysis conducted on the onset of the experiment showed that porosity decreased with increase in spent engine oil contamination while bulk density increased with increase in the application of spent engine oil (Table 1). Soil pH was decreasing with increase in the concentration of spent engine oil. The organic carbon increase with addition of spent engine oil (SEO). Total nitrogen and available phosphorus content of soil decreased with application of engine oil. Available P decreased with increase in SEO concentration. Exchangeable cation decreased while exchangeable acidity and heavy metals increased with increase in SEO concentration.

Growth and yield of Amaranth

The results of the growth and herbage yield *of A. hybridus* grown on spent engine oil bioremediated with liquid organic manure are presented in Table 2. Plant height decreased with increase in spent engine oil contamination. This trend was repeated for stem girth, number of leaves, leaf area, herbage yield and dry weight. There was increase in heights of the plants bioremediated with liquid organic fertilizers over control except rabbit manure. However, *A. hybridus* planted on soil fortified with cattle dung has the tallest plants. While those treated with poultry and rabbit manures had plants with similar girth values but significantly thicker than those produced in the control plots. This observation was mirrored for number of leaves per plant, herbage yield and dry weight of Amaranth. Poly bags treated with poultry manure produced plants with the largest leaf area. There was significant interaction of spent engine oil and liquid organic fertilizer on herbage yield. Unpolluted soil treated with liquid rabbit manure had the highest herbage yield (Table 3).

DISCUSSION

Soil polluted with spent engine soil exhibited poor physical and chemical properties. The presence of spent engine oil in soil probably brought about increased bulk density and decreased porosity, an evidence of low water holding capacity and poor aeration. This was earlier reported by Kayode *et al*. (2009) who reported the presence of spent engine oil in increasing bulk density, decreasing water holding capacity and aeration propensity. The lower pH observed in spent engine oil polluted soil could have been responsible for the lower available P since it availability is pH determinant.

The observation connoted the report of Uchedu and Ogwo (2014) who reported the pH values of polluted soil around a mechanic village were predominantly acidic. The strongly acidic nature observed on spent engine oil polluted soil could have depressed microbiotic acidity leading to reduced total N content. The observed reduced exchangeable cations content and higher level of heavy metal in the contaminated polluted is in agreement with Uchendu and Ogwo (2014) report. The higher organic carbon content observed on spent engine oil polluted soil could be due to its enrichment from the oil which has been found to have high carbon content. However, its higher carbon content could neither depressed the strong acidity nor the higher exchangeable acidity of polluted soils. These unfavourable conditions associated with soil contaminated with spent engine oil could have caused unfavourable growth and herbage yield of amaranth. This observation is in agreement with Odjegba and Sadiq (2002) who report low yield and decreased growth of plant grown in spent lubricant oil contaminated soil.

The retarded growth observed in spent engine oil contaminated soil through evidenced with shorter fewer number of leaves, thinner stems and decreased leaf area. This further decreased with increase in contamination concentration. This observation connoted Udo and Chukwu (2014) who reported the effect of spent lubricant oil pollution on soil properties and growth of plant is dependent on their concentration in a given soil as it is increasingly detrimental to the functional ability of the soil and plant growth. The leaf area decreased in polluted soils, an indication of lower photosynthetic activity, leading lower growth evidenced with shorter plants, thinner stems and fewer number of leaves (Boyd and Murray, 1982). The reduced photosynthetic activity in plants grown in spent engine oil polluted soil occasioned by decreased leaf area led to lower herbage yield due to the production of reduced amount of assimilate. This necessitated the need for bioremediation of the soil through the application of liquid organic fertilizer. The tested liquid organic fertilizers were moderately to slightly acidic with high content of organic carbon and appreciable amount of total N, available P and exchangeable cations. The appreciable total N content could be of enourmous advantages of the fertilizers as Walworth *et al.* (2007) claimed the additional of organic nitrogen rich nutrient is an effective approach to enhance the bioremediation process. The position effects of nitrogen amendment on microbial activity and/or petroleum hydrocarbon degradation have been widely demonstrated by Riffaldi *et al*. (2006).

The application of liquid organic fertilizer to spent engine oil pollution witnessed higher growth and herbage yield of Amaranth compared to untreated soil. This is an evidenced that justified these

amendments reducing the adverse effect of spent engine oil on the soil. The high organic carbon of these amendment activated the activities of microbes to breakdown the organic pollutant through nourishment which was further enhanced through nitrogen.
In this study, higher plant heights thicker stems, higher number of leaves, larger leaf area, herbage yield and greater dry weight, were accrued to soils treated with poultry and rabbit manures than to those with cattle dung. This variation could have arisen as a result of total N content and organic carbon of these amendments. Spent engine oil contaminates the soil and adversely affect the growth and yield of *Amaranth hybridus* but liquid organic fertilizers bioremediated the soil and improved the growth and yield of *Amranth.* Based on these findings, poultry and rabbit manures due to their better performance are suggested as a liquid organic fertilizer to bioremediate soils polluted with spent engine oil.

ABSTRACT

An experiment was conducted to evaluate growth and yield response of okra to NPK and organic fertilizer. It was carried out at the screen house of the Institute of Agricultural Research and Training, Ibadan between April and August 2021. The experimental design was Completely Randomized Design with six treatments, namely; NPK (100%), Neem Extract (100%), Jatropha Extract (100%), Neem extract+NPK (50:50), Jatropha extract+NPK (50:50) in four replicates. Data collected were number of leaves/plants, plant height, leaf area, number of fruits per plant, and fruit yield (g/pot). Data collected were subjected to analysis of variance while the significant means were separated by Duncan Multiple Range Test at 5% probability level. Result obtained showed that plant extract of neem and jatropha improved the growth and yield of okra, as sole application or in combination with NPK than NPK. Neem (100%) gave the highest fruit yield of 377.7 g/pot, followed by neem+NPK (50:50) with 252.9 g/pot and jatropha (233.0 g/pot) which are all comparable but significantly higher than other fertilizer sources. Therefore, use of organic fertilizer sources for growing okra can be an alternative to inorganic sources which are not readily available to peasant farmer.

Keywords: *Extract; Fertilizer; Jatropha; Neem; Okra; Yield*

INTRODUCTION

Okra (*Abelmoschus esculentus* (L.) Moench) is an annual, herbaceous flowering plant in the Mallow family that originated from tropical and subtropical Africa and is natural to the West Africa (Aladele *et al.,* 2008). Okra is mainly cultivated for its young immature fruits and consumed as a vegetable, raw, cooked or fried in countries like Sudan, Egypt and Nigeria; it is also important in other tropical areas including Asia central and South America often used as ingredient of soups and sauces. The fruits can be conserved by drying or pickling, the roasted seed is considered as coffee substitute; the leaves, flower buds, flowers and calyces can be eaten cooked as greens. In Nigeria, okra is grown in both wet and dry season but attract a larger profit in the dry season when the demand is often in excess with limited supplies. Okra is a good source of vitamins, minerals, calories and amino acid found in seeds and compares favorably with those in poultry, eggs and soybean. Growth of vegetables can be greatly improved through regular care. Fertilizer application is one of the most important factors which affect plant growth. Lack of certain nutrients lead to some symptoms such as small leaves, light green or off-color foliage and less elongation of branches and general lack of thriftiness or vigor (Melvin and James, 2001). Nitrogen is one of the basic plant nutrients that is built into the body of simple and conjugated proteins and many of organic substances of plant cell. Phosphorus is considered one of the important macro element nutrients.

Among the various factors affecting successful cultivation of okra, the judicious fertilizer application is one of those. Nitrogen is an essential element and important determinant in growth and development of crop plants. It plays an important role in chlorophyll, protein, nucleic acid, hormone and vitamin synthesis and also helps in cell division, cell elongation. Phosphorus fertilization can influence fruiting and development of okra. Phosphorus is called the "key to life" because it is directly involved in most living processes (Firoz, 2009). The requirements of fertilizers in okra are important for the early growth and total yield of fruit. Okra cultivation requires nutrients such as nitrogen (N), phosphorus (P), potassium (K), calcium (Ca), sodium (Na) and Sulphur (S) for fertility maintenance and crop production. These nutrients are specific in function and must be supplied to plants at the right time and at the right quantity. Lack of sufficient amounts of these nutrients result in poor performance of the okra with growth been affected resulting to low yield (Chauhan, 2012). In developing countries like Nigeria, the population growth rate is so high that improved technologies including rational use of fertilizers must be employed to meet the food requirement of the people (Hedrick, 2012). Improving soil fertility through the application of fertilizers is an essential factor enabling the world to feed the billions of people that are added to its population (Hera, 1996). Declining soil fertility is a major production constraint in Africa, especially in Nigeria, and it is becoming increasingly critical to secure sustainable soil productivity (Oladotun, 2002). Organic manure helps to improve the physical condition of soil and provide adequate amount of necessary nutrients for the soil productivity.

Organic fertilizers application resulted in improvement of growth and yield of different vegetable crops. This effect may minimize the amounts of chemical fertilizers and improve their application efficiency and subsequently avoiding environmental pollution. Use of inorganic fertilizers can improve crop yields and soil pH, total nutrient content, and nutrient availability, but its use is limited due to scarcity, high cost, nutrient imbalance, and soil acidity. Use of organic manures as a means of maintaining and increasing soil fertility has been advocated (Smil, 2000). Despite increasing relevance of okra in Nigeria where it is widely consumed, low yields are obtained in farmers' field because of declining soil fertility due to continuous cropping and disregard for soil amendments, which has led to several nutrients' loss in the soil (Akanbi *et al.* 2010). The application of inorganic fertilizers results in increase of okra yield. Unfortunately, inorganic fertilizers reduce the quality of arable lands. The Economic Commission for Africa (2001) reported that tropical soils are adversely affected by suboptimal soil fertility and erosion, causing a deterioration of the nutrient status and changes in soil organism populations. Akanbi *et al.* (2010) asserted that inorganic fertilizers can improve crop yields and soil pH, total nutrient content, and nutrient availability, but their usage is limited due to scarcity, high cost, nutrient imbalance and soil acidity. Hence, the objective of this study is to determine the growth and yield response of okra (NH47-4) to NPK and organic fertilizer sources.

MATERIALS AND METHODS

The field experiment was carried out at the screen house of the Institute of Agricultural Research and Training (I.A.R&T) Ibadan located on latitude of 7°22N and Longitude 3°05 E. Okra, *Abelmoschus esculentus* (L.) (NH47-4) variety seeds were obtained from IAR&T Seed stores. Five seeds were sown in each of the 5 kg capacity polythene bags, watered and later thinned to two seeds per pot. While the various plant extract was applied two weeks before planting in the appropriate pots, the inorganic fertilizer was applied two weeks after planting at the application rate of 80 kgN/ha. The experimental design was Completely Randomized Design (CRD) with six treatments of NPK, Neem leaf extract, Jatropha leaf extract, Neem+NPK (50:50) and Jatropha leaf + NPK (50:50) and control each replicated four times. Extract from neem and jatropha were obtained by soaking plucked leaves in distilled water, followed by blending and sieving of the extracts before use.

Data collection commenced at two weeks after sowing (WAS) on number of leaves/plant and plant height (cm). Leaf area was estimated by the non-destructive method of Olasantan and Salau (2008). The estimated regression equation between leaf area (Y) and leaf length (X) is: $Y= -386.93 +40.56X$ ($r= 0.91$). Two fully expanded leaves from five sample plants were used whose mean length represent X. This data was taken 8 WAS, at the commencement of flowering to ensure that the peak of vegetative growth was reached. Yield parameter taken are the number of fruit/plant and fruit yield (kg). The data collected were analyzed using analysis of variance to test the significant difference of treatments and mean differences were compared and separated using Duncan Multiple Range Test (DMRT) at 5% level of significance.

Table 1: Nutrient analysis of Jatropha leaf and Neem leaf

Properties	Neem extract	Jatropha extract
Total Nitrogen (%)	0.078	0.081
Total Phosphorus (%)	0.07	0.10
Total Potassium (g / kg)	0.21	0.31

RESULTS AND DISCUSSION

Physical and chemical characteristics of the experimental soil.

The result of the physical and chemical characteristics of soil showed that the soil is moderately acidic with a pH of 5.67, available phosphorus and total nitrogen were moderate with values of 18.97mg/kg and 0.30g/kg respectively (Table 2). The organic carbon was very high with value of 2.59% and the exchangeable cations were high. The textural class of the soil was loamy sand.

Table 2: Physical and chemical properties of soil

Parameters	Soil Test Value
pH	5.67
Organic C (g/kg)	2.59
Total N (g/kg)	0.30
Avail. P (mg/kg)	18.97

Silt	116
Clay	68
Textural class	Loamy sand

Effect of fertilizer source on the growth parameters of okra at 8 WAS

The result showed that organic fertilizer sources had significant effect on the number of leaves of okra at 8 weeks after sowing (WAS) than inorganic fertilizer source (Table 3). Meanwhile, neem extract produced the highest number of leaves (7) which is similar with other fertilizer sources except NPK and control plants which had the lowest value of 5. Similarly, the tallest plant of 92.8 cm was from Neem extract, it was comparable with other fertilizer sources and the control plant. However, Jatropha extract significantly produced the highest number of leaf area of 60.9 cm^2 which at par with other organic sources but higher than NPK (25.2 cm^2) and control plant (16.5 cm^2). This result was in line with the works of Akanni *et al,* (2011) and Olowoake & Ojo (2014) who reported that the combinations or sole application of organic fertilizers perform better on leaf area expansion, higher number of leaves/plant (Ojo *et al.,* 2014) and taller plants according to the findings of Singh *et al.* (2007) who posited that neem extract increased the plant height of okra compared to the control.

Table 3: Effect of fertilizer source on the growth of okra at 8 WAS

Treatments	Leaf area (cm^2)	Plant height (cm)	No of leaves/plant
Control	16.5b	75.2	5.3b
NPK	25.2b	72.6	5.3b
Neem (100%)	56.4a	92.8	7.7a
Jatropha (100%)	60.9a	77.9	7.4a
Neem+NPK (50:50)	54.4a	71.7	6.9a

Jatropha+NPK (50:50)	51.5a	79.2	7.3a
		Ns	

ns - not significant. Means with same letter (s) in a column are not significantly different at 5 % level of probability by Duncan Multiple Range Test (DMRT) WAS – weeks after sowing

Effect of fertilizer source on the yield of okra

The result showed that all the fertilizer source produced similar number of fruit/pot with the highest value from neem (Table 4). In the same vein, neem-based fertilizers gave the highest fruit yield while neem gave the highest value of 377.7 g/pot, followed by neem+NPK (50:50) with 252.9 g/pot and jatropha (233.0 g/pot) which are all comparable but significantly higher than other fertilizer sources. The lowest yield of 88.7 g/pot was from Jatropha extract + NPK. The resultant improvement in the yield of okra may be due to growth enhancement in terms of leaf production and taller plants than other fertilizer sources, which aid photosynthetic ability of the plant. In addition, neem extract is quick acting, provides a slow and steady nourishment and improves yield and quality of crops (Meena et al., 2009). Olaniyi et al. (2005) reported significant increase in the number of fruits and fruit yield of okra raised from organic fertilizer sources.

Table 4: Effect of fertilizer source on the number of fruits and cumulative yield of okra

Treatments	Cumulative yield (g/pot)	Cumulative no of Fruits
Control	120.6b	39.0
NPK	103.3b	22.4
Neem (100%)	377.7a	44.4
Jatropha (100%)	233.0ab	29.3
Neem+NPK (50:50)	252.9ab	35.7
Jatropha+NPK (50:50)	88.7b	22.5
		ns

ns - not significant. Means with same letter(s) in a column are not significantly different at 5 % level of probability by Duncan Multiple Range Test (DMRT)

CONCLUSION

The plant extract of neem and jatropha improved the growth and yield of okra, be it singly or in combination with inorganic fertilizer. Since, similar yield result was obtained using conventional NPK fertilizer which are usually inaccessible to peasant farmer, when compared with organic fertilizer sources investigated, it can be concluded that neem extract and jatropha extract may be considered by farmers and researchers to provide safer and cheaper fertilizer alternatives to the Nigeria populace. Therefore, neem fertilizer applied at 80 kgN/ha is recommended to maximize yield of okra.

ABSTRACT
This research focused on plant parts harvesting techniques from some indigenous woody plant species in different ecological zones of Taraba State. It investigates the different techniques, reasons and impacts of harvesting these species. Two stage sampling design was used to obtain data in the study. In the first stage, the study was stratified into three study ecological zones. The second stage involved the use of purposive sampling technique and e and Yamane's adaptation of Solvin's formula to select a sample size of 399 respondents (133 respondents in each ecological zone). A total of six (6) species (2 species per ecological zone) were selected using purposive and Snowball sampling methods. Data obtained were analyzed using quantitative indices (Fidelity level, plant part value, harvesting impact) and qualitative parameters (Frequencies, Percentages, Tables and Bar charts). The results showed that the stem of Prosopis africana and Pterocarpus erinaceus received the highest harvesting risk. The most preferred plant parts harvested were Vetellaria paradoxa stems and Pterocarpus erinaceus leaves as evidence by fidelity levels. Vitellaria paradoxa stems (37.43%) had the highest plant part value. The rate of reproduction of these species is being slowed down by the rising rates of unsustainable harvest caused by preference choice and the high value esteem of the plant parts. As evidenced by high harvesting impacts scores of 77.50 and 64.00 for Vittellaria paradoxa and Pterocarpus erinaceus stems, decreased rates of reproduction have negatively damaged the species.This calls for the promotion of effective conservation strategies and sustainable harvest of the priority indigenous woody plant species.
Keywords: *Ecological zone, Harvesting impact, Sustainable, Plant part, and Unsustainable*

INTRODUCTION

Indigenous woody plant species (IWPS) are generally harvested for timber and Non-Timber Forest Products (NTFPs) (Gaoue *et al*., 2017). The harvesting and consumption of IWPS parts from natural forests is known to account for a large proportion of livelihood (Ndangalasi *et al*., 2007). These plant parts are used by human beings over time for various reasons like food, fodder, fiber, traditional medicine, agricultural amenities, domestic materials, construction materials and many of these reasons are associated with cultures (Talukdar e*t al*., 2020). In sub-Saharan Africa, extraction for daily livelihood needs often results in uncontrolled exploitation of leaves, bark, and seeds of valuable indigenous woody species. However, overharvesting can threaten reproduction (Nacoulma *et al*., 2017). Majority of IWPS parts harvested are Non-Timber Forest Products (NTFPs) while others are timber forest products.

Various techniques used in harvesting different parts of IWPS have not been investigated and some of these species are poorly harvested. Unsustainable harvest of IWPS parts in Taraba State is widespread and common. The current unsustainable harvesting techniques being practiced and lack of sustainable harvesting knowledge have resulted to severe damage of many species in the state. Most IWPS are harvested for more than one reason (Delvaux *et al*., 2009) and the harvesting techniques focus on the economic reasons thereby, adopting methods of extraction such as lopping of branches, premature harvesting and cutting of trees. The removal of IWPS parts have variable impacts on the plants themselves, depending on the parts harvested. For example, harvesting flowers and fruits has a significant impact on regeneration and on the population viability (Gaoue and Ticktin, 2008; Delvaux *et al*., 2009). However, harvesting bark or roots is more damaging in terms of tree survival (Delvaux *et al*., 2009). The actual impact of harvesting depends on the method and type of resource that is removed. Intensive and uncontrolled harvesting can reduce the abundance of solitary plants (Ndangalasi *et al*., 2007).

Taraba State is blessed with considerable vegetation resources, which is one of the factors that contributed to the development of timber and non-timber forest products markets in the area. The natural ecosystems of the State constitute a main source of IWPS, these species play important role in the survival of man (Meer, 2018). The importance of these species in daily lives cannot be over emphasized. IWPS are making a positive impact on rural economic development of the State but the negative impacts out run the positive impacts as it negatively affects species functions, growth and production. The populations of many IWPS harvested for their foliage, bark and roots have reduced reproductive performance and age at first reproduction which ultimately translated into reduced population growth rate (Gaoue *et al*., 2013). The high rate of different harvesting techniques been practiced in Taraba State needs scientific attention. Therefore, the main objective of this study is to investigate the different harvesting techniques, reasons and impacts of harvesting IWPS in Taraba State. This evaluation will therefore provide adequate information for sustainable use and management of IWPS.

METHODOLOGY

The study area

Taraba State in Nigeria lies between latitudes 7° 00’ 00” N and 9° 30’ 00” N and longitudes 10° 00’ 00” E and 12° 30’ 00” E. It occupies a total land mass of approximately 54, 473 km^2 (Figure 1). The State is bordered on the northwest by Gombe State, west by Plateau and Nassarawa States and by Adamawa State in the northeast. It also shares its southwest boundary with Benue State. An international boundary on the east separates Taraba State from the republic of Cameroon (GIS MAU, Yola, 2023). The state is made up of three (3) major ecological zones which include Southern guinea savanna located in the south western part of the State, Northern guinea savanna in the northeast and Montane Forest in the southeast (Meer *et al*., 2019).

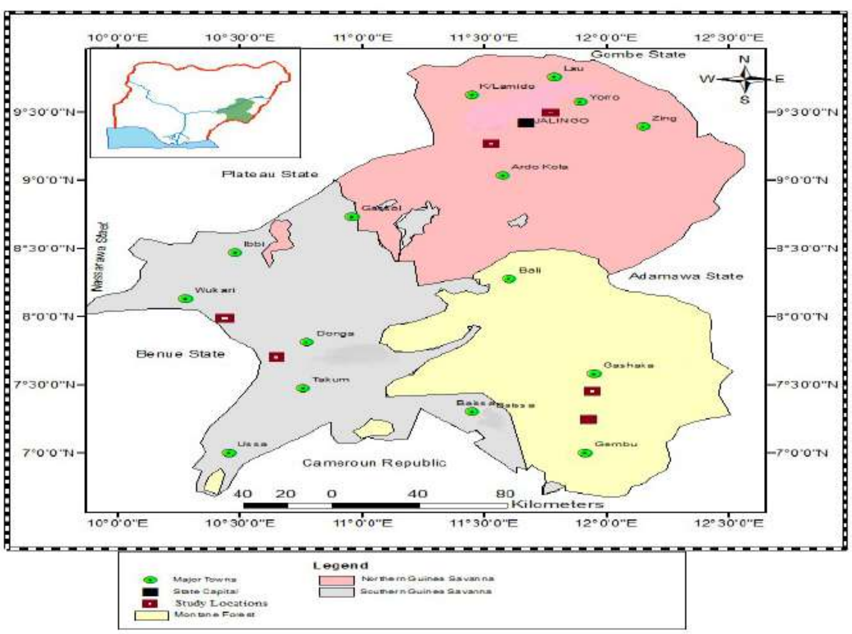

Figure 1: Map of Taraba State Showing the Study Locations

Data Collection

Two stage sampling design was used to obtain data in the study. In the first stage, the study was stratified into three study ecological zones namely; Northern Guinea Savanna (NGS), Southern Guinea Savanna (SGS) and Montane Forest (MF). The second stage involved the use of purposive sampling of respondents who have direct association with indigenous woody plant species or its products and the selection of two (2) most essential IWPS in terms of economic (income generated from tree species products and services); social (food, medicine, cultural, religious, raw materials) and ecological (shelter, climate modification and protection) development in each ecological zone. A total of six (6) species were selected in the study, they are *Pterocarpus erinaceus*, and *Beilchmiedia mannii* in MF, *Ziziphus mauritiana* and *Vetellaria paradoxa* in NGS, *Prosopis africana* and *Vitex donniana* in SGS.

A sample size of three hundred and ninety nine (399) respondents (133 respondents per ecological zone) drawn from the target population of Taraba State (2,300,736) using Solvin's formula adopted by Yamane (1967), Otabor and Obahiagbon (2016) and Sells (2018) were used as shown in equation one (1) bellow:

$$n = \frac{N}{1 + N(e)^2} \qquad \ldots\ldots 1$$

Where:

n = Required sample size

N= Total population of the study area

e = Error to tolerance (95% confidence level at a margin of error of 0.05)

Administration of semi-structured questionnaire was done using Snowball sampling method as adopted by Agbelade *et al*. (2017).

Data Analysis

Data were analyzed using descriptive statistics (Frequencies, Percentages, Tables and Bar charts) and quantitative parameters [Relative Cultural Importance indices (RCI) like Fidelity Level (FL) in percentage, Plant Part Value (PPV) in percentage, Reported use (RU), Reported use Value per Plant Part (RU_{PP})] adopted by Hoffman and Gallaher, (2007). According to Salako *et al.* (2018), Fidelity Level (FL) is an instrument used to identify the most preferred plant part for each use category or reason. It measures how often a use report was mentioned. The formula is giving in equation 2 below as described by Friedman *et al*. (1986) and Omire *et al*. (2020):

$$FL\ (\%) = \frac{x}{n} \times 100 \qquad \ldots\ldots 2$$

Where:

x = Total number of respondents who have mentioned a specific use

n = Total number of respondents

Plant Part Value (PPV) is the ratio between the total reported uses for each plant part and the total number of reported uses for the plant (Hoffman and Gallaher, 2007; Omire *et al*., 2020). It is expressed in equation 3 as:

$$PPV\ (\%) = \frac{\Sigma RU_{PP}}{\Sigma RU} \times 100 \qquad \ldots\ldots 3$$

Where:

Σ = Summation

RU_{PP} = Total number of uses for each plant part

RU = Total number of uses reported for the plant

To determine the harvesting impacts for each of the sampled IWPS and their respective plant parts, a specially developed Harvesting Impact (HI) formula derived from an equation previously proposed by De Lucena *et al*. (2013) as adopted by Bruschi *et al*. (2014) was used. The resultant percentages of local use (LU) and harvesting risk (HR) of each plant part were scored (Table 1). The harvesting impacts were calculated using the formula in equation 4 and the criteria given in Table 1:

$$HI = LU_M \times HR_M \qquad \ldots\ldots 4$$

Where:

HI = Harvesting impact

LU_M = mean value of local use (LU) scores were calculated by considering each single use of that species. This value was obtained by adding up the scores assigned to each use and dividing this sum by the number of all the uses cited for that species.

HR_M = mean value of harvesting risk (HR) scores were calculated by considering each single harvesting method or risk of that species. This value was obtained by adding up the scores assigned to each harvesting method or risk and dividing this sum by the number of all the harvesting method or risk cited for that species.

RESULTS AND DISCUSSION

Demographic Characteristics of Respondents in the Study Area

The results of the demographic characteristics of respondents in Table 2 showed that male respondents (55.89%) were more than their female (44.11%) counterpart. This clearly implies that male and younger respondents commonly extract indigenous woody species than female and older respondents. This conclusion is consistent with Meer (2018), who noted a high percentage of male users of woody species in the three ecological zones of Taraba State, Nigeria. This claim was also in line with a study carried out in India where Talukdar *et al*. (2021) affirmed higher proportion of young persons for NTFPs collection compared to middle and older aged people. Majority (46.12%) of the respondents were below 30 years, followed by the age group of 50 years and above (29.07%). Only 24.81% belong to the age group of 31 to 50 years (Table 2). This suggests that they are of an active age for tree harvesting. In contrast, a study conducted by Ampitan *et al*. (2017) recorded majority of female respondents between the age group of 41 to 50 years with wealth of experience, responding to the uses of the indigenous woody plant parts in New Bussa, Niger State, Nigeria.

The marital status and educational level of the respondents revealed that majority (50.63%) were married, 36.84% had secondary school education, and 25.31% had primary school education while 19.55% and 18.30% represent non formal and tertiary education respectively. Occupational distribution of respondents indicates that 28.82% were herbalists, 26.07% were artisans while 22.81% and 22.30% were traders and farmers respectively (Table 2). The respondents' married status may be a sign of a population that is expanding quickly, which is likely to exert extra strain on indigenous woody species. This observation agrees with McCarty (2001) that rapid human population growth rate is the major cause of wild species loss. Fayera, *et al*. (2014) also noticed deforestation as a result of continuous increment of human population. According to them, the direct causes of deforestation are agricultural expansion, wood extraction (logging or wood harvest for domestic use), and infrastructure expansion such as shelter construction (urbanization).

The secondary and primary educational levels as observed in this study imply that respondents will easily adopt sustainable harvesting methods, if awareness campaign programmes are organized for them. Majority of the population in the study area were herbalists, artisans and indigenous woody species traders who were actively involved in woody species exploitation. This finding is in line with the study by Ndangalasi *et al*. (2007); they reported that woody species harvesting account for a large proportion of livelihood such as farming and trading. According to Talukdar *et al*. (2020), many rural people harvest indigenous woody species parts for earning cash by selling into the market for their livelihood.

Harvesting Techniques and Risks Observed in the Study Area

The results of harvesting techniques and risks in Table 3 showed that the *Prosopis africana* stem had the highest harvesting risk (97.74%) of whole plant removal before harvesting the parts, followed by *Pterocarpus erinaceus* stems (96.24%). This harvesting technique was also observed in the stem bark of *Pterocarpus erinaceus* (90.98%) and *Beilchmedia mannii* (70.68%) in MF. Similar to this, all plant parts of *Pterocarpus erinaceus*, with the exception of the seeds (15.04%), showed increased harvesting risks of whole plant removal. This suggests that the plant parts most harmed by the unsustainable harvesting technique of removing the entire plant, which put the plant species at great risk, were the stem and bark. The decision to extract stem and bark in the study area may be linked to the demand for timber, fuelwood and charcoal production products and medicine. In line with this finding, Adekunle and Olagoke (2010) agreed that severe damage is usually inflicted on the forest ecosystem during logging activities. In contrast, this finding disagrees with the report of Singh *et al*. (2014) who identified root as the plant part that was intensively harvested in India using destructive harvesting technique.

The leaves (60.15%) and seeds (72.18%) of *Ziziphus mauritiana* and leaves (60.90%) of *Prosopis africana*, as well as the roots (57.87%) of *Vitex donniana*, on the other hand, showed minimal risks of harvest, where respondents removed plant parts with little or no effects (Table 3). The minimal risks of harvesting leaves and seeds are consistent with the finding of Andel (2006) who noticed that harvesting leaves and fruits is less damaging than felling entire trees for timber or bark harvesting.

Reasons Attributed to Indigenous Woody Plant Species Harvesting and Fidelity Levels

The Fidelity level (FL) values in this investigation presented in Table 4, expressed a wide range of 100.00% to 0.75%. The generation of charcoal and fuelwood from *Vetellaria paradoxa* stems had the highest FL value (99.25%), followed by *Ziziphus mauritiana* leaves for medicinal (99.25%) and seeds for food (98.49%). It was discovered that *Pterocarpus erinaceus* leaves are also frequently utilized in medicine (96.24%). Only a small percentage of respondents (0.75%) indicated that they trade *Vitex donniana* roots. Furthermore, *Pterocarpus erinaceus*, *Vetellaria paradoxa*, *Prosopis africana*, and *Vitex donniana* stems were frequently utilized for building, fuelwood consumption and charcoal production (Table 4). This therefore means that *Vetellaria paradoxa* stem and the leaves of *Pterocarpus erinaceus*, *Ziziphus mauritiana*, and *Vitex donniana* were the most widely preferred and used plant parts. The observation of leaf as the dominant and preferred plant part in the study area is in agreement with Cakilcioglu and Turkoglu (2010); Akhtar *et al*. (2013); Bano *et al*. (2014); Ahmad *et al*. (2014). Bino *et al*. (2014) and Singh *et al*. (2014) also identified leaves as the most preferred and commonly used plant parts. Meer *et al*. (2019) and Todou *et al*. (2016) identified *Ziziphus mauritiana* and *Parkia biglobosa* as one among the top sixteen most preferred and the most commercialized indigenous woody species in Adamawa north region of both Nigeria and Cameroon respectively.

High FL values suggest frequent use of the plant species component for a certain use category by the respondents (Bibi *et al*. (2014). Therefore, the reasons for harvesting indigenous woody species and the corresponding fidelity levels of this finding imply that the local population of the study area used multiple parts of indigenous woody species, including the leaf, stem bark, seed, root, and stem for food, medicine, shelter, and livelihood. This is in conformity with reports of other authors like Bino *et al*. (2014) from Pakistan, Singh *et al*. (2014) from India and Liu *et al*. (2023) from China, which indicated that many people used multiple parts of plant species for various reasons including medicine and food. The timber products obtained from *Pterocarpus erinaceus*, *Vetellaria paradoxa*, *Prosopis africana* and *Vetellaria paradoxa* stems were used for construction, fuelwood consumption and charcoal production while *Beilchmedia mannii* and *Prosopis africana* seeds were used for food. The properties of the sampled species and climatic conditions of the ecological zone in the State may be responsible for the use variation of these species. In line with this, Tukur *et al*. (2013) reported fuelwood and medicine as the key important reasons for indigenous woody species use in Katsina State of Northern Nigeria.

Important Plant Part Values in the Study Area

Plant part values were recorded in Table 5. For *Vitellaria paradoxa*, the stem was the most significant plant component (37.34%). Similarly, *Beilchmiedia mannii* (37.29%), *Pterocarpus erinaceus* (26.71%), and *Prosopis africana* (35.48%) recorded seeds as the most significant plant part value, but *Ziziphus mauritana* (26.93%) and *Vitex donniana* (28.54%) on the other hand recorded leaves as the most significant plant part value. This confirms that the inhabitants in the study area considered stems, seeds and leaves as the most significant plant parts. The finding is in agreement with previous studies of Amwatta (2004), which reported leaves as the most valuable plant part. In contrast, a study conducted by Omire *et al*. (2020), listed fruit as the highest plant part, valued by people in Kenya. Seeds were thought to be valuable plant parts that are used less frequently as observed on the frequency of harvesting. This might be ascribed to factors including inaccessibility, scarcity and non-availability of the product. This means that the use of species or its products frequently does not ensure their value or worth.

The Impacts of Harvesting Indigenous Woody Plant Species in Taraba State

The harvesting impact (HI) was calculated to establish a conservation priority for the sampled IWPS. The high value of HI for a given species or its part indicates the need for a greater level of attention for conservation and sustainable harvest. According to the result of this finding shown in Table 6, *Vittellaria paradoxa*, *Pterocarpus erinaceus*, *Vitex donniana* and *Prosopis africana* stems had the greatest harvesting impact scores of 77.50, 64.00, 62.50, and 58.00, respectively. The largest harvesting impacts were also documented for seeds and leaves, coming in at 49.50 and 42.63 for *Beilchmiedia mannii* and *Ziziphus mauritana*, respectively. This means that stems and seeds are the plant parts that require attention for conservation and sustainable harvest. This result supports the works of Bruschi *et al*. (2014) who reported that high plant part usage especially seeds can impact a species population's capacity for regeneration and may therefore be harmful.

On the other hand, the least harvesting impact was shown in the *Pterocarpus erinaceus* leaf (17.25), stem bark of *Vitellaria paradoxa* (27.50), and roots of *Beilchmiedia mannii* (22.00), *Ziziphus Mauritana* (25.00), *Prosopis africana* (22.00), and *Vitex donniana* (22.00) (Table 5). Furthermore, *Vitellaria paradoxa* had the highest average harvesting impact score (48.65), followed by *Ziziphus mauritiana* (38.18), *Pterocarpus erinaceus* (36.85), *Vitex donniana* (36.70), and Prosopis africana (35.35), while *Beilchmiedia mannii* had the lowest average harvesting impact score (23.90). The study area's top priority species for conservation appeared to be all of the sampled species with the exception of *Beilchmiedia manii.* These findings were consistent with the findings of Lokonon *et al*. (2017), who determined that *Prosopis africana*, *Vitex donniana*, *Pterocarpus erinaceus*, and *Vitellaria paradoxa* were the top priority species for conservation.

CONCLUSION AND RECOMMENDATIONS

The results of this study unequivocally demonstrated that significant harm was caused to the IWPS during unsustainable harvesting techniques of entire plant removal and premature harvest, which impair the reproductive success in response to demand for timber and NTFPs derived from indigenous woody species. The supply of these products for food, medicine and shelter are the major reasons why local population of the study area used multiple parts of the sampled indigenous woody plant species. Local consumers in MF, NGS, and SGS prefer the leaves of *Pterocarpus erinaceus*, *Ziziphus mauritiana*, and *Vitex donniana*, respectively. As timber extraction, charcoal production, and fuelwood consumption were primarily sourced from the stems of *Pterocarpus erinaceus*, *Prosopis africana*, and *Vetellaria paradoxa*, leaf extracts from these plants were used for medicine, while those from *Vitex donniana* were used for food. The quantitative indices used were helpful in pointing the most frequently used and important indigenous woody species parts as stems and leaves. The rural population of Taraba State valued the stems from *Pterocarpus erinaceus*, *Vetellaria paradoxa, Prosopis africana*, and *Vitex donniana* for building, fuel consumption, and charcoal production, while the seeds from *Beilchmedia mannii* and *Prosopis africana* were valued for food. With the exception of *Beilchmiedia mannii*, all the tested IWPS have been classified as priority species because of the harvesting impact; these species are likely to lose their gene pool due to heavy use. The discovery that these species, along with their parts, have significant harvesting consequences has led to recommendations for immediate conservation, sustainable harvest and awareness campaigns.

Table 1: Scores used to Calculate Harvesting Impacts (HI) for Woody Plants

S/No		Item	Score(s)
1.		**Local use (LU)**	
	a.	High (cited by more than 71% of the respondents)	10
	b.	Moderately high (41–70%)	7
	c.	Moderately low (<41%)	4
2.		**Harvesting Risk (HR)**	
	a.	Destructive harvesting (whole plant or stems) or overexploitation of roots and bark	10
	b.	Removal without causing individual mortality of structures such as bark and roots	7
	c.	Removal of aerial permanent structures such as leaves, stems and sap affecting survival and/or reproductive success	4
	d.	Aerial structures such as flowers and fruits removed without affecting the plant	1

EFFECTS OF LEVELS OF PRUNING ON THE VEGETATIVE GROWTH OF CASHEW PLANTATION IN IBADAN, RAIN FOREST ZONE OF NIGERIA

***Nduka B. A. and Aremu-Dele O.**

ABSTRACT
An experiment was conducted in Ibadan, Oyo State, rainforest zone in Nigeria to determine the effects of different pruning levels as a cashew plantation rehabilitation strategy. The pruning treatments were imposed on two tree per treatment on a twenty-year old unproductive cashew tree at 0% (no pruning/control), 25%, 50%, and 75% pruning, replicated three times which was laid in a complete randomized block design. Data were taken on cashew vegetative growth (girth, canopy spread at different directions as well as the crown size diameter) before and after pruning treatments were measured. . No significant difference was observed in the vegetative growth parameters measured before pruning treatments was applied. Canopy Spread (CanSp), Crown Diameter (CrownD), Canopy Radius (CanR), Canopy Ground Cover (CanGC) and Percentage Canopy Ground Cover (PCanGC) at 25% (9.15m) and 50% (7.03m) pruning levels were not different from each other but different from 75% (5.96m) pruning level. The experiment was a year trial, and it was observed that the regeneration of chupons was slow after 3 months of pruning treatment especially in the plot that received 25% pruning. Moreso, investigation is still ongoing.
Keywords: *Cashew; Canopy; Chupons; Pruning.*

INTRODUCTION

Pruning is a tool for improving both wood productivity and forest quality (Nicholas and Brown, 2002). It is also known for redistributing water, minerals, and nutrient within plants (Saritha *et al*., 2021). Pruning is also one of the many agro-techniques that can be used on tree crops that develops quickly, especially the cashew tree (Nayak *et al*., 2018). It is one of the most common management strategies used in both traditional and contemporary cashew plantations around the world (Costa and Bocchi, 2017). Canopy and unproductive tree management are one of the most common problems farmers of cashew struggle with because when unpruned, the plant has its branches interlocked and sprawl to the ground over time. Pruning also serves as a growth stimulator, a means of modifying the cashew tree's architectural structure, as well as a yield enhancement tool. Alvarez *et al*. (2011a) reported that pruning increased the stem growing potential of pruned trees when compared to unpruned trees. More so, physiological procedures within the tree may be altered if pruning was not performed correctly (Grabosky and Gilman, (2007); Fini *et al*., (2011).

According to Eric and Randol (2003), an increase in nutrient resources was observed after pruning which was in a low state before pruning. On the other hand, Hayes (2002) reported that excessive pruning can lead to plant stress, mechanical failure, and weak development of epicormic shoots. Additionally, Collier and Turnblom (2001) noted that severely pruning epicormic branches could result in reductions in clear hardwood yield. In old cashew plantations, poorly pruned old cashew trees have been observed to negatively affect fruit yield production (Amanoudo, 2022). However, pruning is a costly and time-consuming process (Shahbazi *et al*., 2020). Therefore, it is crucial to research the suitability level for rehabilitation, to increase the yield of unproductive cashew plants, manage the plant canopy and enhance elongations of the productivity of the plant. Therefore, this experiment aimed to determine the most appropriate pruning level for cashew rehabilitation.

METHODOLOGY

Moribund twenty-year-old Cashew trees planted at a spacing of 9 x 9 meters, laid in a complete randomized block design were randomly selected at the Cashew field zone of the Cocoa Research Institute of Nigeria (CRIN) Headquarters, Ibadan, Oyo State, situated in the rain forest zone. The two trees selected per treatment were observed before pruning began to determine their level of productivity, which was zero level of productiveness. The trees received four different treatments i.e-0% (Control-where the branches was left unpruned), 25% (One quarter of the branches prune) 50%,(Half of the tree branches prune), and 75% (One third of the tree branches prune) levels of pruning treatments on the selected cashew trees. To prevent pest and disease infestation on the cut surfaces because of the pruning, red oxide paint was applied to the cut surface immediately after pruning. At 3months after pruning, the emerged chupons were counted and recorded but subsequently thinned to accommodate only two vigorously growing chupons. Data on vegetative growth were taken before pruning with a ranging pole placed in the four east, west, south and north direction of the trees and a measuring rule used in measuring these distanced from the tree to the last tip of each direction of the branch's branches. The girth was measured with a measuring time 30cm from the ground, while the height was measured with the measuring tape hanged at the tip of the ranging pole to the ground and a year after pruning, the same measurement before pruning was carried out. Data were subjected to analysis of variance using SAS (2011) statistical software and treatment means separated using the least significant difference ($P<0.05$).

RESULTS AND DISCUSSION

Cashew tree vegetative growth characteristics

The results of the initial vegetative growth characteristics of the cashew trees before pruning treatments were imposed as shown in Table 1 were not significantly different from each other. This could be a result of the trees being of the same age and biotype. This is in line with Richards (1992), that cashew trees of the same age and land area often possess similar leaf patterns and dry biomass accumulation. After the imposition of the pruning treatments as shown in Table 2, there were various levels of significance observed in the growth characteristics of the cashew trees among the treatments which implies that the pruning treatments influenced the vegetative growth of the cashew trees. A similar influence was also observed by Janani *et al*. (2020) and Nayak, (2015) in cashew vegetative growth and canopy management of cashew respectively. Of all the growth characteristics, only the cashew trunk girth was not significant. This could occur as pruning activities didn't take place in this part of the cashew tree. The control treatment in Table 2 had the highest value in all the growth parameters except in girth. For the North, South, East and West side of the canopy (N, S, E and W), 25%Prun (5.7m, 3.45m, 4.02m and 4.94m) were the closest to the control (8.98m, 8.99m,5.38m and 8.71) with significant difference observed in N, S and W and no comparable difference in E respectively.

No significant difference was observed among 25%Prun, 50%Prun and 75%Prun cashew trees in N and S while 75%Prun (2.34m and 2.03m) had significantly lower values than 25%Prun (4.02m and 4.94m) and 50%Prun (3.49m and 7.03m) in E and W. In North-South canopy spread (NS), No significant difference was observed between 25%Prun (9.15m) and 50%Prun (7.03m) but was not both significantly different from 75%Prun (5.96m). East-West canopy spread (EW) also followed the same trend as NS. The result of the Canopy Spread (CanSp), Crown Diameter (CrownD), Canopy Radius (CanR), Canopy Ground Cover (CanGC) and Percentage Canopy Ground Cover (PCanGC) was similar as 25%Prun and 50%Prun was not notably different from each other but comparably different from 75%Prun being the lowest in value of all the treatments.

The growth of chupons did not follow any distinct pattern as shown in Figure 1. However, the 3 pruning levels brought about a quick regeneration of chupons which was in contrast to the report of Patch and Felker (1997b) that re-sprouting of new leaves from pruned trees is one of the problems of pruning. Figure 1 shows the rate of regeneration of the chupons among the pruned cashew trees, and the highest number of regenerated chupons was recorded in the 75% pruned trees (114). This agrees with the report of Janani *et al*., (2020) that heavy pruning brings about excessive vegetative growth.

CONCLUSION

The degree of pruning affected the regeneration rate of the cashew trees growth characteristics and chupon growth differently. Generally, 25% pruned cashew regenerates the slowest, followed by 50% pruned cashew trees which were faster and 75% pruned cashew trees which were the fastest as observed one year after pruning.

ABSTRACT
The effect of coppicing on the regrowth potentials of mint plant (Mentha spp) was conducted at the Southern eastern part of Nigeria, where farmers are unaware of mint plant and the best practice to grow the crop. The study was evaluated at the Crop science Research Farm, University of Nigeria, Nsukka from October to December 2021. The experiment was carried out in 2021 during the dry season for a period of 2 months. The pot experiment was laid out in a 4 x 3 factorial in Completely Randomized Design (CRD) and replicated three times. The substrates (topsoil, poultry manure and sawdust) were combined in the ratio of 3:2:1, 3:1:2, 3:3:0 and 6:0:0 and left for six weeks to homogenize. The mint species (Peppermint, chocolate mint and normal mint) planted and their replications were cut back 10cm to the ground and allowed to regrow for 6 weeks. Growth parameters (number of nodes, number of internodes, number of leaves and leaf area) were measured at 3 and 6 weeks after coppicing (WAC). The media 3:3:1 produced more nodes, internodes, leaves and broader leaves than media 3:2:1, 3:1:2 and 6:0:0 at 6 WAC. From this study it can be concluded that media 3:3:0 is recommended for farmers who intend on engaging coppicing on their mint plant (Mentha spp).
Keyword: *Coppicing, Regrowth Potential, Substrates, Mint plant (Mentha spp) and Nursery media*

INTRODUCTION

Mentha genus belongs to the family Lamiaceae and it has about 25-30 species (Hawryl *et al*., 2016). Mint plant is widely dispersed in Europe, Africa, Australia and North America. Mint plants grows mostly in wet locations, moist soils and are mostly found near water bodies such as lake, rivers, and in partial shade on cool moist places. Mint plants can also bear full sunlight (Abbas *et al*., 2022). Mentha are aromatic herb which has an extensively scattered stolon both above and below the ground (Abbas *et al*., 2022). Mint leaves can be consumed in their fresh or dried form (Nayak *et al*., 2020). Coppicing is one of the oldest forestry systems known from many countries worldwide (Evans 1992; Fujimori 2001). It is an obvious fact that there is an increase in the interest of coppicing, yet there is few information on the effect of coppices on site conditions and its ecological characteristics which encompasses soil properties, growth properties of plant species and nature protection (Vacik *et al*. 2009; Matula *et al*. 2012).
The principle of coppicing is the ability to allow woody plants such as trees and shrubs to be cut back and allow to regrow (Jarman *et al*., 2013). Mint plant is not well known by farmers in South East Nigeria, the few farmers who are aware of this plant have difficulties trying to minimize cost in production and also difficulty in maintaining the growth all year round. This study therefore is set to create awareness among farmers and the use of coppicing to minimize cost of production and grow mint plant all year round. The aim of this field study which was executed during rainy season was to determine the effect of coppicing on the regrowth potential of different varieties of mint plant grown on different nursery media.

MATERIALS AND METHODS

The experiment was conducted at the Teaching and Research Farm, Department of Crop Science, University of Nigeria, Nsukka for a period of 2 month. This experiment evaluated the effect of coppicing on the regrowth potential of three species of mint plant (*Mentha species*). The experiment was a 4 x 3 factorial replicated 3 times in CRD. The factor A were 4 media which are combinations of three substrates at different ratio. The substrates used are top soil: poultry manure: saw dust at ratio 3:2:1, 3:3:0, 3:1:2 and 6:0:0 (control) respectively. The three species and their replication were cut back to 10cm to the ground. The media composition was analyzed at the Research Laboratory, Department of Soil science, University of Nigeria, Nsukka. Data was taken at the 3rd and 6th week after coppicing (WAC). Growth parameters such length of leaf, width of leaf, number of leaves, number of nodes and number of internodes were collected. The data collected were analyzed using the software GenStat Discovery Edition 12. The data were subjected to two-way analysis of variance (ANOVA), selecting the appropriate procedure for factorial experiment in CRD. In the case of significant treatment effects, mean separation was by the Fisher's Least significant difference (F-Lsd) procedure at 5% level of probability($P<0.05$).

RESULTS

The result in Table 1 shows that the media combination 3:2:1 has higher clay content, higher pH value, higher amount of Mg^{+}, higher CEC, Higher Al^{3+} and higher percentage Base Saturation than the other 3 media formulation. The control (6:0:0) contains higher proportion of fine sand than the 3 media combinations. The media combination 3:3:1 contains higher proportion of clay sand, has larger proportion of carbon and organic matter content, has more exchangeable bases with exemption of Mg^{+} and has more phosphorus content than the 3 media composition (3:2:1, 3:1:2 and 6:0:0(Control)) as shown in Table 1.

Number of internodes, nodes and leaves after coppicing

The results of media composition and mint effect on number of internodes, number of nodes and number of leaves shown in Table 2 show that the treatment means differed significantly(p=0.05) across 6 weeks after coppicing (WAC)

Media: The media composition of 3:3:1 gave the highest number of nodes, internodes and leaves at 6 weeks after coppicing with mean values of 407.0, 406.0 and 1272 respectively as shown in Table 2 which differed significantly(p=0.05) from the media composition of 6:0:0 (control) which gave the lowest number of nodes, internodes and leaves at 6 WAC with mean value of 102, 101 and 326 respectively as shown in Table 2.

Mint: The chocolate mint has the highest number of nodes, number of internodes and leaves at 6 WAC with mean values of 587, 586 and 1563 while peppermint had the lowest number of nodes, internodes and leaves at 6 WAC with mean values of 69, 68 and 378 respectively as shown in Table 2.

Leaf area(cm^2) after coppicing

The results of the media composition and mint effect on leaf area(cm^2) show that there were significantly (p=0.05) different across 6 WAC as shown in Table 3.

Media: The media composition 3:1:2 gave the highest leaf area(cm^2) at 6WAC with mean value of 13.30cm^2 which were significantly(p=0.05) different from the media composition 6:0:0(control) at 6 WAC with mean value of 8.40cm^2 as shown in Table 3.

Mint: The peppermint specie has the highest leaf area (cm^2) at 6 WAC with mean value of 16.95cm^2 while the chocolate mint has the lowest leaf area (cm^2) at 6 WAC with mean value of 9.16 cm^2 as shown in Table 3.

Interaction effect of mint specie and media composition on number of internodes, number of nodes and number of leaves at 3 and 6 WAC

The results of the interaction effect of mint plant and media composition on number of nodes, number of internodes and number of leaves across 6 WAC show that there was no significant(p=0.05) difference between the treatment means as shown in Table 4. The interaction effect of the media composition 3:1:2 and mint specie chocolate mint produced the highest number of nodes and internodes at 6 WAC with mean values of 669.0 and 668.0 respectively while the interaction effect of the media composition 6:0:0 and mint specie peppermint produced the lowest number of nodes and internodes at 6 weeks after coppicing with mean values of 24.0 and 23.0 respectively. For number of leaves, the media composition 3:3:0 and the mint specie chocolate mint gave the highest number of leaves at 6 WAC with mean value of 2430.0 while the media composition 6:0:0 and the mint specie peppermint gave the lowest number of leaves at 6 WAC with mean value of 132.0 as shown in Table 4.

Interaction effect of mint species and media composition on the leaf area(cm^2) at 3rd and 6th WAC.

The results of the interaction effect of mint plant and media composition on leaf area(cm^2) across the 6 WAC show that there was no significant(p=0.05) difference between the treatment means as shown in Table 5.

The interaction effect of the media composition (3:1:2) and the mint specie (peppermint) at 6 WAC has the highest leaf area with mean value 19.47 cm^2 while the interaction effect of the media composition (6:0:0) and mint specie (spearmint) at 6 WAC has the lowest leaf area with mean value 5.53 cm^2 as shown in Table 5.

DISCUSSION

The media composition of 3:3:0 produced more nodes, internodes and leaves than the control 6:0:0 at 6 WAC. This conforms with the findings of Sramek *et al* (2015), that coppiced plants thrive better in soils with higher nutrient content. Media 3:3:0 was higher in organic matter content, exchangeable bases and nitrogen than others as shown in Table 1 which ensured optimal plant growth. This conforms with the findings of Handreck, 1992 who reported that optimal plant growth is ensured only if sufficient nitrogen is available for plants. Mint plant thrives on media with high water holding capacity and good anchorage. This could also be as a result of high ratio of poultry manure to sawdust thereby improving the water holding capacity of the media. According to Kieltyka *et al* (2017) peppermint grows particularly well in soils with high water-holding capacity.

CONCLUSION

This study sought to discover the regrowth potential of three species of mint plant raised in four distinct nursery media after coppicing. After coppicing, the media composition 3:3:0 and chocolate mint performed tremendously well as compared to the others. Though Chocolate mint performed best in the field peppermint, peppermint produced a pungent aroma than other mint species due to the higher methanol (%) and volatile oil content

ABSTRACT
Healthy snacks made from desired-quality fruit were required due to consumer preferences for functional foods. Mango cultivars; Saigon, Ogbomoso, Tommy Atkins, Edward, Haden and Lippene were obtained from NIHORT. Fruits were cut into slices and dehydrated at 52 °C for 10–12 hours. Standard procedures were used to evaluate the samples' production, microbiological composition, and sensory quality. ANOVA was used to evaluate the data at a significance level of 0.05, and response surface approach was used for the sensitivity analysis. After dehydration, the results showed that Haden had the lowest yield, while Saigon had the most. Salmonella, bacteria, and fungi were absent in the samples. In terms of most attributes and overall acceptability, Ogbomoso cultivar received the highest sensory evaluations, which is crucial for the marketing of the product.
Keywords: *dehydration, mango cultivars, yield, sensory properties*

INTRODUCTION

Mango, Mangifera indica, is one of the most important tropical fruits. It is a fleshy drupe of the genus Mangifera, composed of numerous tropical fruit trees of the flowering plant family Anacardiaceae. With a global annual production of 33.5 million tonnes, it was ranked by the FAO as the fifth largest fruit crop in global total production in 2009 (FAO, 2011). Mango has many health-promoting properties, which is why it is at the top of the list of superfruits (Gross, 2010).

Numerous studies (Al-sheraji *et al*., 2011; Hassan *et al*., 2007) have shown that Mangifera species are high in phytochemicals and dietary fiber in all of their constituent parts. They play a big part in fighting free radicals, too (Ajila *et al*., 2010; Abu Bakar *et al*., 2009). Mangos contain sizeable levels of provitamin A, vitamin C, and sugar, and are recognized as a fruit of high commercial worth. Increased fruit consumption, such as that of the mango fruit, has been widely recognised to enhance and preserve quality of life by reducing the prevalence of cardiovascular diseases and particular cancers (Halvorsen *et al*., 2006; Vasco *et al*., 2008).

Food materials can be dried for benefits like quality control, achieving hygienic conditions, and reducing product loss (Corzo *et al*., 2008). According to Dennis (1999), fruit's flavor, as well as the majority of its nutritional value, can be concentrated and conserved by lowering the moisture level of the fruit to between 10% and 20%, which will also prevent bacteria, yeast, mold, and enzymes from spoilage. The market for processing mango into dried slices is still small in developing nations like Nigeria for a variety of reasons, including the availability of cultivars, processing tools, packaging, and consumer preferences. It is essential to create products that meet the needs and tastes of the intended consumer (Grunnert, 2005). Therefore, this study identifies cultivars best for dried slices for optimum yield and sensory attributes.

MATERIALS AND METHODS

Sample preparation

The cultivars of mango used for the experiment were Ogbomosho, Saigon, Lippenne, Edward, Tommy Atkins, Kent and Haden. Each cultivar was washed, air dried and weighed. The fruits were peeled, stone removed and sliced to 0.8 mm using digital Vernier Caliper (Raider Pro RD DC706). Sliced samples were dehydrated (Excalibur 4926T) at 52 °C for 10 - 12 h., allowed to cool and packaged in Polyethylene bag for further analysis. The weights of the fresh and dehydrated samples were noted to determine the percentage of yield.

Microbial and sensory analysis

Microbiological analysis was done on the sample using AOAC 2015 method.

Sensory attributes were evaluated by a group of semi- trained panelists [both men and women (n=25)] using a 5-point Hedonic scale. The dehydrated mango was evaluated for its acceptability with reference to colour, flavour, texture, taste and overall acceptability, as described by Feldeisen and Tucker, 2007.

Data analysis

The I-optimal design module in Design Expert software (Version 13.0.1, Stat-Ease, Inc., Minneapolis, USA) was used to evaluate the data using a response surface methodology to study the interaction between the drying and different cultivars on specific attributes.

RESULT AND DISCUSSION

The pH and Sugar content (brix) of the starting fresh mango cultivars is shown in Figure 1 and 2. Kent had the highest pH but no significant variation was observed among the cultivars while Tommy Atkins had the highest sugar content with no significant variation among the cultivars. The quantity of dried mango after drying showed that Saigon had the highest (Table 1) while Haden had the least quantity, this could be as a result of the ripening stage. The further the maturation, the higher the water content and the water loss after dehydration. Also, the fibre quantities of the cultivars were different but the yields were not significantly different. The moisture content of the cultivars after dehydration will also contribute to the final weight and yield. Cultivar with higher yield after dehydration will be of advantage for the industry. Significant variation was observed among the yield of the cultivars. The moisture content of the dehydrated mango slices ranged from 9.12 and 12.89% (Figure 3), Lipenne had the highest while Haden had the least. Significant variation was observed in the moisture content.

The level of moisture in the slices could account for the shelf stability of the slices. It is known that moisture level above 12% reduces storage time of products. The level of moisture in the samples were lower than 12% except for Lippene hence the samples were expected to have a better storage life.

Table 1: Percentage yield of mango cultivars after dehydration

Cultivar	% yield
Lippenne	18.17
Saigon	19.65
Haden	16.04
Ogbomoso	16.33
Kent	16.33
TommyAtkins	17.92
Edward	18.13
LSD	1.63

Values were mean of triplicate

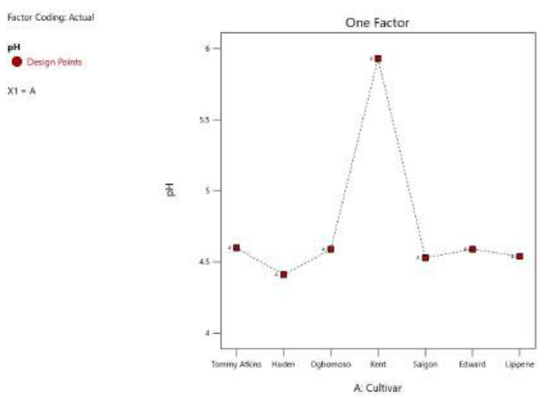

Figure 1: pH of the fresh mango cultivars

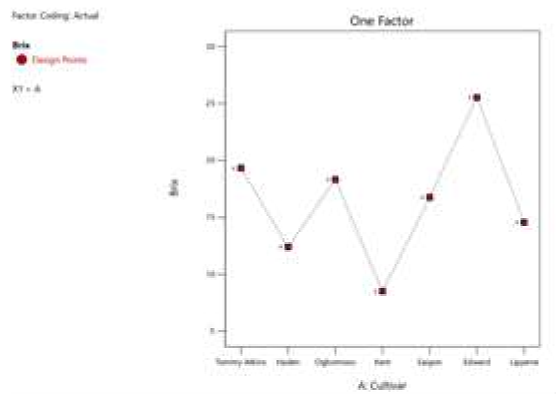

Figure 2: sugar level of the fresh mango culltivars

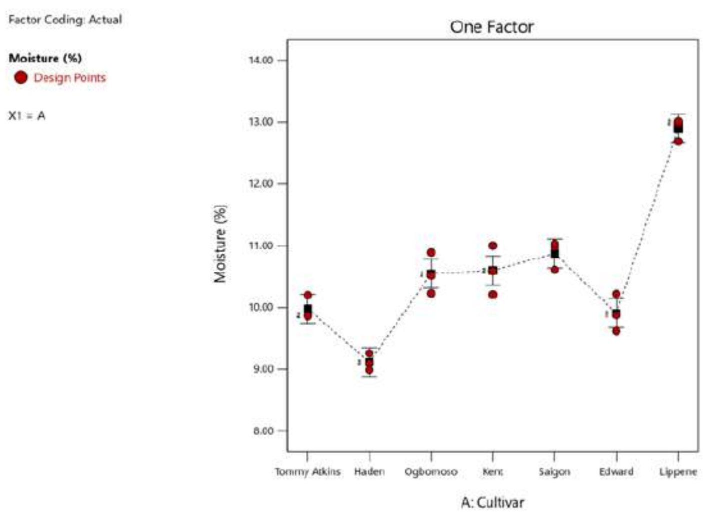

Figure 3 : Moisture content of dehydrated mango cultivars

The result of the microbial evaluation (Table 2) showed no presence of bacterial, coliform and fungal growth after dehydration. This confirms the ability of dehydration process to ensure safe products.

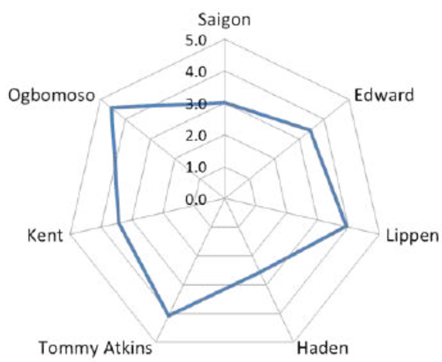
Table 2: Microbial enumeration of dehydrated mango samples

Cultivar	TOTAL BACTERIA COUNT (cfu/g)	TOTAL COLIFORM COUNT (cfu/g)	TOTAL FUNGI COUNT (cfu/g)
Saigon	NG	NG	NG
Kent	NG	NG	NG
Lippenne	NG	NG	NG
Edward	NG	NG	NG
Ogbomoso	NG	NG	NG
T. Akins	NG	NG	NG
Haden	NG	NG	NG

NG – No Growth

Sensory evaluation

The sensory evaluation showed Ogbomoso was the most adjudged (figure 4a-e) in terms of colour, taste and overall acceptability while Tommy atkins were best adjudged for flavour and Texture. This might be because of the varying chemical composition of the cultivars that resulted in the preference in the attributes.



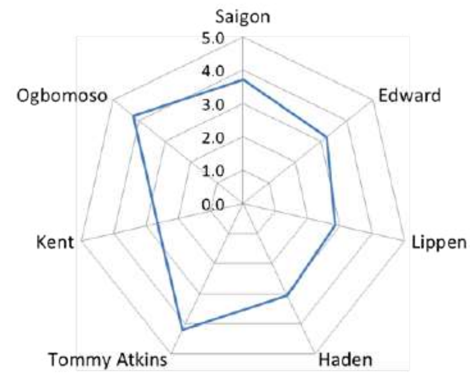


Figure 4a : Sensory evaluation of colour of mango dried Slices **Figure b : Sensory evaluation of flavour of mango dried Slices**

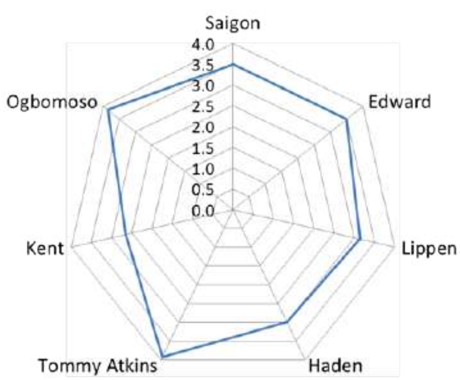

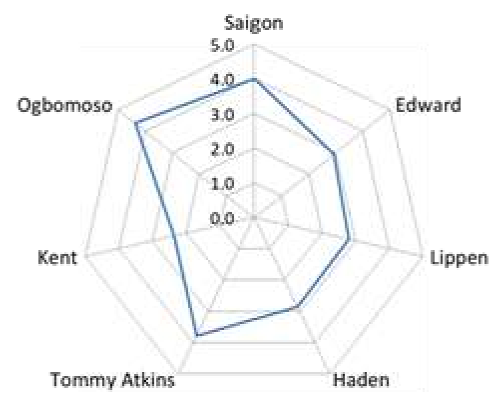

Figure c : Sensory evaluation of texture of mango dried Slices Figure d : Sensory evaluation of taste of mango dried Slices

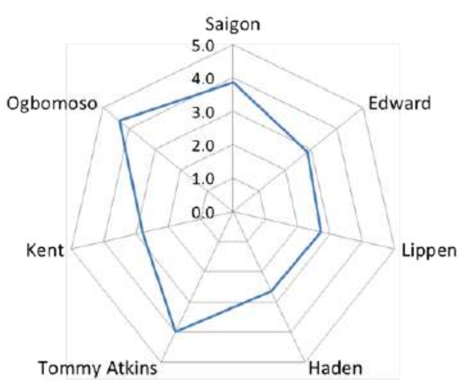

Figure e: Sensory evaluation of overall acceptability of mango dried Slices

CONCLUSION

The cultivars had varying yield and sensory perception/ preferences after dehydration, Saigon had the highest yield which is of advantage to producers of dehydrated slices. However, Ogbomoso cultivar had highest sensory scores in most of the attributes as well as the overall acceptability which is very important in the marketing of the product. Hence, Ogbomoso is recommended for processors to have consumers acceptance and market for the dehydrated slices.

ABSTRACT
An experiment was conducted at Organic farm of Federal college of Agriculture, Ibadan to evaluate effect of different sources of organic fertilizer on the performance of Jute fiber. The experiment was laid in a Randomized Complete Block Design (RCBD) with five treatments replicated three times. The treatment applied at the rate of 45 kg N /ha were: horse dung, Poultry droppings from battery cage, Poultry droppings from deep litter, Cow dung and Control. The variety of seed used was V.35 The parameters taken were, plant height, stem girth, weight at maturity and yield of fibre. The data collected were statistically analyzed the significant means were separated using Duncan Multiple Range Test (DMRT) at 5% level of probability. The result showed that plants of cow dung gave a fibre yield of 0.9g which was not statistically different in weight from those of poultry droppings from deep litter house (0.73g) hence, poultry droppings from a deep litter house is recommended due to its availability.
Keywords: *fibre, jute, droppings, poultry*

INTRODUCTION.

Jute (Corchorus Spp), also called Jew's mallow, bush okra, nalta jute, or jute mallow, the annual herbaceous crop is cultivated as a source of jute fibre and for its edible leaves (Akoroda, *et al.,* 2008). The use of jutta potta cloth was mentioned both in the Bible and Monushanghita-Mahabharat. This indicates the ancient uses of jute materials by the people of these areas (Alim,1978; Islam and Rahman, 2008). The vegetable is cultivated for the stem bark which is used for the production of fibre (Zakaria *et al.,* 2005a). The quest for improvement of soil fertility led to the use of organic manure to improve crop production. Animal manure plays a vital role in soil fertility maintenance due to its intrinsic value as a soil amendment (Williams *et al.,* 1993). The capacity of the manure provides nutrients especially N P and K is one of such benefits. It also increases in cation exchange capacity soil moisture, soil organic matter nitrogen, Phosphorus, pH and reduced soil exchangeable acidity Ano and Agwu (2005), Mbah (2006). However, the release of these nutrients to the plants differ from the various sources of manure for instance, Izunobi (2002), reported that chicken manure, especially those produced in deep litter or battery cage house are the richest known farmyard manure supplying greater amounts of absorbable plant nutrient. Looking at the importance of jute mallow and its benefits, it therefore becomes imperative to consider improving the fertility of the soil for its cultivation, hence the aim of this study.

MATERIALS AND METHODS

The field experiment was conducted at the college organic farm of Federal College of Agriculture Moor Plantation, Ibadan Oyo state. The experimental site is situated at Latitude 7° 24' 3" and Longitude 3° 51' 9". The mean annual rainfall pattern is bimodal. The maximum temperature is about 30.5°c while the minimum temperature is about 21°c.

Land preparation and Experimental Layout

The experimental land was prepared manually, after which the soil was tilled with hoe. Pre- cropping composite soil sample was collected at 0-15cm depth, this was air - dried, sieved with 2 mm diameter mesh , bagged, labelled and taken to the laboratory for analysis. The gross plot size was 96m² which was divided into of three replicates of 2×6 m² (12m²) and each replicate was divided into 5 sub plots of 2×2 m². There was 0.5m furrow between plots and 1m between replicates. Seeds were sown with intra spacing of 5cm and inter row spacing of 20 cm.

Experimental design and treatment

The experiment was laid out in a randomized complete block design (RCBD), with five treatments replicated three times. The treatments were: T 1: horse dung (HD), T2: Poultry droppings from battery cage (PDBC), T3: Poultry droppings from deep litter (PDDL), T4: Cow dung (CD), T5: Control

The various dungs were applied to the soil at the rate of 45kgN/ ha thoroughly spread and mixed with the soil two weeks before planting the viable seeds of corchorus olitorius (Jute mallow)

Cultural practices

Cultural practices carried out include weeding, watering, application of pesticides (Dried Pawpaw leaves were used to prepare pesticide which was applied once every two weeks at the rate of 36 ml/ ha) to combat the attack of caterpillars on the growing jute plant.

Harvesting and Retting

At 16 weeks after sowing, harvesting of jute stems took place by uprooting the whole plant and retting process took place. The harvested stems were retted by soaking them in water for 14 days, thereafter, they were brought out of the water rinsed and beaten with mallet, remove the outer bark and they were then dried and combed out and weighted with a sensitive weighing scale.

Data collection and analysis

Data collections commenced two weeks after sowing, which includes: Plant height(cm), Stem girth(cm), weight of the harvested jute and processed jute fibre. Data collected were taken for statistical analysis using analysis of variance (ANOVA) and the significant means were separated using Duncan multiple range test (DMRT) at 5% level of probability.

RESULTS AND DISCUSSION

Pre- cropping physical and chemical properties of the soil

The result of the physical and chemical properties of the soil used for the experiment is presented in Table 1. It showed that the soil was slightly acidic with pH of 5.03. Total Nitrogen was very low (0.23%), compare to the standard value of (1.6-2) available phosphorus (10.69 mg/ kg) compared to standard value of (7-20) was within range and organic carbon (0.73%) compared to standard value of (1.0-14) was low exchangeable base: potassium, calcium, magnesium and sodium of the soil ranges from 0.03- 1.75 and 2.10 cmol /kg, the texture of the soil was sandy loam.

Nutrient composition of various manure sources used for the experiment

The result of the nutrient composition of the various manure used for the experiment is presented in table 2. Poultry manure from battery cage has Nitrogen content of 0.367, poultry manure from deep litter house has Nitrogen content of 1.63, cow dung has Nitrogen content of 1.23 while horse dung has Nitrogen content of 1.61.

Effect of organic manure on plant height of jute mallow (cm)

The result of the effect of different sources of organic manure on plant height of jute mallow is presented in table 3. At 2WAS, there were no significant differences among all the treatments. At 3WAS It was observed that jute mallow treated manure from battery cage was taller significantly than others (35.56cm) except those treated with dung from deep litter house (29.67cm). However, jute mallow treated with horse dung (22.78cm), cow dung (18.70cm) and manure from deep litter house (29.67cm) were not significantly different from each other in height but significantly taller than control (14.50cm). At 4WAS It was observed that jute mallow plant treated with organic manure from deep litter (57.64cm) was taller significantly than those of horse dung (22.78cm) but at par with those treated with manure from battery cage (50.25cm), and cow dung (56.92cm). However, those treated with cow manure, horse dung and those of control were not significantly different from each other. At 5WAS plants from deep litter manure were significantly (69.67cm) taller than control (33.37cm) but at par with those of battery cage (68.38cm), cow dung (56.00) and horse dung (56.92). The result of this experiment buttresses the work of Izunobi (2002) who reported that chicken manure, especially those produced in deep litter or battery cage house are the richest known farmyard manure supplying greater amounts of absorbable plant nutrient.

Effect of organic manure sources on stem girth (cm) of jute mallow

The result of effect of organic manure sources on stem girth of jute mallow is presented in table 3. At 2WAS, Plant treated with organic manure were significantly higher in girth than control experiment. At 3WAS it was observed that jute mallow treated with organic manure from deep litter was higher significantly (1.31cm) than others except those treated with cow dung (1.07) which in turn was not significantly different from those of battery cage (0.60). Also, plants treated with horse dung (0.49) and control experiment (0.22cm) were statistically similar in girth. At 4WAS it was observed that there were no significant differences among all the treatments except plants from control experiment which had the lowest stem girth (0.48cm). the same trend was observed at 5 WAS. This result might due to the fact that nutrients are easily been released for crop utilization with application of organic manure. Brady, (1999), also opined that, organic manure mineralizes; hence it releases its nutrients for plant uptake and utilization rapidly.

Effect of organic manure on weight at maturity (kg) of jute mallow

The result of effect of various organic manure on weight of jute mallow at maturity is presented in table 4. At maturity it was observed that there were no significant differences among all the treatments. However, jute mallow treated with organic manure from deep litter house had the highest weight (0.40kg) while control experiment (0.10kg) had the lowest.

Effect of organic manure sources on yield of jute fibre (g)

The result of effect of organic manure on yield of jute fibre is presented in table 8, it was observed that jute mallow treated with cow dung gave the highest fiber (0.90g) which was not statistically different from those of deep litter house (0.73) and those of horse dung (0.50) while control experiment had the lowest fibre yield (0.10g). However, jute mallow treated with battery cage (0.47g) and horse dung (0.50g) were not also different significantly from each other in terms of fibre yield but were lower in yield. The effect of litter mixed with the droppings which generates more ammonia and hence more nitrogen could be the reason why manure from deep litter house and the ones from cow dung gave plants with more yield in fibre than those of battery cage house. Researches have also opined that, there is enormous loss of ammonia in the battery cage house which makes the manure to have less nitrogen compare to those in deep litter house Amanullah *et al*., (2010).

CONCLUSION AND RECOMMENDATION

The experiment showed that the use of cow dung or poultry manure at the rate of 45 kg N/ ha was better for production of jute fiber as compared to other sources of organic manure used in this experiment However, poultry manure from deep litter house is recommended due to its availability to farmers.

ABSTRACT
There is a need to educate people about the production of some ephemeral crops at household levels to serve a secure source of nutrient that it is economically accessible, safe, and nutritious to meet man's dietary needs and food preferences for an active and healthy life. Tigernut is one of the nutritious ephemeral crops that can be produced at the household level with little production factors. This nut plays a vital role in the supply of minerals and vitamins for healthy living. A pot experiment was conducted at Lagos State University of Education Oto/Ijanikin Teaching and Research Farm, Epe campus. NPK 15-15-15 fertilizer and cow-dung were applied at 0, 5 g plus 10, 15, and 20 g cow-dung were mixed and applied per 5kg of soil; cow-dung. There were four levels of application; NFA = No fertilizer application, FA L_1 = 5 g NPK + 10 g cow-dung, FA L_2 = 5 g NPK + 15 g cow-dung, and FA L_3 = 5 g NPK + 20 g cow-dung. Which were replicated three times. The experimental pots were arranged in a completely randomized design under field conditions. The results showed that NPK + Cow-dung application at FA L_1 and FA L_3 (FA L_1 = 5 g NPK + 10 g cow-dung and FA L_1 = 5 g NPK + 30 g cow-dung) have the optimum tiger nut yield. The growth parameters such as; the number of leaves and tiller were not of any high significant difference especially at four and ten weeks after sowing (4 and 10 WAS). The results showed that the mixture of cow dung with NPK fertilizer increased the nut yield of tiger nuts. In conclusion, it can be recommended that a combination of NPK and cow dung is a suitable form of soil amendment for tiger nut production for household consumption of minerals and other essential nutrients needed for the household.
Keywords: *Cow-dung, NPK, tiger nut, household, mini-production*

INTRODUCTION

Nutritional security is a critical concept, defined as "a situation that exists when all people, at all times, have physical, social, and economic access to sufficient, safe, and nutritious food that meets their dietary needs and food preferences for an active and healthy life" (USDA, 2017). This concept extends beyond the notion of food security, as articulated by the FAO (2020), by considering not only the availability of food but also its nutritional value and the systemic factors that influence an individual's nutritional status. It underscores the importance of a community's access to essential nutrients, not just calories. To address food security comprehensively, requires a holistic approach, commencing from the production and storage systems and encompassing the transportation and distribution of food systems. Such an approach not only ensures food security but also holds the potential for improving diets and health with minimal impact on natural resources (FAO, 2020).

Diet quality serves as a pivotal link between food security and nutritional outcomes and must be a central component of all efforts aimed at achieving the hunger, food security, and nutrition targets of Sustainable Development Goal 2 (SDG 2). Meeting these targets hinges on ensuring that individuals not only have enough food to eat but also that the food they consume is nutritionally adequate (FAO, 2020).

The intricate relationship between food security and nutrition becomes evident in the various manifestations of malnutrition resulting from food insecurity. The quality of the diet consumed plays a central role in this connection. Research has identified that food insecurity is associated with an elevated risk of diverse health issues, including birth defects, anemia (Carmichael *et al*., 2007), reduced nutrient intake, cognitive impairments, aggression, and anxiety (Howard, 2011). Therefore, establishing sufficient access to nutrient-dense foods, such as tiger nuts, through enhanced cultivation and availability becomes a matter of utmost significance.

Tiger nuts, also known as "underground walnuts," hold immense potential as a global food source due to their high yield and wide-ranging applications. Tiger nuts are small tubers of Cyperus esculentus L., which can be consumed fresh, roasted, or raw and are used in various food and beverage preparations, including the popular "horchata de chufa" in Spain (Rubert *et al*., 2011). Despite their widespread cultivation, research on tiger nuts remains limited, constraining their full utilization (Adejuyitan, 2011). Notably, tiger nuts boast a rich nutritional profile, containing lipids, proteins, starch, fibers, and bioactive substances such as organic acids, alkaloids, and phenols (Adel *et al*., 2015). Tiger nut oil, in particular, is akin to olive oil in terms of nutritional value (Roselló-Soto *et al*., 2018). Additionally, tiger nuts are a valuable source of dietary fiber, which aids in preventing colon cancer, obesity, and gastrointestinal disorders (Viuda-Martos *et al*., 2010), and they possess antioxidant properties due to their flavonoid content (Jing *et al*., 2015).

The annual value of tiger nut production in certain regions, such as Spain, is substantial, totaling approximately 3.3 million Euros (CRDO, 2012). In recent years, the popularity of tiger nuts has transcended geographical boundaries, making their way to countries like the United Kingdom, France, Portugal, Argentina, and the United States of America (Rubert *et al*., 2011). In Nigeria, tiger nuts are cultivated primarily in the middle belt and northern regions, where they are locally sold and widely consumed. Their adaptability to diverse climates and soils, coupled with their nutritional richness, positions tiger nuts as a promising crop for improving food security and nutrition. However, there is limited information available on organic cultivation practices for tiger nuts in Nigeria, given their historical status as a wild grass underutilized in agricultural contexts (Adgidzi, 2010).

Tiger nut cultivation thrives in conditions characterized by moderate sunshine, normal temperatures, and well-drained soil with high organic matter content. The tubers typically grow to depths of about 30 cm, although a significant proportion is found at shallower depths, around 10 to 20 cm (topsoil) from the parent plant (Oladele *et al*., 2013). To optimize tiger nut yields, the use of organic practices, including compound compost and other agronomic strategies, is essential, as fertilizer recommendations remain limited and sometimes contradictory (Yarrow and Yarrow, 2005). Given the increasing cost and environmental concerns associated with chemical fertilizers in Nigeria, organic alternatives, such as poultry manure and cow dung, have gained prominence for enhancing soil health and fertility. Cow dung, in particular, is noted for its rich nutrient content and minimal foul odor, making it a viable option for sustainable agricultural practices (Ewulo, 2005).

In light of tiger nuts' health benefits, versatility in production, and the nutrient content of cow dung, there is a pressing need to investigate the effects of a mixture of NPK fertilizer and cow dung on tiger nut cultivation at the household level. This trial aims to promote the availability of essential minerals and vitamins from tiger nuts for households and evaluate their growth and yield performance under these conditions. Therefore, the concept of nutritional security emphasizes the importance of not only food availability but also the nutritional quality of food. Tiger nuts, with their rich nutrient profile, hold promise as a nutritious food source. Research and experiments in tiger nut cultivation, particularly utilizing organic practices and alternative fertilizers, are essential for enhancing food security and nutrition.

METHODOLOGY

This study was carried out at Lagos State University of Education Teaching and Research Farm, Noforija, Epe, Lagos State. Fifteen (15) experimental units consisting of a container of 5kg capacity filled with sand-loamy soil were arranged in a Completely Randomized Design with three (3) replications, leaving an alley of 1m between rows and 1.0m between the pots; for easy access.

Composite soil samples were taken (0 – 15 cm, depth) from the University Teaching and Research Farm, air dried, sieved and sample taken for laboratory analysis. The soil was distributed into 5kg experimental pots and the fertilizer mixtures were applied 2 weeks before sowing. There were four (4) levels of fertilizer application (treatments) using NPK 15-15-15 fertilizers and cow dung.

The application rates or levels are:

a. NFA = No fertilizer application,
b. FA L_{1} = 5 g NPK + 10 g cow-dung,
c. FA L_{2} = 5 g NPK + 15 g cow-dung,
d. FA L_{3} = 5 g NPK + 20 g cow-dung.

The experiment was manually irrigated throughout except on rainy days. Data collected include; plant height, number of leaf and plant tillers, and at harvest the fresh nut weight, and numbers of nuts. All data were subjected to Analysis of Variance (ANOVA, pr $\leq_{0.05}$) significant treatment means were separated using Duncan Multiple Range Tests (DMRT).

RESULTS AND DISCUSSION

The soil used for the experiment was slightly acidic with a pH of 6.4, moderately low in organic carbon, and low in nitrogen concentration, Moreover, the available P, was high and the exchangeable K, Ca, and Na were low with Mg of 2.8 cmol kg^{-1}. The soil particle size distribution shows that it was sandy loam. Considering these parameters, the soil of the experimental site was low in fertility and could not sustain or enhance the full potential capacity for tiger nut yield without fertilizer amendment (Table 1).

At 4 weeks after sowing the plant height was not significantly different under all the fertilizer applications, however, the least plant height was observed under NFA. Similar trends were observed at 8 and 10 weeks after sowing (Figure 1). Under the applications of the mixture of these fertilizers, at 10 weeks after sowing, there was no significant difference in the number of plant tillers, except under NFA where the least number of tillers were observed. However, at 8 weeks after sowing, the number of tillers was not significantly different under the applications; NFA, FA L_1 and FA L_2 but was significantly different at 10 weeks after sowing under the FA L_3 application (Figure 2)

The level of NPK applied to the tiger nut has significant effects on the number of leaves at 4, 8 and 10 weeks after sowing, however, this effect was not pronounced on the number of plant tillers at 4 and 8 weeks after sowing when compared, but, at 10 weeks (10 WAS), there was a significant increase when compared to number of tiller at 8 weeks after sowing (8 WAS). Under NPK application at; FA L_1 (Fertilizer level 1), tiger nut plant leaf increased throughout but was observed to reduce compared to the performance recorded under both NFA and FA L_2 (Fertilizer level 2). This shows that an increase in NPK fertilizer application reduced the number of leaf production of tiger nuts (Figure 3).

At 4, 8 and 10 WAS; weeks after sowing, there was no significant difference in the number of leaves recorded under NFA; no fertilizer application and a similar trend was observed under (FA $L_{2\ \&\ 3}$) at 8 and 10 weeks after sowing. However, under FA L_1, at 8 and 10 weeks after sowing there was a significant difference but not high when compared with the number of leaves under FA L_3 at 8 and 10 weeks after sowing (Figure 3).

Generally, the plant height at 4 WAS (weeks after sowing) was not significantly different under all the 2 fertilizer application levels, whereas, at 8 WAS, the highest value was observed under (FA L_2) which was not significantly different from plant heights recorded under (FA $L_{1,2\ \&\ 3}$) at 10 WAS when compared, but significantly higher when compared with NAF; no fertilizer application (Figure 2).

The highest nut yield was observed under fertilizer application level 1 (148 g/pot) which was not significantly different from the yield obtained under the application of NPK and cow-dung (FA L_3). The number of nuts per application followed the same pattern, showing that the higher the number of nuts the greater the weight. However, this did not apply to the number of nuts under no fertilizer application (NAF) and application level 3(FA L_3) where the fresh nut weights ranged from 20 - 40 nuts per pot (Figure 4).

CONCLUSION AND RECOMMENDATIONS

Tigernut is a proven crop in terms of its nutrition, economic benefits and flexibility for cultivation at any level with common resources. It can be consumed in a variety of forms and it is quite affordable. This research looked into addressing nutrition security through the enhancement of the cultivation and availability of tiger nuts for all households at easy form. It can therefore be concluded that tiger nut production and availability can be enhanced through the use of a mixture of both cow-dung and NPK 15-15-15 to improve small or micro tigernut production. The choice of cow dung as fertilizer results from its availability and minimal foul odor compared to other organic fertilizers.

Based on this conclusion, it is therefore recommended that:

1. Households or farmers should be encouraged to cultivate tiger nuts to increase tiger nut availability in the market.
2. Necessary inputs such as fertilizers with data on their application rates should be provided through all farmers' platforms for use.
3. Adequate extension services should be embarked upon to ensure the right information on the benefits of tiger nut cultivation among households.

Table 1: Chemical and physical properties of the soil used

Parameters	**Values**
pH (Cl)	6.4
Organic C (g kg^{-1})	1.4

PHYTOCHEMICAL SCREENING, ANTIOXIDANT ACTIVITY AND SENSORY EVALUATION OF TEA FROM AVOCADO (*PERSEA AMERICANA*) SEEDS AND LEAVES

***Olatunji O.A., Ademoyegun O. T. and Rapheal, D. O.**
Product Development Programme, National Horticultural Research Institute, Ibadan.

*Corresponding author: onaola.olatunji@gmail.com

ABSTRACT

Avocados are a potential source for natural medications because of their abundant phytochemicals. These components, with their antioxidant benefits, make avocado herbal tea a rich source of nutrients capable of combating degenerative diseases. In order to evaluate its medicinal potential and generate a valuable product, this study compares tea from avocado leaves (AVL) and seeds (AVS) with La Botti Herbal tea (LBT) and Lipton Calming Chamomile (LCC). The phytochemical screening of the tea infusions showed the presence of flavonoids, saponins, and glycosides in all the samples. AVS is the only sample containing alkaloids. Tannin is present in all the samples except AVS. Among all the samples, AVL showed a distinct composition of Vitamin C, total phenol, total flavonoid content, and 2,2-diphenyl-1-picrylhydrazyl (DPPH) radical scavenging activity. Similarly, AVL possesses distinct sensory attributes and ranks as the most preferred tea sample.

Keywords*: antioxidants, phytochemicals, natural medicine, tea infusion, degenerative diseases*

INTRODUCTION

Plant-based remedies are a cost-effective and less harmful alternatives to synthetic medicines. They are rich in biologically active components and offer the potential for developing novel pharmacological substances (Rouhi-Boroujeni *et al.,* 2015). Among plant species, avocado (*Persea americana*) has been established as a potential natural medicine source due to its diverse phytochemical composition. The fruit is grown in the tropical and subtropical regions of the world for its food and medicinal purposes (Tremocoldi *et al*., 2018; Gupta *et al*., 2018). Avocados are rich in fiber, protein, carbohydrates, sugar, and starch. The fruit is particularly rich in protein, containing about 1–3%, a value higher than that reported in most fruits. Avocadoes are also rich in vitamins, pigments, sterols, and phenolic compounds. (Duarte *et al*., 2016; Tabeshpour *et al*., 2017; Hurtado-Fernández *et al*., 2018; Gupta *et al*., 2018).

The bioactive substances present in avocado exhibit a range of biological actions that can be linked to their antioxidant properties (Tabeshpour *et al*., 2017; Gupta *et al*., 2018; Loh and Lim, 2018; Anwar *et al*., 2022). The peel, seed, and leaves of the avocado plant, however, are often discarded as waste (Tremocoldi *et al*., 2018). The formulation of tea infusions has therefore been proposed as an effective way of utilizing these plant by-products with high phenolic content (Danacioglu and Pekel, M., 2021). The aim of this study was therefore to prepare nutrient-rich herbal tea from avocado seeds and leaves, thereby offering a cost-effective and valuable product, and to compare the prepared formulations with known herbal teas to establish their therapeutic potential.

MATERIALS AND METHODS

Fresh, mature, dark green leaves of avocado plant were collected from the National Horticultural Research Institute in Ibadan. The leaves were washed briefly and blotted dry. Seeds of avocado fruits obtained from Bodija market in Ibadan were removed, washed, and crushed with a manual grater. Samples were dried in an Excalibur Model 4926T Food dehydrator at 50°C.

Extraction Procedure

Tea infusions were prepared using the method of Komes *et al.*, (2010) with modifications. 2g of the sample was boiled in 200 mL of distilled water at 100^{o}C for 5 minutes.

Phytochemical Screening

Tannin and saponin content was determined by the method described by Abulude *et al*., (2022). Glycoside content was determined using the method of Emmanuel and Sani, (2018). Wagner's test for alkaloids was carried out following the method described by Jha *et al*., (2012) and screening for flavonoid content was carried out using the method described by Hossain *et al*., (2013).

Total Phenolic and Flavonoid Content and Vitamin C Content

The total phenolic content using the Folin-Ciocalteu method and total flavonoid content were determined as described by Hossain *et al*. (2013) with modifications. The vitamin C content of the samples was determined using the method of Ikanone *et al*. (2014) with modifications.

Determination of Antioxidant Activity

2, 2-diphenyl-1-picrylhydrazy (DPPH) free radical scavenging assay was carried out using the method described by Patil *et al*., (2015) with modifications.

Sensory Evaluation

On a 5-point hedonic scale, where 1 = dislike extremely, 2 = dislike moderately, 3 = neither like nor dislike, 4 = like moderately, and 5 = like extremely, the sensory evaluation of the freshly brewed tea infusions was carried out by 25 trained panelists. Each panelist received 40 mL of the coded samples to assess its colour, flavor, taste, body and overall acceptability.

Statistical Analysis

The tests were carried out in triplicate. The results were all analyzed in Statistical Package for Social Sciences (SPSS) using one-way analysis of variance and Duncan's Multiple Range Test. The differences were regarded as statistically significant at $p < 0.05$

RESULTS AND DISCUSSION

The results of the phytochemical screening of the tea extracts are presented in Table 2. All the samples contain flavonoids in high concentrations. AVL and LBT contain equal amounts of saponin similarly, AVS and LCC contain equal amounts of saponin. Alkaloids were detected only in AVS, and at low concentration. Glycosides were detected in moderate concentrations in AVS and in low concentrations in the remaining samples. Tannin was not detected in the AVS sample but in other samples with LBT having the highest concentration.

Chemical Properties and Antioxidant Capacity of the Tea Samples

Vitamin C content, total phenolic, and total flavonoids content were analyzed to explain the chemical profile of the tea samples. The results are presented in Figure 1 (b), (c) and (d) respectively. Tea from avocado leaves (AVL) showed a higher content of these components than tea from avocado seed (AVS), La Botti (LBT) and Lipton Calming Chamomile (LCC) samples. For vitamin C content {Figure 1 (b)}, AVL had the highest value of 6.44±0.35 mg/100g. There was however no significant difference at $p <$ 0.05between the LBT (6.09±0.01 mg/100g) and LCC (6.04±0.42 mg/100g) samples while AVS had the lowest value of 5.18±0.50 mg/100g. For the total phenolic content of the samples {Figure 1 (c)}, AVL had the highest concentration of 0.83 ±0.50 mg GAE/100g. This is in agreement with the report of Yamassaki *et al*. (2017) where the amount of phenolic compounds in avocado leaf extract was higher than the levels found in tea, mulberry, blackberry, raspberry, and strawberry leaves. There was no significant difference among AVS (0.08 ±0.01 mg GAE/100g) LBT (0.07 ±0.00 mg GAE/100g) and LCC (0.06 ±0.00 mg GAE/100g). The total flavonoid content showed a significant difference among all the samples in the order AVS (6.25 ±0.80 mg CAT/100g) >AVS (1.14 ±0.80 mg CAT/100g) > LCC (0.43 ±0.04 mg CAT/100g) >LBT (0.20 ±0.02 mg CAT/100g)

DPPH Radical Scavenging Capacity of the Tea Samples

Figure 1 (A) presents the percentage of DPPH radicals that avocado leaves and seeds can scavenge, along with a comparison to other two tea brands. The radical scavenging ability of avocado leaves (AVL) and La Botti Herbal (LBT) tea were significantly higher ($p < 0.05$) than the remaining tea samples. Avocado seed (AVS) had the lowest radical scavenging activity of 40.01%. The value obtained is similar to that reported by Abubakar and Khaerah (2022). These findings indicate that avocado seeds and leaves could serve as natural antioxidant source thereby lowering oxidative stress associated with the development of degenerative disorders.

The results of the sensory attributes of the tea samples are presented in Table 2. There was no significant difference in the color of AVL, LBT, or LCC. AVS, however, received the lowest score. The flavor of AVL is similar to that of LBT. LCC, however, has the lowest score but is statistically similar ($p < 0.05$) to AVS. The taste score was in the order: AVL > AVS > LBT > LC. There was no difference between the tastes of AVL and AVS. Similarly, there was no difference in the taste of AVS, LBT, or LCC. There was no significant difference in the body of the tea sample, and this further confirms that the extraction method described by Komes *et al.* (2010) was acceptable. The overall acceptability score showed that AVL is the most preferred. The sample also compared similarly with AVS and LBT samples. Results also showed similarity among AVS, LBT, and LCC.

Table 1: Phytochemical Constituents of Tea Infusion

Phytochemical	AVL	AVS	LBT	LCC
Saponin	+++	++	+++	++
Tannin	++	-	+++	+
Alkaloids	-	+	-	-
Glycosides	+	++	+	+

CONCLUSION

This study indicated that the development of tea from avocado leaves and seeds resulted in products with pharmacological potential for the treatment of degenerative diseases. This can be attributed to the phenolic, flavonoid, and vitamin C content of avocado leaves and seeds, which confer significant antioxidant activity on these tea samples. The findings also showed that the bioactive components of the avocado tea are similar to those of the well-known and established La Botti Herbal Tea and Lipton Calming Chamomile brands. The sensory study of the avocado tea samples further revealed that it has a beneficial effect on the consumer market.

ABSTRACT

Response of four varieties of cucumber (Cucumis sativus L.) in terms of growth and fruit yield to different types of fertilizer was investigated in a field trial at the National Horticultural Research Institute (NIHORT) Ibadan. The experiment was a 4 × 4 factorial laid out in split plot arrangement with three replicates comprising of the following treatments: variety (poinsett, marketer, marketmore and greengo) and types of fertilizer (control, 100 kg N ha^{-1}organic, 100 kg N ha^{-1} inorganic fertilizer and 1 litre ha^{-1} foliar fertilizer). Growth and yield parameters such as vine length, number of leaves, number of fruits per plant and fruit yield per hectare were investigated and subjected to statistical analysis using the analysis of variance (ANOVA) with the split plots model and significant means were separated using the least significant difference at 5% probability level. The results revealed that the investigated parameters reacted differently to the treatments. It can be recommended from the study that for increased plant growth and fruit yield, greengo cucumber variety should be cultivated with 1 litre ha^{-1} of foliar fertilizer.

Keywords: *Fertilizer, organic, inorganic, foliar, fruit yield.*

INTRODUTION

Cucumber (*Cucumis sativus* L.) is one of the most popular members of Cucurbitaceae (vine crop) family. It is cultivated for fresh fruit which are locally consumed or exported to increase national income. The crop is cultivated in most parts of Northern and Eastern Nigeria. Cucumber (*Cucumis sativus* L.) is thought to be one of the oldest vegetables cultivated by man with historical records dating back 5,000 years (Wehner and Guner, 2004). The crop is the fourth most important vegetable after tomato, cabbage and onion in Asia (Tatlioglu *et al.,* 1993), though its place has not been ranked in tropical Africa because of its limited use. Cucumber is rich in vitamins, calcium, magnesium and other essential nutrient element. In spite of the increasing relevance of cucumber in Nigeria, low yields are obtained in farmers' fields because of declining soil fertility due to continuous cropping and disregard for soil amendment materials. Many studies of various crops have shown significant advantages of applying inorganic fertilizers (Akinrinde, 2006).

Application of fertilizer is one of the ways of improving soil fertility and final yield of crops. Belay *et al*. (2001), Eifediyi and Remison (2010) in their various studies on nutrient requirements of cucumber reported that cucumber responded positively to organic, inorganic or combined nutrient applications for optimum growth and productivity. Scientists seek an alternative means to enhance soil nutrient which is environment friendly and has no lethal effect on the soil. Therefore, the use of liquid fertilizer (which is believed to be organic) was introduced as a panacea to this problem. The objective of this study was therefore to determine the varietal response of cucumber to different fertilizer types.

MATERIALS AND METHODS

The field experiment was conducted at the vegetable research farm of the National Horticultural Research Institute (NIHORT), Idi - Ishin, Jericho, Ibadan (3° 56` E and 7$^0$ 33` N at 168 m above the sea level). The monthly rainfall distribution pattern for Ibadan is bimodal with peaks in June and September. Annual rainfall ranges from 1250 and 1500 mm spanning eight months (March to October) with dry spell in August .The field was ploughed and harrowed twice each to give well pulverized surface. The land area was measured and pegged into three replicates consisting of sixteen plots each, and total of forty eight plots in all. The area of each plot was 4 m^2, separated by alleyways of 1 m between plots. The experiment was designed as a 4 x 4 factorial in a split plots design. Each factorial combination of the factors was replicated three times. The main plots consisted of four varieties of cucumber (Greengo, Poinsett, Marketer and Marketmore). The sub-plots were made up of the control, 100 kg N ha^{-1} inorganic, organic, and 1 litre ha^{-1} foliar fertilizer**.** Two viable cucumber seeds were planted per hill at the depth of 2 cm at the plant spacing of 50 x 50 cm and thinned out to one plant two weeks after planting (WAP). Data collection commenced six weeks after planting. Ten plants were tagged in each plot from which data taken on them were calculated on the average. Vine length, number of leaves per plant, number of fruits per plant and yield per hectare were all determined in this present study. The data collected were subjected to the analysis of variance (ANOVA) using Genstat Discovery for Statistical Package (2014). Means were separated using the Least Significant Differences (LSD) at 5 % probability level ($LSD_{0.05}$)

RESULTS

Results in table 1 revealed that foliar fertilizer application at the rate of 1 litre ha^{-1} produced the longest vine which was significantly higher than those obtained from the same application rate of inorganic, organic and the control. The results also revealed that greengo variety had the longest vine which was significantly longer than that of the other varieties. Table 2 revealed that the number of leaves per plant increased significantly with different types of fertilizer from the control to foliar fertilizer. Foliar fertilizer application resulted in the highest number of leaves which was significantly higher than that of the others. Application of 100 kg N ha^{-1} organic fertilizer gave the number of leaves that was significantly higher than that of the control but significantly lower than that of foliar and inorganic fertilizer types. The results also revealed that greengo variety had the highest number of leaves which was significantly higher than that of the other varieties. There was no significant variation in the number of leaves produced by marketmore and marketer varieties in this present study.

Table 3 showed the effects of variety and types of fertilizer on the number of fruits per plant. Number of fruits increased significantly with foliar fertilizer resulting in the highest number of fruits per plant. Organic fertilizer application gave a value of the number of fruits per plant that was significantly higher than that of the control, but significantly lower than that of the foliar and inorganic application. Greengo variety produced the highest number of fruits per plant that was significantly higher than that of the other varieties, while marketmore variety gave the lowest number of fruits per plant that was significantly lower than that of the other two varieties.

The result as shown in Table 4 revealed that fruit yield ha^{-1}varied significantly with different fertilizer types. Foliar fertilizer application resulted in the highest fruit yield ha^{-1} which was significantly higher than that of the control, inorganic and organic fertilizer types respectively. The value of fruit yield produced by the application of inorganic fertilizer was significantly lower than that of the foliar but significantly higher than that of the control, and organic fertilizer types in this present study. Greengo cucumber variety produced the highest fruits yield ha^{-1} which was significantly higher than that of the others, while Marketmore cucumber variety produced the lowest fruit yield ha^{-1} which was significantly lower than that of other varieties in the experiment.

Table 1: Effects of variety and types of fertilizer on vine Length

Treatment	Vine Length (cm)
Variety	
Marketmore	134.02
Marketer	136.79
Pointsett	140.51
Greengo	144.92
LSD ($_{0.05}$)	1.23
Types of fertilizer (100 kg N $ha^{-1}$and 1 litre ha^{-1})	
Control	128.42
Organic	136.73
Inorganic	141.06
Foliar	143.75
LSD ($_{0.05}$)	0.73

Control	11564
Organic	13975
Inorganic	15752
Foliar	18643
LSD ($_{0.05}$)	189

DISCUSION

Cucumber vegetative and yield parameters (Vine length, number of leaves, number of fruit and fruit yield) were influenced by the different fertilizer types in this present study. The highest values were obtained from the application of 1 litreha^{-1} of foliar fertilizer, followed by inorganic and organic respectively, while zero application had the least value. The relative increase in cucumber yield and growth parameters for foliar fertilizer is likely due to direct foliar feeding that delivered appropriate amount of essential nutrients directly to plants with greater nutrient use efficiency. Nafiu *et al.,* (2017) observed that nutrient uptake via foliar feeding was faster than through root feeding. Shobo *et al* (2016) and Nafiu *et al.,* (2017) observed that chemical residues present in foliar fertilizer also protect crops against foliar pests and diseases. Pandey *et al*. (1974), Bradley *et al.* (1976), Yuasa and Aboaba (1981), El-Badawi (1994), Lawal (2000), Agba and Enya (2005) had all reported increase in growth and yield components of cucumber to applied fertilizer.

CONCLUSION

Overall observation showed that among the fertilizer types tested, foliar fertilizer was the best for optimum growth and fruit yield, while greengo cucumber variety proved to be the best. It is therefore recommended that for optimum growth and increased fruit yield, greengo cucumber variety should be cultivated, and foliar fertilizer applied appropriately.

ABSTRACT
In this study, bioactive composition and antioxidant activity of unripe and ripe plantain peel were compared. Highest flavonoid concentration of total flavonoid was observed in acetone extract of ripe plantain peel while highest phenolic concentration was observed in aqueous extract of ripe plantain peel. Relatively higher antioxidant activity though not significantly different was observed in unripe peels as compared to ripe plantain peels. No significant difference was observed in total phenolic concentration for ripe and unripe peel in acetone extract. Similar findings were observed for aqueous and methanol extract. Findings from this research indicates that unripe and ripe plantain peels are good source of bioactive compounds with therapeutic values and suggests that more research needs to be conducted on value addition in bid to address mounting global challenge of food loss and waste.
Keywords: *Unripe plantain peel, ripe plantain peel, bioactive compositions, antioxidant activities.*

INTRODUCTION

Musa parasidiasca commonly known as cooking banana, is a staple food grown predominantly in tropical parts of Africa, South America, Central America and Asia (Adeniji *et al*., 2005). It is estimated that 2.11 million metric tons of plantain is grown annually in Africa (Cauthen *et al*., 2019), this implies that plantain peels (40% of fresh fruit weight) accounts for 0.84 million metric tons of plantain wasted annually (Okorie *et al*., 2015). Plantain peels are good source of dietary fibre, starch and protein and can also be used as alternative to flour due to its oil and water holding capacity (Agama-Acevedo *et al*., 2016). Studies has shown that plantain peels possess anti-ageing, anti-inflammatory, antibacterial, anti-hypertensive, antioxidant and antidiabetic properties (Ighodaro *et al*., 2012; Islam *et al*., 2023). This aim of this research is to determine differences in bioactive composition, ascorbic acid and antioxidant activities of ripe and unripe plantain peels using various extracting solvents.

Figure 1: Showing image of peels from (A) ripe and (B) unripe plantain peels

MATERIALS AND METHODS

Sample collection

Ripe and unripe plantain was locally sourced from a local market in Ibadan, Oyo State, Nigeria. The plantain samples were washed, cut open and its peels dehydrated at 50°C with the aid of food dehydrator (Excalibur Model- 4926 T, USA). Dehydrated sample was then pulverized and stored in air tight containers for further analysis.

Extraction of sample

Sample extraction was carried out using method by Vinoth *et al*. (2012). Aqua, ethanol and ethanol were used as solvents for extraction.

Extraction and Determination of Yield
Yield was determined using method as adopted by Oyawaluja *et al*. (2020).

Total Phenolic Content (TPC)
Determination of total phenolic content was conducted using method as adopted by Moo-Huchin *et al.* (2014).

Total Flavonoid Content (TFC)
Total flavonoid content was determined using methods by Ademoyegun *et al*. (2013).

Determination of Ascorbic acid
Ascorbic acid determination was carried out using method by Ajayi *et al.* (2020).

Antioxidant activity
Antioxidant activity using DPPH assay was conducted using method as adopted by Islam *et al*. (2023).

Statistical analysis
Results for the experiment were expressed as means ± standard deviation (n=2). One-way analysis of variance (ANOVA) was used to analyze data with the aid of SPSS ($p < 0.05$).

RESULTS

Table 1: Percentage Yield for ripe (RPP) and unripe (URPP) plantain peels.

	RPP	URPP
Percentage Yield (%)	2.57	2.39

Table 2: Ascorbic acid concentration in ripe and unripe plantain peel

	RIPE (mg / 100mg)	UNRIPE (mg / 100mg)
Total Ascorbic Acid	0.43 ± 0.01	0.52 ± 0.003

Table 3: Total flavonoid, total phenol content and antioxidant activities of plantain peels

	DPPH (%)	TFC (mg/100g)	TPC (mg/100g)
Acetone extract			
RPP	47.92 ± 5.37^{c}	534.81 ± 2.08^{d}	114.7 ± 1.90^{a}
URPP	46.61 ± 2.51^{b}	279.42 ± 5.55^{a}	107.2 ± 0.20^{a}
Aqueous extract			
RPP	24.23 ± 0.26^{a}	345.60 ± 2.08^{a}	195.8 ± 5.30^{c}
URPP	32.74 ± 1.14^{a}	282.85 ± 3.47^{a}	148.9 ± 1.20^{c}
Methanol extract			
RPP	28.12 ± 1.41^{ab}	360.79 ± 2.77^{b}	134.5 ± 3.50^{b}
URPP	59.35 ± 2.28^{c}	378.93 ± 24.26^{b}	121.6 ± 0.40^{b}
Ethanol extract			
RPP	35.17 ± 3.20^{b}	409.32 ± 4.85^{c}	113.9 ± 1.40^{a}
URPP	49.03 ± 1.37^{b}	353.44 ± 7.63^{b}	128.0 ± 2.10^{c}

Key: RPP= Ripe plantain peel, URPP= Unripe plantain peel

DISCUSSION

Result as shown in Table 1 indicates higher yield obtained from ethanoic extract of ripe plantain peel (2.57%) as compared to peels from unripe plantain (2.39%). Higher concentration of ascorbic acid was observed in peels of unripe plantain as compared to ripe plantain peel and is in accordance with deduction by Oduje *et al*., (2015). Highest TFC was observed in acetone extract of ripe plantain peel while higher TPC was observed in aqueous extract of ripe plantain peel. No significant difference was observed in antioxidant activity between ethanoic extracts of ripe and unripe plantain peel. Similar finding was observed for aqueous extract while significant differences was observed between ripe and unripe plantain peels in acetone and methanol extract. Findings from this research indicates that no significant difference was observed in total phenolic content of ripe and unripe plantain peel in acetone, water and methanol extracts.

CONCLUSION

Ripe and unripe plantain peels extracts obtained using various extracting solvent showed varying concentrations in antioxidant activity and bioactive composition, highlighting their pharmaceutical and therapeutic values. Existing research studies on plantain has predominantly focused on the pulp and neglect its peel despite accounting for 40% of the fruit weight. There is need for increased research on value addition for plantain peel, its health benefit and possible non-culinary applications,

ABSTRACT

Three Pleurotus species (Pleurotus ostreatus, P. pulmonarius and P. florida) were cultivated on green amaranth shaft moistened with water. It was aimed at finding an alternative use for the shaft. Experiment was laid out in a complete randomized design (CRD) in replicates of five. There was no significant difference in the mycelial extension. Average mycelial extension per day was comparable between P. pulmonarius and P. florida (0.25 cm and 0.26 cm respectively) but least in P. ostreatus. The lowest number of fruits was recorded in P. florida. Biological Efficiency (BE) and Production Efficiency (PE) followed the same trend. The number of days to full mycelial colonization and primordial initiation were significantly highest in P. florida (26.00 and 30.00 days respectively). The widest width of pileus and longest length of stipe were recorded in P. pulmonarius (4.37 cm and 4.30 cm respectively). While the heaviest fruit weight was observed in P. ostreatus, the least was recorded in P. florida. These findings suggested that green amaranth shaft is a good and cheap substrate for production of edible mushrooms.

Key words: *Amaranth shaft, Edible mushrooms, Pleurotus pulmonarius, P. ostreatus, P. florida*

INTRODUCTION

In every sector of life, wastes are generated on daily basis: homes, industries, forests and agricultural sectors, to mention a few. These wastes inflict dangers on the environment, becomes a nuisance and source of pollution. Most agricultural wastes are generally incinerated in the open or dumped indiscriminately and, at times burnt, resulting in air pollution. However, value can be added to wastes generated from agricultural and or horticultural sector by recycling them biologically for mushroom cultivation and production. Mushrooms are important food items consequent of their nutritional contents and therapeutic values (Atila, 2017). *Pleurotus* spp, an edible mushroom, has low fat content but high in fibre, rich in vitamins and amino acids (Chang and Miles, 2004). They possess many health benefits such as anticancer, anti-diabetic, anti-oxidant and anti-viral effects (El-Enshasy and Hatti-Kaul, 2013; Wasser, 2014). They have been cultivated on various agricultural or horticultural wastes such as sawdust, cassava peels, corn cobs, sugarcane bagasse, banana leaves, plantain leaves, straw, cotton wastes, coconut coir/ fibre, maize stover, palm bunches (Idowu, 2003; Otunla and Idowu, 2012; Idowu *et al*., 2015). Green amaranth shaft is a horticultural waste that is usually discarded and burnt. This experiment was therefore conducted to determine the suitability of amaranth shaft as a mushroom substrate.

MATERIALS AND METHODS

Sourcing for mushroom spawn

For this research, the mushroom spawns (*Pleurotus pulmonarius* and *P. ostreatus*) were obtained from the pure culture collections from the Mushroom Unit, National Horticultural Research Institute (NIHORT), Idi-Ishin, Jericho, Ibadan, Oyo State, South-West Nigeria.

Collection of Green amaranth shaft (substrate) and preparation

Green amaranth shaft was collected from Seedtech Unit, NIHORT, Ibadan after the seed has been processed. The experiment was carried out in the mycology laboratory, NIHORT, Ibadan. The composting of the shaft was carried out by moistening it with water, wrapped it in a polythene spread sheet and allowed to stay for 48 hours.

Vertical mycelia growth

The shaft was tucked in test tubes of size 20 x 2.5 cm, plugged with cotton wool and covered with aluminum foil. It was replicated five times for each of the mushroom and sterilized in an autoclave at 121 ºC for 15 min. aseptically in an inoculating chamber after allowed to cool; they were inoculated with the spawn of the mushrooms separately. The test tubes were maintained at room temperature of 30 ± 2 ºC and placed in a test tube rack with a millimeter tape of 150 mm to monitor the mycelia growth. Vertical mycelia extension was recorded and the average extension per day calculated.

Mushroom substrate mycelial growth

300 g of the shaft, moistened with water and left for 48 hours, was weighed into heat-resistant transparent polythene bags of size 35 x 10 cm. The bags were replicated five times for each of the mushroom species. The neck of the bag was made with heat resistant PVC (polyvinyl choride) tube and tucked with a cotton plug. The bags were sterilized in an autoclave at 121°C for 15 minutes, brought out, allowed to cool and spawned separately with the mushroom spawn. The bags were transferred into the vegetative room where vegetative growth took place, temperature maintained at 28-30 °C and relative humidity at 82-85%.

Mushroom fructification, harvesting and yield

The substrate bags fully covered with mycelial were moved out of the vegetative room into the cropping house maintained at 24-28 °C and relative humidity at 84-87%. Mushrooms were harvested manually when the in-rolling margins of the pileus began to flatten. The number of fruiting bodies harvested were counted and weighed. Other parameters observed and recorded were the fruit weight, width of pileus, length of stipe, mycelial extension, days to full mycelia colonization and primordia initiation. Biological Efficiency (BE), Production Efficiency (PE) and average mycelial extension were calculated.

Research Design

The experiment was laid out in a complete randomized design (CRD) in replicates of five.

Data Analysis

Analysis of the data collected was done using ANOVA and significant means were separated using Duncan's multiple range test at 5% probability level

RESULTS AND DISCUSSION

Significant growths of the mushrooms were observed on the shaft. These mushrooms have been reported to be one of the most efficient lignocelluloses solid decomposing white rot fungi (Baysal *et al*., 2003) thus, able to utilize the agricultural and horticultural wastes as substrates for mushroom fruit body production. Also, other researchers reported the utilization of various agro-wastes by the white rot fungi (Jonathan *et al*., 2013; Idowu *et al*., 2015). While comparable mycelial extension was observed in the mushrooms (Table 1) however, the average mycelial extension per day was significantly longest in *P. pulmonarius* but not significantly different from that of *P. florida* while *P. ostreatus* recorded the shortest (0.26 cm, 0.25 cm and 0.22 cm respectively). Days to full mycelial colonization and primordial initiation recorded for the three mushrooms followed the same trend; the longest were recorded in *P. florida* (26.00 days and 30.00 days respectively). The least were observed in *P. pulmonarius* which were not significantly different from that of *P. ostreatus* (Table 1). This agreed with earlier reports by Tan (1981) and Ahmad (1986) that spawn running took three weeks in completion for *Pleurotus* spp. Furthermore, Ahmad (1986) observed that in *P. ostreatus* planted on various substrates, primordial initiation was between 23-27 days.

The numbers of fruits recorded in the mushrooms were significantly different from each other (Table 2). The highest was recorded in *P. ostreatus* but not significantly different from what was observed in *P. pulmonarius*. The least number of fruits was recorded in *P. florida* (7.00). The largest size of pileus was observed in *P. pulmonarius* which was not significantly different from that of *P. florida* while the least was recorded in *P. ostreatus* (4.37 cm, 4.30 cm and 3.47 cm respectively). The length of stipe observed followed the same trend (Table 2). Both Biological Efficiency (BE) and Production Efficiency (PE) followed the same trend. While the greatest were recorded in *P. ostreatus*, the least were recorded in *P. florida* (Figure 1). Furthermore, it was observed that the mycelial density of *P. ostreatus* on the shaft was heaviest than that of other mushrooms. This was contrary to an earlier work by Otunla *et al*. (2016) in which the mycelial density of *P. pulmonarius* was heavier on cassia sawdust substrate. The highest mushroom fruit body weight was harvested on *P. ostreatus* (Figure 2). This could be attributed to the heaviest mycelial density observed in *P. ostreatus* consequent of high porosity, level of aeration and the physical nature of the shaft. It was opined that *P. ostreatus* was more virulent on the shaft than *P. pulmonarius* and *P. florida*. Thomas *et al*. (1998) stated that mushroom mycelial density is directly proportional to fruit body yield.

CONCLUSION AND RECOMMENDATION

Statistically, the mushrooms performed well in terms of number of fruits, mycelial extension, days to full mycelial colonization and primordial initiation. However, *Pleurotus ostreatus* performed better on the shaft than *P. pulmonarius* and *P. florida* in terms of fruit body yield. Amaranth shaft may be recommended for mushroom production and further investigation could be conducted in combination with sawdust.

ACKNOWLEDGEMENT

Appreciation to the Institute management, NIHORT and Seedtech Unit staff members for the support as well as the following people for their technical support in the course of this investigation: Mrs F. O. Akinrinsola, Mr J. A. Abass, Mrs G. A. Majekadegbe and Mr M. O. Daropale.

INTERCROPPING AS A MANAGEMENT OPTION IN TOMATO FUSARIUM WILT SUPPRESSION

Oyedeji, E. O.
National Horticultural Research Institute, P.M.B 5432, Ibadan, Oyo State, Nigeria
ennyhorlar@yahoo.com

ABSTRACT
This study was conducted to determine the effect of intercropping tomato with Marigold or Sorghum on Fusarium wilt incidence and severity. Fungal population and inoculums density of the field was determine before planting. The treatments were; two tomato varieties (Roma VF and Ibadan local) and three cropping systems (tomato-marigold, tomato-sorghum and sole tomato). The experiment was laid out in Randomised Complete Block Design with three replications. The plot size was 3 m x 3 m (9 m^2) separated by 1 m from other plots and blocks with one row of tomato planted between two rows of either marigold or sorghum. Data collected were subjected to statistical and means were separated using Least Significant Difference (LSD) at 5 % probability level. Inoculum density that ranged from 200 - 250 cfu/g^{-1} was obtained in the field. Incidence in Roma –VF/sorghum intercrop was at par with sole cropping and were significantly lower P≤ 0.05 compared to tomato-marigold intercrop. Also. disease severity due to intercropping was not significantly (P ≤ 0.05) different from sole cropping in both years.
***Keywords**: Fungal population, Fusarium wilt, incidence, severity, tomato*

INTRODUCTION

Intercropping is a popular crop production system in subsistence tropical agriculture with effects on pest population dynamics that minimise crop damage. Intercropping guaranteed more profit and less risk of crop failures to the farmers and minimized weed infestation (Reddy *et al.* (1995) as cited by Rajkhowa and Baroova, (2000). Yayock (1988) observed better utilization of soil nutrients, space and reduction in the spread of diseases and pests. Intercropping systems provide greater potential than monoculture for sustained production of food and income, especially for poor farmers in developing countries with limited resources therefore, ensures food security. Intercropping serves as an alternative strategy to traditional application of chemicals for plant disease management by making use of plants with antimicrobial properties (Altieri, 1999). Intercropping tomatoes with onion or garlic has been found to reduce the levels of *Bemisiatabaci, Myzus persicae* and *Phthorimaea operculella* (Afifi *et al*., 1990). Marigold (*Tagetes erecta* L.), a traditional plant in México for the celebration of All Saints Day, has been recognized for its fungicidal, nematocidal and insecticidal properties due to the presence of thiophenes in all its tissues (Riga *et al*., 2005). Tomato plants intercropped with Marigold have shown significantly less foliar and fruit damage by *Alternaria solani* than the non-intercropped tomato (Gómez-Rodríguez *et al*., 2003). They attributed the beneficial effects of intercropping marigold with tomato to three protective mechanisms: allelopathic effect of marigold on *A. solani* conidial germination; reduction in the period with relative humidity ≥ 92%, thus diminishing conidial development; and provision of a physical barrier against conidia spreading. Physiological adaptation due to shading on tomato plants intercropped with marigold could also have some effect on disease suppression (Rojas- Martínez *et al.*, 1999). Intercropping tomatoes with sorghum have controlled whiteflies through effects on arthropod predators and intercropping with cucumber or pepper have delayed the development of *Tomato yellow leaf curl virus* (Al-Musa, 1986). Intercropping tomatoes with sorghum has lead to reduction in fungal disease incidence and severity (Boudreau, 1993), while with cowpea reduced bacterial wilt (*Pseudomonas solanacearum*) on tomato (Michel *et al*., 1997). The objective of this study was to determine the effect of intercropping tomato with Marigold or Sorghum on Fusarium wilt incidence and severity.

MATERIALS AND METHODS

Determination of fungal population in the soil

Soil samples were randomly collected from an endemic field used for the experiment at depth of 0/5cm. Inoculum density of Fusarium species was assessed using soil dilution technique and was expressed as colony forming unit (CFU)/g of soil. The percentage frequency of occurrence was calculated according to Ebele (2011).

$$\text{Percentage frequency} = \frac{\text{Number of times a fungus was encountered}}{\text{Total fungal isolations}} \times 100$$

Experimental Design and treatments

The trial was conducted at Vegetable Research Farm of NIHORT Ibadan, Nigeria. NIHORT is located within latitudes 07° 24.204" N, 003° 50.895" E at 178 m above sea level. The treatments included two tomato varieties (Roma VF and Ibadan local) and three cropping systems (tomato-marigold, tomato-sorghum and sole tomato). The experiment was laid out in randomised complete block design with three replications. The plot size of 3 m x 3 m (9 m^2) was separated by 1 m from other plots and blocks each. Four - week old seedlings of Marigold seedlings were transplanted into the field and sorghum was equally planted the same day. Thirty days after, four weeks old seedlings of Ibadan –Local and Roma VF were transplanted into the field. In the intercrop, one row tomato was planted between two rows of either Marigold or Sorghum.

In these two treatments, rows were 100 cm apart with 50 cm between plants in the intercrop and 75 cm apart with 50 cm between tomato plants in the non- intercrop. Five plants were tagged per plot to serve as representative sample. Disease incidence and severity per plant were assessed every two weeks starting from two weeks after transplanting. Data collected were subjected to statistical using GENSTAT (12^{th} Edition) statistical package. Means were separated using Least Significant Difference (LSD) at 5 % probability level.

RESULTS AND DISCUSSION

Sorghum

F. oxysporum f.sp *lycopersici* had highest frequency of occurrence in both plant and soil collected from the infected field. Occurrence of 80 and 75 % was recorded in infected plant and infested soil respectively. Other pathogens had occurrence that ranged between 5 – 12 % on both plant and soil samples (Table 1). Inoculum density that ranged from 200 - 250 cfu/g^{-1} was obtained in the sampled field under natural infestation which was capable of causing disease (Saremi *et al*. 2011) . *Fusarium oxysporum* f.sp *lycopersici* and other secondary pathogens such as *Penicillium spp*, *Aspergilus niger* and *Aspergilus flavus* isolated from infested field in this study was in agreement with finding of Lim (1972) who stated that secondary pathogens and saprophytes are more likely to be isolated from intensively cultivated soil.

In both years, disease incidence recorded where Ib –local was intercropped with either marigold or sorghum was not significantly different $P \leq 0.05$ from incidence obtained in the sole cropping (Table 2). The result of this study contradicts the findings of Zavaleta -Mejia and Gomez, (1995); Gomez-Rodrigues *et al*., (2003) that tomato intercropped with marigold showed lesser foliar damage by *Alternaria solani* Elis and Martin, Jones and Grout than the non-intercropped tomato. However, disease incidence recorded in Roma -VF intercropped with sorghum was at par with sole cropping although there were significant $P \leq 0.05$ incidence reduction compared to tomato-marigold intercrop (Table 2). This could be that perhaps sorghum acted as a barrier for the movement of pathogen from one place to another in the field. Disease severity in both tomato varieties due to intercropping was not significantly ($P \leq 0.05$) different from sole cropping in both years (Table 3). It could be that proportion of inoculum reduced as result of presence of non host crop (Andrivon, 2003).

CONCLUSION

Intercropping guaranteed more profit and less risk of crop failures to the farmers and minimized weed infestation. Roma-VF-sorghum intercrop could be an alternative strategy to traditional application of chemicals. It could also provide greater potential than sole cropping for the farmers in terms of sustainable food and income generation.

ABSTRACT
Field experiments have been carried out at Teaching and Research Farm of the Federal University of Agriculture Zuru (lat. 12012.99' N; long. 40 21.90'E; 197m above sea level), at some point of 2020/21 and 2021/22 rainy seasons withinside of the Northern Guinea Savannah area of Nigeria. The region has a protracted dry season this is characterized via way of means of cool dry air (harmattan) that prevails from November to February; and warm dry air extending from March to May. The place has been used for cultivation of vegetable and cereal crops. The purpose of the test turned into to look at the reaction of cucumber (Cucumis sativus L.) varieties to poultry manure and NPK (15:15:15). Treatments consisted of three (3) cucumber varieties (Darina, Market-more and Poinsett-75) and two (2) nutrient sources (NPK (15:15:15), poultry manure and the untreated control; each designed to deliver the endorsed nitrogen dose of 120kg N ha-1. Treatments have been specified in a Randomized Complete Block Design (RCBD) with three replications. Results found out that vine length, crop growth rate, imply fruit length, imply fruit diameter, total number of fruits per plant and fresh fruit yield of Market-more and Point sett varieties have been better with the application of either poultry manure or NPK fertilizer. Result, similarly discovered that all the three varieties (Darina, Market-more and Pointsett-75) attained maximum growth with the utility of poultry manure. Based on the results, it could be concluded that, both poultry manure and NPK mineral fertilizer have exceptionally the equal ability as reasserts nutrients on growth and yield of cucumber, but however thinking about the terrible environmental outcomes and the fee of the later, poultry manure may be advocated. Furthermore, varieties Market-more and Pointsett-75 are better than Darina in phrases of yield.
Keywords: *Cucumber, Darina, Market-more, Pointsett-75, Poultry manure, and NPK (15:15:15)*

INTRODUCTION
Cucumber (Cucumis sativus L.) is a member of the Cucurbitaceae own circle of relatives that is made out of 118 genera and 825 species, unfold specially in tropical and subtropical areas of the world (Ume et al., 2017). According FAO (2019), the maximum vital cucurbits in phrases of global wide overall manufacturing are melons (Citrullus spp.) and cucumber (Cucumis sativus L.). Cucumber originated in India and have become famous at some point of the Egyptian and the Greek-Roman Empire (Renner et al., 2007). It is concept to be one of the oldest greens cultivated through guy with ancient facts courting returned 5,000 years (Wehner and Maynard, 2003). It is a critical vegetable crop grown withinside the temperate and tropical zones of the world. With appreciate to financial importance, cucumber ranks fourth after tomatoes, cabbage and onion in Asia and 2nd after tomato in Western Europe (Eifediyi and Remison, 2010). Soft and succulent, the vegetable crop is loved through guy and eaten in salads or sliced into stew in tropical areas. It is one of the maximum critical marketplace greens withinside the tropics, a monoecious annual climber and creeper that has been cultivated for over 3,000 years (Adetula and Dentan, 2003). It is a gentle succulent plant with excessive water content material and has big leaves that shape cover over the fruit. Organic manure launch vitamins slowly and gradually and turns on soil microbial biomass (Belay et al., 2001).
The use of inorganic fertilizer has now no longer been useful beneathneath extensive agriculture due to its excessive price and its miles regularly related to decreased crop yields, soil degradation, nutrient imbalance and acidity. Mineral fertilizers have been used to offer soil vitamins so that you can preserve highest quality soil fertility situations and wholesome increase of vegetation and yield. Chemical

fertilizers assist the developing plants to face up to pressure situations and in a few instances have been used to accurate plant vitamins deficiencies. The call for of cucumber is at the boom because of the continuing focus of its overwhelming fitness benefits. Despite those benefits, the deliver is low because of low yields recorded through farmers – a hassle related to insufficient adoption of suitable manufacturing practices consisting of varietal desire and crop dietary schedule. Productivity of any crop is a feature of its genetic makeup (genotype) and environment (climate, soil fertility etc.); and those range amongst types. The use of natural manure constitutes a constraint to farmer, due to its bulkiness, fee of transportation and handling. This kind of trouble is solved thru the usage of both natural or inorganic fertilizer. Even aleven though the usage of inorganic fertilizers by myself may also reason issues for human fitness and the environment (Aisha et al., 2007), normally farmers practice a long way beneathneath required quantities to greens like cucumber, which ends up low yield (Dauda et al., 2008). The use of inorganic fertilizer through resource-bad farmers is restrained through its scarcity, price and unavailability at proper time. The use of natural manure on the opposite hand, comes with their barriers as excessive danger of infection, excessive price of transportation and labour because of its bulkiness in addition to a sluggish launch of vitamins for plant uptake (Adekiya et al., 2012). Eneje and Uzoukwu (2012) suggested that, the problem to fulfill the crop's nutrient call for with sole natural manure turned into because of its function gradual nutrient launch coupled with constrained availability in lots of components of the country. The intention of this has a look at became to assess decided on promising cucumber sorts and their responses to specific soil fertility reasserts withinside the examine area.

MATERIALS AND METHODS

Experimental Site

The test was performed in Teaching and Research Farm of the Federal University of Agriculture Zuru (lat. 12012.99' N; long. 40 21.90'E; 197m above sea level), at some point of 2021/22 and 2022/23 rainy seasons withinside of the Northern Guinea Savannah area of Nigeria. The region has a protracted dry season this is characterized via way of means of cool dry air (harmattan) that prevails from November to February; and warm dry air extending from March to May. The place has been used for cultivation of vegetable and cereal crops.

Treatments and Experimental Design

The treatments consisted of three (3) cucumber varieties (Darina hybrid, Market-greater and Poinsett-75) and the two (2) level of fertilizers specifically NPK 15:15:15 and poultry manure, plus the untreated control. Both NPK 15:15:15 and poultry manure designed to deliver the encouraged nitrogen dose of 120kg N ha-1 as follows: a 120 kg NPK (15:15:15) ha-1 and 6.6 t PM ha-1 plus the untreated control. Treatments had been specified in Randomized Complete Block Design (RCBD) with three (3) replications.

Seed Source

Three (3) forms of Cucumber: (Darina hybrid, Market-more and Poinsett-75 had been sourced from the National Horticultural Research Institute (NIHORT), Bagauda sub-station, Kano.

Agronomic Practice

The land changed into ploughed and harrowed to a great tilt. Water channels had been built to facilitate loose and green irrigation. Plot length become 4 x 3m (12m-2) with 1m area among plots and 1.5m among blocks. Each plot became made into four ridges spaced 1.5m aside with the 2 internal ridges constituting the internet plot. Planting changed into accomplished at inter and intra-row spacing of 60 x 40cm, respectively. Tube nicely turned into used because the supply of water wherein water pump device became used to attract water, with resource of transport hoses, to the experimental plots. Irrigation turned into finished at three-five days c language relying at the crop's need. Weeds had been managed manually the use of hand hoe at three and six weeks after sowing (WAS). Cucumber culmination had been harvested earlier than they had been completely mature relying at the variety; and became staggered at three-four days over 3weeks.

Data Collection and Analysis

Data have been gathered on vine duration, shoot dry weights, fruit period and diameter, end result in step with plant and fruit yield. Data generated have been analyzed following evaluation of variance procedure, and remedy method have been separated the use of Duncan's New Multiple Range Test (DNMRT).

RESULTS AND DISCUSSION

Influence of Varieties (Darina, Market-more and Pointsett-75) on the Growth and Yield of Cucumber

The found variations among the 3 styles of Cucumber (Darina, Market-more and Pointsett-75) may be attributed to their genetic make-up. According to Ayoub and Afra (2014), variations amongst vegetation with admire to boom and yield beneath Neath comparable environmental situations are usually the end result of variations of their genetic make-up. Results confirmed great impact of range on Vine duration (Table 3). Pointsett-75 and Market-extra accomplished higher in comparison to Darina in phrases of vine duration. This might be because of their genetic nature which allows them to conform nicely to the given climatic situations. The end result changed into much like the findings of Enujeke (2013) who mentioned that genetic charter of crop sorts affects their boom characters. Similar tests have been additionally pronounced in advance through Pal, et al. (2017). Fruit duration and diameter displayed a more version some of the three (3) varieties (Table 4), Pointsett-75 and Darina sorts recorded better values however are statistically in concord with Market extra range this may be because of genetic nature of the specific sorts, because the environmental situations have been the identical for all of the cucumber types. Similar estimation become said with the aid of using Veena et al. (2012) who said that, culmination diameter and culmination period numerous notably the various accessions because of genetic version. The effects of Total variety of culmination consistent with plant (Table 4), indicated that Point sett range recorded the better values however is statistically in concord with Market greater and Darina types. This would possibly have attributed to their genetic make-up. Similar outcomes have been additionally defined in advance through Umeh (2018), who stated that cucumber types confirmed a tremendous courting with recognize to yield characters beneath Neath the same genetic nature and environmental situations. Darina and Market extra types recorded the better values with appreciate to yield (Table 5). This version is because of genetic variety of sorts, variations in environmental and edaphic situations and potentials to move photosynthetic substances inside plants. Similar estimations for this person in unique cucumber types have been suggested through Adinde et al. (2016).

Influence of NPK (15:15:15) and Poultry manure on growth and yield of Cucumber

Influence of Fertilization on boom and yield of Cucumber Fertilization is most of the diverse agronomic practices that affects boom and fruit yield of cucumber. Balanced nutrient control appreciably elevated cucumber fruit yield. Organic manures deliver vitamins in addition to enhancing the soil bodily and chemical conditions (Belay et al., 2001). Fertilizers (natural and inorganic) play critical position in improving vegetative boom, starch synthesis in addition to translocation. Vine period, for the duration of the developing length recorded the better values with the software of both Poultry manure or NPK fertilizer (Table 3). This can be attributed to the better nitrogen content material of Poultry manure (Table 2) and balanced vitamins in NPK fertilizer which better vegetative boom (Ahmed et al., 2007). The elevated in Vine period with appreciate to application of Poultry manure might be attributed to enormous position performed through chicken manure in enhancing the moisture situation of the soil which improved the discharge of greater nutrient factors. Hamma et al. (2012) suggested that better increase reaction of Cucumber because of utility of Poultry manure should in all likelihood because of enhancing bodily and organic residences of the soil ensuing in higher deliver of vitamins to the Cucumber plant. Ayoola and Adeniran (2006) located that Poultry manure can maintain cropping structures thru higher nutrient recycling which might supply upward thrust to crop development in increase. Crop increase price become peaked with the software of both NPK fertilizer or Cow dung (Table 3). This can be attributed to the considerable function performed via way of means of NPK fertilizer withinside the development of soil fertility, nutrient uptake and improving manufacturing of assimilates at some point of increase. This method that the better the vitamins carried out to the soil, the better the boom characters. This remark is constant with works of Aduloju *et al.* (2010) who mentioned and attributed multiplied boom of crop flora to the discharge of extra nutrient factors thru the moisture that has been made to be had with the aid of using the manure. The good-sized high-quality yield reaction of Cucumber to fertilization is an affirmation of the essentiality of vitamins for the general overall performance of Cucumber varieties. Yield characters inclusive of Mean fruit diameter, Mean fruit period, Number of culminations in keeping with plant, and Fruit yield consistent with hectare have been better with the software of both Poultry manure or application of NPK fertilizer (Table 4). This can be attributed to the huge position performed via way of means of NPK fertilizer withinside the development of soil fertility, nutrient uptake and enhancement of crop yields and the position performed through Poultry manure in phrases of enhancing the soil bodily houses through decreasing soil temperature and bulk density, this suggests that chicken manure turned into with ease to be had withinside the satisfactory shape of smooth absorption with the aid of using the plant roots. This statement agreed with the paintings of Muhammad et al. (2018) who said that, the

Application of 120kg of N from hen manure improves moisture availability which ends up in stepped forward nutrient launch to plant life for elevated yield. The sizable superb yield reaction of Cucumber to NPK should possibly attributed to the function of implemented NPK in improving manufacturing of assimilates in the course of boom and consequent partitioning of those assimilates to Cucumber fruits. Shehata et al. (2012) stated that better NPK fertilizer doses resulted to boom withinside the uptake of N, P and K vitamins which superior the Cucumber yield.

Interaction

The full-size interplay among range and natural and inorganic fertilization on Vine period and Fruit yield (Table five and Table 6). Have really indicated the interdependence and complimentary position of fertilization and range in influencing the manifestation of the potentials of Cucumber types in phrases of boom, improvement and yield as pronounced through Umeh (2018) and Shehata et al. (2012). Point sett range attained better boom in phrases of Vine duration with the software of Poultry manure (Table five). Market greater range attained better yield with the software of Poultry manure and Cow dung. This is probably because of quick mineralized and better nitrogen content material of Poultry manure (Table 6) and ample availability of vitamins from each Poultry manure and Cow dung that more suitable the boom and improvement of Cucumber through growing the price of plant metabolic strategies like photosynthesis and breathing which in flip helped to construct the plant tissue. Similar end result become said through Shehata et al. (2012).

CONCLUSION

Based at the results, it can be concluded that, each poultry manure and NPK mineral fertilizer have fantastically the identical ability as reassets of vitamins on increase and yield of cucumber, however but thinking about the bad environmental consequences and value of the later, poultrymanure might be recommended. Furthermore, sorts Market-more and Pointsett-75 are higher than Darina in phrases of yield.

RECOMMENDATION

From the findings of this take a look at, the subsequent suggestions might be made:

a. Application of both chicken manure or NPK fertilizer can be followed for better Cucumber fruit yield withinside the take a look at area.
b. Variety Market-more can also be taken into consideration because it recorded advanced overall performance a few of the types examined withinside the look at area.

FERTILITY AND POPULATION IMPACT ON SEED AND SEED YIELD COMPONENTS: THE CASE OF THREE OKRA (*Abelmoschus esculentus* (L.) Moench) VARIETIES IN THE NORTHERN GUINEA SAVANNAH

Sulaiman, A. J. and Onyibe, J.E.
Agricultural Research (IAR) farm, Samaru, Zaria

ABSTRACT
Two trials were conducted during the 2016 rainy season at the Institute for Agricultural Research (IAR) farm, Samaru and the experimental site for Kaduna Agricultural Development Project (KADP) located at Maigana, Soba Local Government Area in the Northern Guinea Savannah zone of Nigeria to evaluate the impact of fertility and population on okra seed Varieties. The treatments consisted of three okra varieties, four poultry manure rates and two stand densities. The experiment was laid out in a Randomized Complete Block Design (RCBD) with treatments combined and replicated three times at both locations. Based on the results obtained in this study, Yar`balla variety at 2 plants per stand using 6 t ha^{-1} poultry manure gave more seed yield and could therefore be used by farmers to enhance okra seed production in the Northern Guinea Savannah during the rainy season.
Keywords*: seed; yield; density; variety; yar`balla*

INTRODUCTION

Okra (*Abelmoschus esculentus*) is referred to as "a perfect villager's vegetable" because of its robust, productive, fast growing, high yielding nature, fiber content and distinct seed protein (Sanjeet *et al*., 2010). The word "*Abelmoschus*" was gotten from the Arabic word "abu-l-mosk" which means "father of musk" referring to the scent of the seeds while *esculentus* means "full of food". This characteristic is most clearly seen in *Abelmoschus moschatus*. The origin of okra can be traced to Ethiopia (Sathish & Eswar, 2013) from where it spread to the Arabian Peninsula via the red sea, re-entering northern Africa through the Sahara, east into India and South-east Asia (Smith., 2019). 2021 production statistics shows that Nigeria is the second largest producer of okra in the world producing an estimated 1.8 million tonnes per annum, placing the country at second place after India with 10.8 million tonnes per annum (KNOEMA). Okra lays claim to nutritional and medicinal qualities that remain obscured. It has a panoply of culinary traditions all over the world; perhaps the reason why the American college of health care sciences named it a superfood. Among its useful food products are pods, leaves, seeds, industrial fiber and pharmaceuticals. While the unsubstantiated claim that Yang Guifei of China and Cleopatra of Egypt `s outstanding beauty is attributed to their high rate of okra consumption, it is interesting to note that okra`s slime (mucilage) could be the next aloe Vera for skin and hair care (Smith., 2019).

The real substantial food value for okra is found in the ripened seeds which contain oligomeric catechins (2.5 mg/g of seeds) and flavonol derivatives (3.4 mg/g of seeds) while its mesocarp mainly contains hydroxycinnamic and quercetin derivatives (0.2 and 0.3 mg/g of skins). These properties along with the high amount of carbohydrates, proteins, oil content and quality similar to that of soybean enhance its importance in the human diet (Adetuyi *et al*., 2012). The amino acid pattern of the protein renders it an adequate supplement with legumes or cereal based diets (Ndangui *et al*., 2010). Okra seeds have huge potentials to be used; they may be dried and used to prepare vegetable curds, grilled and consumed, roasted and grinded to form or fortify flour (Adelakun *et al*., 2008) and used as caffeine-free substitute for coffee; one of the world`s most consumed beverages (Olivia, 2017). It has industrial applications and is used in confectionaries (Adetuyi *et al*., 2011).

Okra has been considered a minor crop and only little attention is paid to it in the national and international research programs (Schalau, 2002). There is need for more research on okra especially with its seed`s fast growing importance. There is available information on the potential fruit yield of some cultivated okra varieties in the Northern Guinea Savannah region (Okutu and Anika 2010). However, the production of okra seed by farmers is constricted by the dearth of information on high seed producing varieties and thus, warrants the need to find out whether the available varieties in the northern Guinea Savannah could be cultivated efficiently with higher seed yield to meet its increasing domestic and international demands and at the same time produce a healthy alternative to one of the world's most consumed beverages; coffee (Reyes and Cornelis, 2018).

Optimum seed yields have not been attained as a result of continuous decline in soil fertility and decreased use of organic amendments (Akanbi *et al*., 2010). Owing to the growing human and environmental health concerns associated with the use of inorganic fertilizers, there is a need for increased use of organic resources for soil enrichment and improving the productivity and sustainability of already impoverished Savannah soils (Khan *et al.,* 2018). Despite the high nutritive value of okra seeds, organic fertility regimes for high seed production in the Northern Guinea Savannah is yet to be established. Under conditions of sufficient soil moisture and nutrients, suitable population is necessary to efficiently and subsequently produce high seed yields since land is a limiting factor in agricultural production (Danylenko *et al*, 2018). With increasing density, seed yield per unit area increases up to a certain limit, beyond which resources for plant growth and development becomes limited and yield decreases. Therefore, proper stand density is required to attain optimum growth and development of okra that will result in higher seed yield. The result of this research has the potential to advance and transform okra seed production in the Northern Guinea Savannah as it will enable farmers to maximize profit via producing seeds in large quantities by identifying the best variety, the right nutrient regimes and the population density that will produce the highest seed yields. It is in the light of the above that this study was conducted.

MATERIALS AND METHODS

Trials were conducted during the 2016 rainy season at two sites; the Institute for Agricultural Research (IAR) farm, Samaru (11^0 11`N, $7^0$ 38`E and 686m above sea level) and the experimental site for Kaduna Agricultural Development Project (KADP) in Maigana, Soba local Government Area (11^0 39`N;$08^0$ 02`E, 500m above sea level) in the Northern Guinea Savannah zone of Nigeria. The treatments consisted of three varieties of okra (Jokoso, Clemson spineless and Yar`balla), four rates of Poultry manure (0, 2, 4 and 6) t ha^{-1} and two Stand densities (1 and 2) plants per stand (38,167 and 76,334 plants ha^{-1}). Composite soil samples were collected using an Auger at 0-30 cm depth at 4 different points prior to land preparation from each experimental site and analysed in the laboratory for its physico-chemical properties as described by Black, (1965). The poultry manure was also analysed in the laboratory to determine its chemical constituents. The experiment was laid out in a Randomized Complete Block Design (RCBD) with treatments combined, arranged factorially and replicated three times at both locations. Each gross plot was 4.5m x 3m long (13.5m^2) at 75cm and 35cm inter and intra row spacing respectively. Each plot consisted of 6 ridges with the two inner ridges constituting the net plot.

The experimental sites were harrowed and ridged at 75cm apart before planting. A border of 0.5m separated each plot from another while one unplanted ridge separated the replicates. Poultry manure was incorporated into the soil on treatment basis. The ridges were opened at about 15cm depth at the side and manure was measured and incorporated into the soil two weeks before sowing. Okra seeds were dressed with Apron Star 50DS at the rate of 10 g per 4 kg for each variety before sowing. Five seeds were sown per hole at intra row spacing of 35cm on the ridges at both sites. The seedlings were thinned on treatment basis to 1 and 2 plants per stand at two weeks after sowing in both locations. Sowings was done after soaking the seeds in warm water (35^0C) for 6 hours to accelerate and enhance uniform germination. Glyphosate at 1.4 kg ai ha-^{1} was applied prior to land preparation at the rate of 300 ml in 20 L of water to control the emerged weeds before sowing was done at both sites. During the growing period, hoe weeding was done to control emerged weeds at 3, 5 and 7 WAS. A broad spectrum insecticide, Permethrin, was applied at the rate of 300 ml of the formation to 20 litres of water and applied five times during plant growth at five-day interval due to heavy insect pest infestation. It started at 3 weeks after emergence and ended before fruiting (about 6 WAS). Harvesting started at 6 WAS with a picking interval of four days. It terminated at about 9 WAS with a total of 6 harvests in each location. Five plants were randomly tagged from each plot in both sites. Observations on parameters such as number of fruit per plant, number of seeds per pod, seed yield per hectare were carried out. The data collected were subjected to Analysis of Variance (ANOVA) using F-test and the significant differences among the treatment means were compared using Duncan Multiple Range Test (DMRT) as described by Duncan (1955).

RESULTS AND DISCUSSION

Both physical and chemical properties of the soil at the experimental sites at 0-30 cm depth and elemental composition of the poultry manure used are presented in Tables 1 and 2 respectively. The results of the soil analysis indicated that the textural class for the soils at Samaru and Maigana were loam soils. The analysis showed that the soil used in Samaru was moderately acidic while that of Maigana was slightly acidic. The soils were moderate in organic carbon and phosphorus and low in total nitrogen. Exchangeable bases in Samaru were higher than those in Maigana. Calcium and potassium were moderate in both locations while magnesium and sodium were high in samaru, cation exchange capacity was low in Maigana. Chemical properties of the poultry manure (Table 2) used showed a moderate amount of potassium, calcium, phosphorus and sodium while magnesium was low. The nitrogen content in the poultry manure was high.

Table 1: Physical and Chemical Properties of Soil in the Experimental Sites at 0-30cm depth.

Physical properties	**Samaru**	**Maigana**
Sand	430	530
Silt	460	350
Clay	110	120
Textural class	Loam	Loam
Chemical composition		
PH in water (1:2.5)	5.28	6.05
PH in 0.01M$CaCl_2$ (1:2.5)	5.83	5.89
Organic carbon (g kg^{-1})	1.26	1.10
Total nitrogen (g Kg^{-1})	0.43	0.60
Available phosphorus (mg Kg^{-1})	18.31	17.36
Exchangeable bases (cmol Kg^{-1})		
Calcium (Ca)	3.60	3.22
Magnesium (Mg)	1.70	0.80
Potassium (K)	0.22	0.17
Sodium (Na)	0.40	0.23
Cation Exchange Capacity	6.04	4.42

Analyses conducted by Agronomy Departmental laboratory, ABU, Zaria.

Nutrients	**Amount %**
Total K	1.67
Total C	1.73
Total Mg	0.62
Total Na	1.45
Total N	2.87
Total P	2.10

Analyses conducted by Agronomy Departmental laboratory, ABU, Zaria.

The effects of poultry manure on number of fruits per plant, number of seeds per pod and seed yield per hectare of okra varieties during the 2016 rainy season in Samaru and Maigana are shown in Table 3. The result shows a significant difference in okra fruit number per plant for the three varieties at both locations. Yar`balla and Jokoso produced statistically highest and lowest number of fruits per plant respectively in both locations. Application of poultry manure was observed to significantly increase number of fruits per plant up to 6 t ha^{-1} at Samaru while at Maigana, the control and 2 t ha^{-1} were similar but significantly lower than 4 t ha^{-1} which was also lower than 6 t ha^{-1}. There was no significant increase in the number of fruits per plant when stand density was increased from 1 to 2 plants per stand at both locations.

The effects of poultry manure and stand density on number of seeds per pod of okra varieties during the 2016 rainy season at Samaru and Maigana show that Yar`balla produced the highest number of seeds per pod followed by Clemson spineless and Jokoso at both locations. There was significant difference in the number of seeds per pod with varying poultry manure rates in both locations. Application of 4 and 6 t ha^{-1} poultry manure produced statistically equal and highest number of seeds per pod in Samaru. However, this was not the case in Maigana where application of 6 t ha^{-1} produced the highest number of seeds per pod with 2 and 4 t ha-^{1} application producing statistically equal number of seeds per pod. The control (0 t ha-^{1}) produced the lowest number of seeds in both locations. A significant decrease was observed in number of seeds per pod when stand density was decreased from 2 to 1 plant per stand in Samaru.

The result shows that Clemson spineless and Jokoso produced statistically equal seed weight which was lighter than that of Jokoso in both locations. Application of 0, 2 and 4 t ha-^{1} poultry manure produced statistically equal seed weight in Samaru but were statistically similar in maigana. Application of 6 t ha-^{1} produced the heaviest seed weight per hectare in both locations. There was a significant increase in seed weight per hectare when stand density was increased from 1 to 2 plants per stand.

Table 3: Impact of Poultry Manure and Stand Density on Number of fruit per plant and the Number of Seeds per Pod of okra Varieties during the 2016 rainy season at Samaru and Maigana.

DISCUSSION AND CONCLUSION

The significant differences recorded on seed and seed components of the three okra varieties (yar`balla, Clemson spineless and Jokoso) are ascribed to the differences in their genetic component/structure of the varieties used which are attributed to their individual phyllotaxy, light interception and absorption by the leaves, rate of nutrient absorption and utilization, efficiency and transformation of solar energy to chemical energy, efficiency of carbon assimilation, distribution of assimilates to storage points, time taken to produce yield factor and the respiratory losses that take place during the course of their growth and development. These differences are influenced by the dynamics in the climatic and soil factors which they are exposed to, resulting in the production of pods and seeds of various sizes and quantities (Kinder and Umbreen., 2010).

The physical and chemical properties of the soil (Table 1) shows that the Cation Exchange Capacity (useful indicator of soil fertility) for the soil in Maigana was low as compared to that of Samaru which was moderate. This may be the reason for better seed and seed yield components in Samaru than Maigana. This is in line with the studies of Hazleton and Murphy (2007) who stated that Cation Exchange Capacity is an essential soil property that influences nutrient availability, soil pH and soil`s reaction to fertilizers which are all important determinants of crop growth, development and yield.

The number of pods per plant increased with increase in poultry manure application in Samaru. This could be attributed to the high nitrogen content in the poultry manure used as indicated in Table 2 and the beneficial role of manure in mineralization and enhancing soil essential nutrients like nitrogen, phosphorous and potassium for uptake which is essential for vegetable growth and chlorophyll formation as well as promoting root development (Eghball *et al.,* 2002). Manure when decomposed, increases both micro and macro nutrients as well as enhances physico-chemical properties of the soil. Dademol *et al.* (2004) reported that nitrogen content in organic fertilizers enhanced leaf area production, flowering and seed formation in okra. This can be attributed to the fact that poultry manure contains appreciable amounts of magnesium which promotes chlorophyll synthesis that drives photosynthesis. This result is in agreement with the findings of Nehra *et al*. (2001) who stated that higher yield response due to organic manure application is attributed to the improvement of physical and biological properties through mineralization of the soil which resulted in better supply of nutrients that led to better crop yield.

The positive effect of poultry manure on seed components could be due to the contribution made by the manure to the fertility status of the soils. A significant increase was recorded in seed weight per hectare when stand density was increased from 1 to 2 plants per stand. This is due to more number of plants (2 plants per stand) per unit area. This could also be as a result of the higher efficiency of the leaf area for the lower plant population to intercept more solar radiation needed for the production of photosynthate required by okra for seed production. This supports the view of Vargas *et al.,* (2002) who stated that light interception and subsequent growth and development are functions of leaf area index and stand density. It could also be that the adaptation of the varieties to 2 plants per stand in this study which was lower than 111,000 plants ha-^{1} at which Amjad *et al*. (2001) recorded maximum seed yield.

Based on the results obtained in this study, Yar`balla variety at 2 plants per stand using 6 t ha^{-1} poultry manure gave more seed yield and could therefore be used by farmers to enhance okra seed production in the Northern Guinea Savannah during the rainy season.

ABSTRACT
This study focuses on preference of herbal medicine over conventional medicine among adult residents of Ibadan Metropolis, Oyo State, Nigeria. A total of 200 questionnaires were randomly administered to adult residents in the study area. Descriptive statistics (such as percentages, frequencies) and inferential statistics (correlation analysis) was used for the study. The study shows that there is no significant relationship between perception and use of herbal medicine among residents in Ibadan metropolis. The result also revealed that 51.1% were married, 60% of the respondents were educated of which 36% were (HND/B.Sc) and 24% were Masters' degree holders. Also 17.5% prefer herbal medicine because it is cheap and 16% preferred herbal medicine because it is effective. It is therefore recommended that medical health practitioners need to be conversant with herbal medicines and users of herbal medicine should also consult health care professionals before using herbal medicine.
Keywords: *health care professionals; herbal medicine; Ibadan Metropolis; perception*

INTRODUCTION

Herbal medicines are plant based medicines made from different plant parts, examples; roots, leaves, flower or the whole plant. Each part can have different medicinal uses and the many types of chemical constituents require different extraction method (National Institute of Medical Herbalists). Herbal medicine has its roots in every culture around the world, from the Greeks, to the Celts, the Romans to the Arabs, and the Chinese and even to the Indians (Phair, 2021; truechi.com). Since ancient times, humans have been using natural products such as plants, animals, microorganisms and oceanic organisms, in remedies for prevention and treatment of various aliments (WHO, 2013 and Saad et al., 2015). According to WHO, 65-80% of the world's healthcare practice includes the use of traditional medicine in some way (Pan et al., 2014). The world health organization (WHO) estimates that 80% of the world population relies on complementary and alternative medicines (CAM) or traditional medicine. According to Islahudin, (2017) approximately 70% of the world's population from developing countries prefer herbal medicinal products as a primary source of healthcare. African continent is said to have a long history with the use of plants for medicinal purposes. (Lawal et al., 2009). Africa is a continent endowed with an enormous wealth of plant resources. Over 5,000 different species are known to occur in the forest regions alone, most of these have been used for several centuries in traditional medicine for the prevention and treatment of diseases, this is because traditional medicine is often part of the peoples culture, and as a result it is closely linked to their beliefs (Lawal et al., 2009).

Herbal remedies are usually preferred over conventional medicine as it is perceived to be important for reasons of health and well-being. Herbal remedies have been in use for thousands of years by indigenous tribes and cultures like the Africans, Indians and Chinese. Before the introduction of conventional medicine in the West, our pharmacist (apothecaries) were full of medicinal herbs and folk therapies. While some of the weird treatments are unfounded, many of the ingredients used by our ancestors have been proven to have therapeutic effects. This study is aimed at assessing the usage and preference of herbal medicine over conventional medicines. The result of this study can be used as input for policy makers and other stakeholders to identify and prepare directives to control and legalize herbal medicine practice. The general objective of the study is to ascertain why residents in Ibadan metropolis prefer the use of herbal medicine to conventional medicine.

Study Area

The study was carried out in Ibadan metropolis, the capital of Oyo State, Southwest Nigeria, located on seven hills (average elevated 700 feet (200 meters) 100 miles (160 km) from the Atlantic coast. The 2006 national population census estimated the metropolis to be inhabited by 1.34 million people (NPC, 2006). Politically Ibadan metropolis is made up of five urban local governments, Ibadan North, Ibadan Southeast, Southwest, Northeast and Northwest (Tunde-Francis et al., 2020).

Method of Data Collection and Analysis

A well- structured questionnaire was randomly administer to 200 respondents in the study area. Descriptive statistics (such as percentages, frequencies) and inferential statistics (correlation analysis) was used to ascertain preference and usage

RESULT AND DISCUSSION

Table 1 showed that majority (55.5%) of the respondents were females, this is in concordance with other studies where the percentage of people who use herbal medicine is higher in female than male (Aydin et al., 2008). Females have used complementary and alternative medicine (CAM) in the prevention or treatment of illnesses, this also corroborates by Westfall (2003) who also found that women consider herbs to be safer because they are “milder”, more “natural”, “simpler”, more “familiar” and caused fewer side effects. The study also revealed that most of those who use herbs fall in the age range between 20-30, this shows that youths and young adults are now embracing the use of alternative medicine and most have used a form of herbal medical product to cure one illness or the other. The results also show that 78.5%) of the respondents had tertiary education this is an indication that a lot of educated and enlightened people now patronize herbal medicine practitioners. This finding agrees with that of Venkatesh and Garampalli, 2023) that the educated, middle class have turned to herbal remedies and botanicals all over the world.

Table 2 shows other reasons for pivotal to use herbal therapies by the respondents as follows; because it is cheaper (17.5%), less expensive and at the same time effective (16.0%), natural compare to conventional treatment with 14.0%, conventional drugs are too expensive with (12.0%), presence of different phytochemicals (8.0%), mixed with conventional drugs and have strong belief in natural medicine compare to chemicals(6.0%),respondents was forced to use it and to boost the immune system (5.5%), 5.0% of the respondents did not want to take drug but since it was recommended by an old adult. This corroborates the findings of Yinger and Yewhalaw (2007) that traditional medicine has remained the most affordable and easily accessible source of treatment in primary health care system of poor communities where alternative therapy is the major means of medical treatment in such communities. The potency of such alternative medicine in African traditional communities cannot be over-emphasized. This is why Adefolaju (2014) believes that Nigerians, have a deep belief and reliance on traditional medicine, hence about 80 per cent of the population use it almost exclusively while about 95 per cent use it concurrently with western medicine, because to the Nigerian, traditional medicine treats the entire individual rather than one aspect of him or just his disease.

From Table 3, it shows that there is no perceived benefit/health benefit of herbal medicine to users in Ibadan metropolis. Majority, (95.0%) disagreed that it will relieve symptoms of conventional treatment which they are receiving by indicating “NO”, followed by 79.5% respondents that disagreed that it will improve your psychological/emotional wellbeing (hope, optimism) with (Mean=1.80), followed by 78.5% of the respondent who that disagreed that it will allow you to relax and sleep and it will relieve the symptoms of the illness with (Mean=1.79), followed by 72.0% respondents that disagreed that, to do everything possible to fight the illness with (Mean=1.72), followed by 61.5% respondents that disagreed that it will improve your physical well-being with (Mean=1.62) and 56.5% of the respondents disagreed that it will boost your body’s ability to fight disease(1.57) respectively. This corroborates with the findings of Chitty (2009), Hoslt et al, (2009), and Fakeye et al. (2009), that people also use herbal medicine because of the perception that, it is a safe alternative to conventional pharmaceuticals. Moreover, Welz et al.(2018) opined that people also turn to herbal medicine because they are dissatisfied with the care they received from mainstream/conventional/western medicine especially among those with terminal disease or chronic illness.

Based on the findings, there is no significant relationship between perception and use of herbal medicine among residents in Ibadan metropolis. This is supported by Adesina, (2014) who reported that herbal medicine which is an aspect of alternative medicine is a cultural gem of various communities around the world

CONCLUSION

The role played by herbal medicine in the contemporary health care setting can no longer be dismissed as mere vogue accessed by the uneducated and less privileged. It is definite that people use herbal medicine to treat illnesses despite lack of scientific evidence of safety. It is therefore recommended that health care providers especially, medical health practitioners need to be conversant with herbal medicines commonly used to treat illnesses and rid themselves off misconceptions about herbal medicine. Users of herbal medicine should also consult health care professionals before using herbal medicine to know which to use for a particular illness aside the conventional medical treatment so there will not be counter reactions

PERCEPTION OF URBAN GREEN PARK IN IBADAN METROPOLIS OYO STATE

Ugege, B.H., Tunde-Francis, A.A., Kareem, A.T and Ogunsola, J.O
Federal College of Forestry, Ibadan, Oyo State, Nigeria

Corresponding author: bukolasfavour@yahoo.com

ABSTRACT
The study examined the perception of urban green park in Ibadan metropolis Oyo state, Nigeria. Structured questionnaire were administered to eighty respondents. Descriptive statistics and logit regression were used to analyze the data. The result showed that nature friendly environment is one of the major factors that may influence the respondents visit to the park. The logit regression shows that age, gender, educational qualification, monthly income, marital status and awareness of the park variable were not statistically significant. Only the variable "Need for the park was statistically significant which means the odd that respondents will be willing to support conservation of the park. Based on the study it was observed that most of the respondents appreciate nature friendly environment and are willing to support conservation of the nature park.
Keywords: *Perception, urban, Green park, Ibadan*

INTRODUCTION

Green Park is a powerful tool in counteracting urban health dilemma. It is a land partly or completely covered with grass, trees, shrubs or other vegetation. Its presence in an area can serve a lot of benefit like providing recreational space for residents, improving physical activity, improve psychological well-being, enhance air and water quality, build climate resilience to flood risk and heat stress Its principally improves the quality of life of the citizen and contribute to the sustainable development of cities People who have more access to green environments tend to walk and be more physically active than those with limited access. Research has shown that when people are exposed to prolonged periods of excessive heat it creates health issues. This problem is made far worse when there is an absence of vegetation. In the face of expanding urbanization and urban population, which have adverse impact on environmental sustainability (Haq, 2011), green infrastructure is considered one of the best planning tools for adaptation to climate change (Yiannakou and Salata 2017). Studies have shown that lands with trees and vegetation produce more relaxed physiological states in people than lands that lack these natural structures, while supporting ecological constancy by providing habitats for wildlife, conserving soil, and enhancing bio-diversity.

In Nigeria, urban green areas are scarce and well below the acceptable standards (9m^2 of green space per city dweller), as suggested by the World Health Organization (WHO, 2010). Despite all the apparent benefits of urban green space the development of a long-term planning strategy for urban green structure has never been a key priority for local (city and regional) policy makers. In light of the above, it is now predominantly essential to incorporate citizens' concerns, preferences and perceptions into the decision-making and planning processes regarding urban green infrastructure. The benefits derived from urban green area and their objective properties should be understood individually (Kothencz and Blaschke 2017). There is need to examine the perception of open green spaces.to encourage and promote green area.

METHODOLOGY

Study area

The study area is Agodi gardens and park. The garden is located in Ibadan North Local Government area. Agodi garden is situated near the Oyo state secretariat complex. It stands out as a green lung in the surrounding urban landscape with a great recreational potential. The garden was established as a biological and relaxation centre to provide recreational as well as educational services for inhabitant and visitor. In 1967 it lost it glory as a foremost centre particularly following its destruction by the famous 1980 flood disaster dubbed Omiyale that swept through the ancient city. The Agodi garden of Oyo state has been completely renovated to contain a zoo, swimming pool, bar and restaurants. It equally contains an indigenous forest, lake, tree plantation, and an abundant of medicinal plants and some rare tree species.

RESULTS AND DISCUSSION

Table 1 shows that most of the respondents are female (52.6%) this may be due to the fact that female like outing and excitement. This is in line with Ode Sang et al. (2016) who identified that women associate a greater sense of well-being with urban green area than men. In this sample size it was also observed that (40%) were married. High percentage of the respondent have formal education, (34%) have HND/B.Sc and (34%) have postgraduate degrees. This may be due to the fact that they are more enlightened about the need and benefit of recreation. (39.8%) of the visitors to the site are business men and women. This may be due to the nature of their job (not stereotype). It was also revealed that the middle age classes (31-50) have the highest visit to the park. this may be due to the fact that they are in their active age.

The result in table 3.0 revealed the perceived factors that influences visit to the park (that is those in the park during the administration of the questionnaire. (33.3%) consider proximity as one of the factors that influences their visit and 46% consider services rendered as one of the factors that influences their visits to the park, Also, 39.7% sees facilities in the site as one of the factor that influences their visit), 43.6 % consider accessibility as one of the factor that influences their visit. Most of the respondents (60%) see nature friendly environment as a factor that influences visits to the park. 44.9% consider cost of transportation as one of the factor that influences their visit. 34.6% consider health benefit as one of the factor that influences their visit, 52.6% consider relaxation as one of the factor that influences their visit while 50.6% consider fun and entertainment as one of the factor that influences their visit to the park. From the table above it was observed that majority of the respondent appreciate green environment.

From the logistic regression result, age, gender, educational qualification, monthly income, marital status and awareness of the park variables were not statistically significant. This implies that age, gender, education, marital status, monthly income and awareness of respondent of Agodi park do not have any meaningful influence on the decision of the respondents to support the conservation of the park. Only the variable "need for the park" was statistically significant. This means that the odds that respondents will be willing to support conservation of nature park in Ibadan based on their perceived need for the park is about 17.9 times more than those that will not be willing to support conservation of the nature park.

CONCLUSION AND RECOMMENDATION

The study has clearly shown that recreational park in Ibadan is highly esteemed with great multifarious potentials to meet both the social and economic needs of the teeming Ibadan metropolitan populace. Based on the result it is obvious that most of the respondents will be willing to support conservation of nature park in Ibadan based on the variable "need for the park" that is about 17.9times more than those that will not be willing to support conservation of the nature park. It is therefore recommended that Non-governmental Organization should be encourage to go into the establishment of more urban green recreational park, this will generate income as well as stimulate a clean and healthy environment.

ABSTRACT
This experiment was conducted to study the effect of different rooting media and time on roots number and roots length of marcotted Citrus sp, Citrus sinensis, sweet orange at the Federal College of Agricuture, Ishiagu, Ebonyi State, Nigeria. A factorial experiment fitted into randomized complete block design, replicated four times. Ishiagu is a tropical environment which lies on Latitude 5^0 57^1N and longitude 7^0 34^1E with an annual rainfall of 1350mm with average humidity of 88% and a mean annual temperature of 29^0C. Twenty stems of a year old were marcotted, on stands of sweet oranges at different months, using different rooting media. Twenty grammes each (20 grammes) of dry shredded coconut shaft, fresh shredded coconut shaft, cotton wool (clinical cotton wool), decayed banana trunk all laced with five grammes of top soil and a 25grammes of top soil as control were used. This was replicated on four different stands of sweet oranges. The numbers and lengths of adventitious roots formed after two months of incubation were studied. Data were subjected to statistical analysis of variance (ANOVA) using Genstat® version 3.0 (2003) software package and significant means were separated using least significant difference (LSD) at 5% probability level. The decayed banana trunk/top soil had highest number of roots as well as longest roots length, followed by fresh shredded coconut fibers/top soil, cotton wool/top soil and dried shredded coconut fiber/top soil, all had improved performances on roots number and roots length more than the top soil only which had least performance. The month of October had the highest number of roots and with longest roots, followed by July, April and January which had the least roots number and roots length.

INTRODUCTION

Sweet orange, *Citrus sinensis* is a hesperidium. It is a vitamin C rich fruit with many branches and with a shrub habit in growth. It grows to a height less than ten meters tall. It comes to fruiting at age of 2-5 years after planting especially when propagated vegetatively, whereas seeded stands come to fruiting at age of 12-15 years (Opeke, 2012). There are many varieties of sweet orange. The species can be propagated by seeds or budding/grafting. Citrus plants are polyembryonic and apogamic. There are large proportions of the seedlings that are identical with the mother plants which provide propagating plants as clones or pure lines. Cross pollination do occur between different species resulting is variations between seed lots of a pure line. Most seeded stands come to fruiting at 12-15 years after planting depending on the variety. Choice varieties are propagated by bud grafting on a hard variety or by gootee (Phillips, 1977 and Mathew *et al* 1990). Uniformity in performance is obtained by using budding. Budded plants come to fruiting earlier than seedlings (Umeokechukwu *et al.,* 2019). Budding is the accepted method of commercial propagation of sweet oranges. This is the union of scion to stock. Root stocks mostly have advantages of being vigorous in growth, disease resistant, adaptable to soil and climatic conditions (Hartmann et al, 2007).

However, some root stocks are affected by Gumosis a fungi disease and Tristeza a deadly virus disease of citrus in Nigeria (Opeke, 2012), prompting the need for selection of root stocks with the ability to withstand and resist prevalent citrus diseases. (Hartmann et al 2007). The scion and root stock do have interaction which is intrinsic and real, as tastes and nutrient constituents of budded sweet oranges are affected. Different root stocks have shown to affect the different nutrient uptakes for elements like P, K, Ca, Ma and Cu (Njoku and Obasi, 1976). The budding position of the scion on the root stock at lower position increases dwarfness while budding at upper part leads to taller ratios. These inadequacies obtained from clonal scion/root stock propagated citrus crops, prompted the need for air layering/ marcotting. Marcotting is a vegetative propagation method in which stems are rooted while still attached to the mother plant (Hartmann et al 2007). The rooted stems/shoots planted out grow into an exact replica of the parent stock, maintain and being exact of the mother plant in genetic constituents. Marcotting produces seedling that grow to resemble the parent plant when established. This is a vegetative propagation method. The advantage of this method is that all the offsprings have exact characteristics of the parent plants (Maarten *et al*., 1994). The fruits size and the shape are almost same as the parent plant. The taste, colour and nutrient constituent remain exact as with the parent plant, as genetic makeup are the same (Umeokechukw *et al*., 2019)

Plants with soft woods are easily layered by bending the shoot/branch down to the ground with a cut or without a cut on the underside and covered with soil. This causes root initiation, but much faster on the underside of the stem. Such stem is cut off after the production of many roots. However, in an upright hard to bend stems this method becomes impossible or hard. At this point, marcotting becomes the alternative method for multiplication. However, in the developing countries like Nigeria marcotting/layering of trees are rarely carried out for tree crop multiplication and pure line maintenance due to constrains of technical knowledge of required rooting medium, lack of rooting hormones, weather variability and unavailability of controlled environment. This experiment was designed to study the best rooting medium and most appropriate time for marcotting of sweet orange in Ishiagu- Ebonyi state.

MATERIALS AND METHODS

This experiment was carried out at the Federal College of Agriculture, Ishiagu Ebonyi State Nigeria. Ishiagu is located on Latitude 5^0 57^1N and longitude 7^0 34^1E with an annual rainfall of 1350mm, it has an average humidity of 88% and a mean annual temperature of 29^0C (Nwite *et al*., 2008) and is situated on a gentle slope topography. It was a randomized complete block design experiment replicated four times. The treatments were rooting media applied at different months of the year (time). Top soil, dry shredded coconut coir, fresh shredded coconut fibers, cotton wool and decayed banana trunk were used to marcott the sweet orange during the months of January, April, July, October, on stems of one year old with equal diameters. The stems of the sweet orange were girdled with cuts of 2cm, made by removing the bark. The bark was removed to expose the phloem vessel and the cambium. The cambium was scraped off, using a bud knife as to avoid healing back. A ball of medium was placed round the girdle surfaces (each ball medium constituted of fresh shredded coconut fibers/topsoil, dry shredded coconut fibers/top soil, cotton wool/top soil, decayed banana trunk/top soil and top soil only.) The balls were moistening with water and place on the ringed stem and covered with a transparent polyethene (water proof) 1mm thick and tied with twine (Hartman *et al*., 2007). The set ups were allowed to remain for two months before opening. At the end of two months incubation period, they were examined for root initiations. The white polyethene was used for easy examination, (viewing) for root initiation and to reduce the rate of water transpiration (Umeokechukwu *et al*, 2019). The marcotted stems were severed off from the parent plants at the end of the incubation period of two months. The rooting media were carefully removed and the roots washed. Roots in each sample were examined, counted and measured with meter rule.

RESULTS AND DISCUSSION

Number of roots: The analysis of variance indicated a significant difference in the number of roots of the marcotted stems. Result in table 1 shows that decayed banana trunk/top soil had the highest number of roots followed by fresh shredded coconut fiber /top soil. Then cotton wool / top soil was followed by dried coconut fibers /top soil. The least was top soil only which had few roots. Decayed banana trunk/top soil result was influenced by its cool temperature and moisture retention. Hans (1983) reported that temperature of 24-28^{o}C and moisture increased rooting. The decayed banana trunk retained moisture than other treatments. This may had given it advantage over the other treatments as air within the marcotted point was cooler in temperature.

Length of roots: The length of root was significantly affected by the time the shoot was of marcotted. October marcotts, had longer roots than those stems marcotted in the months of July, April and January (Table 2). The months of October and July produced longer roots than April and January and these months of October and July do have more rains with cooler temperatures than April and January. The rains added moisture to the balls reducing transpiration which made the medium to be cooler providing the required temperature for roots initiation.

CONCLUSION AND RECOMMENDATIONS

The rooting of the stems was affected by the medium and the time. The performance of the medium was as a result of the moisture contained in the medium. The decayed banana trunk had higher moisture holding capacity than the rest media. This gave it the advantage over the other media in lowering the temperature of the air around the marcotted stems. Marcotting has shown to require higher relative humidity as obtained in the months of October and July more than in the months of April and January. Marcotting is a good method of producing and maintaining a pure line. It is a promising alternative to budding which is affected by intrinsic scion and root stock interactions. It is recommended that decayed banana trunk/top soil be used to marcott the sweet oranges to produce seedlings and plants of pure lines. It is also believed to contain a phytohormone which promotes root growth based on concentration. It is recommended that decayed banana trunks/ top soil should be used in the marcotting of sweet oranges to produce a pure line of plants with similar character of the parent plants

ABSTRACT
The study compared wet and dry season fluted pumpkin production among smallholder farmers in Okigwe, Imo State, Nigeria. Data were collected with the aid of a well-structured questionnaire and interview schedule using purposive and random sampling techniques. Data were analyzed using descriptive and inferential statistics. Result showed that the smallholder fluted pumpkin farmers in the area had mean age of 39 years with household size of 5 persons and mean farm size of 0.5417 hectare but their mean annual farm income was ₦73,550. Result further showed that, the total costs and total revenues of smallholder fluted pumpkin farmers in wet and dry season production in the study area were ₦148,875 and ₦164,005; ₦280,005 and ₦338,340 respectively. Net return of ₦131,130 and ₦174,335 for wet and dry season production respectively. Benefit to cost ratios were 1.88 and 2.06 respectively and returns on investment were 88K and ₦1.06, with shepherd future of 53.2% and 45.8% for wet and dry season production of fluted pumpkin respectively. Results also, revealed the factors constraining fluted pumpkin production in the area. These factors were inadequate improved varieties of seeds (3.8), high cost of inputs (2.6), inadequate extension contact (3.5), pests and diseases (3.7), instability of product prices (3.4), lack of irrigation facilities (3.3), poor storage facilities (2.7) and lack of processing facilities (2.5). However, the study concluded that fluted pumpkin production in dry season is more profitable compared to wet season production in the study area and recommended that the farmers should join cooperatives, have regular extension contacts and attend seminars and workshops that could improve their production and management skills in both seasons. More attention should be given to dry season fluted pumpkin production to bridge the gap in production for higher profitability.
Keywords: *Comparative, Farmers, Fluted pumpkin, Okigwe, Smallholder*

INTRODUCTION

Fluted pumpkin consumption has increased over the years and it is an important component of the daily diets of Nigerians. The production of fluted pumpkin has increased rapidly as a result of its economic values in terms of monetary return to the growers especially during dry season farming. Fluted pumpkin production can provide all year round income generating employment opportunities for the farmers with little capital investment (Layade, *et al.,* 2020). Fluted pumpkin is perennial when grown on well-drained soils, slightly shaded and mulched but not so soggy soils (Idowu, *et al.* 2007). In the study area, the crop is grown on poor soils as an annual during the rainy season and also during the dry season adopting manual irrigation practices. Majorly, it is grown along-side other crops such as yam, maize, cassava e.t.c. Fluted pumpkin is very important in the diet of children, men, women, nursing mothers as well as livestock due to its high nutritive value. But in Nigeria, the output has not been able to meet the demand for human food not to mention that of livestock feed. As a result of the growing need, the task of producing enough fluted pumpkin poses an increasing challenge. Like other crops, it is affected by the seasonality syndrome, hence, the irrigation practices in dry season. The question is whether there is difference in profitability of dry season/ irrigated and rain-fed practices so far in lieu of excessive dry season or inequitable distribution of rainfall attributed to climate change, hence the need to compare the wet and dry season production in the study area.

However, few studies have compared wet and dry season fluted pumpkin production in Nigeria. Ayoola (2014) assessed the profitability of vegetable farming under irrigation and rain-fed systems using the gross margin, net profit, benefit-cost, shepherd-future and regression approach and concluded that investment on irrigation for vegetable production would be worthwhile for growing commercial vegetable enterprise in the study area.

Olowa and Olowa (2016) assessed the profitability of growing fluted pumpkin on commercial scale in Ikorodu Lcal Government Area (ILGA) using frequency distribution, percentages, means, gross margin, net profit, benefit-cost and Shepherd-Future analyses, and exponential regression model of combined profit function for irrigation and rain-fed systems. Results showed that fluted pumpkin farming was equally undertaken by both male and female mostly between 41-50 years old, with no formal education and average family size of 6 per household, net profit of ₦380,150 and ₦207,150 and benefit-cost ratios of 2.7 and 3 for rain-fed and dry season/irrigated practice respectively. According to them, farm size and level of education have positive correlation while age and costs of fertilizer, labour and planting materials were negatively related to farmer's profit at 1% and 5% significant level and maintained that, farmers should not invest in irrigation for fluted pumpkin production and that, increased access to land, fertilizers and improved seeds would promote profitability and commercialization of fluted pumpkin enterprises in Nigeria. None of thess studies was specifically comparing the wet and dry season production of fluted pumpkin in the study area, hence, the need for this study. Specifically, the study sought to compare the costs and returns of wet and dry season fluted pumpkin production and identify the factors constraining smallholder fluted pumpkin production in the area

METHODOLOGY

The study was conducted in Okigwe, Imo State, Nigeria. It is located on latitude $5^o\ 3^1$ N, and longitude $7^0\ 23^1$E above 131m above sea level with average rainfall of 2330mm per annum. It has agrarian communities and farmers there are horticultural crop producers owing to the presence of the national horticultural research institute in the area. Purposive and simple random Sampling techniques were adopted for this study. The study purposively selected three (3) farming communities that are predominant in fluted pumpkin production, namely; Agbobu, Umulolo and Umuawa Ibu. Twenty (20) smallholder fluted pumpkin farmers were selected randomly from each of the three (3) farming communities to give sixty (60) smallholder fluted pumpkin farmers for the study.

Primary data for this study were sourced with the aid of well-structured questionnaire and interview schedule in the case of illiterate farmers. Data generated for this study were analyzed using the following tools, namely: descriptive statistics such as frequencies, means and percentages; cost and return analysis such as net return, return on investment, cost-benefit ratio and shepherd future; and continuum scale.

Model Specification

The costs and returns analysis that was used for this study is expressed thus:

$$NR = TR - TC \quad (1)$$

$$TR = Q \times P \quad (2)$$

$$ROI = NR/TC \quad (3)$$

$$BCR = TR/TC \quad (4)$$

$$SF = (TC/TR) \times 100 \quad (5)$$

Where,

NR = Net return on fluted pumpkin vines and fruit (Naira)

TR = Total revenue from fluted pumpkin vines and fruits (Naira)

TC = Total Cost of fluted pumpkin production (Naira)

Q = Quantity of fluted pumpkin vines and fruits (Kilogram)

P = Unit price of fluted pumpkin vines and fruits (Naira)

ROI = Return on investment in fluted pumpkin Production (Naira)

SF = Shepherd future (Percentage)

Continuum Scale

The smallholder fluted pumpkin farmers' responses were collected in a 4-point continuum scale as Strongly Agreed (SA), Agreed (A), Strongly Disagreed (SD) and Disagreed (D) by assigning scores 4, 3, 2 and 1 respectively. The results were calculated thus:

$$\text{Mean Score (X)} = \frac{(\sum SA \times 4) + (\sum A \times 3) + (\sum SD \times 2) + (\sum D \times 1)}{\sum(SA+A+SD+D)} \quad (6)$$

Alternatively,

Mean Score (X) = $\frac{\sum FN}{Nr}$

Where; F = Frequency of each response, N = Nominal value, Nr = Number of respondents

The value for decision making was achieved thus:

$$\frac{4+3+2+1}{4} = \frac{10}{4} = 2.5$$

However, any value ≥2.5 was considered a constraint and otherwise, not a constraint on fluted pumpkin production in the study area.

RESULTS AND DISCUSSION

From Tables 1, the total costs and total revenues of smallholder fluted pumpkin farmers in wet and dry season production in the study area were ₦148,875 and ₦164,005; ₦280,005 and ₦338,340 respectively. Net return of₦131,130 and ₦174,335 for wet and dry season production respectively. Benefit to cost ratios were 1.88 and 2.06 respectively and returns on investment were 0.88 and 1.18, with shepherd future of 53.2% and 45.8% for wet and dry season production of fluted pumpkin respectively. The benefit-cost ratios of 1.88 and 2.06 showed that every ₦1 invested on fluted pumpkin, returns on investment were 88k and ₦1.06 respectively. These results implied that dry season smallholder fluted pumpkin production in the area was more profitable and shepherd future of 53.2% and 45.8% showed higher economic efficiency in dry season. These findings were in line with Olowa and Olowa (2016) whose work reported net profit of ₦380,150 and ₦207,150; Shepherd-future of 36.6% and 28.5%; benefit-cost ratios 2.7 and 3.5 for fluted pumpkin farming during rainy season and dry season respectively. They maintained that the results of benefit-cost ratios indicated that fluted pumpkin farming during dry season yielded greater revenue in excess of operational and overhead costs when compared to rainy season farming. Similarly, the shepherd-future indicated greater economic efficiency in the production of fluted pumpkin farming during dry season relative to rainy season. This result disagreed with similar studies in literature (Gani and Omonona, 2009; Ayoola, 2014; Olowa and Olowa, 2016) and maintained that, farmers should not invest in irrigation for fluted pumpkin production and that, increased access to land, fertilizers and improved seeds would promote profitability and commercialization of fluted pumpkin enterprises in Nigeria. Nwauwa and Omonona (2010) maintained that fluted pumpkin production under irrigation system was more profitable compared to rain-fed system, thus agreeing with the findings of this work.

From Table 2, these factors include; inadequate improved varieties of seeds (3.8), high cost of inputs (2.6), inadequate extension contact (3.5), pests and diseases (2.7), instability of product prices (3.4), lack of irrigation facilities (3.3), poor storage facilities (2.7) and lack of processing facility (2.5). These findings were in line with Nwosu, *et al,* (2012) whose work reported poor availability of inputs, pests and disease infestation, inadequate information about input and output prices, and poor road network respectively as constraints on profitable fluted pumpkin production. The result was consistent with Onyebinama (2004) who reported that farm input markets face several constraints which range from accessibility and affordability of inputs owing to its high prices. The result of poor extension contact concurs to the finding of Unammah (2003) who reported that poor ratio of extension agent to farmers in most developing countries resulted in farmers not having access to improved technologies. The results also agreed with Mustapha *et al.* (2016), FAO (2006) who reported pest and diseases, inadequate credit facilities and high interest rate, perishability of produce, water shortage and lack of ready market as major constraints on profitability of vegetable production. Okpeke and Adaigho (2016) agreed with this finding as they reported lack of storage facilities, and scarcity of viable seeds as major constraints on fruited pumpkin production. Goni, *et al.* (2013) generally agreed with the findings of this work that rain-fed agriculture is the most common practice in Nigeria as more than three quarters of the country's agricultural area is rain-fed and subsistence in nature.

Table 1: Costs and Returns on Wet and Dry Season Smallholder Fluted Pumpkin Production

Inputs Used	Wet season unit price P1 (₦)	Wet season quantity Q1	Wet season total cost TC1 (₦)	Dry season unit price P2 (₦)	Dry season quantity Q2	Dry season total cost TC2 (₦)

Table 2: Factors Constraining Fluted Pumpkin Production in the Study Area (n=60)

S/N	Factors	Mean Score (X)	Decision
1.	Inadequate improved varieties of seed	3.8	**A constraint**
2.	High cost of inputs	2.6	**A constraint**
3.	Inadequate extension contact	3.5	**A constraint**
4.	Nature of land ownership	1.6	Not a constraint
5.	Pests and diseases	2.7	**A constraint**
6.	Instability of product prices	3.4	**A constraint**
7.	Poor market information	1.3	Not a constraint
8.	Poor feeder road	1.5	Not a constraint
9.	High cost of transportation	2.3	Not a constraint
10.	Unstable Government policies	2.1	Not a constraint
11.	Lack of irrigation facilities	3.3	**A constraint**
12.	Inadequate credit facilities	2.4	Not a constraint
13.	Poor storage facilities	2.7	**A constraint**

14.	Lack of processing facilities	2.5	**A constraint**

Source: Field survey, 2022

CONCLUSION

From the major findings of the study, the benefit-cost ratios of 1.88 and 2.06 showed that every ₦1 invested on fluted pumpkin production, return on investment were 88k and ₦1.06 respectively and shepherd future of 53.2% and 48.5% respectively implied high economic efficiency for wet and dry season smallholder fluted pumpkin production. This implied that dry season smallholder fluted pumpkin production in the area was more profitable.

ABSTRACT
The study was conducted at the Teaching and Research Farm, Federal College of Horticulture, Dadinkowa, Gombe State, Nigeria during the cropping season of 2022 to evaluate the influence of sowing dates and plant spacing on growth and yield of sweet corn (Zea mays L.). The treatments consisted of two sowing dates; Early sowing (SD1) 6th June and late sowing (SD2) 20th June and plant spacing of 30×20 cm, 30×25 cm and 30×30 cm laid out in Randomized Complete Block Design (RCBD) with three replications. The results showed significant difference between the sowing dates where the second sowing date (SD2/20th June) recorded the highest yield. For spacing, significant difference was also observed on yield per plot and per hectare where 30x30cm recorded the highest values. Therefore, late sowing date of 20thJune and Spacing of 30×30cm were suggested for farmers.
Keywords*: sweet corn, variety, sowing dates, spacing*

INTRODUCTION

Sweet corn (*Zea mays*) is an annual plant from the family of poeceae that comes in three colors: Yellow, White and bicolored (USDA 2016). Sweet corn contains a genetic mutation on the *su locus* that causes the endosperm to store at least twice as much sugar as field corn. As soon as corn is harvested, the sugar begins converting to starch, reducing the sweetness. Therefore, Sweet corn should be refrigerated or preserved within two to six hours of harvest to ensure best quality and retention of sweetness (USDA 2016). Although there is only one maize *(Zea mays L.)* species, it is so variable in its morphological, physiological, and other properties, which makes it the most variable plant species among cereals. This diversity is especially noticeable on seeds that are classified according to their shape, structure, and chemical composition. One of the initial classifications is mainly based on the shape and structure of grain (dent, flint, sweet, popping, soft, waxy, semi-dent and starch sweet maize). Seed heteromorphism is defined as the ability of a plant to produce multiple types of seeds, which is a common strategy of survival under the unpredictable climate conditions (Bhatt and Santo, 2016). This seed trait affects the seed ability to disperse, germinate, to be dormant and persistent in the soil. (El-Keblawy *et al.,*2015).

The seed number to seed size ratio is a starting point in the theory of ecology and evolution of survival and reproduction in the plant world. There are few explanations for the existence of advantages of the development of large seeds under different living conditions. The production of sweet corn (*Zea mays)* in the study area is poorly practiced due to limited technical knowhow that lead to poor emergence and seedling vigor associated with altered starch synthesis alleles in sweet corn which are exacerbated in the presence of unfavourable environmental condition which is the main factors restricting the spread of sweet corn in to the study area

.

MATERIALS AND METHODS

This field trial was conducted during rainy season 2022, at the Teaching and Research Farm, Federal College of Horticulture, Dadin-kowa, Yamaltu Deba Local Government Area of Gombe State, Nigeria. The research area is located at the latitude of 11° 30N, longitude of 10° 20E with an altitude of 24°m above the sea level (Kowal, 2013). The experiment consisted of two sowing dates (Early June 6th as SD1 and late June20th as SD2) and the spacing of 20×30 cm, 25×30 cm and 30×30 cm laid in a Randomized Complete Block Design (RCBD) in three replications each with six plots making up a total of eighteen (18) plots. The size of each plot was 2×2m²(4m²). One meter space was left between replications and 0.5m between plots.

Data were collected on number of cobs, cob length, cob diameter, 100 seeds weight, yield in kilogram per plot and yield in kilogram per hectare (after harvest). Data collected were subjected to analysis of variance (ANOVA) and means were separated using Least Significant Difference (LSD) at 5% level of probability.

RESULTS AND DISCUSSION

The results in Table 1 indicated that there was no significant difference between both sowing dates and spacing intervals on number of cobs per plant which could be due to the fact that one variety was used and genetic influence might have played a vital role in arriving at this results even though the results disagreed with the findings of Chavan*, et al,.(2009)* which revealed that winter sweet corn sown in 45th meteorological week (5–11 November) gave maximum mean cob yield of 199.75 q ha^{-1} with maximum values of nutrient uptake and net returns than the subsequent delayed sowing. The plant spacing of 60 cm x 20 cm (83, 333 plants ha^{-1}) resulted in higher nutrient uptake over wider spacing of 60 cm x 40 cm (41, 666 plants ha^{-1} a) and 60 cm x 20 cm (27, 777 plants ha^{-1}). The results also showed that there was no significant difference between the treatments on Cob Length (cm) and this indicated that this parameter was not influenced by the sowing dates and the spacing intervals used in the research. The results were in contrast with the findings of Ron Goldy *et al*, 2018. These results disagreed with the findings of Mahapatra *et al*. (2004) and Hamzeh A. *et al*. (2015) who revealed significant difference of sowing date and sweet maize hybrids on number of days to emergence tassel, number of days to anthesis, number of days to Emergence spikelet, plant height, cob height, stem diameter, plant dry weight, cob dry Weight, number of grain rows, cob diameter, 1000 kernel weight, cob length and net weight grain harvest per plant. Mean comparisons showed that the highest grain yield was for Ex08716636 variety and it was obtained on 15 May planting date

The results on Cob Diameter (cm) showed significant difference between the sowing dates where 20th June recorded the highest value of 16.25 (cm) while 6th June had 13.86 (cm), but no significant difference was recorded on plant population (spacing). This results agreed with that of Bhutto *et al,*.(2015). Bhutto *et al,*.(2015) who reported that Yield components and grain quality parameters such as plant height, number of cobs per plant, cob length, grains per cob, grain yield, protein, starch and oil content of maize varieties were significantly affected by different sowing dates. The results on 100 Seeds weight per plot showed significant difference between the sowing dates where 20th June (SD2) recorded the highest mean value of 11.44g while 6th June (SD1) had 9.33g but no significant difference was recorded between the spacing intervals. This might be due to the suitability of the second sowing date to the crop in the study area. This result on sowing dates was in line with the findings of Hamzah *et al*.,(2015) whose investigation revealed significant difference of sowing date and sweet maize hybrids on number of days to emergence tassel, number of days to anthesis, number of days to emergence spikelet, plant height, cob height, stem diameter, plant dry weight, cob dry weight, number of grain rows, cob diameter, 1000 kernel weight, cob length and net weight grain harvest per plant but contradicted the findings of Rathod *et al,*.(2018) whose results revealed that, spacing 60×20 cm2 recorded significantly higher green cob (91.93 q ha-1) and fodder yield (318.65 q ha-1) While, Significantly higher protein content in cob (6.97%) and fodder (2.92%) was recorded in spacing 60×30 cm2 (S3)

The results on number of seeds per cob revealed that 20th June (SD2) recorded the highest mean value of 388.1 while 6th June (SD1) had 226.4 but no significant difference was recorded between the spacing intervals on this parameter. The results was in agreement with the findings of Bhutto *et al,*.(2015) who reported that yield components and grain quality parameters such as plant height, number of cobs per plant, cob length, grains per cob, grain yield, protein, starch and oil content of maize varieties were significantly affected by different sowing dates but contradicted the findings of Rathod M. *et al,*.(2018) whose results revealed that, spacing 60×20 cm2 recorded significantly higher green cob (91.93 q ha-1) and fodder yield (318.65 q ha-1) While, Significantly higher protein content in cob (6.97%) and fodder (2.92%) was recorded in spacing 60×30 cm2 (S3). The results on yield per plot revealed that highly significant differences were recorded where 20th June (SD2) recorded the highest mean value of 3.56kg while 6th June (SD1) had 2.25kg. For spacing, 30x30 cm recorded the largest value of 3.03kg while 30x20 and 30x25 cm recorded values that are statistically at par (2.82 kg and 2.88kg respectively). The results was in agreement with the findings of Atakul *et al*,.(2012) who reported that the duration of tasselling, plant height, first ear height, ear length, ear diameter, number of ears per plant, fresh husked ear yield, fresh unhusked ear yield and marketable ear number were statistically significant for sowing times and varieties; Bhutto *et al,*.(2015) who reported that Yield components and grain quality parameters such as plant height, number of cobs per plant, cob length, grains per cob, grain yield, protein, starch and oil content of maize varieties were significantly affected by different sowing dates. The results on spacing was in agreement with the findings of Rathod *et al,*.(2018) whose results revealed that, spacing 60×20 cm2 recorded significantly higher green cob (91.93 q ha-1) and fodder yield (318.65 q ha-1) While, Significantly higher protein content in cob (6.97%) and fodder (2.92%) was recorded in spacing 60×30 cm2 (S3).

The results on yield in kilogram per hectare revealed that highly significant differences were observed between the sowing dates where 20th June (SD2) recorded the highest mean value of 8917kg/ha while 6th June (SD1) had 5639kg/ha. For spacing, significant difference was recorded where 30x30 cm recorded the largest value of 7583kg/ha followed by 30x25 cm with 7208kg/ha while 30x20 had the lowest value of 7042kg/ha. The results was in agreement with the findings of Bhutto *et al,*.(2015) who reported that Yield components and grain quality parameters such as plant height, number of cobs per plant, cob length, grains per cob, grain yield, protein, starch and oil content of maize varieties were significantly affected by different sowing dates, and that of Rathod *et al,*.(2018) whose results revealed that, spacing interval of 60×20 cm2 recorded significantly higher green cob (91.93 q ha-1) and fodder yield (318.65 q ha-1) While, Significantly higher protein content in cob (6.97%) and fodder (2.92%) was recorded in spacing 60×30 cm2 (S3).

Table 1: Influence of sowing Dates and Spacing on the Yield Characters of Sweet corn grown in D/kowa

ABSTRACT
The study examined the comparative advantage and the policy effect on tea production in Nigeria. One hundred and two (102) tea farmers were randomly selected from the study area. Primary data were collected from the sampled farmers with the use of structured questionnaires administered through Open Data Kit (ODK). The data collected were analysed using Policy Analysis Matrix (PAM) which was utilized in determining the comparative advantage and effect of policy on tea cultivation. A budgetary analysis was prepared to estimate the cost of inputs and output and eventual comparative advantage and policy protection on tea farming in Nigeria. Policy indicators such as Domestic Resource Cost (DRC) and Social Cost Benefit (SCB) was make use of in evaluating comparative advantage while indicators such as Nominal Protection Coefficient (NPC), Effective Protection Coefficient (EPC) and Profitability Coefficient (PC) were used for assessing policy protection on tea production. The results from the analysis showed that Nigeria has comparative advantage in tea production, and hence can produce tea for export; earn foreign currency thereof.
Keywords: *Comparative Advantage, PAM, Tea, Effect of Government Policy*

INTRODUCTION

Agriculture is very important to be able to achieve economic sustainability of a nation and it is a vital productive sector in Nigeria apart from oil, in terms of its contribution to Gross Domestic Product and employment it generation (Dike & Njoku, 2019); Afrogha O.O and Afrogha, F.T, 2022). Sustainable agricultural development in any country is propelled by agricultural policy and programmes (Udeh *et al*., 2021). The Nigerian government has come up with various strategies to improve its economic growth and development and move away from mono economy system. Agricultural development policy of government in Nigeria has led to different agricultural policies and programmes (Idowu *et al,* 2007; FMARD, 2016; Onuzurika *et al*., 2020; Kalagbor and Hary, 2021). This commodity policy was targeted at supporting activities of farmers in the areas of research, extension, selling abroad and price control (Manyong *et al*., 2005. Over the years, there have been various agricultural policies with many policies formulation that suffers lack of continuity (Alexander, 2022). Also, political instability and lack of sustainability of policies and programs are the cause of the problems. Most political office holders have the erroneous belief that a government could only be accessed based on completely new policies and programs. Contradiction in policy is another major challenge; some agricultural policies and programs of government are designed to oppose rather than being jointly harmonizing and supportive of the existing one.

Tea (*Camellia sinesis* (L) Kuntze) is an evergreen shrub tree belonging to camellia genus in *Theacea* family that produces young shoots through guided pruning to maintain a plucking table for regular tea leaves harvest that are processed into tea beverages. It is the cheapest beverage in the world and consumed by large number of people across religion and culture hence; it represents one of the major components of world's beverage market (FAOSTAT, 2021; FAO, 2022). Tea plays a major role in local economy development, poverty reduction and food security in emerging nations and is a significant commodity crops in the world (Raj. 2020; FAO, 2022). Tea plants (*Camellia sinesis* L) have being neglected and underutilized in Nigeria (Ipinmoroti, *et al*, 2018; Olasimbo, 2021). Tea is known for its high nutritional value, has high antioxidant, antimicrobial and anticarcinogenic, properties, (FAO, 2022). It is a commodity of high value with extensive value addition capacity for economics of scale and cultivated mostly by women. Tea has contributed largely to the GDP of growing countries and has a growing international market in health food industry (UNO, 2020).

Tea is cultivated mostly in Taraba State of Nigeria; there is over 50,000 hectares of suitable land for tea cultivation on Mambila plateau in Nigeria. Tea was introduced into the country in the mid 70's by Bohea Limited, a United Kingdom Company which established a project comprising 450 hectares of irrigated estate on Mambilla plateau. This is the first commercial Tea planting of a total land areas planted with about 1,200 hectares in the 70's with an annual production of 1,600 tons which meets only 10% of local needs leaving 90% of the suitable land underutilized (Oluyole *et al.,* 2019). The production figure for Nigeria compared to other producing countries globally shows there is need to exploit the potential inherent in tea as a commercial commodity by expanding land areas of tea cultivation (Oluyole *et al.,* 2017; 2018;2019). Nigeria began tea production on a commercial scale in 1982 on the Mambilla plateau of Taraba state situated between longitude 110^{o}E and 120^{o}E and latitude of 6.50^o N and 80^o N. It has a scale-tropical climate and an elevation of about 1550m above sea level (Oluyole *et al.,* 2017).

Comparative advantage is a nation skill to produce a certain good or service at a lower minimal cost than others. The principle of comparative advantage opined that a nation will sell abroad the goods or services in which it has its highest comparative advantage and import those in which it has the smallest comparative advantage. Comparative advantage is therefore the ability to produce a product by optimal input mix relative to other products that could be produced. This theory was first propounded by David Richado in 1817; he focused on international trade and generalized the idea into an economic law, the law of comparative advantage (Smith, 2010). Nigeria has great comparative advantage in tea production. This is because there are large areas of land for tea production in Taraba state that have not been utilized. Also, with the introduction of tea into the lowland areas of some states in Nigeria (Ondo, Lagos, and Edo) by the Cocoa Research Institute of Nigeria. Tea when compared with other crops would have a comparative advantage and could also generate income for the country through its export. Thus, the reason for this study

METHODOLOGY

The study was carried out on Mambilla plateau in Taraba State. Random sampling procedure was used to select a total of 421 tea farmers from randomly selected 30 communities on the plateau. Primary data were obtained from the selected farmers through the use of structured questionnaires administered through Open Data Kit (ODK). The data collected were analysed using Policy Analysis Matrix (PAM) in defining the comparative advantage and effect of policy on tea production (Monke and Pearson, 1989). indicators for measuring comparative advantage are domestic resource cost (DRC), and social cost benefit (SCB) (Javed et al., 2006; Habibullah, 2010; Khai, 2013; Hassanpour et al., 2013; Smith, 2010; Elzaki, 2014) while the effects of policy was measured with nominal protection coefficient (NPC), effective protection coefficient (EPC), and profitability coefficients (PC) (Morris, 1990; Rangasamy, 2003; Marrewijk, 2007; Encylopedia, 2009; Oguntade, 2011). PAM was selected for the study because of its strength in assessing the policy effect on comparative advantage and farm gate profit. PAM is good in influencing investment policy on efficiency in resource allocation and comparative advantage. PAM is also known for its impact on evaluating policy on agricultural research and moving technology. PAM was utilized for the study by incorporating revenue and cost valued at private and social prices for tea production (Master and Nelson, 1995). The budgetary analyses of input and output prices were valued at private and social cost. The data was analyzed to estimate the comparative advantage and effect of government policy on tea production.

RESULTS AND DISCUSSION

The financial analysis for Tea production systems is as presented in Table 1. The total quantity of tea produced among the farmers was 908,042kg and this gave revenue of ₦245,181.32 and ₦433,033.76 valued at private and social value correspondingly. Proceed of ₦224,761.46 and ₦323,335.62 at private and social value in turn was attained in the production system. Tea production system had output transfer of -₦187,258.44. The production system had negative output transfer as shown in the table. This implied higher social returns than the private revenue; existing market price of tea is lesser than the boarder price. This further shows that there was a deterrent to tea output and government policies did not provide incentive for the private prices of tea. The production system had tradable input transfer of ₦-88677.49. The result further showed that tea production system had negative tradable input transfer signifying that private prices for tradable raw materials are lower than their similar international prices. Thus, indicating a hidden tax on the tradable input utilized in the cultivation of tea. The factor transfer of tea production systems had factor transfer of ₦0. The result showed positive values for tea production. The profit transfer of tea production systems had profit transfer of -₦98,574.95. The result showed negative values for the production system. There is an indication that the impact of policies was not favorable to tea production.

Table 1: Policy Analysis matrix for tea production in Nigeria

Item	Revenue	Cost of tradable input	Cost of domestic factor	Profit
Private prices	245,781.32	14, 175.56	34,050.15	197,555.61
Social prices	433,033.76	102,853.05	34,050.15	296,130.56
Divergences	-187,252.44	-88,677.49	0	-98,574.95

Domestic Resource Cost (DRC) for tea cultivation in the study areas is as presented in Table 2a DRC value of 0.1 derived which was less than one. This is an indication that the cost of inputs utilized in tea cultivation was lesser than the value added; signifying efficiency utilization of scare domestic resources in tea cultivation. Also, implying that, it is better off, with the maximum comparative advantage. The standard is, the lower the DRC, the larger the level of efficiency in production (Fazleen, 2017; Ude et al., 2013). Social Cost Benefit (SCB) result for tea production management systems is as shown in Table 2. SCB in production was 0.33. This implied that the value of tradable input cost and domestic factor cost used in tea cultivation at social prices was lesser than the income at social prices under the existing market place condition. SCB results point to the fact that addition of cost of tradable raw material and domestic factors costs are fewer than the gross income under the prevalent output and input market conditions. This is in agreement with (Voinescu & Moisoiu, 2015) which found that rice processing has comparative advantage in the study area.

Nominal Protection Coefficient (NPC) value 0.56 was derived for tea production which was not as much as one, implying that the private price for tea output was lower than the comparable world price for tea. Also, it denotes the system did not receive incentive from government policy since the participants are receiving a smaller amount in private prices in comparison to social prices. The results further showed; that the yield prices are lesser than the boarder prices. This might be due to policy such as currency devaluation and exchange rate which increased the cost of maintaining tea farms. Effective Protection Coefficient (EPC) value of 0.70 was generated for tea production and it was not as much as one. The implication of this is that the gain at market price was not as much as the gain at world price. Therefore, the farmers did not receive incentive from policy interventions. The PC value of 0.91was generated for tea production was less than one implying that private profit was not as social profit. This indicates that the private profit was lower than the profits estimated at the international price. Therefore, there was no motivation in the marketing. There is a further indication that the farmers were not secure by government policy.

Table 2: Indices of comparative advantage and policy effects

DRC	SCB	NPC	EPC	PC
0.10	0.33	0.56	0.71	0.91

Source: Field Survey, 2021

CONCLUSION AND RECOMMENDATION

The study was carried out to evaluate the comparative advantage and policy protection on Tea production in Nigeria for export. Tea budget was prepared for financial and economic cost valued at private and social prices. The study concluded that Nigeria has comparative advantage in production of Tea and it can be produced for export. Present agricultural policy of Nigerian government does not provide incentives and protection to tea production.

RECOMMENDATION

Based on the above the study recommends an urgent government intervention in tea production in terms of input subsidies and price legislation. The Nigerian government must take into account the tea production sub-sector in general agricultural and marketing policies. Policies aimed at providing relevant protection for tea producers must be prioritized to ensure the growth of the sub-sector.Policy should target reducing input cost and increased productivity of tea. Local production should be encouraged to gain maximum income from tea marketing.

ABSTRACT
This research work focused on the Impact of the Adoption of improved (elite) rice varieties on the productivity of the farmers in Shendam Local Government Area of Plateau State. Data for the study was collected through the administration of questionnaire and interview schedule. A multistage sampling technique was used to select the sample size. In the first stage, Durok District was purposely selected being renowned for rice production. Secondly, four villages were randomly selected and finally, twenty rice farmers were randomly selected from each of the villages; giving a total sample size of eighty respondents. Descriptive statistics (means / frequency counts and percentages) was used to analyze the data. The analysis of varieties of rice cultivated reveals that majority of the farmers (70%, $\bar{x}$ = 0.70) cultivated the elite varieties while only 30% ($\bar{x}$ = 0.30) cultivated the local varieties. The impact of the adoption of the elite varieties on the productivity of the farmers was more positive (70%, $\bar{x}$ = 0.70) as against only 30% ($\bar{x}$ = 30) that did not adopt. Major constraints associated with the adoption were inadequate funds and sources of certified seed. Based on the findings, it was recommended among others that Government should grant loans to farmers to enable them procure improved or certified seeds from right sources and other necessary farm inputs.
***Keywords**: Adoption, Elite rice varieties, Productivity of farmers and Yield*

INTRODUCTION

Rice serves as an important staple food in the diet of most Nigerians. It is a very versatile crop and there are many varieties of rice adapted to various environment and cultivation practices (Luc *et al*, 2010). In recent years, rice production in the country has been expanding at the rate of 6% per annum with 70% of the production increase due to land expansion and only 30% being attributed to an increase in productivity (Okoruwa & Ogundele, 2006). Rice production in Nigeria is dominated by small holder farmers who use traditional methods that are characterized with problem of low productivity. Productivity in the last four decades is centered on increasing the number of new varieties and a positive increasing trend in the rate of adoption of modern varieties (Awotide, 2012).
Though increase may not wholly be attributed to varieties improvement in rice production, there is potential for further improvement in productivity (Awotide, 2012). They believed that access to and adoption of improved (elite) rice varieties would go a long way in raising the productivity of small scale rice farmers and consequently improve their livelihood. Productivity increase in agriculture has the capability of reducing poverty through increase in farmer income and reduction in food price, thereby improving food security.
In the West Africa sub-region, Nigeria has witnessed a well-established growing demand for rice as propelled by rising per output consumption and consequently the insufficient domestic production need to be complemented with enormous import both in quantity and value at various time (Afolami and Ragasa, 2015). The enormous importation has however been considered by various regimes as an avoidable drain

on the country's foreign exchange earnings in view of the abundant natural endowments for expanded production in Nigeria (Fashola, *et al*, 2007).

Reports by Oyekanmi (2008) from research stations (based on their on- station and field trials) showed that the adoption of the technologies and improved management practices should lead to substantial yield increase in rice production. The invariability underscores the significant role that technology stand to play in attaining the much needed growing in the rice subsector. Gabre and Haggblade (2001) however predicted such growth on productivity gained through greater technical and allocative efficiencies of the farmers in the response to the changing technological and production environment. This study therefore seeks to determine the impact of adoption of improved (elite) rice varieties on the productivity of farmers in Shendam LGA of Plateau State.

Aim and objectives of the study

The aim of the study is to access the impact of adoption of elite rice varieties on the productivity of farmers in Shendam LGA of Plateau State. The specific objectives include the following:

a. To investigate the varieties of rice cultivated by the farmers in the study area
b. To determine the yield of the rice farmers in the study area
c. To access the level of adoption of the new rice (elite) varieties in the study area.

MATERIALS AND METHODS OF DATA COLLECTION

A well-structured questionnaire and oral interview were used for data collection from respondents. The instruments carry relevant questions that would elicit responses relevant to the study.

Sampling technique and sample size

A multistage sampling technique was used to select the sample size. In the first stage, Durok district was purposively selected due to the fact that it is renowned for rice production. In the second stage, four (4) villages from Durok district were randomly selected including Kalong, Shimankar, Samunaka and U/ Rina. In the third stage, 20 respondents were randomly selected from each of the four villages, making a total of eighty (80) respondents as the sample size considered for the study.

Method of Data Analysis

Data collected were analyzed using descriptive analysis such as frequency counts, means and percentages.

RESULTS AND DISCUSSIONS

Results in Table 1 shows that 56 (70%, $\bar{x}$ = 0.70) respondents have been cultivating improved varieties of rice on their farm while 24 (30%, $\bar{x}$ = 0.30) used the local varieties. This is an indication that the farmers preferred the improved or elite varieties of rice over the local varieties, this agrees with the study of Oyekanmi *et al* (2008) that development and dissemination of improved rice varieties and other inputs as a composite package to rice farmers would increase production through productivity. Table 2 is the distribution of respondents according to their sources of seed and information. The results indicate that 67% ($\bar{x}$ = 0.625) of the respondents secure their seed for planting from right or certified sources e.g. National seed centre, Extension Agents, Agricultural Development Programme while 30 ($\bar{x}$ = 0.375, 37.5%) of the respondents were still using local seed source. It shows that majority of the respondents got their seeds for planting from standard sources. This is in agreement to the findings of Tologbonse (2002) that extension agents are important source of agric information.

In Table 3 which is the distribution of the respondents according to yield indicated that 45 (56.25%, $\bar{x}$ = 0.562) of the farmers got yield range of 10-50 bags, 10 farmers ($\bar{x}$ = 0.125) got yield of between 51 - 100 bags and 13 farmers ($\bar{x}$ = 0.162) got 101 – 150 bags, 12 farmers (15%, $\bar{x}$ = 0.15 got yield ranging from 151 bags and above. This result could be due to the fact that most of the farmers are smallholder farmers.

Table 4 indicates the level of adoption of the modern varieties by the respondents. The result revealed that 38 farmers (47.5%, $\bar{x}$ = 0.475) adopted the cultivation of modern varieties of rice at moderate level, 33 farmers (41.2%, $\bar{x}$ = 0.412) adopted the improved varieties production at high level, 7 farmers ($\bar{x}$ = 0.875, 8.75%) adopted at low level while only 2 farmers (2.5%, $\bar{x}$ = 0.25) do not adopt at all. This shows

that the adoption of the elite rice varieties in the study area is at an appreciable level. There is prospective potential for high adoption of elite rice.
The results in Table 5 is the distribution of respondents according to the impact the cultivation of elite rice varieties had on their livelihood. The results indicated that 56 ($\bar{x}$ = 0.70, 70%) had positive impact while only 24 respondents ($\bar{x}$ = 0.30, 30%) indicated no impact. It is an evidence that the production of modern varieties of rice has gone a long way in improving the standard of living of the respondents in the study area.

CONCLUSION
From the study, it is concluded that the adoption of elite varieties of rice has brought a great positive impact on the lives of the farmers. It has improved the productivity of the farmers greatly evidenced in enormous increase in yield. The use of good seed of improved varieties for cultivation from good sources is commendable and encouraged to maintain and sustain the productivity and continuous adoption of rice elite varieties by small holder farmers.

ABSTRACT:
This study introduces an improved DNA extraction method, focusing on roses as a representative plant species with high secondary metabolite and polysaccharide content. Roses, prized for their essential oil, ornamental value, and economic importance, are increasingly studied using molecular techniques like PCR-based markers. However, the presence of polysaccharides and polyphenols in rose DNA hampers its suitability for PCR analysis. The study employs a modified cetyltrimethylammonium bromide (CTAB) procedure, with the innovative omission of phenol during extraction, to boost DNA yield. A critical step involves washing with HEPES buffer to remove polyphenols and polysaccharides, followed by the combined use of potassium acetate and chloroform to eliminate proteins and polysaccharides. Subsequently, the DNA is precipitated and quantified using a UV-spectrophotometer. This optimized protocol consistently yields high-quality DNA, ranging from 980 to 1800 µg/g of fresh leaf weight, suitable for PCR analysis and gel electrophoresis. It offers a valuable resource for extracting DNA from other plant species confronted with similar challenges related to secondary metabolites and polysaccharides.
Keywords*: Rose, cetyltrimethylammonium bromide (CTAB), DNA extraction, PCR analysis, secondary metabolites.*

INTRODUCTION

Roses are prized not only for their beauty but also for their economic significance and use in various fields, including perfumery and medicine. The fragrant essential oil derived from roses is a key component in high-grade perfumes. Medicinally, roses are known to invigorate the blood and possess astringent properties. Furthermore, their ornamental appeal adds to their value (Chrubasik *et al*, 2006). In molecular biology, PCR-based molecular markers have gained favour over morphological markers (Guena *et al*, 2000), with applications ranging from genotyping to biodiversity evaluation. However, working with rose DNA poses challenges due to its high levels of polysaccharides and polyphenols, which hinder PCR applications (Porebski *et al*, 1997). Polysaccharides make DNA viscous and reduce enzyme activity, while polyphenols covalently bind to DNA, making it less suitable for analysis (Okpodu and Abdullah-Israel, 2011). Obtaining high-quality genomic DNA from roses is essential for various molecular biology applications, including genetic engineering and gene expression analysis (Xu *et al*., 2004). Roses, being rich in secondary metabolites like flavonoids and phenolic compounds, as well as polysaccharides, require tailored DNA extraction protocols. The presence of these compounds often leads to low DNA yields and impurities (Hedman and Rådström, 2013).
Roses are not only beloved for their aesthetics but also hold economic and scientific significance (Schenk *et al*., 2023). Overcoming the challenges posed by their unique chemical composition is crucial for unlocking their genetic potential and harnessing their benefits across multiple domains. Specialized DNA extraction protocols are pivotal in this endeavor (Bocso and Butnariu, 2022). The optimization of DNA extraction from roses with abundant secondary metabolites and polysaccharides offers vital progress in plant molecular biology. It addresses challenges in rose DNA extraction, providing a blueprint for

customizing protocols for similar plants. This advancement will boost the effectiveness of plant genetics and genomics research. This study aims to evaluate a simple, rapid, and efficient protocol for the extraction of DNA from rose specie.

MATERIALS AND METHODS

Sample Collection:

Young and tender leaves of 25 accessions of roses were collected from the floriculture garden of the National Horticultural Research Institute in Ibadan and stored at -80°C until use.

DNA Extraction Method:

The DNA extraction was performed at the Biotech Molecular Laboratory of the National Horticultural Research Institute, Jericho, Ibadan, Nigeria. The extraction method used was the modified hexadecyltrimethylammonium bromide (CTAB) procedure, which incorporates a phenol-absent extraction step to enhance the yield. Prior to extraction, a washing step was performed to remove organic molecules and excess water. The washing buffer used prior to the actual extraction process is the Hepes-NAOH buffer. The inclusion of the Hepes buffer was one of the additional steps tried for the removal of polysaccharide.

HEPES Buffer Solution:

HEPES buffer is one of Good's zwitterionic buffers, which has a pH range of 6.8-8.2. It is widely employed in cell culture media due to its capacity to maintain a stable pH in the face of changes in carbon dioxide concentration. The HEPES Buffer (1 M, pH 7.5) was prepared using the following steps:

- Prepare 800 mL of distilled water (dH2O) in a suitable container.
- Add 238.3 g of Hepes to the solution.
- Adjust the pH of the solution to the desired level using 10N NaOH.
- Add distilled water until the total volume reaches 1 L.

The extraction procedure involves employing high concentrations of polyvinylpyrrolidone (PVP) (4% [w/v]), CTAB (3% [w/v]), and β-mercaptoethanol (3% [v/v]) in the extraction buffer with a high salt concentration. This is done to eliminate polyphenols and polysaccharides. Furthermore, a combination of potassium acetate and chloroform was utilized to remove proteins and polysaccharides. Subsequently, DNA was precipitated by adding an equal volume of isopropanol and 0.1 volume of sodium acetate. The resulting DNA pellet was then re-suspended in 100μL of sterile distilled water, and the DNA concentration was determined using a UV-spectrophotometer at 260 nm. The DNA samples (Stock) were stored at -20°C prior to analysis.

RESULTS

Qualitative and Quantitative Analysis of Extracted DNA

The DNA yield was measured using a UV-Visible spectrophotometer (PerkinElmer) at 260 nm. DNA purity was determined by calculating the absorbance ratio A260/280. Polysaccharide contamination was assessed by calculating the absorbance ratio A260/230 (Pushkoova *et al*., 2019). For quality and yield assessments, electrophoresis was performed on all DNA samples in a 1.0% agarose gel, stained with Ethidium Bromide, and bands were observed using a gel documentation system. This protocol resulted in high yields of DNA. The average yield of DNA ranged from 980 to 1800 μg/g of fresh weight of leaves. The results indicated that the DNA quality is sufficient for polymerase chain reaction (PCR) analyses. It is also suitable for extracting high-quality DNA from other plants with high levels of secondary metabolites and polysaccharides.

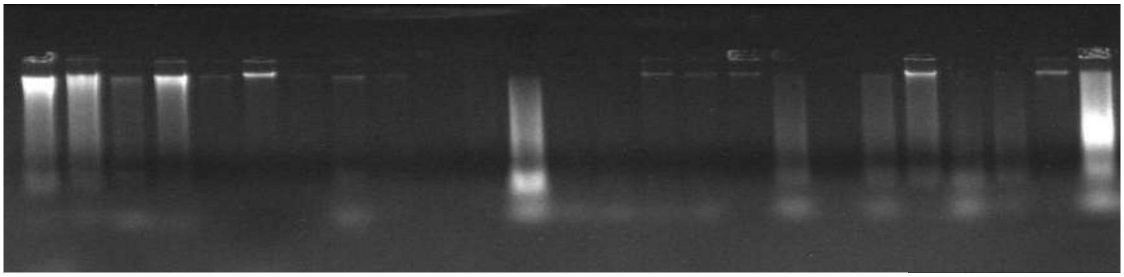

Fig 1: Gel electrophoresis of DNA extraction protocol without HEPES wash.

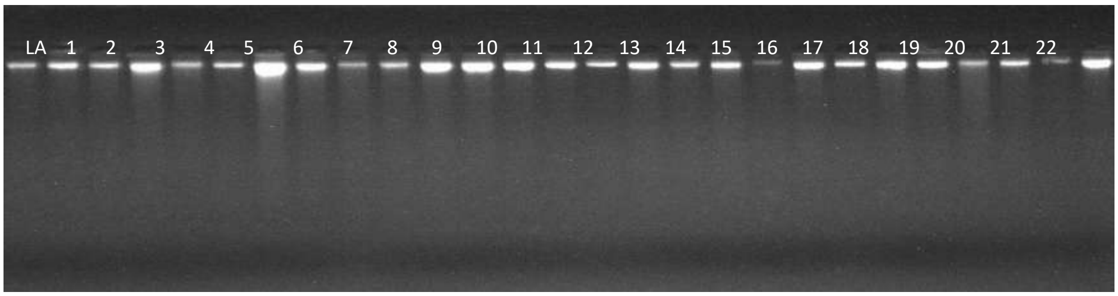

DNA suitable for a broad range of molecular biology applications was successfully extracted from rose plant containing high levels of secondary metabolites. These metabolites oxidized the DNA irreversibly, which hinders amplification of DNA by PCR through inhibiting the action of enzymes such as Taq polymerase (Moreira and Oliveira, 2011). The use of Hepes buffer in the initial washing step helps in the maintenance of enzyme structure and function at low temperatures and standardised pH (Turaki *et al*., 2017). The protocol development is a modification over the CTAB method. The development procedure was optimized by making use of the Hepes Buffer in addition to higher concentrations of other chemical compounds; this is known as the Optimised cetyltrimethylammonium bromide (CTAB) method (Turaki *et al*., 2017). The broad applicability of the optimized extraction method was demonstrated by its success in obtaining high-quality genomic DNA from rose plants. Previous research has shown that the presence of a high level of β-mercaptoethanol effectively eliminates polyphenols (Sahu *et al*., 2012). Consequently, a high concentration of β-mercaptoethanol was incorporated into the protocol, making it suitable for extracting high-quality DNA. Additionally, the inclusion of NaCl at concentrations exceeding 0.5 M, in combination with CTAB, is recognized for its ability to remove polysaccharides during DNA extraction. (Moreira and Oliveira, 2011). Zhang and Stewart, (2000) reported that higher concentration of PVP (2.5%) with lower molecular weight (10,000) rather than 40,000 has the tendency of producing DNA with higher quality. PVP with low molecular weight has less tendency of precipitating with the nucleic acids as compared to PVP with high molecular weight thus yielding sufficient amount of polyphenol-free DNA (Leza *et al*., 2017).

CONCLUSION

In conclusion, this protocol allows for simultaneous DNA extraction from numerous samples of plants with high level of metabolite and secondary polysaccharides, and does not need expensive reagents or equipments while producing clean and high quality DNA that is suitable for most genetic analysis purposes. The protocol should be applicable to other recalcitrant plant species with some modifications.

ABSTRACT
Rhizosphere-living bacteria that exert a global beneficial effect on plant growth are referred to as plant growth promoting rhizobacteria (PGPR). Examples of PGPR for crop development include genera such as Azospirillum, Bacillus, Pseudomonas, Rhizobium, Serratia, and Streptomyces. They play significant roles in biotic stress management when in contact with host plants using different methods. The methods include single inoculation (this involves the use of one bacterium to enhance the growth of plants), double inoculation (this involves the use of two or more bacteria to enhance the growth of plants) or co-inoculation (this involves the use of bacteria and fungi concurrently to enhance the growth of plants). Co-inoculation method has been identified to give the best results. The association of plant growth promoting fungi (PGPF) such as Glomus spp. with roots of various plant species has also been documented to modulate growth, morphology, nitrogen assimilation, resource allocation and mineral uptake of the host plant and also improves host reproductive fitness by enhancing plant growth, increase biomass and grain yield of crop plants. However, adequate knowledge on the mechanisms by which PGPR and PGPF act on the plants are still lacking. Therefore, this study will broadly bring to light various PGPR and PGPF for future research in horticultural crop improvement.
Keywords: *Beneficial microorganisms, horticulture, plant growth-promoting fungi (PGPF), plant growth-promoting rhizobacteria (PGPR), phytohormones, symbiosis*

INTRODUCTION
The use of microorganisms as inoculants in practical production especially plant growth-promoting rhizobacteria (PGPR) played an important role as a supplement to improve the growth and yield of horticultural crops (Jaime and Dilfuza, 2013). It was documented that PGPR are able to improve plant growth by increasing rate of seed germination and seedling emergence, minimizing the adverse effects of external stress factors and protecting plants from soil-borne pests and diseases. Medicinal plants harbor a distinctive microorganism due to their unique and structurally divergent bioactive secondary metabolites that are most likely responsible for the high specificity of the associated microorganisms (Qi *et al*., 2012). PGPR also help plants to grow by providing soluble phosphate converted by acidification from insoluble mineral phosphates, or via mobilization of other essential nutrients that can also help in plant growth improvement (Bertrand *et al*., 2001). Plant growth-promoting microbes found in the rhizosphere of various plants grown in different soils and climatic conditions were established to provide a wide spectrum of benefits to plants which include; (a) increasing the rate of seed germination and seedling emergence (b) minimizing the adverse effects of external stress factors and (c) protecting plants from soil-borne pests and diseases (Souza *et al*., 2015). There are two types of beneficial rhizosphere bacteria, those forming a symbiotic relationship with the plant and those that are free living in the soil and root (Barriuso *et al*., 2005). Various plant growth-promoting rhizobacteria strains have also proven to increase nutrient availability in the rhizosphere through synergism between the plants and the rhizobacteria (Cakmakci *et al*., 2005).

Arbuscular mycorrhizal fungi (AMF) for horticultural crop production

Plant growth-promoting fungi (PGPF) attract considerable interest as bio-fertilizers due to their multiple beneficial effects on plant quantity and quality and also, their positive relationship with the ecological environment. Plant growth-promoting fungi are non-pathogenic saprophytes that suppress diseases of crop plants caused by fungal and bacterial (Shivanna *et. al.,* 1996; Naziya *et. al.,* 2019 and Chandanie *et. al.,* 2006). Colonization of roots with PGPF can also lead to systemic resistance in distal parts of the plant (Meera 1995; Munoz, 2008). The association of PGPF with roots of various plant species affected with microbial infection has been documented to modulate growth, morphology, nitrogen assimilation, resource allocation and mineral uptake of the host plant and also improves host reproductive fitness by enhancing plant growth, increase biomass and grain yield of crop plants (Emmanuel and Babalola, 2020; Fasusi *et. al.,* 2023). The use of *Alternaria* sp. A13 and *Salvia miltiorrhiza* together under greenhouse conditions enhanced the dry root biomass and secondary metabolite accumulation.

S. miltiorrhiza seedlings colonized by *Alternaria* sp. A13 showed significant increment in fresh weight, dry weight, and contents enhancement (Zhou *et. al.,* 2018) (Table 2). Arbuscular mycorrhizal fungi (AMF) played an important role as a supplement to improve the growth and yield of several medicinal and aromatic plants (MAPs). Arbuscular mycorrhizal fungi (AMF) are also known to increase the growth of many plant species, including MAPs when inoculated with the plants (Selvaraj *et al*., 2008) (Table 2). In *Glomus coronatum*, *G. mosseae*, *G. etunicatum*, *G. geosporum*, *G. viscosum*, and *G. rubiforme* in the rhizosphere of *Smilax aspera* and *Helichrysum litoreum* there was occurrence of AMF species (Turrini *et al.,* 2010). AMF increase plant growth and oil content by stimulating the root system which allows the plant to exploit a greater volume of soil. In *Solanum viarum* plant, there was an improvement in plant growth and increase in mineral contents of leaves samples such as phosphorous, potassium, zinc, copper, manganese and iron content after treatment with AMF.

Co-inoculation of different beneficial microorganisms on host plants

Co-inoculation of different beneficial microorganisms on host plants has been reported by many investigators to improve the absorption of nitrogen (N), phosphorus (P) and mineral nutrients by plants when compared to single inoculation (Bashan and Holguin, 1997). *Lysinbacillus fusiformis* PM5 and PM24 produced 100 μg per ml indo-3-acetic acid (IAA) in defined medium, and considered as a promising potential mechanism for developing plant growth in inoculation conditions (Park *et al*., 2005). Inoculation of medicinal plants with PGPR also influenced the quality and quantity of bioactive constituents and their potential in agriculture, pharmaceutical and medicine (Sharma *et al*., 2015). Co-inoculation activity in species belonging to *Azospirillum*, *Azotobacter*, *Pseudomonas*, *Bacillus*, *Burkholderia*, *Bradyrhizobium*, *Sinorhizobium* and *Trihoderma* (Sudhakar *et al.*, 2000; Hemavathi *et al*., 2006; Hossainzadah *et al*., 2011; Rajasekar and Elango 2011) (Table 1). *Ocimum* spp. when inoculated with *Glomus fasciculatum*, there was an increased in shoot and root growth weight, biomass and essential oil content of *Azotobacter chroococcum* and *A. awamori* (Vinutha, 2005) (Table 1).

Hemavathi *et al*., 2006 (Table 1) also made similar observations in *Ocimum basilicum*, where plant growth increased after inoculation with *G. fasciculatum, Pseudomonas fluorescens* and *Bacillus megaterium*. Inoculation of *A. chroococcum* strain into *Adathoda vasica,* there was an improvement in the root, shoot, growth and dry weight (Anantha, 2006) (Table 1). A significant increase in shoot and root growth, increase in nitrogen content of root (20%) and shoot (52%) of *Galega orientalis* after co-inoculation of *Pseudomonas trivialis* strain 3Re27 with *Rhizobium galegae* HAMBI 540. Improved mineral nutrition explains the promotion of root and shoot growth. Plants inoculated with PGPR take up N, P, K and microelements more efficiently from the soil (Cakmakci *et al*., 2005). Two isolates of PGPR, *Bacillus subtilis* and *Pseudomonas fluorescens,* increased the yield of *Chrysanthemum cinerariifolium* up to 27% (Mishra *et al*., 2010) (Table 1). PGPR strains *P. fluorescens* and *B. megaterium* significantly increased plant height, root length, root girth, alkaloid content and N, P, K, Ca and Mg uptake in *Catharanthus roseus* in comparison to the un-inoculated control (Karthikeyan *et al*., 2010) (Table 1).

Zingiber officinale plants inoculated with *G. mosseae* significantly increased plant growth and also inoculation of *Pelargonium graveolens* with *G. fasciculatum*, *A. chroococcum*, and *Pseudomonas* spp. (Sharma *et al*., 1997). The plant growth and NPK uptake of *Stevia rebaudiana* increased after inoculation with *A. chroococcum, P. fluorescens* and *G. fasciculatum* (Earanna, 2007). Combined inoculation of *Begonia malabarica* and *Calamus thwaitesii* with *G. mosseae, B. coagulans* and *Trichoderma viride* enhanced the growth, biomass, nutrients, and production of secondary metabolites (phenols, ortho-dihydroxy phenols, tannins, flavonoids and alkaloids) (Selvaraj *et al*., 2008) (Table 1). In *S. viarum*, there was an improved in plant growth and increase in phosphorous, potassium, zinc, copper, manganese and iron content after treatment with PGPRs (*G. aggregatum, B. coagulans* and *Trichoderma harzianum*) (Hemashenpagam and Selvaraj 2011) (Table 1). There was a positive effect observed by Hosseinzadah *et al*., 2011 (Table 1) when *Azospirillum lypoferum, A. chroococcum* and *P. fluorescens* were inoculated together with increased in the growth dry weights of shoot and root, NPK content of leaves and roots of *Calendula officinalis*. Combination of PGPR strains *Azospirillum, Azotobacter, Pseudomonas* and *Bacillus* significantly increased plant height, root length, and alkaloid content in *Withania somnifera* compared to the un-inoculated control (Rajasekar and Elango 2011) (Table 1). Three strains of rhizobacteria *Pseudomonas plecoglossicida, Bacillus sp*. and *L. fusiformis* strains identified by 16S rRNA gene sequence analysis were co-inoculated with *Arabidopsis thaliana* and two Datura species (*Datura stramonium* and *D. tatula*), the utilization of beneficial PGPR isolates has great potential to stimulate the growth and development of plants under different culture conditions (Bilal *et. al.,* 2016).

CONCLUSION

The role of plants growth promoting microorganisms cannot be over-emphasized. The great potential of microorganisms was found to have a great potential for use as bio-inoculants to increase production of horticultural crops. These microorganisms will be useful in producing toxic chemical free food, herbals and improve sustainable plant production. The use of beneficial microorganisms (PGPR and PGPF) as bio-inoculant in horticulture has been elucidated. Therefore, for healthy and large scale horticultural crop production, beneficial microorganisms are encourage to be used as bio-fertilizer to enhance food production.

ABSTRACT
This study was conducted at the Horticultural section of Adekunle Ajasin University, Akungba Akoko, Ondo State, Nigeria between June and August, 2019 to evaluate the effect of different rooting media on the sprouting and growth of Thuja plant. The experiment was laid out in Completely Randomized Design (CRD) having four replicates. The different rooting media treatments used were: Topsoil (TS), Fresh sawdust (FSD), Cured sawdust (CSD), Topsoil + Fresh sawdust (TS+FSD) 1:1 v/v, Topsoil + Cured sawdust (TS + CSD) 1:1 v/v. At the end of 8 and 10 weeks after planting (WAP) data were collected on the percentage of Thuja survival, number of roots, length of root, number of new leaves and visual quality of the plant at 10 WAP. The results indicated existence of significant differences (p<0.05) among the different rooting media with respect to their effects on sprouting and the growth attributes of Thuja. Of all the rooting media, at 8 and 10 WAP, Top soil + Cured sawdust (TS + CSD 1:1) gave the highest number of roots at 10.75, 12.95 for 8 and 10 WAP, respectively. Similarly, at 8 and 10 WAP, TS + CSD1:1 gave the highest value of Thuja root length of 11.74 cm, and 14.75 cm for 8 and 10 WAP, respectively. TS + CSD1:1 gave the highest value of Thuja number of leaves produced at 7.25, 10.25 for 8 and 10 WAP, respectively. In visual quality assessment, TS + CSD1:1also had the highest value of 5.00. Sprouting and growth of Thuja is thus enhanced by using TS + CSD1:1.
***Keywords**: Plant propagation, Rooting media, stem cuttings, Thuja occidentalis*

INTRODUCTION

Thuja (*Thuja occidentalis*) is a conifer tree widely used as an ornamental plant. It belongs to the family Cupressaceae. It is an evergreen tree growing up to a height of six (6) to thirty- eight (38) meter at a slow rate having an even and symmetrical canopy with a soft compact framework and pyramidal structure in outlook (Gilman *et al*., 2006). It develops well in partial shade, but will perform better under full sunshine. Thuja is mostly propagated through stem cuttings obtained from stem tip. It could also be propagated through seeding and layering. The cutting is taken from the current year's growths that are firm but flexible as cutting from older growth are less likely to root (Dyer, 2018). Thuja possesses beautiful leaf shape and texture and so is used extensively as specimen or spot plant in landscaping.. It is equally used as screen plant to create an attractive privacy around a family gathering spot or children's play area, used as narrow hedges, as background to flower beds, in rockery, for guard strip around parking lots, for median planting in high way, as avenue plant and as reclamant plants also. It is sometimes grown as Christmas tree. In India, it is used as wind breaks. (Ilem 2016; Soga *et al.,2018)*. It attracts high economic returns to the grower as a single Thuja plant costs between ₦1,500.00, and ₦5 ,000.00 in Nigeria, depending on the size (Afrimash, 2020).
Apart from its ornamental uses, Thuja wood is usually utilized for guitar sound board. It is also being extensively used for building of beehives (Bucur, 1995). Medicinally, Thuja is used as an herbal medicine. Thuja leaves and oil (Thujone) are also used for treating cold sores, bacteria skin infection, joint and muscle pain. It is used as insect repellant and as flavouring agent in food and beverages (Thuja, 2018). As important as this plant is, it has a very low genetic and physiological capacity for adventitious

root production. This then, limits its large scale cultivation. Economically, the demand for this ornamental plant compels that the 'difficult-to-root' phenomenon should be resolved. This study was thus carried out with the objective of exploring different locally available, cheap rooting media and determining their effects and the best one for raising *Thuja occidentalis.*

MATERIALS AND METHODS

The experiment was conducted at the Horticultural Nursery Section of Adekunle Ajasin University, Akungba Akoko, Ondo State, Nigeria, between June and August, 2019. Average annual rainfall is between 1100 – 2000 mm per annum with mean temperature ranging between 26ºC and 28ºC and mean relative humidity is about 62%. The experiment was laid out in a completely randomized Design (CRD) with four replicates. Stem cutting of Thuja's tip part (15cm long each) was planted at the rate of one stem cutting per black polythene bag of dimension of 24 x 21cm - filled with required medium. The five rooting media and mixtures used are: Top soil (TS), Fresh Saw dust (FSD), Cured saw dust (CSD), Top Soil + Fresh Saw dust 1:1 (TS+FSD) and Top Soil + Cured Saw Dust 1:1 (TS+CSD).

Data were collected on: Percentage of plant survival as affected by the growth media at ten (10) weeks after planting (WAP), Number of roots and root length – at eight (8) and ten (10) week after planting (WAP), Number of new leaves produced – at eight (8) and ten (10) week after planting (WAP), Visual quality of the treatments at ten (10) week after planting (WAP). Prior planting, the physical and chemical analysis of the media were carried out to determine the texture and the nutrient concentration of the rooting media**.** Data collected were subjected to Analysis of Variance (ANOVA) and the treatments means were separated using Fisher's Least Significance Difference (LSD) at 5% level of probability.

RESULTS

Physical and Chemical properties of soil and rooting media used in the experiment

The textural class of the soil was sandy loam with 80.1% sand, 10.5% silt and 9.4 % clay. (Table 1.) The pH value of TS +CSD 1:1was 5.55, TS + CSD (1:1) had the highest concentration of available nitrogen (3.72g/kg) followed by CSD (3.62 g/kg), Sole TS had the highest concentration of Phosphorus (54.8mg/kg) followed by TS + CSD (1:1) (42.60mg/kg), The highest available Potassium was in CSD (2.60cmol/kg) followed by TS + CSD. FSD had the highest value of organic carbon (430.5g/kg) and sole TS (19.2/kg) had the least value (Table 1).

Growth parameters

The growth media had effect ($P<0.05$) on survival of Thuja at 10WAP. 100% survival of Thuja plant was observed in TS, CSD and TS +CSD 1:1. There was marginal decrease in the percentage survival recorded for TS +FSD1:1(75%). The FSD had the least (25%).(Table 2)

The growth media used also had significant effect on the number of roots produced at both 8 and 10WAP except in treatment with TS and CSD in both 8 and 10 WAP. Thuja raised in TS +CSD 1:1 significantly had higher number of roots than the rest, FSD had the least number of root produced. (Table 3).Thuja root length in TS +CSD 1:1 significantly longer than in others treatments at 8 and 10 WAP except in CSD at 8WAP.The least length of root produced at 8 and 10 WAP was recorded in FSD (Table 4) The number of new leaves produced at 8 and10 WAP was significantly higher ($p<0.05$) in the TS +CSD1:1(7.25) There was no significant difference in TS +CSD1:1in comparison with CSD The mean value of Fresh Sawdust was significantly lower ($p<0.05$) (Table 5)The rooting media had significant effect on the visual assessment of the treatments at 10WAP, except for plants raised in TS +CSD1:1 and CSD that showed no significant variance. (Table 6)

Table 1: Physical and chemical characteristics of soil and other Rooting media used in the experiment

PARAMETERS	TS	FSD	CSD	TS+ FSD 1:1	TS+ CSD1:1

DISCUSSION

The lower survival percentage in Fresh Sawdust is in line with observations of Jose *et al* (2018) and Akintoye *et al* (2012), that Fresh Sawdust greatly inhibits plant survival and growth due to its toxicity, high cellulose and lignin content, hence is not fit for use in raising cuttings or seedlings in the nursery. Studies by, Barbara (2010) and Bhadway (2014) also supported these findings. The 100% survival of Thuja plants in TS, CSD, and TS + CSD (1:1) is a pointer to the suitability of these growth media for its survival. Ade Oluwa *et al* (2014) and Ebere *et al* (2017). The Thuja plant cuttings raised in TS + CSD (1:1)consistently gave the highest mean values of the parameters measured. This could not be unconnected with the desirable physical and chemical characteristics of the rooting media. TS + CSD (1:1) had a pH value of 5.55 which favoured the growth of Thuja. This agreed with Soga *et al* (2018), who stated that coniferous shrubs and trees have preference for lower pH levels of between 5.00 – 5.55 for good growth and development as more nutrients are made available for its absorption at this pH range. The higher number of roots and root length value for Thuja plant at 8 and 10 WAP in TS + CSD (1:1) are in agreement with the report of Olosunde *et al* (2012) and Fagge *et al* (2019), who noted that apical cuttings and some selected stem cuttings raised in TS + CSD and CSD formed the lengthiest roots in their findings. At 8 WAP, there existed no significant difference in the number of Thuja plants' roots and the length of roots between CSD and TS + CSD (1:1) at 8WAP. However, significant differences occurred at 10 WAP in both the number of roots and length of roots produced. The reason could be partly because TS + CSD (1:1) combined good features of both media in terms of rich organic matter, nutrients and porosity which provides better opportunity for growth. So, according to Oluwafemi *et al* (2017) heterogeneity of the media (physically and chemically) is a good factor that makes the medium used in raising ornamental plants the best because of additive relationship between the media component and the complementary role of the mixtures. The highest number of leaves recorded in TS +CSD 1:1 followed by CSD could be attributed to high presence of minerals needed by the plants in the media particularly Nitrogen (3.72g/kg), Phosphorus (42.60mg/kg) and Potassium (1.56cmol/kg) which is higher than that of other media (Table 1) This high fertility status was due to its decomposed organic matter content which is rich in nutrients that in turn translated to vegetative development of Thuja. Mathad and Nalwadi (1989). Akanbi and Togun (2002) also added to this fact that nutrients availability especially Nitrogen greatly influences and determines the vegetative development of plants.The least growth value was consistently recorded for FSD despite the level of Nitrogen in it (3.54 g/ kg) higher than that of the Topsoil. This could be as a result of its having very high organic carbon content (430.50g/kg). This makes the loss of Nitrogen in the medium easy as microbes try to decompose it. In other word, immobilization of available Nitrogen in the medium occur due to high Carbon - Nitrogen ratio (C: N) effect. Olosunde *et al* (2008) Barbara (2010). Visual assessment of Thuja in the different media used showed that the appearance of the plant grown in Topsoil + Cured Sawdust according to the rating index used was better when compared with other media.

CONCLUSION

The Top soil + Cured Sawdust (1:1) proved to be the best medium in raising and for overcoming the difficulty in raising *Thuja* as it produced the highest number of roots, root length, number of new leaves produced and had the best rating in physical outlook.

ABSTRACT
Food insecurity remains a major challenge in Nigeria and insufficient nutrient intake causes severe malnutrition affecting the populace. Six fertilizer application rates were evaluated for their effect on growth and yield of onion at College of Agriculture, Kabba, Kogi State, Nigeria. The fertilizer application rates comprised of 0 kg h^{-1} NPK (20:10:10), 50 kg h^{-1} NPK, 100 kg h^{-1} NPK, 150 kg h^{-1} NPK, 200 kg h^{-1} NPK and 250 kg h^{-1} NPK. The experiment was laid out in completely randomized design (CRD) and replicated five times. Data were collected on plant height, number of leaves, leaf length, bulb diameter, bulb length, bulb circumference, shoot weight, bulb weight, dry matter contents and distribution. The results of the analysis of variance showed that fertilizer rates significantly ($p < 0.05$) influenced plant height, number of leaves and leaf length of onion. Onion plants treated with 150 kg h^{-1} NPK had the tallest plants, more leaves and longest leaves across the sampling weeks. The result also indicated that fertilizer application rates positively impacted yield components and yield with 150 kg h^{-1} NPK taking the lead. Application of 150 kg h^{-1} NPK had similar effect with 100 kg h^{-1} NPK regarding growth and yield traits accessed. For cost effectiveness, application of 100 kg h^{-1} NPK is suitable for pot onion production in homes.

INTRODUCTION
The onion (*Allium cepa* L.) is an herbaceous biennial plant of the family Alliaceae (Ghaffoor *et al.,* 2003). Onion is one of the most important vegetable crops cultivated in different parts of the world commercially. Hussaini *et al.* (2000) reported that the crop ranks second in importance after tomatoes among the vegetables in Nigeria. Bulbs are formed from the seeds in the first season of growth. Seeds are formed from the flowers in the second season. According to variety, the onion bulbs differ in sizes such as small, medium and large. It also produces bulbs with different colours like white, yellow, or red. Various shapes such as flattened, round or globular and texture like fine, or coarse has been documented (Ghaffoor *et al.,* 2003). It is cherished for having flavour and pungent properties, due to the presence of a volatile oil – allyl-propyl-disulphide. Onion is a high value and high income generating vegetable crop for farmers (Dapaah *et al.,* 2014). Onion is important in the daily Nigerian diet, the mature bulbs and green shoots are widely used as a seasoning or a vegetable in various dishes (Abdissa *et al.,* 2011). Being a rich source of flavonoids, its consumption has been linked to reducing the risk of developing cancer, heart disease and diabetes (Renbomo and Kanti, 2017). In addition, its anti-bacterial, antiviral, anti-allergenic and anti-inflammatory potential are noteworthy. Onion contains vitamins A and C, and a good amount of mineral elements for human nourishment (United States Dietary Allowance, 2008; Paul, 2006).
In Nigeria, onion is produced in the Sudan Savanna zones especially Gombe, Kano, Sokoto, Kaduna, Bornu and Plateau States (Falodun *et al.,* 2015). Other zones in Nigeria rely on the onion supply from these parts of the country because they are ignorant of the possibility of onion cultivation in other agro-ecological zones of Nigeria. Another constraint to sustained increased onion production include inadequate information on fertilizer recommendation at optimum level. Onions are sensitive to nutrient deficiencies compared to other crop plants due to their shallow and unbranched root system. Hence, they require and often respond well to addition of fertilizers. The application of NPK fertilizer improves the

growth and yield of onion. The application of balanced macro nutrients (Nitrogen, Phosphorus and Potassium) can enhance plant growth, development and yield (Maisura *et al.,* 2019). Generally, excessive amounts of inorganic fertilizers are applied to vegetables in order to achieve a higher yield (Seran *et al.,* 2010; Stewart *et al.,* 2005) which is uneconomical. There is limited information in the guinea savanna zone of Kogi State on the effects of fertilizer application rates on onion performance. Determining the appropriate fertilizer rate for onion will help to increase onion production, improve the diet of the people and generate income to the farmers. The objective of this study therefore was to investigate the optimum level of fertilizer application for the growth and yield of onion in Kabba, Kogi State.

MATERIALS AND METHODS

Experimental site: The experiment was conducted at Horticulture section, College of Agriculture, Kabba (7.8231˚N, 6.0732˚E and 400 m above sea level), in Southern Guinea Savanna Zone of Nigeria. The monoidal rainfall spans April to November with peak in June and dry season extends from December to March. The mean annual rainfall is 1570 mm per annum with an annual temperature range of 18-32˚C. The mean relative humidity is 60%.

Nursery preparation and seedling transplanting: Onion seeds were sourced from a local market in Gombe State and nursery bed was prepared in late February 2022 to raise the seedlings for six weeks before transplanting into the pots. The seedlings were transplanted into the pots in March 2022. The soil was potted in polyethylene bags of size 48 x 38.5 cm.

Experimental design: The experiment was laid out in a Completely Randomized Design (CRD) and replicated five times. The treatments were no fertilizer (control), 50 kg h^{-1} NPK, 100 kg h^{-1} NPK, 150 kg h^{-1} NPK, 200 kg h^{-1} NPK and 250 kg h^{-1} NPK. Each pot contained one plant.

Fertilizer application: The NPK fertilizer (20:10:10) was applied in split doses, 40% of the required quantity was applied at 2 weeks after transplanting while the remaining 60% was applied at 6 weeks after transplanting. The pots were arranged 40 cm apart.

Irrigation: Irrigation was done when required especially during the dry season when the seedlings were transplanted. This is done to conserve the optimum moisture level of the soil.

Data collection: Data was collected from the five plants that received similar treatment.

The following parameters were recorded from the plants.

Plant height (cm): Plant height was measured in centimeter from the ground level to the tip of the leaf using measuring tape.

Number of leaves per plant: Number of leaves produced by each plant were counted and the average recorded.

Leaf length (cm): The length of leaves was measured in centimeter with a measuring tape and the average leaf length taken.

Bulb diameter (cm): Bulb diameter at harvest was measured at right angles to the longitudinal axis at the widest circumference of the bulb from each plant.

Bulb circumference (cm): The circumference of bulb at harvest was measured at the middle portion of bulb and the average taken.

Bulb length (cm): The height of the bulb was measured using Vernier caliper.

Bulb weight (g): The top of each bulb was removed by cutting the pseudo-stem at 1 cm from the bulb, then weighed using electronic balance.

Harvesting: The crop was harvested in early July when more than 70 per cent of the tops had fallen over. Oven dry weights of the shoot and bulb were also taken from which dry matter content and distribution were estimated. The various plant parts were oven dried at a temperature of 80°C to a constant weight.

Total dry weight: It was calculated by adding dry shoot weight with dry bulb weight.

Shoot/bulb ratio: This was calculated by dividing shoot weight by the bulb weight.

Dry matter accumulation to the shoot: This was calculated as follows: $\frac{\text{Dry weight of shoot}}{\text{total dry weight}} \times 100$

Dry matter accumulation to the bulb: This was calculated as follows: $\frac{\text{Dry weight of bulb}}{\text{total dry weight}} \times 100$

Statistical analysis: Data were subjected to analysis of variance (ANOVA) in completely randomized design (CRD) using the GenStat statistical package (GenStat, 2007). Means were separated using the least significant difference (LSD) at 5% probability level.

RESULTS

Physicochemical properties of the experimental soil used

The physicochemical properties of the soil used for the experimental is shown in Table 1. The soil is characterized as sandy loam. The total nitrogen was very low (0.398%) and the available phosphorus (12.20 ppm) was medium. The potassium content was 0.16 cmol/kg. The cation exchange capacity was 22.70 cmol/kg, the base saturation was 30.89%. Organic carbon and organic matter were 2.212 and 2.932%, respectively, indicating that the soil was low in fertility.

Table 1: Physicochemical properties of the soil used in the study

Mechanical properties	Soil Particle size
Clay (%)	17
Silt (%)	9
Fine sand (%)	38

Growth parameters

Effect of NPK fertilizer application rates on plant height of onion in weeks after transplanting (WAT) is shown in Table 2. Fertilizer application rates significantly ($p < 0.05$) influenced height of onion plants at 4, 6, 8 and 10 WAT. Application of 150 kg h^{-1} of NPK increased plant height across the weeks with respective values of 30.63, 51.00, 56.90 and 61.00 cm. The value recorded at 4 WAT was not statistically different from 28.33 and 26.70 cm obtained when onion plants were treated with 100 kg h^{-1} and 200 kg h^{-1}, respectively. Similarly, the values obtained at 6, 8 and 10 WAT did not vary from 44.00, 49.22 and 55.33 noticed in plants that received 100 kg h^{-1} NPK, respectively. However, plants fertilized with 250 kg h^{-1} produced the shortest plants (16.73, 20.33, 24.17 and 27.73 cm) at 4, 6, 8 and 10 WAT, respectively.

Table 2: Effect of NPK fertilizer application rates on plant height (cm) of onion at 4, 6, 8 and 10 weeks after transplanting

Fertilizer	Plant height in weeks after transplanting			
	4	6	8	10
0 kg h^{-1}	18.00	23.83	30.33	34.67
50 kg h^{-1}	20.67	38.43	43.33	49.00
100 kg h^{-1}	28.33	44.00	49.33	55.33
150 kg h^{-1}	30.63	51.00	56.90	61.00
200 kg h^{-1}	26.70	33.67	38.67	44.67
250 kg h^{-1}	16.73	20.33	24.17	27.73
LSD (0.05)	7.75	10.47	9.85	9.87

Table 3 presents the effect of NPK fertilizer application rates on number of leaves of onion in weeks after transplanting. Number of leaves was significantly ($p < 0.05$) affected by the application of NPK fertilizer rates across the months. More number of leaves (5.67, 9.67, 11.33 and 13.67) was attributed to 150 kg h^{-1} NPK at 4, 6, 8 and 10 WAT, respectively. Although the values were statistically similar to 5.00 and 9.00 recorded when 100 kg h^{-1} NPK was applied at 4 and 6 WAT, respectively. Similarly, at 8 and 10 WAT, the values were not statistically the same with 9.33 and 10.67 and 11.67 and 12.33 recorded when plants were grown with 50 kg h^{-1} and 100 kg h^{-1}. Soil amended with 250 kg h^{-1} of NPK produced the least number of leaves of 2.67, 4.00, 5.67 and 7.00 at 4, 6, 8 and 10 WAT.

Table 3: Effect of NPK fertilizer application rates on number of leaves of onion at 4, 6, 8 and 10 weeks after transplanting

Fertilizer	Number of leaves in weeks after transplanting			
	4	6	8	10
0 kg h^{-1}	3.67	5.333	6.00	7.67
50 kg h^{-1}	4.33	7.67	9.33	11.67
100 kg h^{-1}	5.00	9.00	10.67	12.33
150 kg h^{-1}	5.67	9.67	11.33	13.67
200 kg h^{-1}	4.33	7.33	9.00	11.00
250 kg h^{-1}	2.67	4.00	5.67	7.00
LSD (0.05)	1.13	1.88	1.93	1.92

Effect of NPK fertilizer application rates on leaf length of onion in weeks after transplanting is presented in Table 4. Influence of fertilizer application rates is in this order with respect to number of leaves: 150 kg h^{-1} > 100 kg h^{-1} > 50 kg h^{-1} > 200 kg h^{-1} > 0 kg h^{-1} > 250 kg h^{-1}.

Table 4: Effect of NPK fertilizer application rates on leaf length (cm) of onion at 4, 6, 8 and 10 weeks after transplanting

Fertilizer	Leaf length in weeks after transplanting			
	4	6	8	10
0 kg h^{-1}	8.69	19.30	23.87	29.00
50 kg h^{-1}	11.17	29.90	36.00	44.00
100 kg h^{-1}	16.71	33.95	42.40	52.00

150 kg h^{-1}	18.47	39.25	43.31	53.67
200 kg h^{-1}	13.60	28.14	31.44	37.27
250 kg h^{-1}	7.72	17.63	21.20	26.33
LSD (0.05)	5.24	6.39	7.48	4.15

Yield attributes and yield

Effect of NPK fertilizer application rates on bulb circumference, bulb diameter, bulb length, bulb weight, shoot weight and total weight of onion is presented in Table 5. Fertilizer application rates had positive impact on bulb circumference, bulb diameter, bulb length, bulb weight and total weight of onion. It is important to note that, plants grown with 150 kg h^{-1} of NPK had the widest bulb (18.23 cm), heaviest bulb (71.00 g) and total weight of 99.67 g than others. The least value for bulb circumference (12.10 cm), bulb weight (27.00 g) and total weight (42.67 g) was associated with the application of 250 kg h^{-1} of NPK.

Table 5: Effect of NPK fertilizer application rates on bulb circumference, bulb diameter, bulb length, bulb weight, shoot weight and total weight of onion

Fertilizer	Bulb circumference (cm)	Bulb diameter (cm)	Bulb length (cm)	Bulb weight (g)	Shoot weight (g)	Total weight (g)
0 kg h^{-1}	13.67	13.40	8.00	29.33	20.33	49.67
50 kg h^{-1}	13.60	13.70	7.63	31.00	21.33	52.33
100 kg h^{-1}	16.50	17.20	9.03	59.33	26.67	86.00
150 kg h^{-1}	18.23	18.03	9.70	71.00	28.67	99.67
200 kg h^{-1}	12.40	11.67	8.83	33.00	16.67	49.67

Dry matter attributes

Effect of fertilizer application rates on dry matter attributes of onion is shown in Table 6. Dry matter attributes of onion plant evaluated indicated non-significant influence of fertilizer application rates on all the traits.

Table 6: Dry matter attributes of onion plants grown under different fertilizer application rates

Fertilizer	Dry shoot weight (g)	Dry bulb weight (g)	Total dry weight (g)	Shoot /bulb ratio	% DMDS	% DMDB
0 kg h^{-1}	2.36	7.15	9.52	0.31	23.57	76.43
50 kg h^{-1}	2.77	7.38	10.15	0.46	30.42	69.58

DISCUSSION

Growth

The effect of fertilizer application rates on growth attributes of onion differed significantly. Plant height, number of leaves and leaf length significantly increased with the application of 150 kg h^{-1} of NPK. This observation indicated that this rate is optimum thereby releasing sufficient amount of nutrient element to complement the inherent nutrient in the soil. Adebayo *et al.* (2011) reported that when fertilizer is available in adequate quantity, plants tend to grow at their optimal potential. Earlier reports from Cann (1965); Baiyeri (2002); Abubakari *et al.* (2015) reported that the number of fruits per bunch of plantain is impacted by plant nutrition. Further application of fertilizer above 150 kg ha^{-1} of NPK led to a decrease in growth attributes when compared with the plants treated without fertilizer application. The result implied that onion plants may thrive well on marginal soils but addition of fertilizer could enhance the growth of this plant. The decline in growth parameters obtained above 150 kg h^{-1} could be attributed to acidification. This result corroborates Olajide and Baiyeri (2021) who found that NPK decreased growth of *Ceiba pentandra* which was attributed to acidification of the rhizosphere.

Yield and dry matter attributes

The variability observed in yield and some dry matter attributes of onion in this study is linked to varying rates of fertilizer application. Application of 150 kg h^{-1} positively enhanced yield and some dry matter parameters accessed. This finding could be as a result of sufficient nutrient supplied to onion by this rate that resulted to increased yield. When nutrients are supplied in optimal quantity, high quality and better nutritious plants are produced (Rice *et al.,* 1994; Baiyeri *et al.,* 2009). The result of this finding contradicts the work of Falodun *et al.* (2015) who reported increase in yield characters of onion plants treated with higher rate of inorganic fertilizer over the control. The result also disagrees with those of Abdelrazzag (2002) in onion and Togun and Akanbi (2003) in tomato who found that the yield characters of the crops improved with increased application of inorganic fertilizer. Generally, reduction in yield parameters was obtained when fertilizer was applied beyond 150 kg h^{-1} which may be linked to rising level of soil acidity. Application of NPK decreased soil pH and boosted soil acidification (Qaswar *et al.,* 2020).

The pattern of dry matter distribution of onion plants in which 69.58 – 82.14% of photo-assimilates went to the bulb corroborates Ugese *et al.* (2008) who recorded dry matter allocation to the root of more than 70% in shea tree seedlings. This finding contradicts the report of Baiyeri (2003) in cashew and African breadfruit where dry matter allocation to the root was less than 20%. Ugese (2010) reported that dry matter distribution pattern of tamarind seedlings ranged from 38.9 – 45.3% which seem to be contrary to the findings of this present study.

CONCLUSION

Varying rates of NPK influenced growth, yield and some dry matter traits of onion as obtained in this present study. Although application of NPK fertilizer at 150 kg h^{-1} improved growth and yield of onion, however when compared with plants that received 100 kg h^{-1} of NPK, there was no significant difference in growth and yield parameters measured. Hence, for cost effectiveness, 100 kg h^{-1} of NPK is recommended for onion production in the study area.

ABSTRACT
The optimized protocol for tissue culture will facilitate large-scale production of high-quality planting materials, ensuring a stable supply for commercial cultivation. It also supports genetic research, conservation, and mass multiplication of fluted pumpkin varieties. Ultimately, this research seeks to develop a robust and efficient protocol, enhancing the rapid multiplication of this nutritious vegetable. The application of plant growth hormones had varying effect on the cultivated tissue culture plantlets. In the absence of hormone (plant growth regulator), the plantlets survived, but did not proliferate. Varying the concentrations of the hormones showed varying growth patterns.
Keywords: *Tissue culture, plant growth regulators, fluted pumpkin, plantlets and protocol*

INTRODUCTION

Fluted pumpkin (*Telfairia occidentalis* Hook f.) is a prized leafy vegetable in West Africa due to its nutritional value and versatility (Fajinmi *et al*., 2022). However, conventional propagation faces challenges like limited access to quality planting materials and slow multiplication rates (Ajayi, 2007). Micro-propagation, a controlled environment technique, offers a solution. This study focuses on optimizing the micro-propagation protocol using different hormone concentrations. Hormones are critical for plant growth and can significantly impact micro-propagation success (Harahap *et al*., 2020). Fluted pumpkin, a vital West African leafy vegetable, faces challenges in traditional propagation. Micro-propagation shows promise for rapid multiplication, but optimized protocols are lacking. Hormone concentration optimization is crucial for improving shoot multiplication, elongation, rooting, and plantlet vigor. Research is needed to develop a reliable protocol for high-quality planting materials in commercial cultivation. This research aims to improve conventional fluted pumpkin propagation methods by optimizing micro-propagation. It will increase access to quality planting materials, boost agricultural productivity, and promote sustainability. Additionally, it supports genetic research, contributes to economic development, and addresses various limitations, offering substantial benefits to the fluted pumpkin sector. The aim of the study was to find the ideal hormone mix and concentration for promoting shoot multiplication, elongation, and root formation while minimizing callus formation.

MATERIALS AND METHODS

Healthy fluted pumpkin explants will be cultured on a nutrient medium with varying concentrations of plant growth regulators like auxins and cytokinins.

Media Composition

Table 1: Table showing media composition and concentrations

	Zero Hormone	**BAP + IBA (0.1mg/ml)**	**BAP + IBA(0.2mg/ml)**	**Kin +GA3+**	**BAP + NAA(0.1mg/ml)**	**BAP + NAA(0.2mg/ml)**
Murashige & Skoog (MS)	4.43g	4.43g	4.43g	4.43g	4.43g	4.43g
Sucrose	30g	30g	30g	30g	30g	30g
Mio Inositol	100mg	100mg	100mg	100mg	100mg	100mg
Kinetin	-	-	-	1.0/2.0/5.0	-	-
GA3+	-	-	-	1.0/2.0/5.0	-	-

BAP	-	0.5/0.1/0.05/ 1.0/2.0	0.5/0.1/0.05/ 1.0/2.0	-	0.5/0.1/0.05/ 1.0/2.0	0.5/0.1/0.05/ 1.0/2.0
NAA	-	-	-	-	0.1	0.2
IBA	-	0.1	0.2	-	-	-

Preparation of plant material

Surface Sterilisation

The seeds of fluted pumpkin will be extracted from its pod and washed thoroughly under running water, and then sterilized with 20% Clorox (Sodium Hypochlorite 3,5 v/v) for 15min and 10% Clorox (Sodium Hypochlorite 3,5 v/v)for 15min. Explants will be rinsed thrice with sterile distilled water

Initiation

Explants will be initiated using Nelson and Somogi medium as reported by Nagata *et al*, 2007. This medium contained mineral salts of Murashige and Skoog (1962) medium, Sucrose (30 g/l) and Phytagel (2.5 g/l). Sterilized ugwu seeds will be transferred to the MS initiation media under sterile conditions using a Labconco laminar flow hood (Murashige and Skoog 1962).

Multiplication

Upon establishment, approximately 6 weeks after initiation, the plantlets will be transferred to a multiplication medium in 200 mL glass food jars. The multiplication medium will be made up of Murashige and Skoog (1962) medium, IBA (2.0 mg/l), NAA (1.8 mg/l), Kinetin (2.0 mg/l), Sucrose (30 g/l) and Phytagel (2.5 g/l). Further sub-culturing will be done every 6 weeks to increase plantlet numbers. Mature rooting systems will be established after the plantlets are placed on a rooting medium containing mg NAA.

Fig 1: Measurement of root length after 4 weeks of cultivation under optimum temperature and humidity

Fig 2: Test tube containing cultivated fluted pumpkin using Kinetin and GA3+ (2:2) at 4 weeks

Fig 3: Test tube containing cultivated fluted pumpkin using BAP and NAA (0.1:0.1) at 4 weeks

RESULTS AND DISCUSSION

The results show the effect of increasing concentrations of each of the hormones on the growth parameters.

Number of Roots and Root length:

The model is highly significant ($p < 0.01$), indicating that the various hormone combinations collectively influence the number of roots.BAP and BAP + NAA are highly significant individual factors ($p < 0.01$), suggesting their strong influence on the number of roots.IBA, NAA, KIN, and GA3 do not significantly affect the number of roots. This report tallies with the observations of Vanhala *et al*., (1998). However, hormone combinations of BAP + IBA, BAP + NAA and increasing concentrations of BAP are also significant ($p < 0.05$), indicating their combined impact on root multiplication. This report tallies with the finding of Padmaja *et al*., (2012) who reported that increasing the concentration of IBA and NAA in combination with BAP had an additive effect on root number and root length.

Number of Shoots and Shoot Length:

The overall model is highly significant ($p < 0.01$), showing that the hormone combinations collectively influence the number of shoots. Among the individual hormones, BAP, IBA, NAAare highly significant ($p < 0.05$) and contributed significantly to the number of shoots, while increasing concentration of BAP leads to increase in the proliferation of shoots and shoot length. This report conforms with the findings of Mohapatra and Batra, (2017) concerning increasing the concentration of BAP to enhance shoot proliferation. Other hormone combinations like KIN + GA3+ do not individually affect the number of shoots significantly, while IBA, NAA, KIN, and GA3+ do not affect the shoot length significantly. Interaction factors BAP + IBA and BAP + NAA are also significant ($p < 0.05$), indicating their combined influence on the number of shoots and length of shoots. This is similar with the effects of PGR on tissue culture plantlets of khinjuk pistachio measured after 28 days of planting, (Tilkat *et al*., 2005).

Percentage Survival:

The overall model is highly significant ($p < 0.01$), indicating that the various hormone combinations collectively have a significant impact on percentage Survival of tissue culture of *Telfairia occidentalis*.

Among the individual hormones, BAP is highly significant ($p < 0.0001$) and contributes significantly to percentage survival of the plantlet. Increasing concentrations of IBA, NAA, KIN, and GA3 do not individually have a significant impact on the percentage survival of the plantlet ($p > 0.05$). Hormonal combinations of BAP + IBA and BAP + NAA are also significant ($p < 0.05$), suggesting that the combination of these factors affects percentage Survival. The best % survival was noticed in BAP + NAA (0.05/0.1 mg/1) with 97% survival rate.

In conclusion, the BAP treatments gave better shoot proliferation than the KIN treatments. The best multiple shoot initiation was obtained on MS medium with BAP+NAA at 0.05/ 0.1 mg l-1. All microshoots initiated by BAP hormone combinations showed further growth and proliferation upon transfer onto MS medium supplemented with 0.05- 0.1mg/1 BAP + NAA. Some treatments caused considerable callusing at the base of the explant.

ABSTRACT
The effects of feeding diet containing boiled coffee pulp meal on haematological parameters in rabbit were studied. A total of thirty six (36) mixed breed weaner rabbits (average weight, 550 g) were randomly allocated to four dietary treatments containing 0, 4, 8 and 12% boiled coffee pulp meal (BCPM). Diet 1 (0% BCPM)) served as the control diet. Each of the four treatments was replicated thrice and each replicate had three rabbits arranged in a Completely Randomized Design. The rabbits were fed with the experimental diets for 12 weeks. The results showed that pack cell volume, haemoglobin, mean corpuscular haemoglobin, mean cell volume and red blood cell were significantly affected by the treatments while white blood cell count, neutrophil, lymphocytes, eusnophils, basophils and monocytes showed no significant difference. It was concluded that inclusion of boiled coffee pulp meal in rabbit diets was well tolerated by weaner rabbits without any adverse health condition.
Keyword*: coffee pulp meal, rabbits, anti-nutritional factors, boiling, haemoglobin*

INTRODUCTION

The inability of livestock farmers to supply their animals with high quality feed has been recognized as one of the technical constraints limiting livestock production in the developing countries (Okoruwa, 2015). The livestock are exposed to severe nutritional stress especially in recent time that the prices of conventional feedstuffs such as soybeans, maize and groundnut have been increasing at the same time that the availability is often a problem (Babayemi *et al*., 2006). The case has been worsened during the dry season when fodders are rare and of low nutritive value. To salvage this problem, it is necessary for the livestock farmers to explore the cheapest and readily available agricultural waste products that have high nutritive value as feed ingredient in the diet of their animals. Typical among such feed ingredients is coffee pulp. The presence of essential nutrients such as proteins, carbohydrates fibre and some minerals especially potassium in coffee pulp suggest that it could be used as livestock feed ingredient (Barcelos *et al*., 2001), nonetheless high content of anti-nutritional factors in this by-product has restricted its use as an animal feed to a large extent (Padmapriya *et al*., 2013). Therefore, total elimination or reduction of anti-nutritional factors in coffee pulp through physical, chemical or biological processing technique is of paramount important. The major limitations of these anti-nutrients are related to its physiological effects on the central nervous system and its influence can alter the constituents of the animal blood (Mazzafera 2002). The aim of this study was to determine the effect of feeding boiled coffee pulps meal on the haematological parameters of weaner rabbits.

MATERIALS AND METHODS

About 25kg of coffee pulps were collected from the coffee pulping centre, Cocoa Research Institute of Nigeria, Ibadan. The pulps were subjected to boiling process. The process involves putting sterilized coffee pulp into heat water at 100^0C at a pulp: water of 1:5 for 30 minutes. At this temperature, majority of hard pulps were expected to be softened, After which the boiled pulps were removed, put into sieve to drain the water, later sun dried and stored in jute bags until it was used. Thirty-six (36) mixed breed weaner rabbits were purchased from Adeeko Farm, Ibadan, Oyo State. Before the commencement of the experiment, the rabbits were acclimatized for seven days. During this period, rabbits were all fed control diets and were also treated against endo and ecto-parasites using sodex (dewormer) and ivomectin respectively. The animals were randomly divided into four treatment groups andach group comprised of nine rabbits. Each group was further sub-divided into three, such that replicate groups of three rabbits were obtained for each sub-group with three rabbits per replicate. The boiled coffee pulp was mixed into rabbits ration at 0, 4, 8 and 12% inclusion level designated T_1, T_2, T_3 and T_4 respectively (Table 1). All diets were formulated to meet the nutritional requirements of weaner rabbits based on NRC (2007) recommendations and the experimental diets were offered to rabbits twice in a day at about 7:00 am and 4:30 pm. The animals were allowed *ad libitum* access to feed and water throughout the trial. On the last day of the feeding trial, two sets of blood samples were collected from each rabbit via jugular vein puncture using a 5 ml needle fitted syringe. About 5 ml blood sample each was collected into labeled sterile bottles containing anticoagulant for the determination of hematological parameters while the blood samples for serum analysis were taken with sterile bottles without anticoagulant, so as to allow the blood to coagulate at room temperature. The supernatant was then collected and stored in a freezer for subsequent biochemical analysis. The blood samples were analyzed using the procedure described by AOAC (2001). Data collected from this study were subjected to statistical analysis (SAS, 2008 version 9.2) and significant means were separated using Duncan multiple range test (Duncan, 1955). The trial lasted for 84 days.

Table 1: Feed composition and calculated nutrient values of the experimental diets

Parameters	**T_1 (0%CPM)**	**T_2 (4%CPM)**	**T_3(8%CPM)**	**T_4 (12%CPM)**

Monocytes	$1,85^{a}$	1.70^{a}	1.62^{ab}	1.50^{b}	0.41

abc= mean with different superscripts on the same column are significantly different (P<0.05), SEM= Standard error of mean

RESULTS AND DISCUSSION

The results of haematological parameters of rabbits fed graded levels boiled coffee pulp are presented in Table 2. The results showed significant (P<0.05) differences in most of the haematological parameters investigated. The least packed cell volume (PCV) was recorded in rabbits fed control diet which increase progressively as the level of boiled coffee pulp increase in the diets. The increase in the PCV concentration in the blood of rabbits in this experiment indicated the good health status as low PCV values are taken as an index of anaemia. This is in agreement with the finding of (Abdelati *et al*., 2008) who reported reduction in the PVC of broiler chickens fed roasted *Leucaena leucocephala* at various levels and attributed it to toxic factor (anti-nutritional factor) in the diet. PCV is a symbol of toxicity (Ahamefule *et al*., 2008). Haemoglobin (Hb), mean corpuscular haemoglobin (MCH), mean cell volume (MCV) and red blood cell (RBC) counts were also significantly (P<0.05) affected by the dietary inclusion of boiled coffee pulp which increase progressively as the level of inclusion is increased in the diet. The increase in Hb, MCH, MCV and RBC denotes that coffee pulp meal positively contributed to the synthesis of blood forming metabolites such as copper, iron and magnesium which augments effective transportation of oxygen and other nutrients in the body of animals (Oyebode, 2015). The white blood cell were not significantly (P>0.05) different. This shows that boiled coffee pulp meal neither enhanced nor impaired the ability of rabbit to ward off infection. There was also no significant (P>0.05) difference in the neutrophil, lymphocytes, eusnophils, basophils and monocytes, and their values fell within the normal range established by Research Animal Resource (2009) for growing rabbits.

CONCLUSION

It was concluded that inclusion of boiled coffee pulp meal in the rabbits diet was well tolerated by weaner rabbits without any adverse health condition.

ABSTRACT

A field experiment was conducted at the horticulture garden of the Federal College of Agriculture Ibadan to assess the effects of an aqueous extract of Tithonia diversifolia and a synthetic foliar fertilizer on the vegetative growth parameters of Amaranthus hybridus. The experiment was laid out in a randomized complete block design (RCBD) with eleven treatments replicated three times. The treatments were Tithonia diversifolia extract at 1kg/L, 1.5kg/L, and 2kg/L with a soaking duration of 1, 2, and 3 days, synthetic foliar fertilizer (positive control) and negative control (no fertilizer). Data were collected on plant height, number of leaves, stem girth and leaf area. The result revealed that Tithonia diversifolia-based foliar fertilizer had a significant effect on the vegetative parameters of Amaranthus hybridus. Tithonia diversifolia of 1kg/L with a soaking duration of 1 and 3 days at 4 weeks after transplanting had the highest plant heights (54.90 cm and 54.10 cm respectively) which were significantly higher than the negative control (no fertilizer) which had the lowest plant height (42.30 cm). The use of Tithonia diversifolia-based foliar fertilizer could therefore be recommended as an alternative to synthetic foliar fertilizer for the sustainable production of Amaranthus hybridus.

***Keywords**: Amaranthus hybridus**,** Tithonia diversifolia, foliar fertilizer, synthetic foliar fertilizer*

INTRODUCTION

Fertilizers are indispensable components of modern agriculture, playing a pivotal role in augmenting crop yields and addressing global food security challenges. Depending on how crops absorb nutrients, fertilization techniques can be categorized as either root fertilization or foliar fertilization (Niu *et al*., 2021). Numerous variables, including soil temperature, humidity, salinity, and microbiota, have an impact on how well soil fertilizer nutrients are utilized (Li *et al*., 2009); however, foliar fertilization has emerged as an effective means of delivering essential nutrients directly to plants through aerial parts, thereby reducing the negative impacts on the soil such as nutrient fixation, toxicity and antagonism (Bindraban *et al*., 2015). It is also characterized by rapid nutrient absorption and the ability to rectify nutrient deficiencies promptly, thus contributing to improve crop health and increased agricultural productivity. Foliar fertilizers exist in both organic and synthetic forms. Organic-based foliar fertilizers, derived from natural sources and organic materials, embody a holistic approach to plant nourishment, addressing concerns related to soil health and environmental impact while synthetic foliar fertilizers are chemically manufactured to contain specific nutrient compositions, offer precise and readily available nutrients. This study explores the effects of organic-based and synthetic foliar fertilizers on the vegetative growth parameters of *Amaranthus hybridus.*

MATERIALS AND METHODS

The field experiment was conducted at the horticultural garden of the Federal College of Agriculture, Moor Plantation, Ibadan, Oyo state. The land was cleared manually and later ploughed and harrowed. *Amaranthus hybridus* seeds were obtained from the Institute of Agricultural Research and Training

(I.A.R&T) seed store. A seedbed of 2m x 2m was made for raising *Amaranthus hybridus* in the nursery. Thirty-three beds measuring 1m × 1.5m each with a 0.5m alleyway were constructed as permanent beds/sites onto which the *Amaranthus hybridus* seedlings were transplanted. The *Amaranthus hybridus* seedlings were transplanted 3 weeks after sowing using a ball of earth method at a spacing of 20cm x 20cm. Leaves of *Tithonia diversifolia* collected were chopped into small pieces and soaked in water; 1kg/L, 1.5kg/L and 2kg/L. The soaking durations were 1 day, 2 days and 3 days. The synthetic foliar fertilizer was diluted according to the specification of 3kg/ha and applied at 2-week intervals while 250 ml of *Tithonia diversifolia* extract was applied per plot at 5-day intervals. The foliar fertilizer application regime started one week after transplanting. Vegetative data were taken on number of leaves, plant height, stem girth and leaf area at 4 Weeks After Transplanting (WAT) using standard procedure. The data generated were subjected to analysis of variance (ANOVA) and the treatment means were separated using DMRT at a 5% probability level.

RESULTS

Table 1 shows the result of the soil physical and chemical analysis of the study area with a pH (H_2O) of 6.21, texturally sandy loam with a composition of 888 g/kg sand, 32 g/kg silt, and 80 g/kg clay (Table 1). *Tithonia diversifolia* (1kg /L) with a soaking duration of 1 and 3 days at 4WAT had the highest plant heights (54.90 cm and 54.10 cm respectively) which were significantly higher than the negative control (no fertilizer) which had the lowest plant height (42.30 cm) (Table 2). However, there were no significant differences in plant height treated with the same concentration (4WAT) soaked for different durations (1 day and 3 days). These heights were also comparable to the plant height of the positive control, which implies that the soaking duration did not significantly affect plant height (Table 2). *Tithonia diversifolia* (2kg/L) with a soaking duration of 2 days had the highest number of leaves (37.00) which was significantly higher than *Tithonia diversifolia* (2kg /L) with a soaking duration of 1 day that had the least number of leaves (24.90). The number of leaves under *Tithonia diversifolia* (1kg/L) and 1.5kg/L did not differ significantly with respect to the duration of soaking. *Tithonia diversifolia* (2kg/L) with 2 days soaking duration gave the highest number of leaves (37.00) which was significantly higher than 1 and 3 days soaking durations, respectively (Table 2). *Tithonia diversifolia* (2kg/L) with a soaking duration of 2 days had the highest stem girth (4.17) which was significantly higher than the negative control (No treatment) and some of the other treatments. With *Tithonia diversifolia* (1kg/L), the stem girth decreased as the days for soaking increased. *Tithonia diversifolia* (1.5 kg/L) with a soaking duration of 2 days gave the highest stem girth and for *Tithonia diversifolia* (2kg /L) the stem girth decreased as the days for soaking increased and these were also comparable to the stem girth of the positive and negative control (Table 2).

T1(1kg sunflower/L soaked for 1 day); T2 (1kg sunflower/L soaked for 2 days); T3 (1kg sunflower /L soaked for 3 days); T4 (1.5kg sunflower /L soaked for 1 day); T5 (1.5kg sunflower /L soaked for 2 days); T6 (1.5kg sunflower /L soaked for 3 days); T7 (2kg sunflower /L soaked for 1 day); T8 (2kg sunflower /L soaked for 2 days), T9 (2kg sunflower /L soaked for 3 days); T10 (Synthetic foliar fertilizer); T11 (Control)

DISCUSSION

The result from the experiment revealed the positive effect of the *Tithonia diversifolia-based* foliar fertilizer on the vegetative growth parameters of *Amaranthus hybridus* L. Several studies have reported the potential of *Tithonia diversifolia* to enhance vegetative growth parameters of crops which is an indicator of overall plant health and vigor (Ademiluyi and Omotosho, 2007; Liasu and Achakzai, 2007). On the other hand, the soaking duration did not seem to have a significant impact on the vegetative parameters during the period of growth. This finding implies that for the recommended concentration, there is no added benefit to extending the soaking duration from 1 day to 3 days. This suggests that *Tithonia diversifolia* when soaked quickly releases its components into solution to be taken up by the plants or reaches its maximum effectiveness within the first day of soaking.

CONCLUSION

This study showed that the application of *Tithonia diversifolia-based* foliar fertilizer had significant effects on the vegetative growth of *Amaranthus hybridus.* However, the soaking duration of *Tithonia diversifolia* did not have significant effects on the vegetative parameters of *Amaranthus hybridus*. Therefore, in order to promote organic agriculture, *Tithonia diversifolia* can be used as an alternative to synthetic foliar fertilizer.

ABSTRACT
Organic mulches as one of the agronomic practices used at different rates and types could increase the yield of turmeric grown all over the world for its spice and medicinal values. The use of locally available mulches like cassava peel and sawdust enhanced the sprouting, emergence and establishment of turmeric rhizomes. A field experiment was carried out on the field of National Horticultural Research Institute, Ibadan, Oyo State, Nigeria (Lat. 7^0 30' N; Long. 3^0 50'E) between 2017 and 2018 rainy seasons on the emergence of turmeric rhizomes on a 2 x3 factorial arranged in Randomized Complete Block design, the first factor is two types of mulches (sawdust and cassava peel) and the second factor is the three rates of mulch (No mulch (control), 5t/ha and 10t/ha. The results showed that 10t/ha cassava peel mulch produced the highest rhizome emergence of 99.20% in 2017 and 100. 0% in 2018 after 30 days of planting followed by 10t/ha sawdust with 94.44% in 2017 and 94.43% in 2018 and the least of 20.64% in 2017 and 21.43% in 2018 with no mulch. The yield of the rhizome varied with the type and rate of mulch used with 10t/ha cassava peel having the yield of 8179kg/ha in 2017 and 8183.6kg/ha in 2018, followed by 10t/ha sawdust mulch with 5956kg/ha in 2017 and 5964kg/ha in 2018 and the least yield of 1401kg/ha in 2017 and 2209.5kg/ha in 2018 with the control.
***Keywords**: Cassava peel, sawdust, organic waste, mulch, seedling, emergence*

INTRODUCTION
Turmeric (*Curcuma longa* L.) is an herbaceous plant belonging to the family Zingiberaceae. The consumption is multidisciplinary as food, cosmetics and medicine (Uchechukwu, 2020). India is the leading producer of turmeric in the world; it produced about 75% of the total world supply (Prahakaran, 2013). India occupies the first position in production area with 195.10 thousand hectares (78 %) followed by China with 16.61 thousand hectares (8 %), Myanmar with 8.80 thousand hectares (4 %) and Nigeria and Bangladesh together contributing 12.71 thousand hectares (6 %) of the global production (Anonymous, 2012). The climatic condition in Nigeria favours turmeric production and makes its intensive cropping more common especially in the rainforest transition (Ihenacho *et al.*, 2017). In Nigeria, productions of turmeric are prominent in 19 states depending on the locality where it assumes different names. Meanwhile, other minor crops such as rizga and Hausa potato play significant roles as turmeric in the food chain in Nigeria (Olojede *et al.,* 2005). Mulching is an application of any plant residues or other materials for covering top soil surface for conserving soil moisture, reducing the runoff and manages soil erosion, checking weed control, improving soil temperature, modifying the micro environment of soil to meet the needs of seeds for their good germination and better growth of seedlings (Chavan *et al.,* 2010).
Different materials may be use for mulching including crop residues and organic mulches (Masarirambi *et al.,* 2013). Organic mulches derived from plant material, will decompose in time and develop the soil. It also reflected positively on the cultivated crops in influences the growth and improvement of plants and increases the yield (Majkowska- Gadomska, 2010). A lot of organic materials litter our environment resulting in environmental hazards. Some of these organic materials such as cassava peel and sawdust could be utilized as a source of mulch as reported by various researchers (Shiyam *et al.,* 2011; Ewere *et al.,* 2017; Amenkhienan *et al.,* 2018; Angus *et al.,* 2019). Information on the use of cassava peels or sawdust as a source of mulch on turmeric is lacking. It is therefore pertinent to examine the use of both

cassava peels and sawdust as a source of mulching materials in turmeric cultivation in order to obtain a uniform seedling emergence.

MATERIALS AND METHODS

A field experiment was carried out at National Horticultural Research Institute, Ibadan (Lat. 7^0 30' N; Long. 3^0 50'E; in an altitude of 234m above sea level) between 2017 and 2018 rainy seasons on the emergence of turmeric rhizomes on a 2 x3 factorial arranged in Randomized Complete Block design, the first factor is two types of mulches (sawdust and cassava peel) and the second factor is the three rates of mulch (No mulch (control), 5t/ha and 10t/ha with turmeric planted at a spacing of 50cm x 40cm and the treatments combinations were replicated three times. Planting was done on the same day for all the treatments. Data collected includes sprouted turmeric which was manually counted at 20, 25 and 30 days after planting. This was expressed as the number of sprouted to the total number of rhizome planted as a percentage. Data were subjected to analysis of variance using linear model procedure of Statistical Analysis software Gen-Stat Discovery Edition 4 (2013). Significant means was separated where appropriate using the least significant difference at 5% probability level ($LSD_{0.05}$).

RESULTS AND DISCUSSION

Sprouting is the natural process, by which seeds, spores and rhizomes germinate and put out shoots, and already established plants produce new leaves or buds or other structures experience further growth (Wikipedia, 2022). Sprouting and emergence of the turmeric rhizome seedlings did not start until 20 days after planting on the field. The percentage sprouting in 2017 was statistically different among the treatments. In 2018, there were also significant differences ($P< 0.05$) in sprouting 30DAP (Table 1). The use of 10t/ha dried cassava peels as mulch produced the highest sprouted rhizome emergence of 99.20% in 2017 and 100% in 2018 after 30 days of planting. The higher sprouting and emergence percentage obtained from 10t/ha cassava peels mulch is an indication that heavy coverage with mulch encouraged higher sprouting and emergence according to Akinwumi *et al*., (2013). Fariyike *et al*., (2020) also attributed higher rhizome emergence as the key to good crop stand establishment. Next to cassava peel was closely followed by 10t/ha sawdust as mulch with 94.44% in 2017 and 94.43% in 2018 also after 30 days of planting. The least sprouted and seedling emergence was noticed with the un- mulched plots having the lowest percentage of sprouting of 20.64% in 2017 and 21.43% in 2018(Table 1).

This is in agreement with the findings of Islam *et al*., (2015) who observed higher percentage emergence from mulched ginger and the least percentage emergence from the control. The results also buttressed the importance of mulching in turmeric production and supported by Ahaiwe *et al*., (2016) who reported that mulching enhanced early sprouting of ginger rhizome which is in thesame family with turmeric. Ohiri and Njoku, (1997) also emphasized that mulching enhanced early sprouting in ginger rhizome. Kaya and Coskun, (2020) on the other hand referred mulch as a good soil conditioner, its use as organic extracts (fertilization, plant growth regulators, mulch etc.) has also proven effective in improving sprouting and early seedling emergence under abiotic stress conditions.

The yield of the rhizome varied with the type and rates of organic mulch used with 10t/ha dried cassava peels having the yield of 8179kg/ha in 2017 and 8183.6kg/ha in 2018 (Table 2). The highest yield with 10t/ha cassava peel revealed that turmeric requires heavy mulching to obtain high yield according to Akinwumi *et al*., (2013) which was closely followed by 10t/ha sawdust with 5956kg/ha in 2017 and 5964kg/ha in 2018. The lowest of the yields was obtained with the control in 2017 with 1401kg/ha and also with 2209.51kg/ha in 2018. Manhas *et al*., (2011) and Satyareddi and Angadi, (2014) improved the yield of fresh rhizomes of turmeric with mulching. Irene *et al*., (2015) also used different types and rates of organic mulches to obtain sustainable production and yield of waterleaf (Table 2).

CONCLUSION

The study revealed that both sawdust and cassava peels are very good as mulching materials to enhance sprouting and rhizome establishment, but sprouting percentage was higher with cassava peels establishing its superiority over sawdust in both years under study in Ibadan, Oyo state, Nigeria.

ABSTRACT
Compounds that prevent or slow down the oxidation of lipids or other molecules like free radicals are known as antioxidants. This study evaluates the total antioxidant capacity and hydrogen peroxide scavenging capacity of four spices (fenugreek, Star anise, Cinnamon and black Cardamom). Dry samples of the spices were extracted in distilled water and analyzed using spectrophotometric and titrimetric methods to determine total antioxidant capacity (TAC) and Hydrogen peroxide (H_2O_2) scavenging activity. TAC results ranged from 232.79 - 64.32 mg/100g, with cinnamon and black cardamom exhibiting the highest and lowest antioxidant activity respectively. The spice extracts showed H_2O_2 scavenging activities with fenugreek having the highest scavenging activity with an inhibition of 92.04%. Black cardamom had the least H_2O_2 scavenging activity with 40.41% inhibition. The results showed that black cardamom had the lowest values for both TAC and H_2O_2 scavenging activity. Spices could be substituted for synthetic antioxidants in the food industry and also as dietary source of natural antioxidants.
***Keywords**: spices, antioxidant capacity, star anise, cinnamon, black cardamom, fenugreek*

INTRODUCTION
Spices have long been utilized as aromatic and pungent food components that are used in a variety of dishes to enhance their flavor. They are made from many plant components including bark (cinnamon), flower buds (clove), roots (ginger), fruits (pimento), completely ripe berries (white pepper), and other dried, edible, aromatic plants (Przygodzka *et al*., 2014). Majority of these spices are known to have a wide range of potential medical benefits, including their favourable effects on lipid metabolism, effectiveness as anti-diabetics, capacity to stimulate digestion, potential as anti-inflammators, and antioxidant qualities (Strabbiol and Murcia, 2001). When used in various food applications, natural antioxidants extracted from herbs and spices show varying degrees of efficacy. They not only add specific antioxidant vitamins like vitamin C, vitamin E, and pro-vitamin A to the human diet, but also a complex mixture of other naturally occurring compounds with antioxidant capacity. Aromatic plants have also been studied as sources of different classes of natural antioxidants (Bowser *et al.*, 2014; Ozcan *et al*., 2009).
Antioxidants are compounds that can delay or inhibit the oxidation of lipids or other molecules by inhibiting the initiation or propagation of oxidative chain reactions. As a result, antioxidants can prevent or repair damage caused to the body's cells by oxygen due to the redox potential of phenolic moieties (Choudhary *et al*., 2017; Suhartono *et al*., 2012). They exert their effects by one or more of the following mechanisms: by acting as reducing agents, scavenging free radicals, potentially complexing pro-oxidant metals, and quenching singlet oxygen (Bowser *et al.*, 2014; Suhartono *et al*., 2012). The most frequent type of food product deterioration is oxidative rancidity, which results in significant flavour changes and structural damage to proteins that reduces freshness and deters consumers from making more purchases. (Saini *et al*., 2019). Integrating antioxidants into formulations is the most efficient way to prevent oxidative deterioration in food items, and herbs and spices are a rich natural source of antioxidants (Saini *et al*., 2020; Choudhary *et al*., 2017). The present study was undertaken to explore the total antioxidant capacity and Hydrogen peroxide scavenging activity of some spices (fenugreek, Star Anise, Cinnamon and black Cardamom) sold in Ilorin, Kwara State, Nigeria.

MATERIALS AND METHODS

Collection of materials

All sample materials (fenugreek, Star anise, Cinnamon and black Cardamom) were purchased from Yoruba road market, Ilorin, Kwara State, Nigeria.

Sample preparation

The purchased samples were ground to fine powder by a high speed blender machine and stored in airtight containers until analyses was done. A portion of 20 g of each sample was weighed separately and extracted with 100 mL distilled water at 60°C for 1 hour. The sample solutions were filtered and the filtrate collected in amber bottles and kept airtight for further use.

Determination of total antioxidant capacity (TAC)

The total antioxidant capacity was determined spectrophotometrically by the phosphomolybdenum assay. One (1) mL of each extract was mixed with 3mL reagent solution of 0.6M H_2SO_4, 28nM Sodium Phosphate and 4 mM Ammonium molybdate. The blank contained 4mL of reagent solution only. The mixtures were incubated at 95°C for 150 min and then cooled to room temperature. A set of varying concentrations of ascorbic acid as standard were prepared and treated as test samples. The absorbance of both test samples and standards were taken 695 nm. TAC was expressed as Ascorbic Acid equivalent.

Hydrogen peroxide scavenging assay

This was determined using replacement titrimetric method explained by Zhang (2000). A portion of 2 mL of 1mM H_2O_2 and 1 mL of each extract were separately mixed, followed by 2 drops of 3% ammonium molybdate, 10 mL of 0.2 M Sulphuric acid, 7 mL of 1.8 mM Potassium Iodide and 2 drops of starch indication. The reaction mixture was titrated against 0.5 mM Sodium thiosulphate until blue colour disappeared. Percentage of scavenging of H_2O_2 was calculated as:

$$Inhibition\,(\%) = \frac{Vo - V1}{V1} X100$$

Where V_o and V_1 are volume of thiosulphate used for blank and samples respectively.

Statistical analysis

All experiments were carried out in triplicate. Results were expressed as mean ± SE (Standard Error). Analysis of variance (ANOVA) was carried out to determine any significant differences of measurements by the SPSS statistical software (Version 20.0, SPSS Inc., USA). The significance of the difference was checked by the Duncan test and the differences were considered as significant with $P<0.05$

RESULTS AND DISCUSSION

Scavenging of different types of reactive oxygen species, mostly free radicals is thought to be one of the main mechanisms of antioxidant action exhibited by phenolic phytochemicals (Shan *et al*., 2005). The results of TAC and H_2O_2 scavenging activity are expressed in Table 1. Cinnamon had the highest total antioxidant activity (232.79 mg/100g) while black cardamom gave the lowest activity (64.32 mg/100g). Star anise and fenugreek also had relatively moderate antioxidant activities of 122.46 and 153.37 mg/100g respectively. The strong antioxidant activity of cinnamon might be attributed to its high cinnamaldehyde content in addition to eugenol (Hossain *et al*., 2008). This result is similar to the findings of Lu *et al*. (2011) where cinnamon showed a strong total antioxidant activity. Shan *et al*. (2005), also reported results where cinnamon of two different species and origins exhibited high antioxidant activities that were significantly different from each other. The different result observed in the two species were attributed to genetic and environmental factors.

All the spice extracts had effective H_2O_2 scavenging activity. The inhibitory percentages varied from 40.41 % for Black cardamom to 92.04 % for fenugreek. Fenugreek showed the strongest H_2O_2 scavenging activity, this was followed by cinnamon and star anise with H_2O_2 scavenging activity inhibitions of 85.76 and 48.59 % respectively. According to Shan *et al*. (2005), the presence of phenolic compounds in plants and plant parts and their redox properties accounts for their antioxidant effect. This could be a justification for the scavenging strength of the spice extracts analyzed.

Table 1: Total Antioxidant Capacity and H_2O_2 Scavenging Activity of Selected Spices

Spices	**Total Antioxidant capacity (mg/100g)**	**H_2O_2 scavenging activity (% inhibition)**
Fenugreek	$153.37^{c}\pm0.03$	$92.04^{d}\pm0.04$
Star anise	$122.46^{b}\pm0.00$	$48.59^{b}\pm0.16$
Cinnamon	$232.79^{d}\pm0.05$	$85.76^{c}\pm0.10$
Black cardamom	$64.32^{a}\pm0.02$	$40.41^{a}\pm0.05$

Result shows mean ± Standard Error of triplicate values. Means on the same column with unshared superscripts are significantly different ($p<0.05$)

CONCLUSION

In the study, most of the spices were found to possess high levels of total antioxidant capacity and H_2O_2 scavenging activities. These natural spices have good potentials as substitute to synthetic ones being used in food industry in processing and storage, in order to prevent oxidative deterioration of foods and would also be a promising and economic dietary source of natural antioxidants for improving human nutrition and health.

Corresponding author: bukolaodeyinka@gmail.com

ABSTRACT
*Redesign of a nation's currency is done through appropriate policy implementation, however it can bring untold hardship if not appropriately implemented. This study examined effect of currency redesign on vegetable farmers' production activities in Ibadan North West Local government area of Oyo State. Multistage sampling techniques which involves purposive selection of local government area and prominent farmers association in the LGA was used. This was followed by random selection of forty farmers that were present at the association's monthly meetings. Data were collected using questionnaire and analyzed using descriptive statistics. Major occupation of respondents was farming (40%), **p**rominent fruits planted are Sweet orange (23.3%) and plantain/banana (13.4%). Vegetables mostly planted are Corchorus (26.6%), Amaranth (23.3%) and okra (16.7%). Most (56.7%) respondents strongly agreed reduced attendance in family function, reduced sales (50.0%), loss made through online cash transfer (46.7%) and transportation problem (46.7%). Reduction in unnecessary spending (40.0%), feeding (36.7%) and adjustment of family food budget (33.3%), reduced spending on family and friends (33.3) were observed. Most (50%) respondents disagreed with increase in number of customers, family association (36.7%) and more profit through online cash transaction (36.7%). Majority agreed that land clearing (83.3%), weeding (80.0%) and marketing of produce (80.0%) were affected, 76.7% was of the opinion that transportation of goods, purchase of inputs and payment of labourers were affected. The currency redesign brought more harm to the vegetable farmers in the LGA, subsequent policy involving currency redesign must be done appropriately using people oriented approach.*
***Key words**: Currency redesign, Farming activities, Fruits and vegetables*

INTRODUCTION

Cashless economy is an economy where transaction can be done without necessarily carrying physical cash as a means of exchange of transaction but rather with the use of credit or debit card payment for goods and services (Omotunde et al 2013). The cashless economy policy initiative of the Central Bank of Nigeria (CBN) is a move to improve the financial terrain but in the long run sustainability of the policy will be a function of endorsement and compliance by end-users (Ejiro, 2012). Studies have further shown that the crucial role played by financial inclusion to strengthen the growth and development of any economy in the world cannot be over emphasized. In fact to achieve its desired development, there must be easy access to mobilization and fund circulation within all strata of the economy (Huseni and Abdurrauf 2023). This in turn propelled the Central Bank of Nigeria (CBN) in 2012 led by Sanusi Lamido to introduce the cashless policy with the aim of reducing the bulk of cash being carried about and to track the amount of money in circulation and it was finally implemented in February 2023. The introduction of the cashless policy / currency redesign affected a lot of business in which the agricultural sector was not exempted. The agriculture sector, which contributes significantly to the economy, suffered from depressed spending, affecting farmers' ability to pay for labor and resulting in reduced production as stated by the SBM report. Coincidentally the currency redesign clashed with the emergence of planting season in the country, which has further in turn has its weight on the food productivity hence causing shortage of food in the country presently. The study assessed the effect of currency redesign on farmer's production activities in Ibadan North West Local government area of Oyo State

The specific objectives are to:

1. Determine the socio-economic and enterprise activities of respondents
2. Ascertain farmers' perception about cash withdrawal and currency redesign
3. Assess the effect of currency re-design on farming activities among farmers in

METHODOLOGY

The study area was Ibadan Northwest local government area, Oyo State Nigeria. The study area was Ibadan Northwest local government area, Oyo State Nigeria, which belongs to the Yoruba ethnic group. The target population were Vegetable Farmers in Ibadan Northwest Local Government Area, Oyo State. Multistage sampling techniques was used, the first stage was the selection of local government area which is Ibadan Northwest Local Government Area. The second stage was purposive selection of vegetable farmers group from the selected local government and this was followed by random selection of farmers during the association's monthly meeting. Data were collected using questionnaire. A total of forty farmers were interviewed. The data collected were analyzed using descriptive statistics such as frequencies, percentages.

Socio-economic characteristics of farmers

Table 1 reveals that sizeable proportion (70%) of the respondents are male, an indication that more male participates in agricultural practices among the respondents, but was argued by (Opio 2003) that in most parts of Africa, women have traditionally been responsible for producing food for the family on land to which they gain access upon marriage but do not necessarily control. Their fundamental role is in securing food for the family and therefore their role in national food security must be stressed. While men have generally been responsible for bush clearing and land preparation. 80% married and 63.3% has number of children ranging from 0-4 and 56.7% has a total household size of 5-7 while majority 50% of the respondents had secondary school leaving certificate as their highest level of education. Major occupation of 40% of the respondents is farming, others generate income through civil service (13.3%), trading (23.3%), share investors (3.3%), animal production (13.3%) and technical services (6.7%)

Table 1: Frequency distribution of the Socio-economic characteristics of farmers

	Variables	Frequency	Percentage
Sex	Male	21	70.0
	Female	9	30.0
Marital Status	Single	1	3.3
	Married	24	80.0

Enterprise characteristics of farmers

Prominent fruits planted by the farmers are Sweet orange and plantain/banana planted by 23.3% and 13.4% respectively. Vegetables mostly planted are Corchorus, Amaranth and okra cultivated by 26.6%, 23.3% and 16.7% respectively. Arable crops planted by few of the respondents were cassava (16.7%) and maize (13.3%) (Table 2).

Perception of farmers about cash withdrawal and currency redesign

Table 7 shows that most (56.7%) respondents strongly agreed reduced attendance in family function, less was sold due to lack of cash (50.0%), loss made to online cash transfer (46.7%), Transportation problem encountered (46.7%) and that goods were expensive (33.3%). Some respondents also agreed on reduction in unnecessary spending (40.0%), Reduction in feeding (36.7%), Adjustment of family food budget (33.3%), reduced spending on family and friends (33.3%), goods were expensive (30.0%). Most respondents disagreed with increase in number of customers (50%), increase in family conflict (33.3%), increase in family association (36.7%) and more profit made through online transaction/transfer of cash (36.7%).

Table 3: Perception of farmers about cashless policy implementation

Variables	Missing	Strongly agreed	Agreed	Undecided	Disagreed	Strongly disagreed
Increase in family conflict	5(16.7)	10(33.3)	8(26.7)	4(13.3)	10(33.3)	_
Increase in family association	4(13.3)	5(16.7)	4(13.3)	6(20.2)	11(36.7)	_

Effect of currency redesign on vegetables farmers farming activities in Ibadan North West Local government area of Oyo State, Nigeria

Majority of the respondents representing 83.3%, 80.0% and 80.0% agreed that land clearing, weeding and marketing of produce were affected during the period. In addition, 76.7% of respondents was of the opinion that both transportation of goods, purchase of inputs and payment of labourers were affected during the period. A cursory observation on the level of difficulty revealed that 50%, 43.3%, 43.3% were of the opinion that payment of labour, land clearing and purchase of inputs very greatly affected. In addition weeding, marketing and transportation of produce were very greatly affected as testified by 40% respondents in each of the cases.

ABSTRACT

This study was conducted to determine the effect of parkia pulp extract as vitamin/mineral source in broiler. A total of 204 'Ross 308' day old chicks were used for this study. At third week old, birds were randomly allotted into four treatments as follows; 1% PPE (1% Parkia Pulp Extract 10gm in 1litre of water), 2% PPE (2% Parkia Pulp Extract 20gm in 1litre of water), CMLT (Conventional Multi-Vitamin) and 0% PPE (0% Parkia Pulp Extract; only water). Treatment was added to their drinking water intake thrice in a week, there were fifty one birds per treatment; Seventeen (17) birds per replicate, each treatment was replicated thrice. The experiment lasted for nine weeks. Data on weight gain, carcass quality and sensory evaluation of cooked chickens were determine. Weight of broiler on CMLT were significantly higher at 3rd and 4th week of treatment administration but at 5th and 6th week of treatment there were no significant different ($p > 0.05$). The percentage of dressed to carcass weight was highly significant in 2% PPE (94.44%). There was no negative influence on all the parameter of sensory evaluation and the overall acceptance of chicken. Hence, addition of parkia pulp in broiler drinking water improved the percentage of dressed weight to live weight and carcass quality and does not have negative influence on the sensory attributes of the chicken.

***Keywords**: Parkia pulp, organic broiler production, sensory evaluation, organic vitamins/mineral, carcass quality*

INTRODUCTION

Parkia biglobosa is a non- timber forest products used as food, medicine, glazes, animal fodder, soil amendments, charcoal, and firewood. It is a horticultural crop that contain seeds that are used in preparation of spice called dawadawa, iru and ogiri in Hausa, Yoruba and Igbo respectively (Sadiku 2010). The spice is rich in protein and fat but bulk of the pulp covering the seed is usually washed off during processing of the seed to spices, in Nigeria few household process the pulp into drink by mixing it with water and fermented to fine refreshing drink (Akoma *et al.,* 2001). Locus bean pulp is high in vitamin C and carotenoids both important in the immune function of animals (Gernal *et al*., 2005). Poultry industry requires vitamins and mineral premix for optimal performance of birds which is usually derive from synthetic. Quest for organic products due to financial, environmental and health benefits has necessitated promotion of organic products. Hence, this study was conducted to determine the weight gain, carcass and sensory evaluation of broiler *on Parkia biglobosa* pulp drink extract.

MATERIALS AND METHODS

This experiment was carried out in Kensim Farm located at Aquatech College of Agriculture and Technology, Ibadan, Oyo State, Nigeria. Two hundred and four (204) 'Ross 308' day old chicks were purchased from Agrited hatchery in Ibadan and used for this study. The birds were raised in a deep litter system, at third week birds were randomly allotted into four treatments, there were fifty one birds per treatment; Seventeen (17) birds per replicate, each treatment is replicated thrice. The treatment was added to their drinking water thrice in a week as follows: 1% PPE (1% Parkia Pulp Extract 10gm in 1litre of water), 2% PPE (2% Parkia Pulp Extract 20gm in 1litre of water), CMLT (Conventional Multi-Vitamin) and 0% PPE (0% Parkia Pulp Extract; only water). Birds were supplied feed (commercially available feed) and water *ad libitum*. When the birds were three weeks old the initial weight of the birds was recorded, treatment was introduced into drinking and they were subsequently weighed weekly throughout the study by using Carmy digital scale. The average temperature and relative humidity of the pen were 29.8℃ and 72.71%. The experiment lasted for nine weeks. Data on weight gain, carcass quality and sensory evaluation were determine. The Sensory evaluation of cooked broiler without salt or seasoning on treatment was done through 30 consumers by 5 points hedonic scale to test, for smell, colour, juiciness, taste, tenderness, and overall acceptances. The data was analyzed by analysis of variance (ANOVA) using SAS package version and the significant treatment means were separated with Duncan option.

RESULT AND DISCUSSION

The effect of Parkia Pulp concentrate on weight of broilers is shown in table 1. There was significant difference ($p>0.05$) in the weight of the broilers at the 3rd and 4th week of administration of treatment on broiler with conventional multivitamin leading but at 5th and 6th week of administration of treatment, the weight of broiler across the treatments were not significantly different. The parkia pulp is known to contain antioxidants, vitamins and minerals which work synergy to prevent fat accumulation and good growth; muscle build up (Kenneth-Obosi *et al*., 2023). Parkia pulp is a horticultural crop that can sever as organic source of vitamins and minerals that can be used to replace synthetic vitamin and mineral premix that is commonly used. There were no significant preference ($p>0.05$) for all the sensory parameters of broiler on observed across the treatment (Table 3). However, chicken from broiler on 2% parkia pulp extract was evaluated to have highest juiciness and tenderness. This may be a reflection of the sweet and juicy taste of ripped parkia pulp (Campbell-Platt, 1990). The overall acceptances of the chicken from the treatments preference is 0%PPE (4.03). This was followed by chicken from broiler raised with 2% parkia pulp extract drink (3.86). Carcass evaluation of broiler on Parkia pulp extracts drink is shown in table 2.
There were no significant ($p>0.05$) differences in the percentages (%) of the traits measured across the treatment. As revealed in table 2, the utilization of parkia pulp as alternative vitamin/mineral premix in drink did not suppress the physiological development of the birds. This is an indication that Parkia Pulp has no detrimental effect. The ratio of dress weight to live weight of birds on supplements was significantly higher (Fig. 1) than bird on water (85.80%) with highest ratio from birds on 2% parki pulp extract (93.44%). This is an indication that broiler on mineral and vitamin supplement have more flesh than broiler on water. Abeke *et al*., 2013 reported that the prime cuts expressed as a percentage of live weight showed that the breast, thighs and drumsticks which are the most preferred and meaty parts of the chicken followed the weight pattern of the bird and decreased as the level of Parkia pulp increased in the diets. That may be due to the level of phytochemical present when high quantity of parkia pulp was used in replacement of maize in poultry diet but when small quantity is used as supplement the dress and live weight ratio of broiler on parkia pulp was encouraging (Kenneth-Obosi and Babayemi, 2017). Hence, bigger and meatier birds have better prime cuts than smaller and leaner birds.

Table 1: Weight gain of broiler on parkia pulp extract drink (Kg)

CONCLUSION

African locust beans (*Parkia biglobosa*) pulp usually washed off can be put to used as source of organic vitamins and minerals in the drinking water of broilers for better growth response and carcass traits without any adverse effect on the sensory attributes of the broiler meat.

ABSTRACT

This study examined the constraints and coping strategies in Lagos state by ornamental palms producers. Data for the study were obtained from different local government area in Lagos state. Snowballing sampling technique was used to select a total of 20 respondents for the study and the data collected were analysed using descriptive statistics. The result showed that majority (75.0%) of the respondents were male and all (100.0%) were married. Majority (60.0%) were within the age range 31-60 years. The result showed various constraints facing ornamental palms production in the study area which include pest and diseases, theft, land unavailability, and labour scarcity. Different coping strategies were adopted by the respondents in the study area. The respondents hire security agents to assist in safeguarding the garden and frequently choose to take expensive palm trees home to prevent theft. It was recommended that for the development of the ornamental palm industry in Lagos there is the need for improved research and development efforts to address the constraints facing florists in the region.

Keyword: *Constraints, Coping strategies, Ornamental palms*

INTRODUCTION

Ornamental palms have significant economic potential in Nigeria due to their aesthetic appeal, cultural significance, and various commercial applications (Market watch, 2020). Ornamental palms in Nigeria are used for landscape beautification, religious and cultural festivals, and as raw materials for crafts and furniture making (Udo *et al*. 2015). Additionally, ornamental palms such as the Royal Palm (*Roystonea regia*) and the Coconut Palm (*Cocos nucifera*) have commercial value as a source of edible oil, coconut water, and palm wine (IITA, 2019). According to a study by Imaobong *et al*. (2018), the production and profitability of ornamental palms can be influenced by various factors, such as the species of palm, the size of the plant, and the market demand for the product. The cultivation of ornamental palms for commercial purposes is a growing industry in Nigeria, with many farmers and entrepreneurs taking advantage of the high demand for ornamental plants (Folarami *et al*. 2020). Ornamental plants cultivation has the potential to generate income and create employment opportunities, especially in rural areas. Furthermore, the export market for ornamental palms is also significant. Nigeria is well positioned to develop its ornamental palms cultivation due to the favorable tropical climatic conditions in the country.

Previous studies on ornamental plants which includes Akintoye *et al* (2018), Muhammed-Lawal *et al*. (2012), Imaobong *et al*. (2018), Udo *et al*. (2015), and Adeduntan (2015). Akintoye *et al* (2018) examined the profitability of ornamental plants production in southwest, Nigeria and also prospects and challenges of floriculture business in Nigeria. While Mohammed Lawal *et al* (2012) examined economic analysis of floricultural plants production and Adeduntan (2014) contribution of some ornamental plants to the socio-economic development of urban household. The aforementioned studies did not focus specifically on ornamental palms. Therefore, in view of the economic benefits derived from ornamental palms production in other countries, it is important to examine constraints in ornamental palm production node in order to be able to come up with strategies that may improve efficiency of the production of the commodity.

MATERIALS AND METHODS

Study Area

Lagos state is a coastal state located in the southwestern part of Nigeria. It is the economic hub of Nigeria and one of the fastest-growing cities in Africa. Lagos state is bounded by Ogun state to the north and east, by Benin to the south, and by the Republic of Benin to the west. The state is mainly filled with the Yoruba tribe which has grown diverse with the migration of other Nigerians, West Africans and people for all other parts of the world. Lagos state has an estimated population of over 21 million people, making it the most populous state in Nigeria (National Bureau of Statistics, 2021). Lagos state is also known for its cultural diversity, vibrant nightlife, and beautiful scenery, which include beaches, parks, and gardens. Lagos state is comprised of thirty seven local government areas (LGAs), including Amuwo-Odofin, Ojo, Ajeromi-Ifelodun, Agege, Alimosho, Ifako-Ijaiye, Ikeja, Kosofe, Oshodi-Isolo, Somolu, Lagos Island, Apapa, Eti Osa, Lagos Mainland, Mushin, Surulere etc.

Sampling Technique and Data Collection

Snowball sampling technique which was used to locate florists in the study area. This method was used because of the population of florists is small. Primary data were collected through interview and the use of structured questionnaire administered to twenty respondents.

Data Analysis: Data generated in the survey were analyzed using descriptive statistics (frequency, percentage, and mean).

RESULTS AND DISCUSSIONS

Socio-economic characteristics of respondents

Table 1 presents the socio-economic characteristics of ornamental palms producers in the study area. The results showed that most of the respondents (75.0%) were male and married (100%), this is supported by Larinde and Santus (2014), who reported 68.4% married in a similar study. This shows that males are more involved in ornamental palms production than female. Most of the ornamental palms producers were within the age bracket of 31-40 years (30%). This clearly shows that most of the respondents were young adults. This agrees with Muhammed-Lawal *et al*. (2012) who reported the dominant age range of 26-40 years for a similar study in Kwara State, Nigeria. The results showed that 55.0% and 30.0% of the respondents has secondary and tertiary education respectively with average year of experience of 16 years in ornamental palms production. This shows that most of the respondent involved are highly literate and have experience in ornamental palms production. Similarly, Shalnim (2009) reported that 80% of the ornamental plant producers he interviewed had attended tertiary institutions. This high literacy level of the respondents could affect their choice of inputs and also their willingness to adopt improved technologies. On the basis of income distribution, most (45.0%) of the respondents realized less than 100,000 naira per month. In table 3, the respondents (50.0%) were visited by extension agents.

Resource use information

Table 2 reveals that 90.0% of the respondents operate on less than one acre of land with a mean land size of 0.38 acre and most of them (70.0%) obtain the land through leases. This agrees with Nelson and Jacob (2018) who reported that (90.48%) of the ornamental plants nursery operators were lease/rented lands. This is an indication that they are small scale producers. However, this might limit the expansion of their business. Half (50.0%) of the respondents used hired labour and 60.0% of the respondents make use of organic fertilizer. None of the respondents make use of growth regulator to enhance the performance of their palms. The use of PGRs for palm cultivation should be based on careful consideration of the potential benefits and risks, and should be done in accordance with local regulations and guidelines (Yasar *et al*. 2017).

Constraints to Ornamental palms production

Table 4 shows the constraints facing palms production in the study area which include pest and diseases (70.0%), theft (60.0%), land unavailability (50.0%), labour scarcity (45.0%), water scarcity (40.0%) and financial constraints (5.0%). Ornamental palms are susceptible to various pests and diseases, which can reduce their yield and quality. This agrees with Akintoye *et al* (2018) who also reported some challenges among which are water scarcity, lack of permanent site for production and inadequate fund. According to Ogbuehi et al. (2020), pest and disease management is a major challenge in ornamental palm production in Nigeria. According to Akinbile *et al*. (2017), poor infrastructure is a major constraint to the development of the horticulture industry in Nigeria. In conclusion, the production of ornamental palms in Nigeria faces several constraints that limit its growth and development.

Coping strategies adopted by the respondents to manage the identified constraints

The respondents were asked to state how they have been coping with the constraints identified. The respondents undertake palm fumigation on a monthly basis as a preventive measure against pest and disease attacks. This proactive measure helps maintain the health and vitality of their palms, ensuring their long-term well-being. Furthermore, regular fumigation assists in preserving the aesthetic appeal of the garden and promotes a thriving environment for other plants and vegetation. The garden owners hire security agents to assist in safeguarding the garden and frequently choose to take expensive palm trees home to prevent theft. In addition, they procure water from nearby sources as a solution to address water scarcity issues (Table 5).

CONCLUSION AND RECOMMENDATION

Ornamental palms have enormous economic potential in Nigeria, with their cultural significance, commercial applications, and export market value. The development of this industry has the potential to boost the country's economy and create employment opportunities in both rural and urban areas. However, several constraints such as pest and diseases, poor access to quality inputs, water scarcity, land unavailability and inadequate funding limit the growth of the industry. It is recommended that for the development of the ornamental palm industry in Lagos there is the need for improved research and development efforts to address the constraints facing florists in the region. Additionally, there is a need for the government to provide adequate support in terms of funding, training, and access to quality inputs for producers to ensure sustainable growth of the industry.

DETERMINATION OF PERCENTAGE GERMINATION OF TEN VARIETIES OF SWEET CORN (*Zea mays convar. saccharata var.rigosa*) UNDER VARIED SUCROSE CONCENTRATION

Abdulrazak, K. B.
khalifababba@gmail.com

ABSTRACT
The research experiment was conducted at crop science laboratory, University of science and technology, Wudil Kano State in 2015. The aim of the experiment was to identify the promising sweet corn genotypes with higher germination percentage in various sucrose concentration and to recommend the suitable genotypes of sweet corn to maize breeders for further development of drought tolerant varieties to farmers. The experiment was laid out in a randomized design and replicated three times. The results of the experimental findings indicated that, the proper germination percentage of sweet corn seeds tested shown that six genotypes were promising and found to have significant percentage germination and they include Jarobama white 96.6 %, Wari white 90 %, El-yellow local 83.3, Zaria E 76.3 %, Yar gangara yellow 75 % and Zaria D 73.3 % while Yar Ghana 26.67 and Yar tasau recorded the least germination percentage.
***Keywords**: Maize, Genotypes, Variety, Sucrose, Radicle, Plumule and Concentration.*

INTRODUCTION

Sweetcorn (*Zea mays* convar. saccharata var. rigosa) also called sugar corn or pole corn is a variety of maize with high sugar content (Erwin,1951). It is gradually becoming an important vegetable crop in Nigeria, since it forms a useful ingredient in both homes and hotels (Akintoye and Olaniyan,2012). it is an important source of fibre, mineral and certain vitamins (Leitrat and Pulam,2007). Germination is the process by which an organism grows from a seed or a spore. The most common forms of germination include a seed sprouting to form a seedling and the formation of spore ling from a spore. Thus, germination occurs primarily in a plant and fungal species. Sugar is a white odorless, crystalline powder with a sweet taste. It is best known for its role in food. The molecule disaccharide composed of the monosaccharide glucose and fructose with the molecular formula $C_{12}H_{22}O_{11}$.The word sucrose was coined in 1857 by the English chemists William Miller (John W. Parker, 1857) from the French ("sugar'') and the generic chemical suffix for sugar -ose. The effects of prolonged droughts such as those that have struck eastern and southern Africa in recent years, have been disastrous. With the aid of this practical, drought resistant varieties of sweetcorn can be used to contribute to a significant expansion in sweetcorn in many countries of west Africa, notably Benin republic, Burkina Faso, Cameroon, Niger republic and Nigeria.

Developing new sweetcorn Varieties, tolerant to drought stress will expand sweetcorn production not only in the eastern and southern Africa, but also in many countries in West Africa including Nigeria. Sweetcorn is an important crop which serves as a vital source of energy in human diet in developing Tropical countries. However, in a view of the vast important of sweetcorn, still it is affected by drought. This fact necessitates the development of more Varieties tolerant to moisture deficit that can be produced in various agro ecological zones. Therefore, the objective of this study is to determine the percentage germination and identify genotypes with higher germination percentages in sucrose solutions and also recommend the genotype to sweetcorn breeders for developing drought tolerant varieties.

MATERIALS AND METHODS

The experiment was conducted in crop science laboratory Kano science and technology wudil. The materials used were petri dishes, spoon, filter paper, masking tape, measuring tube and water. The maize samples tested for germination and their sources are represented in table1. Ten seeds from each sample were counted and planted in a labelled petri dish lined with filter paper in a complete randomized design (CRD) and replicated three times each germination test in water,5%and 10% sucrose solution. 5% was made by measuring 5ml of sucrose in measuring cylinder and filling the cylinder with distilled water to the level of 100ml.The same procedure was followed in preparation of 10% of 100ml.For germination test with water, filter paper in labelled petri dish was moistened and ten seeds were widely spread on it. The Petri dishes in three replicates for each sweetcorn sample were kept in a germinator, the procedure was followed when setting the germination test with 5% and 10% sucrose. The petri dishes were checked for germinants. Germination was considered to have taken place when radical and plumule emergence was noticed from a seed. Number of germinant with radicle and plumule were counted and recorded daily. They were considered as normal seeds (NS). Number of germinants with either radicle or plumule, considered as abnormal seedlings (AS) were also recorded daily on data sheet. Observation was stopped when the germinants counts in each replicate remains constant and no more seed was expected to germinate. Germination percentages in water and sucrose solutions were computed based on the number of seedlings only. The data was subjected to statistical analysis using SAS and the mean were Separated using Duncan ranking

RESULTS AND DISCUSSION

Table 1 indicated that Wari White, Zaria E, Yar Gangara yellow, Zaria D, El yellow local and Jorobama White had highest germination percentage in water of 90% and above in water, at 5% sucrose they have the highest percentage of 50% and above. The more the increase of sucrose concentration the percentage germination reduces. The least percentage germination was found at MI307-8, IITA variety. This might be that favorable environmental condition was created for germination of the above varieties as reported by (Miles and Brown 2007) Seeds generally "wake up" and germinate when soil moisture and temperature conditions are correct for them to grow. Also, the least germination percentage due to unfavorable environmental condition created which did not favour germination[7].

Table 2 shows that the highest mean of radicle length was found in 6 six varieties that have mean radicle length in water of 4cm and above, they include Wari White, Zaria E, yar Gangara Yellow, Zaria D, Jorobama White and Yar Tasau Yellow. The highest mean radicle length at 5% sucrose concentration of 1cm and above was found on the following varieties Wari White, Zaria E, Yar Gangara Yellow, zaria D, El yellow Local and Jorobama White. Similarly, the more concentration the lesser the mean radicle length. This might be that more concentration of sucrose retarded the germination and reduce the radicle length as reported by (stefanello *et al*.2020) if sucrose concentration is too high, the seed would be under stress and as a result the seed's growth rate would slow down or, in extreme cases, would end up in the seed dying. The least mean radicle length was found in MI307-8 variety and at 10% sucrose concentration. Table 3 shows the mean plumule length in water and sucrose concentration at different rate. The result indicated that four varieties have the highest mean plumule length of 2cm and above, they include Wari White, Yar Gangara Yellow, Jorobama White and Yar Tasau Yellow. The least variety was M1307-8 in 10% sucrose concentration. This is due to the highest concentration that affected the germination percentage.

CONCLUSION AND RECOMMENDATION

The present result showed that germination percentage of sweetcorn seeds was significantly reduced by increasing sucrose concentration. The study also showed reduction in radicle and plumule length with increase sucrose concentrations. The germination, root and shoot development were more arrested in 10% than in 5% sucrose solutions. Sweetcorn samples jarobama white, Wari white, Zaria E,yar gangara yellow,El yellow local and zaria D with respective germination percentages 96.7%,90%,83.3%,76.3%,75%, and 73.3% in 5% sucrose solution are therefore recommended to breeders for the development of drought tolerant sweetcorn Varieties.

ABSTRACT

There had been recent increase in the demand and use of marigold and its essential oil as there are claims of its many potential medicinal benefits. The experiment was to evaluate the acute and sub-chronic effect of the essential oil and its toxic effect on the blood of wistar animals which will stand as a standard for its recommendation. The essential oil was applied at 0.1ml on the cleared surface of the skin as the test was a dermal test and the period of exposure was varied between 2 weeks to 6 weeks. At the end of the experiment, it was observed that the treatment had no significant effect on the blood parameters of the treated animals and the animals likewise did not show any sign of toxicity. This study shows that at the applied quantity, the essential oil does not have a toxic effect on the test animals.

Keywords: *Dermal, Essential oil, Marigold, Toxic, Wistar rat.*

INTRODUCTION

Many essential oils or their constituents are known to be potent antibacterial as well as anti-fungal and insecticidal agents. The genus *Tagetes* belongs to the Asteraceae family and comprises 56 species, 27 of them annuals and 29 perennials. It is a plant which is native to America, but it is naturalized in other countries in Africa, Asia, and Europe (Babu, 2007; Politi, et al., 2017). *Tagetes* sp. are grown all over the world as multi-purpose plants of which these species, *T. minuta, T. erecta, T. patula* and *T. tenuifolia,* are the most common (Vasudevan et al., 1997) that are studied because of their application in the field of agriculture, where they exhibit fungicidal, bactericidal, and insecticidal activities, as well as anticancer properties (Kashif, et al., 2015; Padalia, 2015; Politi, et al., 2017), resulting in their exploitation as beverages and condiments in folk medicine (Girón et al., 1991; Laferriere et al., 1991), to treat intestinal and stomach diseases and some of them have been found to possess biological activity (Tereschuk et al., 1997; Broussalis et al., 1999). This genus is recognized as a source of very interesting biologically active products, that is, carotenoids used as food colorants and feed additives (Timberlake and Henry, 1986) and possessing anticancer and anti-ageing effects (Block et al., 1992), essential oils known for their antibacterial and insecticidal properties (Piccaglia et al., 1996) and flavonoids having pharmacological properties (Tereschuk et al., 1997).

Volatile oils of *T. minuta* L. are used as antibacterial (Senatore et al., 2004), flavour components in food products and perfumes (Chamorro et al., 2008). They also have a suppressive biological activity against some insects and pathogens (Vasudevan et al., 1997). *T. minuta*, which also presented cytotoxic (Shirazi, et al., 2014) and anti-inflammatory activities.

Objective:

To evaluate the toxic effect of marigold essential oil on the blood of experimental animal through dermal application.

MATERIALS AND METHODS:

The experiment was carried out at the National Horticultural Research Institute Ibadan as well as Veterinary and Physiology Department, University of Ibadan, Nigeria. Twenty wistar rats were used for the experiment containing both males and females with average weight of 100g, animals were grouped and placed in a plastic cage. Acclimatization was done for 10 days after which treatment commenced. The animals were grouped into four (4) containing five (5) rats each of both sex and treatments were based on the period/time of exposure to the essential oil which was 2, 4 and 6 weeks. About 0.1ml of ketamine was injected to the animal inter-peritoneal (IP) and after 10 mins the animal fore/hair were scrapped off on the right side with soap and water using blade and exposing the skin in preparation for treatment application.

Data collected include weight gain or loss, change in appetite, physical changes, behavioral changes, hair growth, skin and blood. After hair removal, the animal skin was observed for possible surface damage and after 48 h treatment commenced. Two drops (0.1ml) of marigold essential oil was applied and evenly spread on the exposed skin every other day, it was allowed to dry so as to prevent oral contamination, then animals were returned to its cage. Food and water were given to the animals ad-libitum. At the end of the experiment, the bloods of animal were collected through ocular veins, animals were sacrificed through cervical dislocation and organs of interest was carefully harvested.

RESULT AND DISCUSSION

Plate 1: wistar rats in cages

At the third day of application, a set of the test animal showed slight discolorations on the sight of application of treatments but by the fifth day it cleared off, and on the termination of experiment there was no damage done to both skin and blood. This agrees with the findings of Devika *et al* who said *T. erecta* showed that its compounds have anti-inflammatory potential with no sign of toxicity.

Table1: Blood parameters

Parameters	Control	2 wk	4 wk	6 wk
PVC	39.42a	41.25a	39.00a	40.50a
HB	13.00a	13.125a	12.100a	12.800a
RBC	7.1231a	6.8150a	7.4175a	7.1800a
WBC	4986.83a	5073.00a	3183.13a	5435.50a
PLT	120006.00a	118000.00a	105750.00a	122000.00a
LYM	68.12a	70.25a	62.00a	67.50a
NEUT	25.40a	26.00a	24.50a	27.25a
MON	1.35a	1.75a	1.25a	1.75a
EOS	2.43a	2.50a	2.75a	2.25a

PCV; pack cell volume, HB; hemoglobin, RBC, red blood cell, WBC, white blood cell, PLT; Platelet, LYM; Lymphocytes, NEUT; Neutrophil, MON; Monocytes, EOS; Eosinophil a =means on the same row with same letter are not significantly different ($p>0.05$).

From the table above, it was observed that there were no significant differences among the blood parameters across the weeks for both control and treatments. PCV shows no significant differences among the weeks although; 2 weeks had the highest value (41.25) while 4 weeks had lowest (39.0). Same trend was observed for HB, PLT and LYM respectively. But for RBC, WBC, NEUT, MON and EOS there were variation in the trend where highest value in WBC and NEUT wasobserved at 6 weeks and lowest at 4week respectively. While RBC was highest at 4 weeks and lowest at 2 weeks, EOS had the highest value at 4 weeks and lowest at 6 week and MON was highest at both 2 and 6 weeks and lowest at 4 weeks. This agrees with the findings of Shetty (2008); Shetty et al. (2009) and Manisha et al. (2013) who reported that both aqueous and ethanolic fractions *T. erecta* flowers were found to be safe during acute toxicity study. The study was in accordance to OECD Guidelines 425 procedure using albino Wistar rats.

CONCLUSION

From the result, it is confirmed that marigold essential oil at the evaluated dosage does not have damaging effect on the wistar blood. It is therefore recommended that a step should be taken further to investigate its oral toxicity as marigold is suggestive to be used as food preservative.

ABSTRACT

Sesame (Sesamum indicum L.) is one of the oldest domesticated oilseed crops. Due to the presence of high oil, protein and other nutritional elements, its seed has become an important ingredient of food and feed. Poor soil fertility is among the major production problems responsible for poor growth and low yield of sesame in Nigeria. A pot experiment was carried out at the experimental plot at Ladoke Akintola University of Technology, Ogbomoso, Nigeria to evaluate the effects of fertilizer types on cumulative yield and nutrient uptake of sesame (Sesamum indicum L.) plants. Six treatments were used: T_0 (control), T_1 (2g of NPK/pot), T_2 (30g of organic neem /pot), T_3 (30g of organomineral/pot), T_4 (20g of poultry manure/pot), T_5 (30g of cow dung/pot). Data were collected on growth and yield parameters and were analyzed using ANOVA. Sesamum indicum responded best to the application of NPK but not significantly different (p = <0.5) from other treatments applied; Application of T_1 (NPK) produced the best of the yield parameters measured and therefore recommended for improving nutrients availability and sesame performance in the study area.

INTRODUCTION

Sesame (*Sesamum indicum*) belongs to the family Pedaliaceae. The genus consists of about thirty-six species of which the most commonly recognized is *Sesamum indicum L.,* popularly known as beniseed in Nigeria (Alegbejo, *et al*., 2003). It is an erect, flowering annual plant which grows up to 50 to 250 cm tall or more, as determined by the soil or environmental conditions and varieties (Sharma, 2005). Sesame is usually propagated by seeds and matures within 70-150 days after sowing, depending on the varieties (Indu and Savithri, 2003). Flowering commences at 38-45 days after sowing and stops at 70-120 days after sowing (Langham and Wiermeers, 2006). Although sesame is relatively ranked amongst the drought-tolerant crops, but can dies in stagnant water (Weiss, 2000; Ray *et al.,* 2004). The precise natural origin of the species is unknown but numerous wild relatives are occurring mostly in Africa and a smaller number found in India (Ashri, 1998). However, it is believed to have originated from the tropical Africa where the greatest genetic diversity exists but was believed to have been introduced to India at a very early date, where a secondary center of diversity is well developed (Alegbejo *et al.,* 2003; Olaoye, 2007).

Sesame is primarily grown for its edible seeds and oil, with 65% of the seeds being used for oil extraction and 35% for food. Sesame seeds have outstanding amounts of oil and a desirable nutty flavour after cooking. For these reasons, they are much appreciated in bakery, the candy industry and for other food specialties (Hansen, 2011).

Research on the nutrition of sesame in the tropics shows significant yield increase due to application of N P K fertilizers in India, Pakistan, and Tanzania. In Ethiopia, N P fertilizers are commonly applied. Nitrogen is the most dynamic nutrient element and the most important nutrient that is required for the survival of all living things. Increases in N supply within limits are associated with increase in leaf area, carboxylases, and chlorophyll content, all of which determine the photosynthetic activities of leaf and ultimately dry matter production and allocation to the various organs of a plant. Similarly, good supply of P is usually associated with increased root density and proliferation, which aid in extensive exploration and supply of nutrients and water to the growing plant. N contributes up to 50% of all the nutrient inputs, and therefore, nitrogen is the determinant of farmers' crop yield. A general rule of thumb is that N is for leafy top growth, phosphorus is for root and fruit production, and potassium is for cold hardiness, disease resistance, drought tolerance, and general durability. Since N is the most dynamic nutrient and building block of all plant structures, its inclusion in the sesame production is critically important. Seed quality in sesame is determined by seed color, seed size, aroma, oil, and protein contents. (Shehu *et al.,* 2009).

MATERIALS AND METHODS

This research was conducted between March and August, 2021 at the Teaching and Research Farm, Ladoke Akintola University of Technology (LAUTECH), Ogbomoso, Oyo state, Nigeria, to assess the effects of fertilizer types on the cumulative yield and nutrient uptake of sesame in Ogbomoso, southern guinea savanna eco-region of Nigeria. The materials used were seeds of Sesame indicum (ncriben 05E), NPK. 1515-15 fertilizer, organic neem, organomineral, poultry manure, PH meter and cow dung caper-cropping soil samples were collected randomly using soil auger at 0-15 cm and samples collected were bulked into a composite sample, air dried and sieved through 2 mm and 0.5 MM meshes for the determination of particle size, pH (H20), total nitrogen (N), organic carbon, available Phosphorus (P), Iron (Fe), Copper (Cu), Znic (Zn), exchangeable captions (Ca, Na, Mg and K) and exchangeable acidity (H^+ and Al^{+3}). The experiment was carried out using completely randomize design (CRD). A total of 36 pots were each filled with 10kg soils and used for the experiment. The six fertilizer treatments used at recommended rate and the control as T_0 (no treatment), T_1 (NPK, 2 g/pot), T_2 (organic neem, 30 g/pot), T_3 (organomineral, 30 g/pot), T_4 (poultry manure, 20 g/pot), T_5 (Cow dung, 30 g/pot). Two pots per treatment were used, replicated three times. Soil available P was determined by extraction with Sodium bicarbonate (Olsen *et al.,* 1954). Organic carbon was determined by chromic acid digestion.

Dry weight and the total biomass production of the harvested Sesame plants shoot and root were determined by oven drying at 80°C to a constant weight for three days (72 hours). The plant samples were then milled in Wiley mill to pass through 1mm sieve and subjected to kjeldah digestion at 360°C for 4 hours with concentrated sulphuric acid, using selenium and sodium sulphate as catalyst. plant content of P, K, Ca, Mg, Mn, Zn, and Cu were determined by ash plant samples in muffle furnace at 600°C for 2hours, the ash was cooled and dissolved in 1N hydrochloric acid and the solution pass through filter paper into Smi volumetric flask and made up to the mark with distilled water. Total N was determined from the digest steam distillation with excess NaOH. From the digest P concentration was determined by the Vanadomolybdate yellow colorimetric method using spectrophotometer (spectromic 20). The K and Ca were determined by using flame photometer (comin model 400) while Mg, Fe, Zn and Ca were determined with atomic absorption spectrophotometer (AAS) of the Bulk Scientific Model (Akanbi *et al*., 2005). The nutrients accumulated in plants were calculated as; Nutrient uptake=% Nutrient content X sample dry with according to (Ombo, 1994) and (Gungunila, 1999). Yield parameters measured were dry shoot weight per plant, number of capsules, capsules fresh weight, root fresh weight, root dry weight.

RESULTS AND DISCUSSION

The pre-cropping soil chemical and physical analysis shows that the soil is slightly acidic with pH 6.20 (Table 1). The soil was grossly low in essential nutrients particularly total N (0.16%), and exchangeable bases (cmol kg–1); K, 0.30 and Fe. 10.20. The results were in line with findings of Olabode, *et al., (*2007) and Babajide, *et al*., (2008) which indicated that the soils at the study area was slightly acidic and that they were grossly low in essential nutrients.

Table 1: Physico- chemical analysis of the soil sample used

Soil properties	Values
pH (H_2O)	6.20
Organic Carbon (g kg^{-1})	3.16
Total N (g kg^{-1})	0.16
Available P (mg kg^{-1})	5.14
Fe (mg kg^{-1})	10.20
Cu (mg kg^{-1})	2.60
Zn (mg kg^{-1})	2.19
Exchangeable K (cmol k^{1})	0.30
Exchangeable Na (cmolkg^{1})	0.22
Exchangeable Ca (cmol kg^{-1})	0.11
Exchangeable Mg (cmol kg^{-1})	3.22
Sand (g kg^{-1})	779.00
Silt (g kg^{-1})	91.00
Clay (g kg^{-1})	130.00
Textural class	Sandy loam

Fertilizer application significantly improved the number of capsules produced, T_1 produced the highest number of capsules (102.83) but not significantly different from other treatments except over the control with the least value (42.6cm). For capsules fresh weight, T_1 had the highest value (67.62g) but was not significantly different from other treatments applied except over the control with least value (29.29g). For root fresh weight, T_1 had the highest value (87.36g) but not significantly different from other treatments applied except for the control which has the least value (36.22g). For root dry weight, T_1 has the highest value (19.45g) but not significantly different from other treatments applied except over the control which has the least value (4.03g). For shoot dry weight, T_5 has the highest value (24.80g) but not significantly different from other treatments applied except over the control which has the least value (12.42g).

Table 2: Effect of different fertilizer types on yield parameters of sesame

Treatments	Number of capsules	Capsules fresh weight	Root fresh weight	Root dry weight	Shoot dry weight
T0	42.6b	29.29b	36.22b	4.03b	12.42b
T1	102.83a	67.62a	87.36a	19.45a	19.55ab
T2	57.0b	46.05ab	49.36ab	8.89b	15.18ab
T3	69.5ab	48.71ab	82.47a	10.55a	22.63ab
T4	81.5a	65.42a	79.25ab	9.37a	22.39ab
T5	80.3ab	52.23ab	78.16ab	8.43b	24.80a

Means followed by same letters are not significant different at P=0.05 using least significant different (LSD), T0 = Control, T1=NPK, T2= neem, T3= organomineral, T4= poultry manure, T5= cow dung.

Uptake of nitrogen (N) was more with the application of T_1 but the value obtained (37.66g Kg) had no significant mean difference from other treatments except for the control it the least value (7.8kg). The uptake of phosphorus (p) was enhanced by the application of T_1 with the value (3.66g kg) but not significantly different from T_4 but significant different over other treatments least for the control (1.13kg). Similarly, the uptake of potassium (k) was enhanced by the application of T_1 (24.86kg) and not significantly different from T_5 but over other treatments and the control that had the least value (2.8kg). Calcium (Ca) uptake was more enhanced by the application of T_5 but not significantly different from other treatments except the control with the least value (0.83kg). Magnesium (Mg) uptake was enhanced by the application of T_4 and the value obtained (3.8Mg/kg) had no significant difference from T_5 but significantly over other treatments except the control with the least value (1.7kg). Sodium (Na) uptake was enhanced by all the treatment applied. Iron (Fe) uptake was enhanced by the application of T_2 with the value obtained (86.46Kg) but had no significant difference from other treatments but significant over T_5 while the control has the least value (35.3kg). The uptake of copper (Cu), was enhanced by the application of T_1 which had the highest value (10.4kg) but not significantly different from other treatments but significant over other treatments except for the control (7.42kg). The uptake of manganese (Mn), was enhanced by the application of T_1 which has the highest value (85.9kg) but not significantly different from other treatments except the control (31.5kg). The uptake of Zinc (Zn), was enhanced by the application of T_1 which has the highest value (85.9kg) but not significantly different from other treatments except over the control (24.4kg)

Table 3: Effects of Nutrients uptake of sesame under different fertilizer types applied

Treatments	N	P	K	Ca	Mg	Na	Fe	Cu	Mn	Zn
T0	7.8f	1.13d	2.8c	0.83c	1.7c	0.9a	35.3c	7.42b	31.5b	24.4b

T5	27.4e	2.46c	24.26a	2.53b	3.53a	0.8a	74.53b	7.5a	33.13a	22.73a

Means followed by same letters are not significant different at P=0.05 using least significant different (LSD), T0 = Control, T1=NPK, T2= neem, T3= organomineral, T4= poultry manure, T5= cow dung

CONCLUSION

All the fertilizers applied significantly improved the yield parameters of *Sesamum indicum* measured. Application of NPK significantly improved the performance of *Sesamum indicum* and the value obtained when compared to the other fertilizer materials used. Nutrient uptake particularly N, P and K were also significantly enhanced through application of NPK fertilizer. Application of NPK is therefore recommended in the study area to improve the production of *Sesamum indicum in the locality*.

ABSTRACT

Low yield in tomato production has been partly traced to attack by Fusarium wilt. The most sustainable control option remains the use of resistant varieties. Participatory development and selection of resistant or tolerant varieties during breeding process is germane to adoption and expected impact. The National Horticultural Research Institute (NIHORT) developed three high yielding Fusarium wilt tolerant varieties (HORTITOM1, HORTITOM2 and HORTITOM3) in line with appropriate breeding guidelines. On-farm evaluation trial was conducted on farmers' field to evaluate the three improved varieties and two local checks. Farmers' field day was organized by NIHORT for field evaluation of the tomato varieties by selected farmers in the locality. Thirty farmers were selected from different communities from Agricultural Development Programme, Iwo zone, Osun State for participation. Interview schedule and Focus Group Discussion were used to collect data. Data were analyzed using ranking, assignment of positions and frequency distribution. HORTITOM1, HORTITOM3 and HORTITOM2 ranked first, second and third respectively. Most (75%) respondents selected HORTITOM1 as the most preferred variety. Top priority outstanding traits of HORTITOM1 are high yielding, fruit colour, growth pattern with a score of 105, 95 and 95 respectively. Participating farmers are expecting release of the improved varieties for adoption due to their involvement in the selection process. Participatory selection of resistant or tolerant crop varieties is germane to adoption of improved crop varieties for optimum yield and income.

INTRODUCTION

Globally, tomato (*Lycopersicon lycopersicum*) is one of the priority fruit vegetable crops consumed among the populace (FAO, 2010). It has all-year round demand due to its usefulness in both fresh and processed form (Alwis *et al*., 2008). In Nigeria, it is the most cultivated fruit vegetable (Borisade *et al*., 2017) and one of the priority agricultural commodities in horticulture under the agricultural transformation agenda of the Federal government of Nigeria (Akinwumi, 2013). Red coloured tomatoes contains high lycopene and beta-carotene which are very important anti-oxidants that fight against cancerous cell formation by neutralizing free radicals that can damage body cells (Bhowmik *et al*., 2012). It is rich in Chromium which helps in regulating blood sugar in diabetic patients and a very good source of minerals and vitamins (Bhowmik *et al*., 2012). Low production of tomato (3-10t/ha) has been reported in African countries compared to European countries with over 400t/ha (FAO, 2016). The low production of tomato in Africa has been attributed to the problem of pests and diseases leading to loss of large quantity of the produce (Cladius *et al*., 2015). In Nigeria, tomato plant is subject to attack by insect pests and diseases from nursery until harvest. Pests such as green peach aphids *Myzus persicae*, whitefly *Bemisia tabaci,* cutworm *Agrotis ipsilon*, and fruitworm *Helicoverpa zea* were the major pests causing damage to tomato until 2015 devastating invasion of *Tuta absoluta* (Oke *et al.*, 2017b). Plant-parasitic nematodes also pose a major threat to tomato production with the estimated loss of USD 80 billion per year (Nicol *et al* 2011). Low yield in tomato has also been traced to the attack of *Fusarium* wilt which occurs at any growth stage of the plant causing great loss both on the field and in the screen houses (McGovern, 2015).

Fusarium wilt of tomato, caused by *Fusarium oxysporum* f.sp. *lycopersici* is a devastating disease in major tomato-growing regions worldwide and has been reported in at least 32 countries and particularly severe in countries with warm climate (Mui-Yun, 2003). The pathogen is soil borne and can persist for many years in the soil in the absence of a host. *Fusarium* wilt is known for causing serious damage during production which could lead to 30-40% damage and the losses could go up to 80%. Agro chemicals are commonly used for pests and diseases management. However, they are costly, with adverse effect like mammalian toxicity due to chemical residue, environmental pollution, with limitations such as unavailability of the chemical and lack of technical know-how. The current trend on “near to zero tolerance” to pesticide residue in fresh fruit and leafy vegetables, development of resistant to chemicals by the pathogens, damaging effects of chemicals on the environment and human necessitate the search for non-chemical means of controlling pests and diseases (Reuveni *et al*., 2002). The most viable, cost effective and environmentally safe control option remains use of resistant varieties.

Participatory selection is an inclusive approach to plant breeding that actively involves farmers, researchers, and other stakeholders in the process of varietal development, selection and release. Participatory breeding initiatives encourage farmers to participate in the selection process in order to create crop varieties that are more suitable for the region's agro-ecological conditions, satisfy farmers' preferences, and increased agricultural productivity. Cases of non-adoption of developed technologies have been reported due to non-involvement of relevant end-users in development process. Therefore, technology rejection is not just a mere negation of its acceptance, it needs to be discerned (Murty and Wani, 2013) and prevented accordingly to enhance adoption.

In a bid to solve the problem of *Fusarium* wilt and low yield in tomato production, a multidisciplinary team of Scientists from NIHORT developed 3 candidate tomato varieties (HORTITOM1, HORTITOM2 and HORTITOM3). In accordance with National Centre for Genetic Resources and Biotechnology (NACGRAB) guidelines, on-farm trials were conducted following appropriate protocols to ensure farmers participation in production, selection and release of the new varieties. On-farm is to test new technology on farmer’s field, validate farmers’ perception about the candidate varieties whether it will be accepted or not, whether it is better than what they have or not and whether it can be adaptable or not and for comparison of farmer’s varieties and the candidate varieties (NACGRAB, 2016). The major objective of the study was to assess farmers’ participatory selection in the release of high yielding *Fusarium* wilt tolerant tomato varieties in Nigeria. The specific objectives were to:

1. Conduct ranking of evaluated varieties by participating farmers at the on-farm trial field
2. Identify most preferred tomato varieties among farmers
3. Ascertain priority traits preference in the most preferred variety by farmers

METHODOLOGY

Five tomato varieties comprising three best candidate varieties from NIHORT with two local checks (existing variety and farmer’s variety) were taken to farmers’ fields for on-farm trial. Appropriate agronomic practices were done both at on station and on-farm using standard procedures. In order to gain farmers participation in the evaluation and selection process, farmers’ field day was organized by NIHORT on 15th November, 2022 at Iwo, Osun State. Thirty farmers were selected to participate at the farmers’ field day by the collaborating Agricultural Development Programme (ADP), Osun State, however, twenty six and 28 farmers participated at the on-farm ranking and varietal selection respectively. Selection cuts across both direct and indirect beneficiaries from Idi Araba, Oke Oba, Iwo, Eleko, Ejigbo, Molefon, Kara, Akindi, Olukotun, Patara, Olodo, Ajenisiwa, Gidigbo, Bode Osi Ola Oluwa in Osun State. Questionnaire and Focus Group Discussion (FGD) were used to collect information from farmers. Farmers were asked to assign positions 1-5 to the evaluated varieties at the on-farm trial field with the best variety taking the first and the least taking the fifth position. Visual assessment was done by each farmer on the field to select the most preferred variety among the five evaluated varieties. In addition, each farmer was asked to assign a score from 1-5 to desirable traits in the most preferred varieties, this was to identify the most desirable traits in the preferred variety. Data were analyzed using ranking, assignment of positions and frequency distribution.

RESULTS AND DISCUSSION

Ranking of the three evaluated varieties at the on-farm trial field by participating farmers

The different positions (1-5) assigned by farmers were added together and the variety with the least total score ranked first as the best variety and vice versa. In terms of performance on the field, HORTITOM 1 had a total score of 30, HORTITOM 3 had a total score of 63 and HORTITOM 2) had a total score of 75 while Ibadan local and kerewa had a total score of 94 and 130 respectively. HORTITOM 1, HORTITOM 3 and HORTITOM 2 ranked first, second and third respectively while Iwo local and kerewa varieties came fourth and fifth respectively (Table 1). Results of the FGD confirmed that farmers did not observe any challenge on the field during the evaluation period thus farmers are willing to grow and adopt the new varieties and also ready to pay for seeds depending on the prevailing market price. Farmers are of the opinion that the new varieties are highly marketable. As far as the participants are concerned, no threat is envisaged from adopting the new varieties. Farmers requested for capacity building in value addition to tomatoes especially at the period of glut when many farmers harvest for sale at the same period. This is to promote storability of produce. Request was made for irrigation facilities by farmers to promote dry season tomato production. The three new tomato varieties were selected by majority of the end users and were subsequently released by NIHORT during Varietal Release Committee Meeting at NACGRAB in January, 2023.

Table 1: Assignment of positions to evaluated varieties on the field

Participants	HORTITOM 1	HORTITOM 2	HORTITOM 3	Ibadan local	Farmers' varieties (local check)

Total score	30	75	63	94	130
Position	1st	3rd	2nd	4th	5th

Selection of the most preferred varieties by farmers

Table 2 reveals that most respondents (75%) selected HORTITOM 1 as the most preferred variety, 17.9% and 7.1% preferred HORTITOM 3 and Ibadan local respectively while none chose HORTITOM2 and Iwo local as the most preferred based on field performance of the different varieties at the time of evaluation. Few (7.1%) respondents still preferred the local varieties because it has been with them, however scoring appearance on the field, the local variety still ranked last confirming the uniqueness of the HORTITOM series. With reference to the observation and judgment of the farmers, HORTITOM1 was the most preferred variety followed by HORTITOM3. Despite the outstanding performance of the new tomato varieties on the field, few farmers still preferred the old varieties, this could be due to the fact that the old varieties has been with them for quite a number of years and they could actually predict its behaviour on the field rather than voting for a completely new variety. During FGD, all farmers agreed that the improved varieties are better and different from varieties grown by them in the locality, HORTITOM3 was singled out in terms of firmness and big fruit size while HORTITOM1 was observed to be high yielding and early maturing. Most farmers preferred HORTITOM1 and confirmed uniformity in growth, flowering and fruiting pattern on the field.

Table 2: Frequency distribution of farmers based on selection of the most preferred among the evaluated tomato varieties

S/N	Evaluated varieties	Farmers preference Frequency	Percentage	Ranking
1.	HORTITOM1	21	75%	1st
2.	HORTITOM3	5	17.90	3rd
3.	Ibadan local	2	7.1%	2nd
4.	HORTITOM2	Nil	-	-
5.	Iwo local	Nil	-	-
	Total	28	100	

Characteristics traits in most preferred variety by farmers

From Table 2, among the 28 farmers that participated in the scoring exercise, 21 farmers selected HORTITOM 1. Highest score that each trait can attract is 5 and the highest score for 21 respondents will be 21x5=105. Top priority outstanding traits of T4 among majority of the respondents are high yielding, fruit colour, growth pattern with a score of 105, 95 and 95 respectively. This is an indication that all the 21 respondents assigned a score of 5 to high yield. Adaptability to environment, fruit shape and firmness attracted a score of 94, 90 and 90 respectively. During FGD, most of the respondents preferred HORTITOM1 and confirmed uniformity in growth, flowering and fruiting pattern on the field. Value for money was not among the top priority traits because the participatory farmers were selected from both beneficiaries and non-beneficiaries farmers during the farmers field day. Value for money can only be determined when farmers are fully involved in production and marketing of the produce.

Farmers revealed during FGD that no challenge was observed on the field during the evaluation period, meaning that no threat is envisaged from adopting the new variety. Farmers expressed willingness to buy at the prevailing market price, grow and adopt the new variety whenever seeds are made available. Farmers requested for capacity building in value addition to tomatoes especially at the period of glut when many farmers harvest for sale at the same period. Irrigation facilities were also requested for to promote dry season tomato production.

Table 3: Assignment of scores to characteristics traits in most preferred variety

Variety	HY	TOL	FC	FSize	FSH	FRM	ST	ERL	APP	VFM	GRP	ADE	Total score
HORTITOM1	105	87	95	87	90	90	81	86	93	90	95	94	1,093
HORTITOM3	25	19	22	21	22	23	21	21	19	21	23	23	260
Ibadan Local	10	5	8	8	9	8	9	4	9	9	10	10	99

Key: HY=High Yielding; TOL=Tolerance; FC=Fruit Colour; FSize=Fruit size, FSH.=Fruit Shape; FRM=Firmness; ST.=Storability; ERL+ Earliness; APP=Appearance; VFM=Value for Money, GRP=Growth Pattern; ADE=Adaptability to Environment.

CONCLUSION AND RECOMMENDATION

The three HORTITOM series are highly acceptable to farmers, however, HORTITOM1 ranked first and most preferred by 75% respondents. Unique traits identified include high yield, fruit colour and growth pattern. Participatory varietal selection is germane to acceptability of improved technologies among farmers. To make our research more inclusive and acceptable, there is the need to always involve end-users in development and selection process.

ABSTRACT
This study was conducted to assess the perception of research scientists about the environment for horticultural technology generation and dissemination in Nigeria. National Horticultural Research Institute (NIHORT) with mandate for horticultural crops development in the country was purposively selected. The 137 research scientists in the institute in 2022 was the study population. Fifty percent of the population was sampled using stratified random sampling based on cadre, place of assignment, and sex. This resulted in 70 respondents comprising 41 males and 29 females. Data was collected with the aid of pretested structured questionnaire, and were analyzed using descriptive (frequency counts, percentages, and ranking) statistics based on completed and returned questionnaires (87.1%). Most (59.0%) of the respondents were male with a mean age of 45.2 ± 7.4 years, mainly less than 50 years old (70.5%). They have worked in the institute for an average of 12.0 ± 5.7 years. A sizable proportion (47.5%) had PhD, and they are mostly (80.3%) biological scientists. Majority (52.5%) of them perceived that the environment was conducive for horticultural technology generation and dissemination. Those with favourable perception towards the environment are slightly above half of the respondents. Concerted efforts should be instituted by the government to further improve research institutions' environment for horticultural technology generation and dissemination in the country.
Key words*: Horticulture, validity ranking, environment, structure, integrity*

INTRODUCTION

Technology generation and dissemination is the primary responsibility of any research organization (Ogungbaigbe, 2004). This is because appreciable development could only be guaranteed through innovation emanating from technology generation and dissemination. The Agricultural Research Council of Nigeria (ARCN) as entrenched in its mission posits that generating appropriate technologies is germane to achieve significant improvement in agricultural productivity, marketing and competitiveness (ARCN, 2021). Generation and dissemination of horticultural technologies is very vital to ensuring nutrition and food security, wealth creation, reduction of hidden hunger and generating employment among other myriads of advantages. Horticultural crops have great economic, health, social, cultural and environmental benefits that could only be accessed through innovation creation along the value chain. This is bordering on new and creative activities in the pre-production, production and post-production areas of the value chain. The National Horticultural Research Institute (NIHORT) is the organization saddled with national mandate for generating horticultural technologies in Nigeria. The Institute also disseminates these technologies via different fora in collaboration with partners.

Environment plays a key role in technology generation and dissemination. Olajide-Taiwo (2022) documented that right or conducive environment is needed to ensure the integrity of any system on any issue. If the research organizations' environment is conducive, generating and disseminating problem-solving technologies would be facilitated more effectively and efficiently with associated level of integrity. Research scientists are key staff in the research organizations who provides leadership in the conception, design, execution, documentation, and dissemination of research activities leading to output, outcome and impact in form of technologies to address problems for horticultural development. Their perception of the environment under which technology generation and dissemination are carried out is germane to determining the adequacy and relevance of the generated and disseminated technologies for national development.

Over the years, it has been presumed that research for development in agriculture generally, and horticulture in particular have been hampered as a result of environment-related challenges. Reported challenges include insufficient funding, dilapidated and inadequate infrastructures, substandard laboratory, inadequate transportation facilities, and personnel with insufficient capabilities among other problems (Wopreis, 2018; Akinyemi, Adejoro, Layade and Adegbite, 2018; Akinpelu, Adebayo, Farike and Adewale, 2013). Studies focusing on the perception of research scientists about the environment for horticultural technology generation and dissemination are very scarce. Therefore, the general objective of this study is to assess the perception of research scientists about the environment for horticultural technology generation and dissemination in Nigeria. Specifically, the objective is to:

i. Analyze the personal characteristics of the research scientists involved in horticultural technology generation and dissemination.
ii. Assess the respondents' perception about the environment for horticultural technology generation and dissemination

METHODOLOGY

Study population, sampling procedure and sample size

Study was purposively conducted in NIHORT being the research only institute with national mandate for horticultural technology generation and dissemination in Nigeria. The population of the study comprise all Research Scientists who have been in the Institute before 2022. A total population of 137 Research Scientists were obtained through the nominal roll, and information supplied by the Planning, Monitoring and Evaluation Department (PMED).

Respondents were selected using stratified random sampling technique. The population were stratified into different cadre and sex across the eight Research Programmes, three Research Units, Planning Monitoring and Evaluation (PME) Department, Information and Documentation (ID) Department in Ibadan headquarter (Oyo State) and Outstations (Bagauda - Kano State, Mbato - Imo State, Dadinkowa - Gombe State, Otukpa - Benue State, and Riyom - Pleteau State). Thereafter, 50% of samples totaling 70 made up of 41 males and 29 females were randomly obtained from each stratum (Table 1).

Table 1: Sampling population and sample size

Population	AD – Director		PRO – CRO		RO1 – SRO		Total		Sample (60%)	
	Male	Fem.	Male	Fem.	Male	Fem.	Male	Fem.	Male	Fem.
Programmes	11	13	30	24	11	15	52	42	26	21
Units	0	3	7	2	1	4	8	9	4	5
PM&ED	0	0	1	1	0	1	1	2	1	1
Info &Doc D	0	1	0	1	0	1	0	3	0	2
Outstations	1	0	10	0	9	0	20	0	10	0
Total	12	17	48	28	21	21	81	56	41	29

Data collection and analysis

Data were collected using pretested structured questionnaire. The 61 (87.1%) returned questionnaire was used for data analysis using descriptive (frequency counts, percentages and ranks) statistics.

RESULTS AND DISCUSSION

Most (59.0%) of the respondents were male, less than 50 years old (70.5%) with a mean age of 45.2 ± 7.4 years. They have worked in the institute for an average of 12.0 ± 5.7 years. A sizable proportion (47.5%) had PhD, and they are mostly (80.3%) biological scientists. Majority (63.9%) have worked somewhere before their present organization, predominantly (52.5%) in non-research organization (Table 2). This indicates that the respondents are highly resourceful with sufficient experience to hear their views about their perception of the environment, and existing structure on horticultural technology generation and dissemination. Going by their background, they could make valid and valuable contribution to horticultural research for development through their perception.

Table 2: Personal characteristics of respondents (n = 61)

Personal Characteristics	Frequency	Percentage	Mean	SD

Perception of respondents about the environment for horticultural technology generation and dissemination

Few (3.3%) of the respondents perceived as "Not true" that "both relevant laws and principle are applied", and "appropriate and relevant personnel are involved" in the process of horticultural technology generation and dissemination. For every statement, the extent to which they were perceived to be true vary in proportion ranging from "True to a very small extent" to "True to a very large extent." A sizable percentage (44.3%) perceived that the statement that "there is no freedom from crisis and unrest" was not true (Table 3). The most valid statement perceived by the respondents in relation to the environment for horticultural technology generation and dissemination was, "Relevant laws and principles are applied" while the least valid was, "There is no freedom from crisis" (Table 4). This is an indication that the environment is perceived to be conducive for technology generation and dissemination by majority (52.5%) of the respondents as depicted in Figure 1

Table 3: Percentage distribution of respondents according to their perception of the environment for horticultural technology generation and dissemination (n = 61)

SN	Statements on perception of the environment for horticultural technology generation and dissemination	Not True	True to a very small extent	True to a small extent	True to an average extent	True to a large extent	True to a very large extent
1	Physical environment are not conducive	41.0	6.6	8.2	16.4	21.3	6.6
2	Relevant laws and principles are applied	3.3	8.2	18.0	14.8	32.8	23.0
3	Appropriate and relevant personnel are involved	3.3	8.2	3.3	18.0	32.8	34.4
4	There is no freedom from crisis and unrest	44.3	4.9	8.2	4.9	21.3	16.4
5	Equal opportunities are given to all actors	16.4	3.3	19.7	21.3	19.7	19.7

Table 4: Percentage distribution of respondents according to validity and ranking of perception statements about the environment for horticultural technology generation and dissemination (n = 61)

SN	Statements on perception of the environment for horticultural technology generation and dissemination	Mean	SD	Not valid	Valid	Validity Rank
1	Physical environment is not conducive	1.90	1.8	47.5	52.5	4
2	Relevant laws and principles are applied	3.34	1.40	29.5	70.5	1
3	Appropriate and relevant personnel are involved	3.72	1.36	32.8	67.2	2
4	There is no freedom from crisis and unrest	2.03	2.06	49.2	50.8	5
5	Equal opportunities are given to all actors	2.83	1.67	39.3	60.7	3

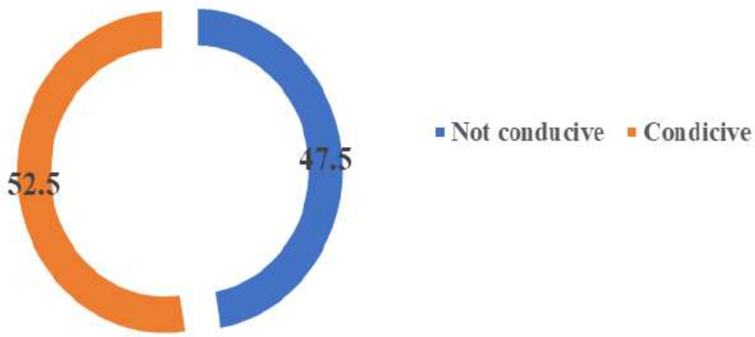

Figure 1: Percentage distribution of respondents according to their perception about conduciveness of environment (n = 61)

CONCLUSION AND RECOMMENDATION

A conducive environment is very vital for horticultural technology generation and dissemination. Majority of the respondents perceived that NIHORT's environment is conducive for horticultural technology generation and dissemination. However, those who sees environment in good light are slightly above half of the respondents. Concerted efforts should be put in place by the government to further improve research institutions' environment to enhance the quality and impact of research in the country.

ABSTRACT
Inappropriate fertilizer application and poor soil fertility management practices are among the factors constraining onion production in Gombe state. Field experiment was conducted at students' demonstration farm, Department of Agricultural Education, Federal College of Education (Technical) Gombe, from June to October, 2022 to assess the effect of different rates of organic and inorganic fertilizer on growth and yield of onion. Treatments included To (0 t/ha PM + O kg NPK), T_1 (20 t/ha PM), T_2 (15 t/ha PM + 50 kg NPK), T_3 (10 t/ha PM + 100 kg NPK), T_4 (5 t/ha PM +150 kg NPK) and T_5 (200 kg NPK/ha). The experiment was laid out in a randomized complete block design (RCBD) with three replications. Plant treated with 20 t PM/ha recorded the tallest plants (45.17 cm), produced more leaves per plant (12.67), average thin bulb neck (4.80 cm) and average big bulb neck (12.77 cm) while the least values were obtained from the control. Longest leaf (17.37 cm) was recorded from plants treated 10 t/ha poultry manure + 100 kg/ha NPK and longest days to maturity was obtained from plants treated with 200 kg/ha NPK while least values of 11.10 cm and 76 days respectively. In conclusion, Plant treated with 20 t/ha PM performed relatively better than other treatments in most of the parameters measured but not significantly different from those applied 10 t/ha + 100 kg/ha NPK, thus, either of the treatments is recommended for the farmers in the study area for optimum production of onion.
Keywords: *organic manure, NPK, onion, gombe, growth, yield*

INTRODUCTION

Onion (*Allium cepa* L.) is one of the most vital vegetables in the world (Shigyo and Kik 2008). It is commonly used as flavorings or as vegetables in stews and salads. It is one of the richest sources of flavonoids in the human diet which has been associated with a reduced risk of cancer, heart disease and diabetes. Globally, the area under onion production is increasing due to its high profitability per unit area and ease of production (FAO, 2011). Onions is used in the preparation of most of the popular Nigerian delicacies. Some of its numerous health benefits include lowering of cholesterol, blood sugar and blood pressure levels. There are different varieties of onions. These include the red, white and yellow onions. The red is the popular one in the country and it is of great commercial value for farmers that cultivate it. Although many farmers are involved in the cultivation of red onions there is still a shortfall in meeting the demand of the Nigerian market especially during the rainy season. Onion is important in the daily Nigerian diet and all the plant parts are edible, although the bulbs are widely used as a seasoning or a vegetable in various dishes. Onion is valued for its distinct pungency and form essential ingredients for flavoring varieties of dishes, sauces, soup, sandwiches, snacks as onion rings *etc*. It is popular over the local shallots because of its high yield potential per unit area, availability of desirable cultivars for various uses and ease of propagation by seed (Lemma & Shimelis, 2021).

Organic fertilizers has positive effect on root growth by improving the root rhizosphere conditions (structure, humidity, etc) and also plant growth is encouraged by increasing the population of microorganisms (Shaheen *et al*., 2017). It is obvious that continuous use of inorganic fertilizers and inappropriate soil fertility management practices are among the major factors limiting productivity of onion. Continuous use of inorganic fertilizers without supplementation with organic manure has often resulted in micronutrient deficiencies imbalance and unsustainable crop production (Yohannes *et al*., 2017). Decomposition of organic materials would provide additional nutrients to the growing medium, which may lead to higher uptake of nutrients by the crop and subsequently high yield (Gererufael *et al*., 2020). There is increased interest in utilization of organic manure because of increased demand of onion and other vegetables as they grow faster and give considerable amount of yield (Boyhan and Torrance., 2020). Onion growth, number of leaves and bulb size were increased with the use of organic fertilizer (Lee, 2018). There is also limited information about application rate of organic manure to onion in the study area. Thus, the main objective of this study was to determine the effects of different rate of organic and inorganic fertilizer application on growth and yield of onion.

MATERIALS AND METHODS

The experiment was conducted at the Demonstration farm, School of Secondary Education (Vocational), Federal College of Education (Technical), Gombe, which is located between latitude 9° - 30° and 12° – 30° North, longitude 8° - 45° and 11° – 45° east in the Sudan Savannah zone Nigeria. The wet season starts from April/May to October with an annual rainfall of about 650-900 millimeters. The dry season begins from November to March, temperature varies from *18⁰C* – 41°C. The treatments consisted of six levels of combination of NPK and poultry manure (PM) (T_{0} = control; T_{1} = 20 t/ha PM; T_2 =15 t/ha PM+50kg/ha NPK; T_3 = 10 t/ha PM + 100kg/ha NPK; T_4 = 5t/ha PM + 150kg/ha NPK and; T_5 = 200kg/ha NPK). The organic fertilizer was applied two weeks before transplanting. The seedlings were transplanted when they have reached 3 to 4 leaves stage or attain the height of 12 to 15 cm. NPK was applied two weeks after transplanting. The experiment was laid out in a randomized complete block design (RCBD) with three replications.

A nursery bed of 5 m long and 1 m wide was marked out and cleared. The land was ploughed thoroughly and made into a fine tilth. Onion seed variety Red Wing was sown at 10 cm distance between rows lightly covered with soil and mulched with grass until seedlings emerge. All proper agronomic practices were carried out until seedlings were transplanted to the main field. Data on plant height, number of leaves per plant, leaf length, days to maturity, bulb diameter, neck diameter, average fresh bulb weight and total bulb weight were collected from five randomly selected plants, and total bulb yields were recorded per plot. Plants in the central rows were used for data collection, leaving aside plants in the border rows and those at the end of each row. Data collected were subjected to analysis of variance (ANOVA) using Star software version 2.0.1. Treatment means were separated using Fisher's Least Significant Difference (LSD) test at 5% probability level.

RESULTS AND DISCUSSIONS

The soil of the experimental site is sandy loam, slightly acidic, low in organic carbon, nitrogen and phosphorus (Table 1). Exchangeable bases are moderate for soil (Esu, 1991). The composition of the poultry manure showed that the pH value is slightly alkaline (7.22) high in organic carbon (28.87 g/kg), total nitrogen (3.62 g/kg), available phosphorus (1.22 mg/kg) and moderate exchangeable bases. Results of the effects of organic and inorganic fertilizer on plant height, number of leaves per plant, leaf length and days to maturity are shown on table 2. Results showed highly significant ($p<0.01$) on days to maturity and significant ($p<0.05$) on plant height and leaf length but showed no significant on number of leaves per plant. Plants applied 20 t/ha poultry manure recorded the tallest onion plant (45.17 cm) but not significantly different from other treatment combinations except the control with shortest plants (17.07 cm). The result is in agreement with the findings of Kokobe *et al*. (2013), Negasi *et al.* (2017) and Yohannes *et al*. (2017). The increment in plant height in response to increased application of the fertilizers is attributable to the role the different nutrients play in the plant in terms of enhancing photosynthetic rate and cell division, elongation and vegetative growth.

Plants treated with 10 t/ha PM and 100 kg/ha NPK produced longest leaf (17.37 cm) followed by those treated with 20 t/ha poultry manure (16.60 cm) while the control had the least (11.01 cm). Messele (2016) reported similar findings where significant increase in vegetative growth parameters of onion with increasing N supply from zero to 50 kg N ha−1. Maximum rate of N showed the highest increment in mean leaf length and number of leaves (Kokobe *et al*. 2013). This might be attributed to the simulative effect of N on vegetative growth, as it is involved in production and use of carbohydrate through photosynthesis and metabolism (Jeyakumar *et al.,* 2007 cited in Gererufael *et al.* 2020). Plants treated with 200 kg/ha NPK reached maturity late in 89.67 days followed by those treated with 5 t/ha poultry manure and 150 kg/ha NPK (87 days), while the control matured earlier in 76.33 days (Table 2). The findings of the present study is in line with the reports of (Girma 2011; Negasi *et al.,* 2017). Delayed maturity with increasing dose of fertilizer application might be attributed to the role that NPK plays in promoting vegetative growth before start of bulb development. Though the effect organic and inorganic fertilizer on number of leaves per plant of onion indicated no significant effect, nevertheless, plants treated with 20 t/ha poultry appeared to produce more leaves (12.67) than other treatment combinations, while the control produced the least number of leaves (9.67). Jeyakumar *et al.* (2007) also reported similar findings. The increase in number of leaves in response to increased application of fertilizers might be due to the role of the different nutrient elements such as N and phosphorus plays in root and shoot growth and development and formation of phosphoproteins and phospho-lipids that encourage meristematic activity of plants, resulting in increased number of leaves per plant (Bagali *et al.*, 2012).

Results of organic and inorganic fertilizer on the number of bulbs per plant, total bulbs weight, average bulb weight, average bulb thin neck and average bulb big neck are shown on table 3. The results indicated no significant effect ($p>0.05$) effect on the number of bulbs per plant, total bulbs weight and average bulb weight but showed significant ($p<0.05$) effect on the average bulb thin neck and average big neck. Plants treated with 5 t/ha PM + 150 kg/ha NPK appeared to produced more number of bulbs per plant (14.33) while control had the least (12.00). In the same vein plants treated with 20 t/ha poultry manure appeared to produce highest total bulb weight (179.60) while the control had the least (6.03). Also, plants treated with 20 t/ha poultry manure had the highest average bulb weight of 23.34 g, while control had the least with 0.99 g. Plants treated with 20 t/ha poultry manure recorded the thinnest and biggest bulb neck with values 4.80 cm and 12.77 cm respectively, while the control having the least (1.56 cm and 2.98 cm for average thin and big neck respectively). Corroborating result was reported by Kokobe *et al.* (2013) who indicated a highest (36.85 t ha−1) bulb yield of onion was obtained at combined application of 100 kg N ha−1 and 45 t FYM ha−1. Similarly, Bashir and Qureshi (2014) reported higher bulb yield of onion at application of 180 kg N ha−1 and 24 t FYM ha−1.

The lowest total bulb yield in the control or zero application of both fertilizers might be due to the fact that plots were deficient of the essential plant nutrients of N and organic manure. The findings in the present study could be due to the activities of NPK and poultry manure in promoting physiological and metabolic processes in plant which improved dry matter production and accumulation. Moreover, the beneficial effect of organic manures on yield might be due to additional supply of plant nutrients and improved physical and biological properties of soil (Datt *et al.*, 2003). The result is in agreement with the findings of Kokobe *et al.* (2013) who reported that interaction effects of N and FYM significantly affected bulb weight of onion. Moreover, integrated use of organic and chemical fertilizers increased bulb weight by about 8.1–12.2% over control (Jayathilake *et al.* 2002). The increase in bulb weight could be attributed to the increase in plant height, number of leaves produced and leaf length in response to the highest rate of N (Shedeed *et al*. 2014).

CONCLUSION AND RECOMMENDATIONS

The findings of this study indicated that organic and inorganic fertilizer significantly influence the growth and yield of onion. Application of 20 tons of poultry manure per hectare improved most of the growth and yield parameters of onion assessed. Thus application of 20 t/ha PM is hereby recommended for optimum production of onion in the study area.

ABSTRACT

A pot experiment was carried out at the Teaching and Research Farms, Ladoke Akintola University of Technology (LAUTECH) Ogbomoso, Nigeria around March-April 2021 to determine the effects of proportionate application of NPK fertilizer and neem compost on performance of sesame (Sesamum indicum) plants. Six treatments were introduced which are: T0 (no fertilizer application); T1(100% NPK fertilizer application) ; T2(75%NPK +25% neem compost); T3(50% NPK + 50% neem compost) ; T4(25%NPK + 75% neem compost): T5(100% neem compost). The experiment was arranged in a completely randomized design (CRD) with each treatment replicated three times. Data were collected on growth and yield parameters and were analysed using ANOVA. The significant means were compared using Duncan's Multiple Range Test (DMRT). Soil sample used was relatively low in major N, P, and K. Application of 100% NPK(T1) significantly improved the performance of sesame. The value obtained from T1 was not significantly different from T2, T3, T4 and T5 while the control (T0) had the least performance. Nutrient uptake particularly N, P and K were also significantly enhanced through application of T1(100% NPK). T2(75%NPK +25% neem compost) is however recommended for improved performance of sesame in the study area.

Keywords: Fertilizer, Neem compost, NPK, Sesame, Performance, treatments.

INTRODUCTION

Sesame (*Sesamum indicum L.*) is one of the most ancient crops and oilseeds known and used by mankind mainly due to its ease of extraction, great stability, and resistance to drought. It is known by many names such as beniseed, gingelly, sinsin, sesame, and till. Sesame crop is cultivated in almost all tropical and subtropical Asian and African countries for its highly nutritious and edible seeds (Iwo *et al.*, 2002). Sesame is grown mainly for its seeds that contain approximately 50% oil and 25% protein (Burden, 2005). The seeds serves as ingredients in soup and a source of oil (Biswas *et al.*, 2001) and the cake after oil extraction is used in livestock feed. It is also used in local preparation of weaning food (Lalude and Fashakin, 2006). Seeds are used as raw food as well as in confectioneries, sweets, bakery products and also the oil is used in industries in preparation of soap, perfume, and carbon papers as well as in vegetable oil (Khan *et al.*, 2001). The sesame plant measures 60 to 120 cm tall, it is whitish to brown or black seeds depending on the variety with a high oil content of 44-60%, deep rooting. In Nigeria, the crop has remained a popular cash crop among farmers due to its good local and international markets potentials even though its production volume is fluctuating in recent years. For optimum development and yield, sesame requires 25°C to 37°C temperature throughout its growth period. A temperature of 25°C to 27°C encourages rapid germination, initial growth, and flower formation. Temperature below 20°C for any length of time inhibits germination or delay, and a temperature of less than 18°C after emergence will severely retard growth of seedlings. The seeds will not germinate at all at temperature below 11°C (Bennet, 2011). In Nigeria, sesame is cultivated on over 80,000 ha across most of the Northern States. Benue and Nasarawa States are the highest sesame producer in Nigeria with an annual output of not less than an average of 40,000MT each per annum (Raw Materials Research and Development Council, 2004). It will grow on relatively poor soils in climates generally unsuitable for other crops, and so it is widely valued for its nutritional and financial yield from otherwise inclement areas. It is well suited to smallholder farming with a relatively short harvest cycle of 90 – 140 days allowing other crops to be grown in the field (USDA, 2005).

Sesame seed oil is being investigated as a cell growth regulator that slows down cell growth and replication partly through its antioxidant properties. Research shows that the oil can neutralize free oxygen radicals within the skin and surrounding tissues. other experiments have demonstrated positive effects for helping clear blocked arteries. The oil quickly permeates and penetrates the skin, entering the blood stream through capillaries. While in the blood stream, molecules of sesame seed oil maintain good cholesterol and assist the body in removing bad cholesterol (Bergougnoux, 2004). The above benefits and more is the reason for the research carried out on sesame with an objective to evaluate the effect of proportional application of NPK fertilizer and neem compost on the performance of sesame.

MATERIALS AND METHODS

The experiment was conducted at the experimental plot of Agronomy Department, Ladoke Akintola University of Technology, Ogbomoso. Materials used were NPK fertilizer, sesame seed, mesh wire, iron pole, hoe, measuring tape, cutlass, vernier caliper, watering can, shovel, soil sample, rake, wheelbarrow, plastics pots and sensitive scale. Pre-planting collection of the soil sample was carried out using soil auger at depth of 0-15 cm. Samples were collected randomly from the arable experimental plot located behind Bee-Hall, Faculty of Agricultural Sciences, LAUTECH and were bulked into a composite sample. The samples were air dried, crushed and sieved through 2 mm and 0.5 mm meshes for the determination of particle size for physical and chemical analysis of the soil pH, organic C, total N, P and K%, and also the exchangeable cations Ca, Mg, Na and k. Pots used for the experiment were perforated at the bottom with 8 kg soil. Sowing was done 12^{th} April, 2021. Shallow holes(1cm) were made in the pots and few seeds were sown in each hole and lightly covered with soil. Regular watering was done throughout the experiment with the use of watering can. Tinning was carried out two weeks after sowing and the plants were reduced to two plants per pot. NPK fertilizer and neem compost was integrated four weeks after sowing.

Weeding of pots was done by uprooting with hands. Hoe weeding was done around the surrounding at weekly intervals. Cypermethrin was used for the control of insects by spraying with a knapsack sprayer at two weeks interval. The treatments introduced were NPK and neem compost; T0= control (no fertilizer applied), T1= 100% NPK at recommended rate (2.7g\pot), T2= 75%NPK (2.1g\pot) + 25% Neem (2.8g\pot), T3=50% NPK (1.35g\pot) + 50% Neem (5.6g\pot), T4=25%NPK (0.7g\pot) + 75% Neem (8.4g\pot), T5=100% Neem (11.1g\pot). The experiment was arranged in a Completely Randomized Design (CRD) with each treatment replicated three times. The fertilizer treatments were applied at two weeks after sowing (2 WAS). Data collection commenced at 5 weeks after sowing, (5WAS). The growth parameters observed were number of leaves, number of branches, plant height and stem girth. Yield parameters obtained were shoot fresh weight, shoot dry weight, root fresh weight, root dry weight, seed wet weight, seed dry weight, number of capsule and extracted seed weight.

Number of leaves was determined by visual observation and direct counting of fully opened leaves per plant. Number of branches was also determined by visual observation and direct counting of branches away from the stem. Plant height was determined using tape rule at the stem base and run to the tip of the plant. Stem girth was determined by using vernier caliper to give the actual stem girth. The weight of the yield parameters was measured with the use of sensitive electronic weighing balance citizen model. All data collected were subjected to Analysis of variance (ANOVA) and significant means were compared by Duncan Multiple Range Test (DMRT) at 5% probability.

RESULTS AND DISCUSSION

The pre-cropping chemical and physical analyses of the soil sample used showed that the soil is slightly acidic with a pH of 6.10 (Table 1). The soil sample was low in essential nutrients particularly N (0.18 g kg^{-1}) P (3.72g kg^{-1}) and Na (0.24 cmol kg^{-1}). Also, the soil was texturally sandy loam. The results correspond with the earlier researcher finding of (Babajide *et al*., 2008) which stated that the soil in the study area are grossly low in essential nutrients**.**

Table 1: Physical and chemical Analysis of the soil used

Soil characteristics	**Values**
pH (H_2O)	6.10
Organic Carbon (g kg^{-1})	2.42
Total N (g kg^{-1})	0.18
Available P (mg kg^{-1})	3.72
Fe (mg kg^{-1})	12.52
Cu (mg kg^{-1})	2.84
Zn (mg kg^{-1})	3.14
Exchangeable K (cmol kg^{-1})	0.19
Exchangeable Na (cmol kg^{-1})	0.24
Exchangeable Ca (cmol kg^{-1})	1.96
Exchangeable Mg (cmol kg^{-1})	2.60
Sand (g kg-1)	780.04
Silt (g kg-1)	120.03
Clay (g kg-1)	99.93
Textural class	Sandy loam

Table 2: Effect of NPK fertilizer and Neem compost application on the yield parameters of *sesamum indicum*

Treatment	**FSW (g)**	**DSA(g)**	**FRW(g)**	**DRW(g)**	**WSW(g)**	**DSW(g)**	**NC**	**ESW(g)**
T0	168.4a	41.6a	45.6b	13.3b	50.9ab	21.3a	54.7a	12.4ab
T1	394.4a	86.9a	134.5a	47.2a	96.1a	34.9a	90.7a	23.9a
T2	216.9a	44a	79.2ab	22.4b	68.1ab	30.5a	78.4a	20.6ab
T3	201.6a	45.3a	47.3b	10.2b	73.3ab	30.2a	75.6a	18.2ab
T4	169.1a	37.9a	29.5b	10.5b	31.3b	18.1a	35.8a	9.6b
T5	202.1a	34.1a	34.1b	9.5b	36.9ab	19.0a	37.5a	11.7ab

Means followed by the same letters within the same column are not significantly different at $p<0.05$, using DMRT. T0= No application, T1=100%NPK fertilizer application, T2=75% NPK + 25% neem compost, T3= 50% NPK + 50% neem compost, T4= 25% NPK + 75% neem compost, T5= 100% neem compost. FSW= Fresh shoot weight, DSA= Dry shoot weight, FRW= Fresh root weight, DRW= Dry root weight, WSW= Wet seed weight, DSW= Dry seed weight, NC= Number of capsule, ESW= Extracted seed weight.

Table 2 shows the effect of NPK fertilizer and Neem compost application on yield parameters of sesame. At fresh shoot weight (FSW), T1 had the highest mean value of (394.4g) which is not significantly different from the mean of other treatment tested and the control had the least mean value (168.4g). At dry shoot weight (DSW), T1 had the highest mean value (89.9g) but not significantly different from the mean of other treatment tested. T5 had the least mean value (34.1g). At fresh root weight (FRW), T1 had the highest mean value (134.5g) but not significantly different from T2, but significantly different from other treatment tested. T4 had the least mean value (29.5g). At dry root weight (DRW), T1 had the highest mean value of (47.2g) which is significantly different from the mean of other treatment tested. T5 had the least mean value (9.5g). At wet seed weight (WSW), T1 had the highest mean value (96.1g) but not significantly different from other treatment tested but significantly different from T4 which also had the least mean value (31.3g). At dry seed weight (DSW), T1 had the highest mean value (34.9g) but not significantly different from the mean of other treatment tested, T4 had the least mean value (18.1g). At number of capsule (NC), T1 had the highest mean value (90.7g) but not significantly different from the mean of other treatment tested, T4 had the least mean value (35.8g). At extracted seed weight (ESW), T1 had the highest mean value (23.9g) but not significantly different from the mean of other treatment tested but significantly different from the mean value of T4(9.6g) which had the least mean value.

CONCLUSION

The control which is the zero application of fertilizer had the least value of all the parameters measured. It can therefore be deduced from this research that application of NPK and Neem compost could be appropriate to supply adequate nutrient required for optimum growth of *sesamum indicum* in the study area. In conclusion, varying application of NPK and Neem compost improve the growth and fruit yield of *sesamum indicum.* Therefore, I would recommend the use of Neem compost and NPK fertilizer integrations to local farmers for good yield of sesame and also to increase the economic supply of sesame to the society.

ABSTRACT
A pot experiment was carried out at the teaching and research farm, Ladoke Akintola University of Technology (LAUTECH), Ogbomoso, Nigeria to evaluate the growth and fruit yield of okra (Abelmoschus esculentus) under sole and combined application of NPK fertilizer and poultry manure in Ogbomoso. Six treatments introduced were: T0 (Zero fertilizer application), T1(100% NPK), T2(75% NPK and 25% poultry manure), T3(50% NPK and 50% poultry manure), T4(25% NPK and 75% poultry manure), T5(100% poultry manure). The trial was arranged in Completely Randomized Design and replicated three times. Data were collected on growth and yield parameters and were analyzed using ANOVA. Significant means were separated using Duncan's Multiple Range test (DMRT). Application of 25% NPK and 75% poultry manure (T4) produced significantly higher number of branches, shoot fresh and dry weight, root fresh and dry weight, and fruit weight, while 100% poultry manure (T5) significantly enhanced plant height, number of leaves, although the values obtained were not significantly different from T4 (25% NPK and 75% poultry manure).
***Keywords**: Abelmoschus esculentus, NPK, and Poultry manure*

INTRODUCTION

Okra (*Abelmoschus esculentus* (L.) Moench) belongs to the genus *Abelmoschus* of the family *Malvaceae*. Okra also known as lady's finger or gumbo is believed to have originated from East Africa and is an important vegetable crop consumed worldwide. It is ranked third to tomato and pepper (Ibeawuchi, 2007). It is widely cultivated in the tropics and subtropics for its immature edible green fruits which are consumed as a vegetable (Iyagba *et al*., 2013). In Nigeria, it is produced mainly for its young leaves and green pods by peasant farmers, in-home gardens or in mix-cropping with cereal. Okra pods contain a mucilaginous substance used to thicken soups and stews, and as plasma replacement or blood volume expander (Onunkun, 2012). The young leaves and fruits are boiled or fried and eaten as a vegetable or in a soup. The crop plays an important role in human diet due to the supply of carbohydrates, proteins, fats, minerals and vitamins (Abd El-Kader *et al.,* 2010). Okra is a good source of vitamin A, B and C including minerals especially iodine and amino acids found in the seeds; which competes favorable with those in poultry, eggs and soybean (Senjobi *et al*., 2000). The stem is useful as fiber, while the leaves are considered good cattle feed and are sometimes consumed by man.

According to Adekiya *et al*., the yield of okra in Nigeria is currently very low about 2.7 t ha−1 owing to low native soil fertility status among other factors. Lack of sufficient amounts of nutrients result in poor performance of the crop with growth been affected resulting to low yield. It has been reported that the maintenance of soil organic matter (OM) is the basis of sustainable crop production in Nigeria and other tropical countries (Oladipo *et al*., 2005). Hence, there is need to improve the fertility of the soil for continuous and increased crop production. Okra cultivation requires nutrients such as nitrogen (N), phosphorus (P), potassium (K), calcium (Ca), sodium (Na) and Sulphur (S) for fertility maintenance and crop production. These nutrients are specific in function and must be supplied to plants at the right time and at the right quantity. The improvement of soil fertility through the application of fertilizers has become an essential factor that enables the world to feed billions of people (Abdul-Elkader *et al*., 2010). (Majanbu *et al.,* 2016) reported that NPK are the most important macro-nutrients that okra required for proper growth and yield. NPK fertilization among the various agronomic practices also influenced the growth and yield of okra. Mixing organic and inorganic fertilizers may be a sound soil fertility management strategy in many countries. Apart from enhancing crop yields, the practice has a greater beneficial residual effect that can be derived from use of either organic or inorganic fertilizers applied alone. Okra responds well to the application of poultry manure and NPK fertilizer.

MATERIALS AND METHODS

This experiment was carried out at the experimental plot, Ladoke Akintola University of Technology, Ogbomoso in the guinea Savannah zone of Nigeria, between March and July, 2021. The materials used were: seeds of *Abelmoschus esculentus* (Clemson spineless variety), planting pots, NPK 15-15-15 fertilizer, poultry manure, insecticide, hoe, cutlass, watering can, rake, knapsack sprayer and water etc. Land clearing and preparation were carried out manually, using hoe, cutlass, rake etc. and the area was fenced with wire mesh to protect the crops and materials from predators (animals, thieves, etc.). The top soil was then collected at the depth of 0-15cm and sieved with a 2mm sieve to remove the stone and some large particles for physical and chemical analysis. The pots were then filled up with 10kg soil and the number of pots was thirty-six (36). The six treatments used were: T0 = control (zero fertilizer application), T1 = (100% NPK fertilizer application), T2 = (75% NPK + 25% Poultry manure fertilizer application), T3 = (50% NPK + 50% Poultry manure fertilizer application), T4 = (25% NPK + 75% Poultry manure fertilizer application), T5 = (100% Poultry manure fertilizer application). The trial was arranged in completely randomized design (CRD), with three replications. Okra seeds were sown directly into the pot at 2 seeds per pot, and the seeds germinated 5days after. The first fertilizer application was 3weeks after sowing, and watering continued throughout the experimental period and it was harvested after maturity. Pots were manually weeded with hands. Data collection commenced at fourth week after sowing (4WAS). The growth parameters observed were Plant height, number of leaves, number of branches and stem girth. All the data collected were analyzed using the following procedures of analysis of variance (ANOVA). Duncan Multiple Range Test (DMRT) was used to compare differences in means (SAS, 2009).

RESULTS AND DISCUSSION

Effect of fertilizer application on yield parameters and nutrient uptake of *Abelmochus esculentus* as affected by different fertilizer types.

T4 (25% NPK + 75% poultry manure fertilizer application) had a highly significant effect on the shoot fresh weight (SFW) and root fresh weight (RFW) and the values obtained (65.1 and 26.8) had no significant difference from other treatments tested except the T0 (no fertilizer application) which had the least values. (Table 4.6). T3 50% NPK + 50% poultry manure fertilizer application had a highly significant effect on the shoot dry weight (SDW) and the value obtained (26.3) had no significant difference from other treatments tested except the T0 no fertilizer application which had the least values, while T4 (25% NPK + 75% poultry manure fertilizer application) had a highly significant effect on the root dry weight (RDW) and the value obtained (7.6) had no significant difference from other treatments tested except the T0 no fertilizer application which had the least values (Table 4.6). T4 in the first harvest (HAR1) had the highest mean fruit weight of 18.2g which is significantly different from other treatments tested, while T0 had the least value of 2.9. At second harvest (HAR2), T3 had the highest mean fruit weight of 25.4g which was not significantly different from other treatments tested except T0, T1 and T2 which had the least value of 4.9. T1 in the third harvest (HAR3) had the highest mean fruit weight of 3.6g which was not significantly different from other treatments tested except T3, T0 and T2. While T4 in the fourth harvest (HAR4) had the highest mean fruit weight of 11.5g which was not significantly different from other treatments tested except T3 (Table 4.7).

Table 1: Effect of fertilizer application on yield parameters of *Abelmochus esculentus* as affected by different fertilizer types.

Treatments	SFW(g)	RFW(g)	SDW(g)	RDW(g)
T0	38.7b	14.5b	13.4b	4.0b
T1	61.3a	24.2a	21.4ab	4.8ab
T2	53.8ab	22.0ab	23.9ab	5.5ab
T3	59.6ab	23.1ab	26.3a	6.3a
T4	65.1a	26.8a	25.7a	7.6a
T5	48.0ab	17.1ab	25.7a	6.7a

Mean followed by the same letters within the same column are not significantly different at p≤0.05, using DMRT. T0= No application, T1= 100% NPK fertilizer application, T2= 75% NPK + 25% poultry manure, T3= 50% NPK + 50% poultry manure, T4= 25% NPK + 75% poultry manure, T5= 100% Poultry manure. RFW= Root fresh weight, SFW= Shoot fresh weight, RDW= Root dry weight, SDW= Shoot dry weight..

Table 2: Effect of fertilizer application on yield parameters (fruit weight) of *Abelmochus esculentus* as affected by different fertilizer types.

Treatments	HAR1	HAR2	HAR3	HAR4
T0	2.9c	6.3c	0b	3.7ab
T1	5.9bc	12.2b	3.6a	5.5ab
T2	4bc	4.9c	0b	8.4a
T3	3.3bc	25.4a	0.9b	1.1b
T4	18.2a	16.5ab	2.3a	11.5a
T5	7.7b	19.5a	2.8a	3.5ab

Mean followed by the same letters within the same column are not significantly different at p≤0.05, using DMRT. T0= No application, T1= 100% NPK fertilizer application, T2= 75% NPK + 25% poultry manure, T3= 50% NPK + 50% poultry manure, T4= 25% NPK + 75% poultry manure, T5= 100% Poultry manure. HAR1=First Harvest, HAR2 = Second Harvest, HAR3 = Third Harvest, HAR4 = Fourth Harvest.

CONCLUSION AND RECOMMENDATION

All fertilizers that were applied significantly enhanced plant growth of okra, the control which is the zero application of fertilizer has the least values of all the parameters measured except in the 8, 9, and 10WAS when the T1 got infected with okra leaf curl virus, it can be therefore deduced from this research that application of NPK and poultry manure could be appropriate to supply adequate nutrients required for optimum growth of okra in the study area. Soil sample used was very low in major soil nutrients which include; Nitrogen (N), Phosphorus (P), Application of NPK fertilizer and poultry manure produced the best growth parameters measured, with this research I thereby concluded that varying application of poultry manure and NPK fertilizer improve the growth and fruit yield of okra.

ABSTRACT
The study aimed to assess the effect of Tephrosia vogelii and application frequencies on various parameters related to larval population and infestation in eggplants by L. orbonalis. The results showed that T27 x 1W treatment had the most significant effect on reducing the larval population, with only 0.46 larvae observed. Furthermore, this treatment also resulted in the lowest number of adult moths, with an average of 1.44. Additionally, the application of treatments resulted in a significant reduction in percentage fruit infestation and fruit damage. Overall, these findings highlight the potential of T. vogelii and application frequencies in controlling adult moth and larval populations, and minimizing fruit damage in eggplants.

INTRODUCTION

This trial explores the effects of different levels of *Tephrosia vogelii* leaf extracts and their application frequencies on the control of eggplant fruit and shoot borer, *Leucinodes orbonalis*. The study holds great significance as *L. orbonalis* is known to cause significant damage to eggplants, leading to substantial economic losses for farmers. This experiment aims to investigate the potentials of ethanolic and aqueous extracts of *T. vogelii* as natural control method, and to develop a sustainable and environmentally friendly solution to mitigate the impact of this insect pest on eggplant.

MATERIALS AND METHODS

The experiment was carried out at the Vegetable Research Farm, National Horticultural Research Institute (NIHORT) Mbato Outstation, Okigwe, Imo State during 2019/2020 cropping season. Eggplant, *Solanum gilo,* locally known as Ngwa large was used for the experiment.

Botanical/ Preparation and Application of Plant Extract

Fresh leaves of *Tephrosia vogelii* were collected and dried at room temperature for 14 days. Aqueous extract of the plant material was formulated by mixing the powdered plant material with distilled water (Inades, 1996; Sihwinarni, 1999). The mixture was soaked overnight. Before spraying, soap was added at 1 tablespoon per litre (Fohring, 1998; Adams, 1998) as sticker to increase the effectiveness. Thereafter, the mixture was stirred vigorously for 3 minutes and filtered through muslin cloth (Stoll, 1998). Three aqueous rates were of *T. vogelii* extracts were made:

1. 10 %w/v (T10), 10 g of *T. vogelii* aqueous extract per 100 ml (10 g/ml or 1.6 kg/16 L)
2. 15 %w/v (T15), 15 g of *T. vogelii* aqueous extract per 100 ml (15 g/ml or 2.4 kg/ 16 L)
3. 20 % w/v (T20), 20 g of *T. vogelii* aqueous extract per 100 ml (20 g/ml or 3.2 kg/16 L)

Ethanolic extract of *T. vogelii* leaf extract was formulated by mixing grounded 25 kg of freshly collected leaves with 20 L of ethanol and 1 cup of detergent (Karlsson, 1995). The mixture was allowed to stand for 24 hours and thereafter, it was filtered through muslin cloth. From the stock solution formulated, serial dilution was made by adding adequate proportion of water to obtain:

4. 9 %v/v (T9) of *T. vogelii* ethanolic extract
5. 18 %v/v (T18) of *T. vogelii* ethanolic extract
6. 27 %v/v (T27) of *T. vogelii* ethanolic extract
7. Cypermethrin (CYP) was applied at the rate of 5 ml of the product per 3 L (i.e., recommended rate of 800 ml/ha (Hamman *et al.,* 2012),
8. Control (C)

Application Frequencies:

The application frequency consisted of three (3) spraying regimes as shown below:

1. Spraying once a week (1W)
2. Spraying once in two weeks (2W)
3. Spraying once in three weeks (3W)

Experimental Design and Layout

The experiment was 8 x 3 factorial experiments consisting of the eight levels of *T. vogelii* leaf extracts and three levels of application frequencies laid out in Randomized Complete Block Design (RCBD) with three replications.

Data collection:

Data were collected on populations of *L. orbonalis* moth and larvae, percentage fruit damage and percentage reduction in fruit damage

Data analysis:

Data collected were subjected to Analysis of Variance (ANOVA) using GenStat Software Programme (2010). The significant means were compared with Least Significant Difference (LSD) at $P \leq 0.05$.

RESULTS AND DISCUSSION

Treatment combination of *T. vogelii* extracts and frequency of application had significant effect ($P \leq 0.05$) on the number of larvae and adult moth of *L. orbonalis* (Tables 1 and 2). Their application reduced the population of this insect pest on eggplants in the field compared to the untreated plots (Tables 1 and 2). This is consistent with the long-established use of plants and their extracts against insect pests (Isman, 2000). *T. vogelii* is a source of rotenone, which is an important non-residual insecticide (Adebayo, 2003). The plant contains high amounts of insecticidal phytochemicals, including flavonoids, tannins, alkaloids, steroids, cardiac glycosides, and saponins (Dafam *et al*., 2014). These phytochemicals possess toxic, growth regulating, and anti-feedant effects against various insect pests (Sunita and Lalijee, 2008). The lowest number of larvae (0.18) was counted at CYP × 1W and this result varied significantly from the other combinations except CYP × 2W (0.44), CYP × 3W (0.76), T27 × 1W (0.46), and T27 × 2W (0.92) (Table 1). The active components in *T. vogelii* leaves have been reported to have anti-feedant, insecticidal, acaricidal, ovicidal, and ichthyotoxic properties, responsible for stomach poisoning in insects (Gaskins *et al.,* 1972).

The number of adult moths per plant per plot were significantly reduced with the application of treatments (Table 2). Results showed that, T27 × 1W resulted to significant reduction in the number of adult moths (1.44) (Table 2). Treatments had significant effect ($P \leq 0.05$) on percentage fruit infestation by *L. orbornalis* larva (Table 3). Treatment combination of T27 × 1W had the least percentage fruit infestation of 2.28 % compared to other *T. vogelii* extracts, it also exhibited high efficacy against the activities of *L. orbonalis* by recording 4.51 % fruit infestation (Table 3). This result may be attributed to the fact that higher concentrations of insecticidal phytochemicals produce greater effects in controlling insect pests as earlier reported by Matovu and Olila (2007).

Results presented in Table 4 revealed that treatment application caused significant reduction in percentage fruit damage. Treatment combination of T27 × 1W (91.14 %), T27 × 2W (87.64 %), T27 × 3W (87.90 %), T18 × 1W (86.08 %), and T18 × 2W (83.29 %) were effective in reducing fruit damage compared to other treatments evaluated (Table 4). These results are in line with previous studies that have shown that increased concentration and application frequency of insecticides greatly decrease the biological activities of insect pests (Prabhat and Johnsen, 2000; Solange *et al.,* 2017).

ABSTRACT

Fruit flies attack can severely damage important fruit crops worldwide. Bactrocera dorsalis (BD) an invasive fruit fly, is a destructive pest causing high yield loss. Synthetic insecticides have been widely used to control BD but they pose serious environmental problems. The use of biopesticides, such as Azadirachta indica (AI) and Moringa oleifera (MO) have proven effective in managing some field pests, therefore, the biological activity of MO and AI seed oil extracts against BD was investigated. Adult fruit flies were sprayed with MO and AI seed oil extract (SOE) at different concentrations to assess their potency. Percentage adult mortality was assessed at 24, 48 and 72 hours. Mated females were introduced into a cages and allowed to lay eggs on the treated fruits. Fruits sprayed with AI extract recorded highest percentage mortality (HPM) of (65.0±4.7) at 72 hours and lowest percentage mortality (LPM) of (17.5±5.4) at 24 hours. While, HPM of (60.0±3.5) was observed at 72 hours and LPM of (8.8±2.7) was observed at 24 hours from fruits treated with moringa SOE. Adult emergence was higher in moringa treated fruits when compared to AI extract. Azadirachta indica SOE of 8.0% concentration caused higher mortality and suppressed adult emergence of fruit fly. This study suggests that A. indica seed oil extract can be used in fruit fly management strategies.

INTRODUCTION

Fruits play a significant role in human nutrition, as sources of vitamins, minerals, and dietary fiber (Wargovich, 2000), these include mango, citrus, cherries, cashew, grapes etc. Fruit production provides raw material for various agro-based industries. Major production constraints include pests, diseases, drought, shortage of fertilizer, and the price of fuel for pumping irrigation water. They are attacked by wide varieties of pests and diseases which include fruit flies, codling moth, stem borers, brown rot fungus, fire blight, scab, bacterial canker, leave rollers (Yoder *et al*., 2017). Fruit flies attack and severely damage important fruit crops. Fruit flies can be a problem year round; as they are mostly attracted to ripened fruits and vegetables.

Bactrocera dorsalis (Diptera: Tephritidae) is an invasive species commonly known as the oriental fruit fly, it is a very destructive pest of fruit in areas where it occurs (Umeh and Onukwu, 2016). Invasive *B. dorsalis* has proved to be highly competitive with native fruit flies where it has established, quickly becoming the dominant fruit fly pest (Duyck *et al*., 2004; Vargas *et al*., 2007; Vayssières *et al*., 2015). At present, the main aspect of the fruit fly control programme is based on the use of chemical insecticides. Traditional control measures using chemical insecticides experience disadvantages such as pest resistance, residues in food, environmental contamination, outbreaks of secondary pests, reductions in populations of beneficial insects and inability of insecticides to penetrate infested fruits to kill larvae (Sultana *et al*., 2013). The use of botanical alternatives to synthetic pesticides has become popular for their environmentally safe activity (Ivbijaro and Agbaje 1986). Thus, the objectives of the study is to determine the efficacy of different concentrations of moringa (*Moringa oleifera)* and neem (*Azadirachta indica)* seed oil extracts on *Bactrocera dorsalis* adult mortality in the laboratory and adult emergence on treated fruits.

MATERIALS AND METHODS

Ripe Ogbomosho mangoes were purchased and sorted to remove damaged ones. Punctures were made on the surface of the mangoes with a needle to allow easy penetration of the female ovipositor to lay eggs. *Bactrocera dorsalis* of both sexes were gotten from an already existing fruit fly culture in an Insectary at the National Horticultural Research Institute, Ibadan. The experiment was carried out in the laboratory with a room temperature of 25±5ºC and relative humidity of 72±6%.

Moringa and Neem seed oil extraction

Moringa and neem seeds were shelled, ground and sent to the National Institute of Science and Laboratory Technology (NISLT), Ibadan for essential oil extraction using soxhlet extractor and n-hexane as a solvent following the method of Tesfaye and Tefera, (2017).

Neem and moringa seed oil extract sprayed on adult fruit flies

A total of 20 adults fruit fly made of 10 males and 10 females were introduced into each cage. Each cage was covered at the side by fine wire mesh and at the top by a Perspex glass while the bottom was made of wood. Using 2 L hand spray, fruit flies were separately sprayed with neem and moringa seed extract at 2.0, 4.0, 6.0 and 8.0%. Thirty jets of sprays were applied in each cage. Artificial feed and water was placed in each cage to serve as food for the adults. A control was set up whereby the fruit flies were sprayed with distilled water. Each treatment was replicated four times and arranged in a Completely Randomized Design (CRD). Observations for mortality were made at 24, 48, and 72 hours.

Mango treatments with neem and moringa seed oil extract.

Mango fruits were weighed and separately sprayed with moringa and neem seed extracts using a 2 L hand spray. Twenty (20) mated female fruit flies were introduced into a cages with two (2) treated fruits each. Treatment concentrations were 2.0, 4.0, 6.0, and 8.0% each of moringa and neem seed oil extracts. Artificial diet and water were also put in each cage. Control experiment was set up with mango fruits sprayed with distilled water with the same number of mated fruit fly.

The experiment was arranged in a completely randomized design (CRD) with four replicates. After 72 hours, the fruits were collected and incubated and 10 days after, emerged adults were counted from each fruit.

Statistical analysis

Mortality were calculated and expressed as percentage mortality. Data were analysed using Analysis of Variance (ANOVA) to establish significant differences between treatments. Significantly different means were separated using Student Newman-Keuls (SNK) Test. All statistical analyses were judged significant at 5% probability level (P=0.05).

RESULTS

Neem and moringa seed oil extracts sprayed on adult fruit flies

There were no significant differences ($p>0.05$) in the percentage mortality of adult fruit flies sprayed with neem seed oil at 24 and 48 hours after spraying (Table1). At 72 hours, significant differences ($p<0.05$) were observed among the treatments applied with percentage mortality increased with increase in time and concentration after spray. However, no significant difference was observed between 6 and 8% treatment concentrations. There was no mortality recorded in the control experiment. (Table1).

Moringa seed oil spray showed significant differences ($p<0.05$) at 24, 48, and 72 hours (Table 2) with exception of 6 and 8% concentration at 24 and 48 hours. Highest mortality (60.0%) was recorded at 72 hours for 8.0% concentration. There was no mortality recorded in the control experiment.

Table 1: Effects of neem seed essential oil (NSEO) sprayed on adult fruit flies in a laboratory bioassay

Treatments	Percentage mortality		
	24 hours	48 hours	72 hours
2% NSEO	$17.5±5.4^a$	$27.5±1.3^a$	$28.8±2.1^c$
4% NSEO	$35.0±5.6^a$	$36.3±3.7^a$	$41.3±3.7^b$
6% NSEO	$35.0±8.3^a$	$43.8±4.0^a$	$55.0±4.0^a$
8% NSEO	$35.0±11.4^a$	$50.0±6.9^a$	$65.0±4.7^a$
Control	$0.0±0.0^a$	$0.0±0.0^b$	$0.0±0.0^d$

Means with the same letters down the column are not significantly different ($p>0.05$) using Student Newman-Keuls (SNK) Test.

Table 2: Effects of moringa seed essential oil (MSEO) sprayed on adult fruit flies in a laboratory bioassay

Treatments	Percentage mortality		
	24 hours	**48 hours**	**72 hours**
2% MSEO	8.8±2.7^{b}	12.5±2.2^{bc}	16.3±2.1^{cd}
4% MSEO	10.0±3.5^{b}	17.5±4.2^{b}	23.8±2.1^{c}
6% MSEO	23.8±3.3^{a}	37.5±2.2^{a}	45.0±5.6^{b}
8% MSEO	22.5±5.1^{a}	43.8±4.8^{a}	60.0±3.5^{a}
Control	0.0±0.0^{b}	0.0±0.0^{c}	0.0±0.0^{d}

Means with the same letters down the column are not significantly different (P>0.05) using Student Newman-Keuls (SNK) Test.

Number of adult emergent from mango treated with neem and moringa seed oil extracts.

Figure 1 shows the number of adult emerging from mangoes treated with neem and moringa seed oil extracts. The result shows that higher number of adult emergence was recorded in moringa seed oil extract treated fruits compared to neem extract that recorded fewer number of adult emergence. There was no significant difference (p>0.05) in adult emergence between the neem experiment and moringa seed oil treatment concentrations except at 2.0% concentration. Increase in concentration of the seed oil extracts of both neem and moringa reduced the number of adults emerged.

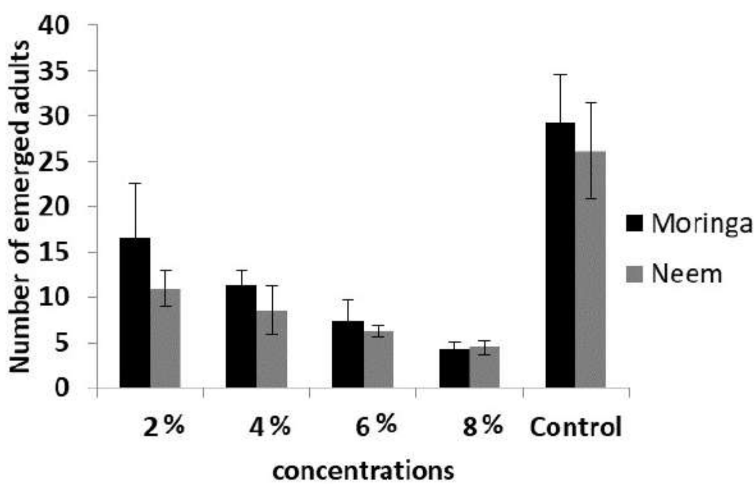

Figure 1: Number of emerged adults from mango treated with neem and moringa seed oil extracts in the laboratory.

DISCUSSION

When fruit flies in cages were sprayed with neem and moringa seed essential oil, mortality recorded was lower in moringa-sprayed fruit flies compared to neem extract with higher mortality. There were significant differences between the mortality rate of moringa and neem. This is in agreement with the findings of Irikannu *et al*., (2015) who reported the pesticidal effect of *Moringa oleifera* seed oil extract against *Tribolium castaneum* and *Tribolium confusum* on milled maize. The mortalities observed in this study increased with time and concentrations. Sharma *et al.* (2016) observed in a similar study that neem spray formulations can be effectively used to manage fruit fly due to its lethal effects.

Experiment carried out on adult emergence on treated mangoes showed that there were fewer number of adult emerged when neem was applied compared to moringa. This is due to the repellent properties of neem, which repelled most of the females and prevented them from perching and laying eggs on the treated mangoes. Hence the reduced number of adult emergence. Singh and Singh (1998) had reported deterrent effects of neem seed kernel extracts and Azadirachtin against *B. cucurbitae* and Oriental fruit fly, *B. dorsalis*. Similar findings have been reported for *B. dorsalis* after the insect was treated with neem extracts (Chen *et al*., 1996). Mahmood and Shoeib (2008) observed a high effect of neem formulation in repelling oviposition in *B. zonata*. Since the treatments were applied on the fruits, they had no effects on the development of the fruit flies that escaped the repelling effect and were able to lay eggs inside the fruits probably because the treatments were not ingested. In the control experiment there were higher numbers of adult emergence because no treatment was applied.

CONCLUSION

Biopesticides have proved to be a better option for the control of pests due to its eco-friendly nature, low pollution level, affects only target species, they are cheap due to the fact that they occur naturally and reduce cost of production making it beneficial to local farmers.

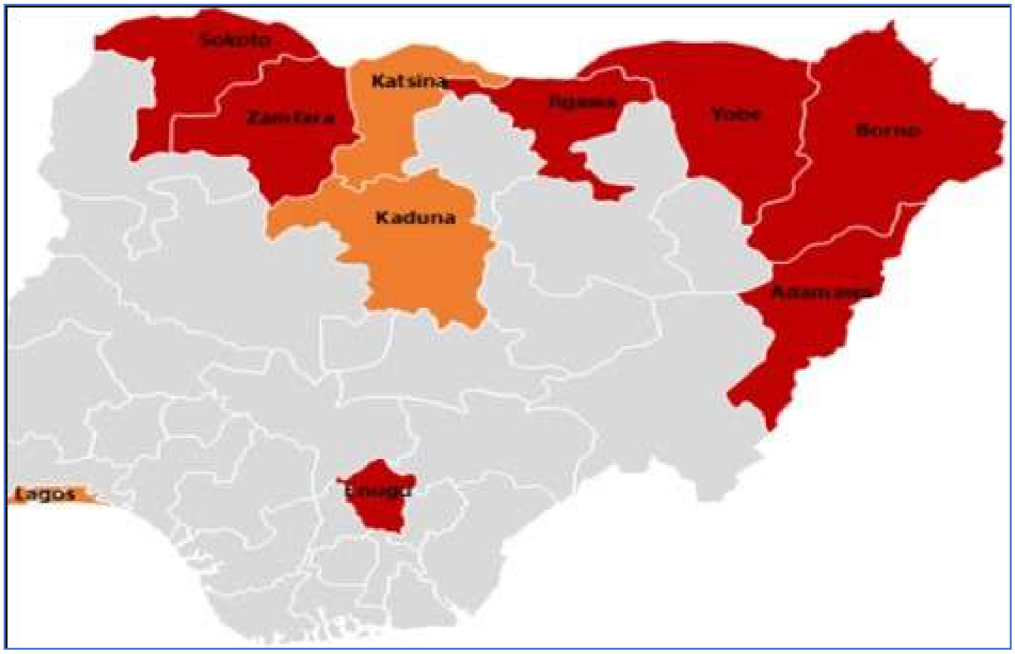
ABSTRACT
The growth in the population of Nigeria with its attendant increase in food demand calls for an urgent strategy and policy framework for rapid transformation in our agricultural production system. There is a need to continue strengthening our focus on farm produce which has huge prospects for food security and economic empowerment. Bananas as one possess the capacity to provide food and nutrition security among millions of people in Nigeria and largely other developing countries in the African region who are at risk with the problem of food insecurity. Bananas have gone beyond the enclave of backyard cultivated fruit to the most consumed and exported fruit in the world; occupying a leading position for economic prosperity and nutritional security. They are rich sources of potassium, calcium, magnesium, sodium, and zinc as well as vitamins A and C. It is free from fat and cholesterol. Nigeria can scale up banana production to have more market share in the global banana trade. In the Local market; a bunch of bananas could go as much as four thousand naira (#4000) or more depending on the period of harvest and variety. Thus, Banana can strengthen food security and reduce poverty levels in Nigeria.
Keywords: *Nigeria, Food security, Banana production, Economic prosperity*

INTRODUCTION

Food and nutrition security is an indispensable prerequisite for the survival of mankind, it is essentially needed to guarantee and support the good quality of his existence. Thus; food must be sufficiently and appropriately provided for; to achieve this goal, a very strong framework as well as institutional reforms that will support production and make agriculture attractive particularly to the youth, to raise productivity must be a priority. Nigeria has a large expanse of fertile land that can be productively engaged to boost supply and insulate the populace from the unpleasant effect of food insecurity. Food security is a situation that exists when all people, at all times, have physical, social, and economic access to sufficient, safe, and nutritious food that meets their dietary needs for an active and healthy life and the opposite of this scenario is referred to as food insecurity (Otaha, 2013). The problem of food insecurity in many developing countries has become a serious challenge and burden where many merely rely on what is available to fill stomach and not necessarily to meet dietary needs and requirements. The problem of food insecurity; because of the dire consequences it portends for our collective socioeconomic stability remains a strong subject of discussion in many forums among International Development institutions.
There are about 17 million people currently at the risk of food insecurity and this figure may further rise to 25 million or more if the situation is not urgently addressed. (WFP,2023). Factors such as continued conflict, changes in climate, and an increase in inflation are factors that have been implicated to likely trigger the increase in the number of people that will be at risk of food insecurity and its attendant consequences in the near future. However, we can do something urgent and radical as necessary intervention by encouraging production. In the Northern part of Nigeria; North East in particular; access to food has been affected by persistent violence, armed banditry, and kidnapping in the states like Katsina, Kaduna, Benue, and Niger as shown in (Figure 1) with states highlighted in color as the worst hit.



Banana (*Musa Paradaisica*) is a tropical plant cultivated in more than 130 countries. India ranks first in the total world's production of bananas (Alemu, 2017). In 2018, around 155 million metric tons of bananas were produced around the world, of which 27% came from sub-Saharan Africa (SSA) (FAOSTAT, 2020). Banana is a valuable fruit crop globally whose production could advance economic growth and reduce the problem of food insecurity in any country where its production is well harnessed. Improving banana production to meet demand beyond local consumption through massive production would not only benefit the rural poor, but it will also create jobs and improve the outlook of the national economy for competitiveness among her peers. According to the FAO, banana is consumed across major countries and region globally: - Japan, India, China, Russia, the USA, and Europe (FAO, 2021). The increase in consumption will continue to rise as long as the world population grows; thus opportunity in banana production will continue as the leading fruit crop in terms of volume and value in the world market (Woldu *et al*., 2015). The top 10 producing countries in the world are represented in Figure 2.

Banana production comparatively is still underdeveloped in Nigeria considering the volume of trades globally (Shahbandeh, 2O23); probably due to a lack of incentives from the government and constraints in marketing. In smallholder farming, the absence of modern technology and harvesting practices, fruits are always susceptible to physiological and physical damage (Akinyemi *et al*., 2017). The farmers need to develop themselves into cooperative clusters for effective banana production and marketing management. The banana export market in Nigeria is largely unnoticeable in world ranking despite being one of the top producers in Africa. The farmers ought to be engaged and informed about modern farming operations, varieties, and qualities that will meet export requirements and specifications. Bananas are largely imported to Europe because they depend on external supply and it very popular among consumers due to its health benefits. They are important source of potassium, calcium, magnesium, sodium, iron, copper, zinc as well as vitamins A and C. It is easy to digest, and free from fat and cholesterol.

An estimated 1,000 varieties of bananas are grown in several countries. However, the Cavendish has become the most consumed and exported variety, now accounting for almost half of all varieties grown worldwide and nearly 100% of internationally traded fresh bananas (FAO,2020).

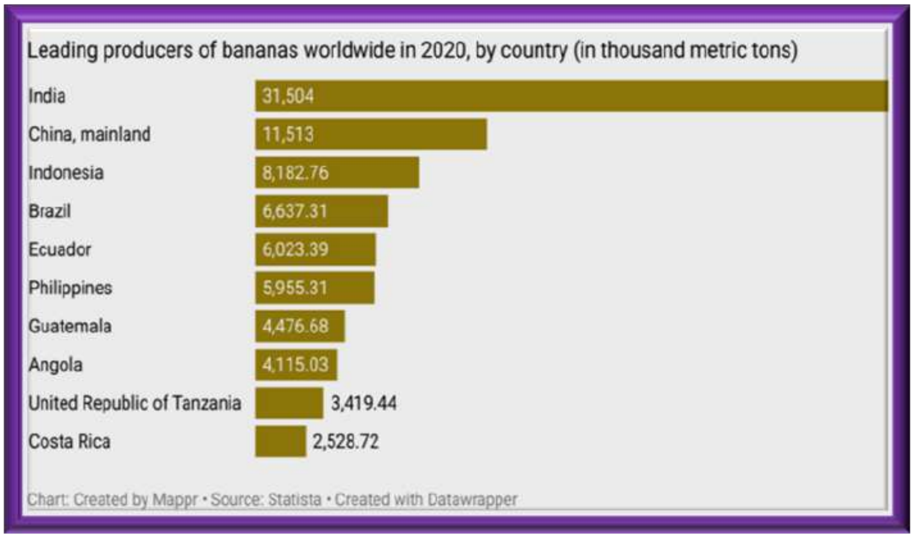


Fig 2: The 10 largest producers of bananas in the world (FAO 2021)

Bananas are exported mostly by sea freight between the production zones and destination markets, in ships in refrigerated containers. Bananas destined for export are washed, cut into bunches of four to eight bananas, labelled, and packed into boxes for shipping (Dole, 2013). On arrival at the destination ports, the boxes of bananas are still green, stored in ripening centers under a regulated temperature of between 16 and 18°C, and a gaseous mixture of ethylene and nitrogen is injected into its atmosphere to trigger maturation. After a few days (4 to 6 days, depending on the market requirements), yellow bananas will be available for the market as in Figures 3a and 3b. The hands are graded based on the number and size of fingers in each hand. Overripe and injured fruits are discarded at this stage. However, Bananas are usually sent to the local market as bunches.

Overview of African banana trade between 2021-2022

Table 1: Banana export in Africa between 2021 and 2022(FAO,2022)

Countries	2021 Total Export in thousand	2022 Total Export in thousand
Cameroon	188	216
Cote d'Ivoire	339	322
Ghana	63	51

Table 2: Banana import in Africa between 2021 and 2022 (FAO,2022)

countries	2021 Total import in thousand	2022 Total import in thousand
Algeria	159	60
South Africa	162	203
Tunisia	66	35

Overview of global banana trade between 2018-2022

Table 3: Global banana export in millions between 2018 - 2022

Regions	2018	2019	2020	2021	2022
Latin America &Caribbean	15.5	15.9	16.4	15.9	15.1
Asian	3.5	5.9	5.2	3.9	3.9
Africa	0.7	0.7	0.6	0.6	0.7

Table 4: Global banana net import in million in 2022 (FAO, 2022)

Region/Country	Percentage import
European Union	26.3%
USA	21.3%
China	10.6%
Russian Federation	7.4%
Japan	5.7%
Latin America & Caribbean	4.6%

Although, Nigeria is one of the leading producer of bananas in Africa with an estimated annual production of 2.73 million metric tons, her market share in the global banana trade still largely remain unnoticed as shown in (Table1). The government and other stakeholders can develop strategies that will boost the production of more bananas, especially for export. This will shift Nigeria from a crude oil mono-economy that is susceptible to external shock to a more resilient economy built around promising agricultural produce like bananas. Other countries such as Cameroon, Coted'lvore, and Ghana in Africa are already making their footprint known in the global banana market and Nigeria too can make an impact if the government can look into the direction of maximizing bananas production potentials to reduce food insecurity, create more jobs, boost foreign earning and improve overall economic growth.

CONCLUSION

The interest of Nigeria in maximizing the potential of banana production for food security and export market demands could be a viable option for the solution against the emerging threat of food insecurity and poor economic outlook. To achieve this, however, building a sustainable banana production system cannot be in the back seat. Farmers must be supported and effective market structures that will take up farmers produce should be developed to ensure fair reward of effort. These along with other measures will strengthen our food security and promote economic prosperity.

ABSTRACT
Field trials were conducted during the 2019 wet season at research farms in the Institute for Agricultural Research, Samaru, in the Northern Guinea savanna, and the National Horticultural Research Institute, Bagauda sub-station, in the Sudan savanna agro-ecological zone of Nigeria to study the effects of poultry manure rates and intra-row spacing on cucumber growth (Cucumis sativus L.). Four poultry manure rates (0, 2, 4, and 6 t/ha) along with NPK fertilizer were tested, combined with three intra-row spacings (100 cm, 75 cm, 50 cm). Results showed that applying 6 t/ha poultry manure led to broader, heavier, and longer fruits with higher total yields similar to the NPK application. Intra-row spacing of 100 cm resulted in size improvement in one location, while 75 cm spacing gave higher total yields in both locations. In conclusion, using 6 t/ha poultry manure and adopting 75 cm intra-row spacing improved cucumber growth and yield.
***Keywords**: Fruit yield, Intra-row spacing, Poultry manure, Northern Guinea Savanna*

INTRODUCTION
Cucumber (*Cucumis sativus* L.) belongs to the family Cucurbitaceae. It is an annual creeping vine that grows up trellises, wrapping around them with thin, spiral tendrils. It has a soft succulent watery green fruit. It ranks fourth in importance in Asia after tomato, cabbage and onion and is second after tomato in Europe (Eifediyi and Remison, 2010). Cucumber originated in India and has grown widely traded in the global market. It has been cultivated for 3,000 years. FAO (2020) reported that China produced 60% of the global output of cucumber in 2005, followed by Turkey, Russia, Iran and the United States. The top ten cucumber producers in 2010 were China, Iran, Turkey, Russia, USA, Ukraine, Spain, Egypt, Japan and Indonesia.
It is adapted to warm climates. The plant trails or climbs to heights ranging from 1.5- 4.5 meters using tendrils. It is a creeping vine that roots in the ground and grows up trellises or other supporting frames, wrapping around supports with thin, spiralling tendrils. Leaves are large and form a canopy over the fruit (Pandey and Kujur, 2022). Fruits are cylindrical when ripe and produced between 5-8 weeks after planting. The cucumber is a short-maturing crop. It is harvested 7-9 weeks from planting. Cucumber requires warm temperatures for growth. Optimum temperatures for germination and growth ranged from 11 - 18ºc (Bharathi and John, 2013) and 18.3 - 23.9ºc respectively. Long days also favour cucumber growth and development. High winds and high relative humidity are detrimental to its growth and development as they cause flower loss and foliar diseases. Moisture deficit leads to flower drying and abortion (Rout *et al*., 2021). Cucumber grows well in almost any fertile, well-drained soil. However, lighter soils like sandy loam or silt loam, which warm up rapidly during the wet season are preferred for early maturity. For higher yields, loamy or clay loam is better, mainly when the moisture supply depends on rainfall. Heavy soils promote larger fruits and extend harvesting periods. Well-drained soils with good moisture retention and an abundance of humus or organic matter are considered most desirable for the growth of cucumbers (Bharathi and John, 2013).
Cucumbers are sensitive to acid soils and grow better on near-neutral or slightly alkaline soils with acidity of 6.6- 7.2 (Šimek and Cooper, 2002). Cucumber is used for salad dishes or consumed fresh, as desserts after meals, as juice or in combination with other food materials. (Adeoye and Balogun 2016). As a vegetable, the fruit is low in nutrients but contains good levels of essential minerals and vitamins. The seed is a rich source of food protein, it contains 57% edible oil. The fruit and foliage are reported to have medicinal properties and used as pot herbs in East Africa and Asia (Aremu *et al*., 2021). Cucumber has 90% water and is used as a cooling agent. In many tropical and arid environments, it promotes hair growth due to its high silicon and sulphur content; it cures constipation as a good diuretic and relieves a burning sensation in the stomach from hyperacidity and ulcers. Cucumber production is constrained by many factors which include fertilization and plant spacing.

Studies revealed that cucumber responded to poultry manure application up to 20 t ha^{-1} (Mangila *et al.* (2008), Agbede *et al.* (2008)). Adekiya and Ojeniyi (2002) and Ewulo *et al.* (2008) attributed the improved yield performance of cucumber to the release of more nutrient elements and moisture available in the manure. John *et al.* (2004) observed that poultry manure released essential elements which promote high photosynthetic activities that enhanced the growth and yield of crop plants. They attributed vigorous growth and increased fruit yield to a high supply of nutrient elements from applied manure. Intra-row spacing is an index of plant population and plant density which directly influences competition for growth resources needed among individual plants. Spacing is one factor that affects the productivity of cucumbers. However, the effect depends on the soil regime, varietal vigour and cultural management being used.

Ningaraju and Joseph (2014) reported that plants grown at low densities had longer vines, higher growth rates and number of flowers with higher fruit yield than those at higher densities. Likewise, Sanni and Adenubi (2020) evaluated different spacing (density) and irrigation intervals and observed that plants spaced at 40cm and planted in 2 plants per hill recorded the highest yields. Geboluglu and Saglam (1999) in Tokat, Turkey found that 20cm inter-row spacing resulted in the highest yield/ha. However, Jaffar and Wahid (2014) observed no significant effect of the interaction of cucumber varieties and different intra-row spacing on cucumbers' growth and yield parameters. This study therefore, was conducted to determine the effects of poultry manure rates and intra-row spacing on the yield of cucumber (*Cucumis sativus* L.) in the Sudan savanna agro-ecological zone of Nigeria.

MATERIALS AND METHODS

Two field trials were conducted during 2019 wet season at Research farm of the Institute for Agricultural Research, Samaru, in the Northern Guinea Savanna (Latitude 11°11′ N and Longitude 07°38′ E 686 metres above sea level) and its Irrigation Research Station of farm ~~at~~ Kadawa (Latitude 11°39′ N and Longitude 8°03′ E 500m above sea level) in the Sudan savanna ecological zone of Nigeria. Treatments consisted of four poultry manure rates (0, 2, 4, and 6 t/ha) in addition to recommended NPK (15:15:15) fertilizer (10:50:50 kg ha^{-1}) and three intra-row spacings (100cm, 75cm and 50cm) replicated three times and laid out in a Randomized Complete Block Design. The gross plot size was 4.5m x 3m (13.5m^2) while the net plot size was 3m x 3m (9m^2). Cucumber salad variety *Mona lisa* with uniform cylindrical dark green fruit was used. It has distinct fruit quality, earliness to maturity, higher yields and disease resistance. Meteorological data, (daily temperature, sunshine hours and relative humidity during the experiment were obtained from the meteorological station of the Institute for Agricultural Research Samaru and Kadawa.

Soil samples were randomly collected from the experimental site using an auger from the two locations at a depth of 0-15 cm. Soil samples were taken after ploughing before poultry manure application. The sample in each location was bulked, dried, ground, sieved and subjected to physical and chemical analysis using standard procedures (Hazelton and Murphy, 2016). Using the standard procedure, a representative sample of poultry manure was analysed for organic carbon, organic matter, total nitrogen, available phosphorus and exchangeable bases such as potassium, magnesium, calcium and sodium. The experimental sites were harrowed twice at the onset of the rainy season. Ridges were made 75 cm apart, and the area was marked out into plots of 13.5m^2 and 9m^2 gross and net plots, respectively. Four levels of poultry manure rate (0, 2, 4, 6 tonnes/ha) were applied. NPK fertilizer was applied in two doses. The first dose of 100:50:50 kg/ha using NPK (15:15:15) as basal fertilizer was applied at 2 WAS, and a further 50kg N/ha was applied at 6 WAS as top-dressing using urea (46% N) as the nitrogen source Planting was done two weeks after poultry manure application at the intra-row spacing of 50cm, 75cm and 100cm. Planting was done on 14th August 2019 at Samaru and 15th August 2019 at Bagauda. Weeds were controlled manually by hoeing. This continued based on the weed infestation until foliage covered the crop and was dense enough to smother competing weeds. Fruits were harvested by hand picking 45 to 50 days after sowing when the fruit's skin changed from dull green to glossy green. Data were collected at harvest on number of fruits, diameter of fruits, weight of fruits per plant and total fruit yield per hectare. Data collected were statistically analyzed using an analysis of variance (ANOVA~~,~~ Duncan's Multiple Range Test was used to evaluate differences among treatment means (Murphy *et al*., 2014).

RESULTS AND DISCUSSIONS

Table 1 shows the physical and chemical properties of soils at experimental sites during the 2019 wet season. The textural class was sandy loam in both locations. At Samaru, it is moderately acidic (5.51) with low organic carbon (1.02 g kg^{-1}) and total nitrogen (0.95 g kg^{-1}). Available phosphorus (10.54 mg kg^{-1}), calcium (2.61 cmol kg^{-1}), magnesium (0.36 cmol kg^{-1}), potassium (0.18 cmol kg^{-1}) and sodium (0.21 cmol kg^{-1}) contents were medium, cation exchange capacity was low (3.65). At Bagauda, the soil pH was moderately acidic (5.84). Organic carbon (1.22 g kg^{-1}), total nitrogen (1.18 g kg^{-1}) and available phosphorus (6.26 mg kg^{-1}) contents were low. In contrast, calcium (3.15 cmol kg^{-1}), magnesium (0.56 cmol kg^{-1}), potassium (0.18 cmol kg^{-1}), and sodium (1.18 cmol kg^{-1}) contents were all medium, cation exchange capacity of the soil was low (4.32). this implies that the soils at each location are ideal and suitable for cucumber production. Its structure, composition, aeration and nutritive composition are within the recommended for cucumber production. Table 2 shows the chemical composition of poultry manure used in the experiment. Available nitrogen content was 20.15 g kg^{-1} while available phosphorus and potassium contents were 15.60 g kg^{-1} and 13.16 g kg^{-1} respectively. The calcium was 5.61 g kg^{-1}. These indicate that poultry manure is rich in essential nutrients that are readily available for crop growth and development.

Table 3 presents cucumber fruit yield and its contributing characteristics as influenced by poultry manure application and intra-row spacing at Samaru and Bagauda during the 2019 wet season. Application of 2 and 4 t ha^{-1} poultry manure recorded numerous and longer fruits with wider diameters at par with 100:50:50:kg ha PK (15:15:15) in Samaru and Bagauda respectively. Likewise, higher fruit weight per plant and total fruit yield was recorded by 2 and 4 t ha^{-1} in Samaru and Bagauda respectively. Enujeke (2013) reported that cucumber responded up to 20 t ha^{-1} poultry manure. Beyond these rates, there was no significant increase in values of all parameters assessed in each location. This could be attributed to the beneficial effects of poultry manure through the provision of readily available nutrients especially N, P K as well as calcium and magnesium. This further enhanced soil porosity and water-holding capacity for proper crop growth and development. Similar results were reported by several workers who attributed the nutrient and soil-enhancing properties of the poultry manure (Oke *et. al*., 2020 Tahir *et. al.,* 2019).

The effect of intra-row spacing on number of fruit per plant, fruit length and weight per plant was not significant at Samaru. However, 50 cm intra-row spacing recorded a higher number of fruits that were longer at Bagauda though comparable to 75 cm spacing. The fruit diameter and weight per plant were not significant at Bagauda. In contrast, total fruit yield recorded linear response up to 100cm spacing although it was not significant at Bagauda. This could be attributed to few plants and less competition for light, space and nutrients at wider spacing. The contrasting results obtained in this study are similar to the findings of Ansa and Garjila (2019) and Jaffar and Wahid (2014). Izaj *et al.* (2017) reported higher fruit weight per plant while Sanni and Adenubi (2020) observed higher fruit numbers at wider spacing respectively. No poultry manure and intra-row spacing significant interaction was observed on any of the parameters assessed in both locations.

CONCLUSION

Based on the results of this study, application of 2 and 4 t ha^{-1} poultry manure at Samaru and Bagauda respectively and adoption of 75 cm intra-row spacing in both locations were optimum for cucumber production in the areas.

Acalypha wilkesiana Muell. Arg.: A PLANT WIDELY APPRECIATED FOR ITS ORNAMENTAL USE BUT LARGELY UNDERUTILIZED FOR ITS MEDICINAL POTENTIALS - A REVIEW

Edagbo D. E.
National Biotechnology Development Agency, Abuja (National Centre for Genetic Resources and Biotechnology, Ibadan) Nigeria

dedagbo@yahoo.com

ABSTRACT
Acalypha wilkesiana Muell. Arg. widely known and accepted for its aesthetic value as ornamental plant has yet to be maximally exploited as herbal medicament for the wellness of man. There is a gradual growing consciousness on the traditional herbal remedy of the plant; this has been aided by its embrace for use in tackling some gastrointestinal and dermatological disorders especially relating to infants by the resource constraint rural settlers. Also, the antimicrobial potentials of this nature's endowed plant are attracting interest in the therapeutic prospect of Acalypha wilkesiana in the healthcare domain. This work seeks to collate information on the various ethnomedicinal uses for which Acalypha wilkesiana had shown great promise and to equally highlight its encouraging antimicrobial potency. With a background work as this, a baseline is established for the manufacture of drugs with proven efficacy.
***Keyword**: Acalypha wilkesiana, ornamental plant, traditional medicine, antimicrobial, cultivar*

INTRODUCTION

Plants are a valuable life support and sustaining resource to man. The usefulness of plants to man abound in many ways than can be imagined. Many plants are of multipurpose value ranging from their use as food, medicine, furniture, aesthetics (ornamental), clothing, fuel, and the likes. Quite a number of plants become known for one usefulness or the other due to their overriding acceptance in that particular area of utilization. Oftentimes, the wide usage of a plant for a specific purpose beclouds its other valuable impact and derivatives. Typical of such a plant is the Bush Mango (*Irvingia gabonensis*), targeted mainly for its kernel seed extracts as condiment for soup as opposed to the consumption of its edible fruit (Oben, 2011). Another notable example is the Eggplant (*Solanum melongena*) with its fruit as the primary focus of consumption by a vast majority undermining the usefulness of the leaf as a veritable vegetable resource in soup preparation (Ibe *et al.,* 2022). Many plants with multipurpose use abound that are underutilized and herein lies the onus on researchers to venture deep and wide in the continued quest to fully exploit the vast resources of nature's potentials at our disposal. In this vein, a plant like *Acalypha wilkesiana* commonly used as ornamental plant but underutilized for its medicinal value; is placed in the spotlight for its ethnomedicinal uses and therapeutic potentials.

Acalypha wilkesiana Muell. Arg. is a plant which by taxonomical alignment is placed in the family Euphorbiaceae. It is popularly known as copper leaf, Jacob's coat, fire dragon with other local names like "awor-oso" by the Yorubas and "Jiwene" or "Jinwinini" by the Hausas. *Acalypha wilkesiana* is an evergreen shrub that grows to between 2 – 4 metres and in some cases higher. It grows to maturity showcasing a blend of alluring colour variants ranging from bronze red to mild red, including either of pink, purple, white, orange, yellow or green depending on the cultivar. There are widespread cultivars the world over, with Nigeria having a rich reserve which include the godseffiana, hispida, macrophylla, macefeena, hoffmanni, racemose and marginata (Ikewuchi *et al.,* 2010; Awe *et al.*, 2013). A cultivar of the *Acalypha sp*. is shown in Fig. 1.

The flowers of *Acalypha wilkesiana* lack petals and nectar discs but possess distinct male (hang downwards in long spikes) and female (in short spikes) phenotype on the catkin-like racemes beneath the foliage on the same plant. February to December is usually its flowering season (Sagun *et al.,* 2010). The convenient and appropriate means of regeneration for the plant throughout the year is by air layering or stem cutting (Edward, 2011).

COMPILATION OF SOME OF THE ETHNOMEDICINAL USES INCLUDING ANTIMICROBIAL PROPERTIES OF *Acalypha wilkesiana*

The healing and health promotion attributes of many of the plants in our environment have attracted several individuals to engage their patronage as a cost-effective alternative to maintaining their wellness drive in the face of depleting financial power. One of such useful plants for ethnomedicinal application is *Acalypha wilkesiana*. This plant has become a valuable herbal remedy for several health challenges as are highlighted in Table 1 below. Many laboratory research expeditions have been undertaken to further give credence to the ethnomedicinal usefulness of *A. wilkesiana*.

Table 1: Some of the various medicinal uses of *Acalypha wilkesiana*

S/N	Traditional Medicine Uses	Plant parts used	Mode of preparation and application	Reference
1.	Management of hypertension	Leaves	Nutraceutical (leaves eaten as vegetable)	Iwu M. M., 1993; Ikewuchi *et al.,* 2008
2.	Treatment of dermatological challenges like fungal / bacterial skin infections	Leaves	The leaves are rubbed in between palms and the juice is smeared on the affected part of a patient	Neuwinger, 2000; Lim *et al.,* 2013
3.	Remedy for headache, swellings, cold and malaria	Leaves	leaf-poultice	Akinyemi *et al.,* 2005
4.	Treatment of diarrhoea and dysentery	Leaves	Leaves are squeezed into water and the resulting solution drunk	World Health Organization, 2009
5.	Treatment for pleurisy	Leaves and bark	Infusion of leaves and bark	Acalypha wilkesiana (PROSEA), 2022
6.	Treatment of babies with skin infection	Leaves	cold extract of the leaves is used to bath the subject	Adesina *et al.,* 2000
7.	Mitigation and handling of haemorrhoids.	Roots	Roots are boiled to wash haemorrhoids	Ong, 2006
8.	Treatment of gastritis and lymphoid swellings	Leaves	Decoction of the leaves	Acalypha wilkesiana (PROSEA), 2022
9.	First aid for ruptured appendicitis	Leaves	Leaves are chewed on	World Health Organization, 2009
10.	Treatment of gastrointestinal	Leaves	Strain out juice / boiled	Oliver, 1959;

	disorders		decoction	Ogundaini, 2005
11.	Treatment of neonatal jaundice	Leaves	Aqueous leaf extract administered orally	Alade and Irobi, 1993
12.	Treatment of malaria, breast tumors and inflammation	Seeds	The seeds are used in compounding a complex plant mixture	Bussing *et al.,* 1999; Taraphdar *et al.,* 2001; Oyelami *et al.,* 2003; Akinyemi *et al.,* 2005
13.	To regulate menstruation	Leaves	The leaves are squeezed and mixed with water, and drunk	Acalypha wilkesiana (PROSEA), 2022
14.	As abortifacient	Leaves	Fresh shoots are squeezed into water and solution drunk	World Health Organization, 2009
15.	Remedy for stomach ache and as worm expellant	Stems and roots	Chopped pieces of dried stem and root steeped in alcohol	Onocha and Olusanya, 2010

Some findings on the Potentials of the Leaf Extracts of *Acalypha wilkesiana*

The several test results on the leaf extracts of *Acalypha wilkesiana* revealed the presence of active constituents capable of inhibiting the growth of many of the common pathogenic microorganisms of bacterial (active against both gram positive and negative strains) and fungi origin including antioxidant properties (Alade and Irobi, 1993; Oladunmoye, 2006; Majekodunmi and Nubani, 2014; Anokwuru *et al.,* 2015).

CONCLUSION

Acalypha wilkesiana Muell. Arg. is a household ornamental plant accepted for its appealing allure and aesthetic impact. However, the plant is now exploited for its several medicinal potentials. It has become pertinent that the therapeutic values of this plant are given prominence in the pursuit of alternative medical approach to wellness. *Acalypha wilkesiana* gaining patronage as herbal medicament is therefore a good candidate plant for the pharmaceutical industry in search of pharmacological solution to a handful of the health challenges of man.

ABSTRACT

Poor soil fertility is among the major production problems responsible for poor growth and low yield of sesame in Nigeria. A field experiment was conducted at the Teaching and Research Farm, Ladoke Akintola University of Technology, Ogbomoso, Nigeria to determine the effects of application of fertilizers types on growth and yield of sesame variety E8. Five fertilizer types and two modes of propagation were assessed. The 5 by 2 factorial experiment was laid out in a Randomized Complete Block Design (RCBD), replicated three times. FO = zero application, Fl = NPK fertilizer, F2 = Organic Neem fertilizer, F3 = Organo-mineral, F4 = poultry manure, F5 = Cow Dung, M0 = Direct Seeding, M1 = Transplanting. All data collected on the growth and yield parameters were subjected to analysis of variance (ANOVA). Means were separated using Duncan Multiple Range Test at 5% probability level. The application of Zero fertilizer and Transplanting (M1F0) had the least values across all the parameters measured. Nutrient uptake particularly N, P and K were also significantly enhanced by the application of Organomineral and Transplanting (M1F3). Therefore, the application Organomineral and other organic fertilizers are recommended, so as to alleviate chemical loads on the soil.

Keywords: *Fertilizer, NPK, Propagation, Sesame*

INTRODUCTION

Sesame (*Sesamum indicum L)* is an annual flowering plant in the genus Sesamum and family Pedaliaceae. It is an erect plant which grows between 50 to 250 cm tall depending on the variety, soil and environmental conditions (Sharma, 2005). It is an important oil seed crop with great commercial attributes by virtue of its oil having an edible quality and medicinal value. It yields 50-60% oil and the oil is highly stable against rancidity due to the presence of the natural antioxidants sesamin and sesamolin (Weiss, 2000 and Sabah El-Khier *et al.,* 2008). Sesame seeds have been widely employed in culinary as well as in traditional medicines for their nutritive, preventive, and curative properties. It is potentially capable of producing large quantities of seeds per unit area but the yield is low ha-1 (Ahmad *et al.,* 2001) due to lack of improved varieties and improper fertilization (Rao *et al.,* 1994). Sesame (*Sesamum indicum* L.) is described as the "queen of oil seeds" because of its high oil, protein, calcium and phosphorus (Prasad, 2002; Misari and Iwo, 2000) Sesame is cultivated in tropical and sub-tropical Africa for its highly nutritious and edible seeds (Iwo *et al*., 2002).

The use of fertilizers is considered one of the most important factors to increase crop yields on per unit basis. The base element of all biological cells starts with nitrogen and its role cannot be substituted in crop production. Nitrogen is a component of protein and nucleic acids and an integral component of many other compounds essential for plant growth processes including chlorophyll and many enzymes. It also mediates the utilization of phosphorus, potassium and other elements in plants good seed and dry matter yield. Incorrect application of chemical fertilizers and lack of appropriate soil management /conservation strategies are the major causes of rapid depletion of soil nutrients and subsequently low crop productivity persisting in the tropics. Tropical farmers apply chemical fertilizers "anyhow" regardless of scientific recommendations for different crops as well as the importance of improving and maintaining organic matters in the soil system (Sobulo, 2000). Also, human activities (such as incessant yearly bush burning, continuous cropping, monocropping, overgrazing, mining, bulldozing, open-clean-clear cultivation, ridging-along-the-slope, excessive logging etc.) and other climatic attributes (such as torrential rainfall and high solar radiation) are equally aggravating nutrient balances and rapidity of nutrient depletion in the tropics (Babajide *et al*., 2008).

MATERIALS AND METHODS

The Experiments was carried out during the rainy seasons of 2021 at the Teaching and Research Farm, Ladoke Akintola University of Technology, Ogbomoso, Nigeria. The seed of sesame (*Sesamum indicum* L.) was obtained from the National Cereals Research Institute Badeggi, Niger State. Sowing of the seeds was done at the rate of 10 seeds per hole. Seedlings were then thinned to one plant per stand and also transplanted at two weeks after sowing (WAS). Regular watering was maintained. Also, weeding was done manually using hoe and cutlass on regular basis. Application of NPK, Organic Neem fertilizer, Organomineral, poultry manure and Cow dung was done at four weeks after sowing and another was applied eight weeks after sowing. Six fertilizer types and two propagation methods were introduced, FO = zero application, Fl = NPK fertilizer, F2 = Organic Neem fertilizer, F3 = Organomineral, F4 = poultry manure, F5 = Cow Dung, M0 = Direct Seeding, M1 = Transplanting.

Data collection commenced at five weeks (5 WAS) after sowing. The growth parameters determined were plant height, numbers of leaves, numbers of tillers, and stem girth. Number of leaves was determined by the visual observation and direct counting of all the fully opened leaves per plant. Plant height was determined by using tape rule placed at the stem base and run into the tip of the longest leaf. Stem girth was determined by measuring the stem diameter using venier caliper (3cm above the soil). The value obtained was then converted to stem girth using a formula π D (where $\pi = 3.142$ and D = stem diameter). The yield parameters determined were fresh and dry weight after harvesting immediately (fresh weight) while after oven drying of plants samples at 80°C for 72 hours, the dry shoot weight was-determined using electronic weighing balance.

Dry weight and the total biomass production of the harvested sesame plants shoot and root were determined by oven drying at 80°C to a constant weight for three days (72 hours). The plant samples were then milled in Wiley mill to pass through 1mm sieve and subjected to kjeldah digestion at 360°C for 4 hours with concentrated sulphuric acid, using selenium and sodium sulphate as catalyst. plant content of P, K, Ca, Mg, Mn, Zn, and Cu were determined by ash plant samples in muffle furnace at 600°C for 2 hrs, the ash was cooled and dissolved in 1N hydrochloric acid and the solution pass through filter paper into Smi volumetric flask and made up to the mark with distilled water. Total N was determined from the digest steam distillation with excess NaOH. From the digest P concentration was determined by the Vanadomolybdate yellow colorimetric method using spectrophotometer (spectronic 20). The nutrients accumulated in plants were calculated as; Nutrient uptake=% Nutrient content x sample dry with according Gungunla, (1999).

RESULTS AND DISCUSSION

The application of M0F2 greatly enhanced the number of capsules at 9WAS, 10WAS and 11WAS which were observed to have the highest values (98.3g), (165.0g) and (210.0g) respectively which was not significantly different from the other treatments but significantly different from M1F0 which had the least values (13.3g), (41.7g) and (76.0g).

At 12WAS, it was obtained that M1F2 increased the number of capsules with the highest value (227.7g) observed, which was not significantly different from the other treatments but significantly different than the M1F0 which has the least value (88.7g) as shown in the Table 1

Table 1: Effects of Fertilizer Types and Mode of Propagation on the Yield Parameters of Sesame.

	WEEKS AFTER SOWING (WAS)			
TREATMENT	SFW	SDW	RFW	RDW
M0F0	221.8a	53.9a	96.9a	21.6a
M0F1	197.4a	44.9a	56.6a	3.5a
M0F2	171.9a	46.5a	53.1a	17.5a
M0F3	197.2a	48.3a	82.4a	18.2a
M0F4	214.8a	54.2a	80.6a	18.0a
M0F5	192.7a	52.1a	63.4a	20.4a
M1F0	145.2a	38.1a	41.7a	11.9a
M1F1	157.5a	44.4a	63.2a	17.6a
M1F2	223.4a	61.5a	86.7a	21.1a
M1F3	266.1a	61.7a	85.5a	22.4a
M1F4	189.5a	53.5a	59.9a	18.8a
M1F5	229.2a	53.7a	88.3a	19.8a

Means with the same letter are not significantly different from each other at P = 0.05 using DMRT. FO = zero application, Fl = NPK fertilizer, F2 = Organic Neem fertilizer, F3 = Organomineral, F4 = poultry manure, F5 = Cow Dung, M0 = Direct Seeding, M1 = Transplanting, SFW= Shoot Fresh Weight, SDE= Shoot Dry Weight, RFE= Root Fresh Weight, RDW= Root Dry Weight.

Effects of Fertilizer Types and Mode of Propagation on The Nutrients Uptake

Among all the treatments introduced, M1F3 significantly enhance Nitrogen uptake with a value of 45.8. The control M0F0 had the least value (5.6) of N-uptake. In terms of phosphorus (P) and Potassium (K) uptake, M1F3 was observed to have the highest values of 47.1 and 38.0 respectively, which is significantly different from the other applied treatments. But the control had the least values of 0.9 and 0.8 respectively.

The uptake of Ca was enhanced in M1F3 with value of 8.8, which is significantly not different from M0F3, M0F5 and M1F1 but significantly different from the other treatment, while the control M0F0 has the least value of 0.8. M1F3 enhances the uptake of Mg which is significantly different from the other applied treatments while the control M0F0 has the least value of 0.7. The uptake of Na was significantly enhanced in M0F1 which was significantly different from the other applied treatments. The uptake of Fe was enhanced in M0F2 with obtained value of 145.7 which is significantly different from the other applied treatments while the control M0F0 has the least value of 81.3.

Cu uptake was greatly enhanced in M1F4 which is not significantly different from M1F3 but significantly different from the other applied treatments with the control having the least value. The Mn uptake was influenced in M0F1 which is significantly not different from M0F0 but significantly different from the other treatments. While the M1F0 has the least obtained value of 44.0. Zn was influenced in M0F2 which was found not to be significantly different from M1F3, M1F4, M0F0 and M1F5 but significantly different than what other treatments, with the M0F4 having the least value of 16.5.

Table 3: Effects of Fertilizer Types and Mode of Propagation on The Nutrients Uptake of Sesame.

WEEKS AFTER SOWING (WAS)

TREAT	gkg^{-1}			$mgkg^{-1}$						
MENT	N	P	K	Ca	Mg	Na	Fe	Cu	Mn	Zn
M0F0	5.6g	0.9e	0.8f	0.8e	0.7g	0.6f	81.3f	1.8f	90.4a	30.9ab

M1F2	21.8cd	17.2d	18.5bcde	3.7d	0.7g	1.7b	105.0de	6.6b	63.7b	31.3ab
M1F3	45.8a	47.1a	38.0a	8.8a	6.7a	1.1cde	102.9e	7.9a	53.1c	34.8a
M1F4	34.1b	25.0b	22.9b	6.9b	4.3c	1.2bcd	104.5de	8.5a	53.3c	34.2a
M1F5	37.1b	20.3c	22.1bc	6.5b	2.6ef	1.4bc	107.6cde	6.5b	59.9bc	32.1ab

Means with the same letter are not significantly different from each other at P = 0.05 using DMRT. FO = zero application, Fl = NPK fertilizer, F2 = Organic Neem fertilizer, F3 = Organomineral, F4 = poultry manure, F5 = Cow Dung, M0 = Direct Seeding, M1 = Transplanting

CONCLUSION

All treatments applied significantly enhanced the growth and yield parameters of *Sesamum indicum L.* The application of Zero fertilizer and Transplanting (M1F0) had the least values across all the parameters measured. The growth, yield parameters and nutrient uptake particularly N, P and K were also significantly enhanced through the application of Organomineral and Transplanting (M1F3). Therefore, the application Organomineral and other organic fertilizers are recommended, so as to alleviate chemical loads on the soil.

ABSTRACT

Micro propagation is the best method to rapidly propagate healthy and high uniformity rose cultivars. In this study the effect of some plant growth regulators on the in-vitro propagation of rose were investigated. Cultures of surface sterilized single bud nodal rose explants were initiated on MS media supplemented with 30 g/l sugar, 8g/l agar and different concentrations of BAP (0, 1, 2 and 3 mg/l) in combination with (NAA) along with other plant nutrients. The longest shoot was found to occur in treatment III with BAP at 2 mg/l. There was no significant difference as compared to treatment IV with BAP at 3 mg/l while the best shoot proliferation was found to occur with treatment IV. The least response in shoot length and proliferation was found with the control (treatment I) in which BAP and NAA were not present.

INTRODUCTION

Rose, popularly known as the queen of flowers is one of the most important ornamental plants in the world and also the most widely cultivated cut flower with high demand. One of the primary problems with its cultivation aside their susceptibility to diseases like black spot, powdery mildew, bacterial blight, etc. is its difficulty in propagation. Rose is generally propagated by vegetative methods like cutting, layering, budding and grafting. Although propagation by vegetative means is a predominant technique in roses, it does not ensure disease-free plants. Moreover, dependence on season and slow multiplication rates are some of the other major limiting factors in conventional propagation (Aggarwal *et al*., 2020). Plant tissue culture refers to the micro propagation or *in vitro* culture of plants from plants parts such as tissues, organs, embryos, protoplasts, single cell on a suitable nutrient medium supplemented with the required amount of plant hormones which include auxins, cytokinin and growth regulators with similar metabolic effects under aseptic conditions (Kaya and Karakutuk, 2018, Kaya and Huyop 2020).

Statement of research problem

Roses can be propagated by seeds, cuttings, layering, and grafting. These vegetative methods of rose propagation are conventionally slow and sometimes produce unhealthy plants. Therefore, there is need to use an efficient method for improved propagation of roses and one of such method is by "Plant tissue culture". The aim of this research is to develop an effective protocol for the rapid production of healthy rose plants via *in vitro* propagation.

Objective

To ascertain the effect of BAP (6-Benzyl Amino Purine) on rose (Rosa *spp.*) via *in-vitro* propagation

MATERIALS AND METHODS

Preparation of explant: Rose explants used for the tissue culture were obtained from mature roses (Rosa *spp*.) from the Floriculture garden of the Institute, NIHORT. The explants were brought into the laboratory, cuttings of about 3 cm were obtained from it and surface sterilized starting by placing them under running tap for one hour to wash off surface dirt with the application of a few drops of tween-20. The clean cuttings were later immersed in 20% chlorox for 30 minutes and rinsed thrice with sterile distilled water. This was followed by immersing in 70% ethanol (under the laminar flow) for 10 minutes and then rinsed thrice with sterile distilled water.

Sterilization process: The forceps, scalpels, Petri-dishes, boiling tubes and cutting slab were wrapped in aluminum foil, sealed with tape and sterilized in an autoclave at 121ºC. The laminar hood was thoroughly cleansed with absolute ethanol, UV-light was also initiated to completely sterilize the chamber before commencing to work. All activities were carried out inside the laminar hood. Other sterile measures and procedures were strictly observed.

Media Preparation: Full strength MS medium (Murashige and Skoog, 1962) supplemented with 3% sucrose, 50 mg Adenine sulphate, 0.125g Myoinositol and 0.8% Agar and different concentrations and combination of BAP and NAA were used for shoot initiation. The pH was adjusted to 5.8 prior to melting the gel and autoclaving.

Experimental Design: Four treatments with varying concentrations and combination of BAP and NAA as shown in Table 1 were used in this experiment. Each treatment consists of 15 cuttings having at least one apical node. All experiments were carried out in two replicates. MS medium without growth hormones was used as control. All the in vitro cultures were incubated at 26 ± 2°C in a growth room on a 16/8 hour light/dark and 3,000 lux light intensity provided by cool-white fluorescent light. All data were subjected to analysis of variance and mean comparison were performed using the least significant difference (LSD) with a significance level of 5% according to (Gomez and Gomez, 1984).

RESULTS

The sterilization procedure showed significant difference with a contamination rate of 7% as compared to previous trials with a contamination rate of 90%. Increasing the sterilization time from 10 minutes to 30 minutes and using a higher concentration of sodium hypochlorite from 10% to 20% greatly impeded the growth and expression of microorganisms in the cultures. Treatments with BAP and NAA showed significant growth difference on the shoot initiation stage as compared with treatment having no growth hormones. The longest shoot length was observed in treatment III with 2 mg/l of BAP and 0.1 mg/ml of NAA while the lowest was observed with treatment I with no growth hormones which serve as control (Figure 1). There was no significant difference in the number of shoots between treatments III and IV at week 4 respectively however there were significant difference compared to treatment II with 1mg/l as well as treatment I (control). The highest proliferation rate was found in treatment IV with 3 mg/l as shown in figure I while the least response in proliferation rate was observed in treatment I as seen in plate II.

DISCUSSION

The *in-vitro* propagation of rose is for the rapid supply of healthy quality plants with desirable characteristics especially for commercial purposes. A major concern when it comes to the tissue culture of any plant is contamination. As a result of this, it is imperative that the surface sterilization step be taking handled meticulously (Tawfik *et al*., 2018). The use of 20% chlorox for a longer time range was observed to be effective as the sodium hypochlorite greatly impede the growth and expression of endogenous microbes. Studies have shown that the use of appropriate plant growth regulators (PGRs) is a major contributory factor to the successful initiation and multiplication of any plant under *in-vitro* conditions. Cytokinins are known to stimulate or initiate shoot induction and multiplication (Lella *et al*., 2021). The basal media was MS medium supplemented with necessary plant growth regulators. Butyl Amino Purine (BAP) was the cytokinin used in this investigation. Different concentrations of BAP were studied to investigate their effects on the shoot initiation and multiplication / proliferation rate *in-vitro* propagated roses. It was observed that treatments with 2 and 3mg/l BAP was significantly different in the rate of proliferation compared with treatments with 0 and 1 mg/l. The longest shoot (4.5 cm) was recorded with 2mg/l BAP while the least shoot length was recorded with the control (1cm). Ash *et* al., 2020, also state that 3.5mg/l BAP in combination with kinetin produced the maximum response of shoot regeneration of rose. Lower concentrations of BAP may be responsible for the slow growth response of the plant. This is similarly reported by (Thi *et al*., 2021), pointing that BAP 3mg/l was suitable for shoot initiation and multiplication of rose (Hybrid rose *spp*.)

CONCLUSION

The influence of BAP at 2mg/l and 3mg/l on the *in-vitro* propagation of rose is very significant and this can be utilized and optimized for the rapid mass propagation of roses for commercial scale.

ABSTRACT
The postharvest losses of horticultural products are very high and the rate of losses significantly depends on the type of products and postharvest handling practices. Effect of gum Arabic coatings combined with cinnamon oil on freshly harvested mature scotch bonnet fruits during storage was studied. The scotch bonnet was grouped into 3; Group A was the control and it was dipped in distilled water, group B was dipped in 10% gum Arabic + 3 ml of cinnamon oil and group C was dipped in 10% gum Arabic. The coated fruits were stored for 16 days and observed every 4 days for nutritional and physicochemical changes using standard methods. It was observed that Group C had the least incidence of decay and moisture loss at 40.80 % and 49.91 % respectively. Significantly (p<0.05) lower pH (5.98) and 0.56 % Total Titratable Acidity (TTA) values recorded for Group B revealed that the coating caused a reduction in the ripening rate of the fruit compared with the control (Group A) and Group C. Group B was effective in preserving the carotenoid contents of the stored fruits as it recorded the significantly highest values at day 16 for both Lycopene and β-carotene. Results from this study has revealed that 10 % Gum Arabic coating is an effective storage medium for scotch bonnet fruits, while the presence of Cinnamon essential oil helps to maintain the nutritional contents and as well slow down the ripening rate.
Key Words: *Postharvest, essential oil, horticultural, coating*

INTRODUCTION
On a global scale, postharvest losses of fresh produce are estimated to range from 15% to 50%. The main causes of this loss are microbial deterioration, a rapid rise in respiration, and the generation of ethylene, which causes fruit to ripen quickly even after harvest (Borah *et al*., 2016; FAO, 2019; Bist and Bist, 2021). In developing nations, where appropriate methods for storing fruits and vegetables are unavailable, this percentage is far higher (FAO, 2019). The principal causes of losses across the supply chain are postharvest pathogens and disease incidence, which are favored by these changes. Due to the non-degradability of synthetic coating materials, awareness is being drawn to use of eco-friendly biodegradable and bio-polymeric materials in preservation, of which Gum Arabic and essential oils are part. Essential oil, which is a natural compound extracted from aromatic plants. Most of these oils are generally recognized as safe (GRAS) for the environment and human health, and there is growing interest in using these oils for sustainable agriculture. A lot of research has been done with records to backup this claim that plant essential oils and extracts can serve as pharmaceuticals and food preservatives (Miguel *et al*., 2006).
In order to decrease these post-harvest losses, decay-control measures must be developed to retain the quality of fruits and vegetables and offer protection against post-harvest diseases.Thus, this study aims at development of an edible coating from natural bio-materials (gum Arabic and cinnamon oil) for postharvest management of scotch bonnet.

MATERIALS AND METHODS
Collection of materials
Cinnamon bark was procured from mandate market, Ilorin, Kwara state, while fresh Scotch Bonnet was obtained from a farm in Ilorin, Kwara State and transported to Nigerian Stored Products Research Institute (NSPRI), Ilorin, Kwara State laboratory in reusable plastic crates in the early hours of the morning.
Extraction of cinnamon oil

Cinnamon oil was extracted as described by Abubakar *et al.* (2014)

Preparation and Application of coating medium

Gum Arabic coating was prepared according to the method of Utami *et al*., (2014) with modification. Ten gramme (10 g) Gum Arabic was dissolved in 100 mL distilled water at 50 °C on a hotplate and stirred for 60 minutes using a magnetic stirrer. The solution was filtered using a muslin cloth to eliminate impurities and 2 mL of glycerol was added to the solution mixture as plasticizer to enhance the potency and elasticity of the solution. This was followed by the addition of 3 mL cinnamon oil and tagged solution A. Solution B was prepared as solution A above but without the addition of cinnamon essential oil. The Scotch Bonnet fruits were sorted washed and surface sterilized by immersing in 0.01% hypochlorite solution for one minute and air-dried. The fruits were divided into three (3) lots; Group A (control) was dipped in distilled water for 1-2 minutes, group B was dipped in solution A, and group C was dipped in solution B and allowed to air dry. The treated and untreated fruits were subjected to the same storage conditions and closely monitored with a data logger and stored for 16 days with chemical analyses carried out at 4 days interval.

Estimation of Decay Incidence (%) and Weight Loss (%)

The decay incidence and weight loss was calculated according to the procedure outlined by Lawal *et al*. (2019) and Fashanu *et al.* (2019) respectively.

Determination of Moisture content, Total Soluble Solid (TSS), pH and Total Titratable Acidity (TTA) (%)

Moisture content, pH, TTA and TSS of the stored fruits were determined according to the methods of AOAC (2019).

Carotenoids determination

Lycopene and β-Carotene contents were determined and calculated using the spectrophotometric method reported by Fashanu *et al*. (2019)

Determination of vitamin C content

Vitamin C content was determined using the 2, 6-dichlorophenol indophenol titrimetric method described by Lawal *et al*. (2019).

Statistical analyses

Triplicate data was subjected to Analysis of Variance (ANOVA) and tested for significant difference among treatments by New Duncan's Multiple Range F-Test (DMRT) at ($p<0.05$) using SPSS software package version 20.0.0

RESULTS AND DISCUSSIONS

Decay incidence and weight loss

Figure 1 shows the decay incidence and weight loss of the tested and control groups. Group C had the lowest decay incidence and weight loss at 40.80 and 49.91 % respectively after the experimental period. This group showed more pronounced effects in reducing the decay incidence and weight loss as compared with Group B, (treated with gum Arabic + cinnamon essential oil) and Group A (control). However, the increased decay incidence recorded in group B could be as a result of reduced respiration rate caused by cinnamaldehyde; a major organic compound of cinnamon essential oil (Shen *et al*., 2021) thereby putting the fruits in a complete anaerobic state. This result is in agreement with the findings of Maqbool *et al*. (2011) where Gum Arabic and essential oil was used to prevent anthracnose in banana and papaya.

Total soluble solid (TSS)

The total soluble solids, ranged from 0.1 to 0.9 ºBrix (Fig. 2) with group A having significantly ($p<0.05$) higher value (0.9 ºBrix) compared to groups B (0.6 Brix°) and C (0.7 Brix°) respectively at the end of the experimental period (Day 16). Generally, there was an increase in TSS as the storage days progressed, however there was no significant ($p>0.05$) difference between groups B and C at day 16. The increase in TSS of both the treated and the control groups might be due to change in carbohydrate composition from starch to sugar as well as increased respiration rate which can be attributed to environmental conditions thus causing an acceleration to ripening of the fruits (Fashanu *et al.,* 2019).

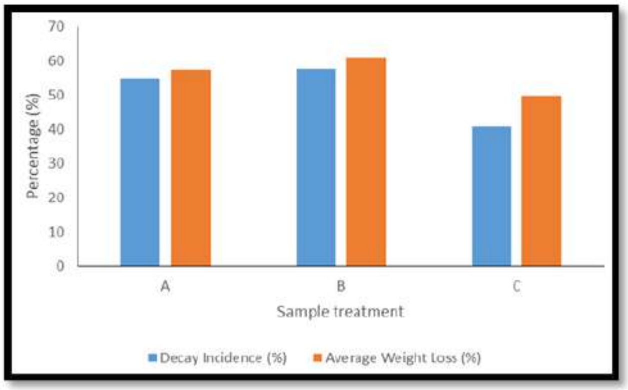

Figure 1: Effect of gum Arabic functionalized with cinnamon oil coating on Decay incidence and average weight loss of scotch bonnet. A=Control; B=10% Gum Arabic + 3mL cinnamon oil; C=10% Gum Arabic

pH and total titratable acidity (TTA)

The pH of both the control and tested groups ranged from 5.8 to 6.8 as shown in Figure 2. The control group had a significantly ($p<0.05$) higher value (6.8) at day 16 which was above the normal pH range of scotch bonnet (5.0 - 6.0) as reported by Bray, (2022). This result indicates that group B maintained the normal pH range of scotch bonnet and thus could be used in extending the shelf life of scotch bonnet. On the other hand, the TTA value recorded within the storage period ranged from 0.48 – 0.95% (Table 1). There was no significant ($p>0.05$) difference in the TTA of control and treated samples at day 0, this was expected because they were all from the same source. Conversely, a significant ($p<0.05$) decrease was recorded for all Groups at day 16,with Group A and C showing no significant ($p<0.05$) difference. This showed that the acidity of the scotch bonnet reduced over the storage period. The results of pH and acidity are in agreement because, increase in fruit acidity correspond to decrease in pH. This result shows similar trend with the findings of Maqbool *et al.* (2011) where Gum Arabic and essential oil was used to prevent anthracnose in banana and papaya.

Moisture Content (MC)

The moisture contents of the stored scotch bonnet fruits, as shown in Table 1, reduced as the storage days progressed and it ranged from 71.08 to 88.07%. Group C had a significantly higher MC (79.98%) at the end of the experimental period. This showed that Gum Arabic alone is capable of reducing water loss during the storage period, which is in agreement with Ogungbemi *et al.* (2020).

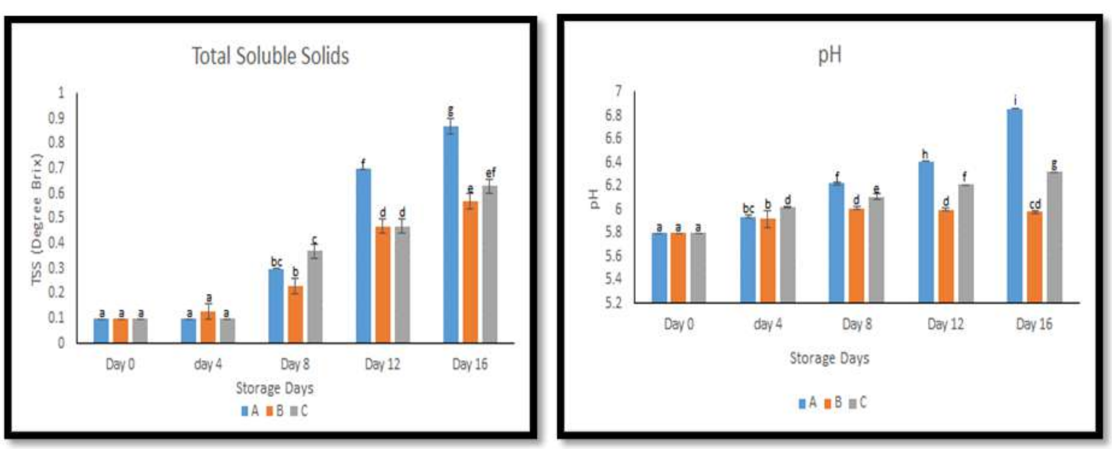

Figure 2: Effect of gum Arabic functionalized with cinnamon oil coating on total soluble solids and pH of scotch bonnet. Each bar represents mean of triplicate readings (n=3). A=Control; B=10% Gum Arabic + 3 mL cinnamon oil; C=10% Gum Arabic. Bars with unshared alphabet are significantly different ($p<0.05$). Error bars represent standard error (SE) of the mean

B	16	$71.08^{a}\pm0.88$	$0.56^{b}\pm0.01$
C		$79.98^{d}\pm0.29$	$0.49^{a}\pm0.00$

Result shows mean ± SE of triplicate readings (n=3). A=Control; B=10% Gum Arabic and 3ml cinnamon oil; C=10% Gum Arabic. Bars with unshared alphabet are significantly different (p<0.05)

Lycopene, β-carotene and Vitamin C content

The lycopene contents range from 14.91 to 64.21µg/100g (Table 2) with group B having a significantly (p<0.05) higher value (64.2 µg/100g) while group C was significantly lowest (33.53 µg/100g) after the experimental period which lasted for 16 days. β-carotene content ranged from 14.34 to 36.77 with group B having a significantly (p<0.05) higher value (36.77 µg/100g) and group C (15.30 µg/100g). The Ascorbic acid content observed in Group C was significantly higher (p<0.05) than the other groups (28.27mg/100g) at day 16. The result from this study correlated with the studies of Guo *et al*. (2020) who noted that the incorporation of cinnamaldehyde with the carboxymethylcellulose based film packaging helps to maintain the storage quality of cherry tomatoes by suppressing some metabolic activities including respiration.

Table 2: Effect of gum Arabic functionalized with cinnamon oil coating on lycopene, β-carotene and vitamin C content of scotch bonnet

Sample	Days	Lycopene (µg/100g)	β-Carotene (µg/100g)	Ascorbic Acid (mg/100g)
A		$14.91^{a}\pm0.15$	$14.34^{a}\pm0.61$	$10.42^{a}\pm0.17$
B	0	$14.91^{a}\pm0.15$	$14.34^{a}\pm0.61$	$10.35^{a}\pm0.11$

B	16	64.21i±0.07	$36.77^{h}\pm0.72$	$18.90^{c}\pm0.07$
C		$33.53^{f}\pm0.21$	$15.30^{a}\pm0.10$	$28.27^{g}\pm0.04$

Result shows mean±SE of triplicate readings (n=3). A=Control; B=10% Gum Arabic and 3 mL cinnamon oil; C=10% Gum Arabic. Bars with unshared alphabet are significantly different (p<0.05)

CONCLUSION

The study has revealed that 10 % Gum Arabic coating is an effective storage medium for scotch bonnet fruits, while the presence of Cinnamon essential oil helps to maintain the nutritional contents and as well slow down the ripening rate.

MANAGEMENT OF BACTERIAL WILT OF TOMATO (*Solanum lycopersicum* L.) USING CALCIUM-RICH SOIL AMENDMENT

Odesola, D. E. and *Aduramigba-Modupe, A. O.
Department of Crop Protection and Environmental Biology, University of Ibadan, Ibadan

ABSTRACT
The study focused on the management of bacterial wilt disease in tomato plants caused by Ralstonia solanacearum. Current control methods have limitations, such as environmental and human health risks associated with chemical control. The effect of soil amendment with calcium-rich chicken eggshell powder on disease management was investigated. Bacterial isolates were collected from wilting tomato plants and identified as R. solanacearum. Pathogenicity tests showed that two isolates, along with a reference isolate, caused severe wilting in tomato cultivars. Soil was amended with three levels of chicken eggshell powder at 5, 10 and 15% and two tomato varieties (Beske and Roma VF seedlings were inoculated with the virulent bacterial pathogen and transplanted into soils in 5 kg pots replicated four times. The study found that treating Roma VF tomato seedlings with 5% eggshell powder resulted in the highest seedling vigor, and lower disease incidence compared to other treatments. The findings suggest that chicken eggshell powder can be a cost-effective and environmentally friendly approach for managing bacterial wilt disease, but further research is needed to determine optimal application rates.
***Keywords**: Bacterial wilt, disease incidence, Ralstonia solanacearum, chicken eggshell powder.*

INTRODUCTION

Tomato (*Solanum lycopersicum* L.) is a flowering plant in the nightshade family, known for its edible fruit (Petruzzello, 2018; Quinet *et al*., 2019). It originated in South America and was later introduced to Europe and other parts of the world (Petruzzello, 2018). Tomato fruits are rich in vitamins and phytochemicals, particularly lycopene, which gives them their characteristic red color (Dasgupta and Klein, 2016; Quinet *et al*., 2019; Story *et al*., 2010). They are the second most important fruit or vegetable globally, with a production of 182.3 million tonnes annually (FAOSTAT, 2019). Nigeria is the largest tomato producer in sub-Saharan Africa (Umar, 2019; Ibirogba, 2021). Vascular wilt disease is a significant threat to tomato production worldwide. It can be caused by bacteria and by fungi such as Fusarium and Verticillium species (Rhoades, 2021). These diseases affect the plant's vascular system, leading to wilting and plant death. Bacterial wilt, caused by *Ralstonia solanacearum*, affects various plant species and causes symptoms like droopy foliage, stem collapse, and bacterial ooze (Champoiseau and Momol, 2009). Several management strategies have been developed to control bacterial wilt, including grafting, the use of biocontrol agents, biofumigation, and resistant varieties (Le *et al*., 2020; Pradhanang *et al*., 2003; Rivard *et al*., 2012; Suchoff *et al*., 2019). Chemical pesticides have also been used but have negative side effects. However, due to the pathogen's wide host range and genetic diversity, bacterial wilt management remains challenging. Integrated management approaches are commonly employed (Rahman *et al*., 2021).

Nutrient management, including the provision of essential nutrients, can contribute to disease control. Calcium is crucial for plant growth and plays a role in plant defense against pathogens (Liu *et al*., 2015). External application of calcium has been shown to enhance plant resistance to *R. solanacearum* in tomato and reduce disease severity caused by other pathogens (Jiang *et al*., 2013; Yamazaki *et al*., 1997, 1999, 2000). Calcium can be supplied to plants through chemical fertilizers or organic sources like eggshells, animal bones, or oyster shells (Hassani and Leverette, 2021; Rhoades, 2021). This study used calcium-rich soil amendment derived from chicken eggshells for the management of bacterial wilt in tomato plant. Therefore, the objective of this study was to evaluate the effects of eggshell-amended soil on seed germination, seedling vigor, and survival, and assessing the impact on disease severity and tomato growth.

MATERIALS AND METHODS

Experimental site: The research was conducted at the Roof Top Garden and Pathology research laboratory, Department of Crop Protection and Environmental Biology, University of Ibadan, Oyo State, Nigeria.

Soil and eggshell preparation and analysis: Topsoil was obtained from the Teaching and Research Farm, University of Ibadan and sterilized at 190°C for six hours, using an electrical soil sterilizer. Chicken eggshells were obtained from students' hostels in the University of Ibadan and local markets in Ibadan. The eggshells were washed with warm water to remove oil and dirt and then air dried. The eggshells were ground into fine powder and stored in plastic bags. Soil and eggshell samples were taken to the laboratory for physical and chemical analyses following standard laboratory routine procedure.

Isolation of *Ralstonia solanacearum* from infected plant samples: Wilting tomato plants were obtained from a tomato experimental field at the Federal College of Agriculture (Moor Plantation), Ibadan, Oyo State, the Crop garden in the Department of Crop Protection and Environmental Biology, University of Ibadan and a Tomato field at Ajibode, Ibadan, Oyo State. *Ralstonia solanacearum* was isolated from the infected tissues by suspending them in water and streaking on Triphenyl Tetrazolium Chloride (TTC) agar. Gram staining, Potassium hydroxide (KOH) solubility test, catalase test and tobacco hypersensitivity test were carried out on the isolates (Khasabulli *et al*. 2017; Pawaskar *et al*. 2014; Lozano and Sequeira, 1970).

Treatments and experimental design: The experiment was set up in a completely randomized design of four replicates consisting of two tomato varieties (Beske and RomaVF) sown in 2kg trays of eggshell treated (5, 10 and 15%) soil inoculated with *R. solanacearum*. The seeds were sown at fifteen seeds per tray. Two week old seedlings of the same varieties were also transplanted into 5kg of eggshell treated (5, 10 and 15%) soil in pots replicated four times.

Data collection and analysis: Germination data on the tray experiment was collected daily for three weeks and this was used to determine seedling vigour. The seedling vigour was determined by calculating the germination index using the following formula: $G.I = \frac{n}{d}$ where n represents the number of seedlings that emerge on day 'd' which represents the day after planting (Gupta, 1993). Data collection for the pot experiment was done weekly for eight weeks. Number of leaves and disease severity using a modified method of Ayana *et al*., (2011) were assessed. Data were analysed using Analysis of Variance (ANOVA) and means were separated using Fisher's LSD at 5% level of probability.

RESULTS

Identification of bacterial isolates from diseased tomato plants: Twelve bacterial isolates were obtained from the three sampling locations. Only five of the isolates (ART, ERT, JST, F4R and OST) were *R. solanacearum* exhibiting mucoid, fluidal and irregular colonies with pink centres surrounded by big white or cream-coloured margins. All isolates were pink coloured and rod-shaped indicating that they were gram negative. All isolates also formed a viscous elastic string when smeared in KOH and lifted with an inoculating loop. After 36 hours of tobacco leaf infiltration, the leaves presented with necrosis or browning in the middle surrounded by yellow halos, typical of Race 1 *R. solanacearum*.

DISCUSSION

Five isolates of *R. solanacearum* were obtained from infected plants exhibiting wilt symptoms. Two isolates showed virulent characteristics with mucoid pink-centred colonies and white edges, while the other three isolates had similar colonies but with thinner white edges. This correlates with the findings of Liu *et al* (2004) who described the colonies of virulent strains of *R. solanacearum* to be irregular, fluidal or highly mobile, humid with a pink spot in the middle surrounded by a large white edge while the avirulent strains possess more rounded colonies that are immobile, dry and grow on TTC as red-centred colonies with thinner or no white edge. Hypersensitivity tests revealed that all isolates belonged to race 1, characterized by brown necrotic regions with yellow halos and this is in agreement with the findings of Lozano and Sequiera, (1970), Lemessa and Zeller (2007) and Popoola *et al*. (2015) that symptoms of *R. solanacearum* belonging to Race 1 present as brown necrotic regions with yellow halos 36 hrs after inoculation. The tomato varieties used in the study exhibited wilting symptoms, indicating susceptibility to *R. solanacearum* as previously reported by Nwanguma *et al*. (2001), Popoola *et al*. (2015) and Tokpah (2019). Calcium-rich chicken eggshells were analyzed and found suitable as a soil amendment or calcium fertilizer for tomato growth (Ertürk, 2021). Treatment with 5% eggshell powder resulted in higher seedling vigor and better germination compared to controls. This indicates that calcium influences some seed quality parameters of tomato (Harish *et al*., 2016; Sajid, 2020). Also, the plants treated with 5% eggshell powder also showed improved growth performance in terms of leaf production. This might be explained by different bioactive chemicals found in eggshells, which have been reported to enhance tomato growth, yield, and quality (Taufique et al., 2014). However, treatment with 15% eggshell powder inhibited plant growth and led to stunted growth and fewer leaves, suggesting that higher concentrations of calcium can have adverse effects on plant performance.

CONCLUSION

In conclusion, poultry eggshells are cheap and organic sources of calcium that have potential as amendments for managing bacterial wilt. Chicken eggshells contain a substantial amount of calcium and have potential as an organic soil amendment and moderate levels of chicken eggshell powder can be employed for the control bacterial wilt disease, whereas high concentrations of calcium in tomato plants can cause toxicity and aggravate disease. Further studies to determine a more precise amount of chicken eggshell powder (application rate) that can be added to the soil which will be efficient for combating bacterial wilt disease without harming the plant are important.

ABSTRACT
This study examined the effects of Tuta absoluta on food security status of tomato farmers in selected local governments in Kano state. A sample size of sixty farmers was interviewed for the study through questionnaire. Result shows that the average age of the respondents in the study area is 34 years, 86.0% of the respondents were married, 92% are male, 65.0% had household size of between 6-10 persons and about 42.11% had spent 10-19 years in tomato farming. The logit regression analysis showed that intercept, age and T. absoluta invasion are significant at 1% while age and Tuta invasion are positively related to the food security status. Household size and marital status are also significant at 5% and they are negatively related to the food security status. It could be concluded that the farmers are impacted by infestation of T. absoluta, leading to a reduction in their income generation and a subsequent decline in food security. It is recommended that all stakeholders in the value chain should respond promptly by providing essential support to affected farmers.
Keywords: *Tuta absoluta, Food security, and Tomato farmers*

INTRODUCTION

The continent of Africa is still battling to eliminate hunger by 2030 while according to FAO (2019), the prevalence of food security in terms of African malnutrition has increased to 19.1% in 2019 compared to 17.6% in 2014. The issue of adequate food security in Nigeria has persisted as a crucial matter for attention by numerous government administrations over the years. (Ejikeme, 2017; Osabohien *et al*., 2020). According to FAO (2019), about 75% of the Nigeria population engaged in agriculture and the agricultural sector has about 90% of Nigeria's agricultural output is produced by small scale farmers (Ayinde *et al.*, 2020) while those farmers still depend on traditional system of farming that constrained them to have small level of income, low productivity and live below the poverty line. The low productivity has proven by Abdulazeez et al (2023) is mostly due to fragmented land ownership, over reliance on rain-fed agriculture, climatic change that breeds pests and illnesses, limited access to input, and a weak economic base. There is about one out of every five Nigerians were experiencing hunger 2020 (Osabohien *et al*., 2020). Similarly, Erokhin and Gao (2020) also reported majority of Nigerians live below the poverty level of 1.9 USD. The score of the Global Food Security Index (GFSI) of 2019 showed that out of 113 countries, Nigeria came in at position 94 and this makes the country to the most destitute nation in the world, surpassing India (Ayinde et al., 2020). Low level of food security can be traced to inability to meet the food demand although the larger population engaged in agriculture but the productivity is relatively low due to the damage caused by pests and diseases.

One of the major crops that many farmers cultivated is tomato in the northern part of the country. More than 70% of the tomato production in Nigeria comes from the northern states especially Kano and Jigawa states. Tomato production from these part of the country remains the hope for the country as it attracts high pricing during the dry season and this makes the tomatoes farmers to have high income due to high demand in the recent time, around 2015 when tuta absoluta invasion was experienced in the northern part of the country as the migratory pest that visited the country from the neighbouring country. According Abiola (2020), the estimated loss caused by tuta invasion is as much as total rampage of the tomato farm leaving the farmers with great loses. This study will focus on the effects of T. absoluta on food security status of tomato farmers as major objective. The justification of the study are the source of reference to minimize the possible scarcity of the tomatoes thereby instigating the foreign sourced of tomato from the neighbouring country and this will seriously affect the economic status of the farmers that have been dwelling in abject poverty.

METHODOLOGY

Study area

Kano State is situated between longitude 8° 31' 0.19" and latitude 12° 00' 0.43" north of the equator in Nigeria. About nine million people live there (National Population Commission (NPC), 2006) and the anticipated annual growth rate is 2.27%. (Raimi et al., 2020).

Method of data collection

A well-designed questionnaire was used to gather primary data on the social economic characteristics, demographic information, yield, food expenditure and other relevant information

Sampling procedure

A multiple-stage sampling approach was adopted to choose participants for the study. The first stage involves random choice of two Local Government Areas in Kano State were noted for their noteworthy tomato production. Five villages were chosen at random from the second stage's purpose sampling approach. These communities were; Bunkure town, Zango, Galadanci, Nasarawa, and Kuruma. In the third stage, simple random sampling technique was used select 60 tomato farmers for the study.

Model specification

Coping strategy Index

The Coping Strategies Index (CSI) was used to measures what tomato farmers do when they cannot access enough food due to low income from their tomato production. A simple numeric score is generated from a series of questions about how households deal with a shortage of food for consumption.

Probit model

Logit model will be deployed to the analysis on effects of T absoluta on food security status as one of the independent variables will be measure in binary method

$Y=a+b1x1+b2x2+b3x3+b4x4+b5x5+b6x6+b7x7+b8x8+ b9x9+ b10x10+ b11x11+\mathcal{E}$

Y = food security status (using Coping Strategy Index)
X1= size of the farm (hectares)
X2= Education (years of formal schooling)
X3 = Farming Experience (Years)
X4= Age of head (Years)
X5= Sex (Female = 0, Male = 1)
X6 = Household size (Actual number)
X7= Tuta absoluta infestation (yes = 1, No = 0)
X8= Marital status
ε = Error term

RESULTS AND DISCUSSION

The Table 1 below explains the demographic characteristics of the tomato farmers in the study area. The result revealed that the average age of the tomato farmers in the study area; 34, 92% are male, 86% of the respondents are married, the average household size is 9 persons, 36% of the respondents have primary school education, average farming experience of the respondents is 15 years and average farm size is 3.3 hectares and this revealed that the tomato production is still at small scale based on the specification of FAO (2019) that the commercial agriculture production for crop is about 10 hectares.

Table 2 explained the causes and effects of T. absoluta on food security status of the respondents. The R square explain the goodness of fit of the model which is about 85% (0.852) while adjusted R square explained the percentage of dependent variables explained by independent variables. The result showed that intercept, age and T. absoluta invasion are significant at 1% while age and Tuta invasion are positively related to the food security status but the intercept is negatively related. Household size is also significant at 5% and it is negatively related to the food security status while marital status is also significant at 5% but it is also negatively related to the food security status.

Table 2: Effects of Tuta absoluta on food security status of the respondents

Variables	*Coefficients*	*t Stat*	*P-value*

Tuta invasion	0.004167	2.42E+16	0.00000***

CONCLUSION

T. absoluta infestation has been affecting the farmers in terms of their revenue generation which has influenced the level of food security. Despite the declining in food security status of the tomato farmers, the current infestation of T. absoluta does not allow the farmers to produce what is sufficient to meet their need not to talk of having marketable surplus for sales. High loss of tomato will increase the level of poverty of the tomato farmers and farming households. The recommendation are for the swift response from all stakeholders along the value chain to provide the necessary aids for the farmers especially through grant and training of extension agents thereby enlighten farmers on how to prevent the destructive T. absoluta. In as much as crop diversification is not the best but the farmers have to find crop of economic worth so as to absorb the shock in the industries.

ABSTRACT
This paper examines the economic analysis of citrus production in Ibadan, Nigeria from 2018 to 2022. The profitability of orange production is affected by production costs as well as inflation and interest rates over time. Primary data were collected from 100 orange farmers in Ibadan. The average farm size is 4 hectares. Costs of production in Ibadan over 5 years are presented, Revenue per hectare ranged from 3.7 million naira in 2018 to 3.8 million naira in 2022. Using a discount factor (r = 0.11), the discounted revenue declined from 2.7 million naira in 2018 to 1.8 million naira in 2022. The benefit-cost ratio declined from 3.4 in 2018 to 1.5 in 2022. It was concluded that orange production is profitable but profitability declines when taking into account the temporal value of money and inflation. The study recommended that farmers should consider the time value of money for production decisions.

INTRODUCTION
The citrus fruits are part of the same family of fruits as tangerines, oranges, lemons, and limes. In terms of international trade, citrus fruit is the fruit crop with the highest value (Olife et al, 2015). Citrus is one of the most widely grown fruit trees in sub-tropical Africa. Acording to new world encyclopedia, the family which orange belongs to is Rutaceae and it contains various species among which is Citrus sinensis which is also known as sweet orange. Orange reproduces asexually (apomixis through nucellar embryony); Orange variants develop as a result of mutations (Orange fruit, 2018). A region that includes Southern China, Northeast India, and Myanmar is where the orange first appeared, (Talon, 2020). Fresh orange fruit or oranges that have been processed for their juice or fragrant peel can both be consumed (GRIN, 2017). Citrus was introduced to Nigeria and has since fully adapted. It is now a part of the country's cropping systems, notably in areas between latitudes 6oN and 9oN. Nigeria has a huge comparative advantage and the potential to dominate global citrus production and trade due to the variety of ecological and climatic conditions that are favorable for the production of citrus. As of 2020, orange accounted for two-third of citrus production (FAO,2021).
Orange is a perennial crop that fruit two times in a year and it has economic lifespan of 30 years although it can produce for about 100 years (Musasa et al., 2015). In 2021, sweet orange yield for Nigeria was 48,419 Kg per ha (knoema, 2021) Trend of sweet orange yield is on geometry rise for about 20 years after which it will maintain the yield for about five to ten years. Justification of this study is that despite the several works that have been done on profitability but less to no attention has been given to inflation rate and interest rate especially for perennial crops. As the price level of orange is increasing, so as the cost of production but not at the same rate. Objective of this study is to examine the profitability analysis of the sweet orange production in Nigeria. The labour wages have not been increasing in the same proportion with the interest rate and this can be traced to high level of unemployment. According to law of demand, surplus in supply gives room to the decline in the price of labour used in the production of orange. According to IMF (2022), Inflation is expected to reach 11.5 percent on average in 2027. This indicator measures inflation based on the annual change in the average consumer price index, as defined by the International Monetary Fund.

METHODOLOGY
Study area
The study was carried out in Ibadan of Nigeria. The area lies between longitude 7°23′47″N and latitude 3°55′0″E with a total land area of about 77,800 km2 and a projected population of with a total population of 3,649,000 as of 2021 (NPC, 2022).
Method of data collection

Primary data was collected with the aid of a well-structured questionnaire which was administered to the Orange farming household head in particular to collect the social economic characteristics, costs, revenue, and other relevant information.

Sampling procedure

A multistage sampling procedure was used in selecting the respondents for this study. The first stage involved a purposive selection of two (2) local government areas that have large area of farm settlements where orange is being cultivated (Ido and Akinyele local government areas). Stratified sampling method was used in selecting 5 wards from each local government and random selection of 10 orange farming household heads was selected.

Model specification

Time value of the money was captured with discounted factor. The trend of real value of income

$$\frac{Bt \div TC}{(1 + r)\, t}$$

Where r = inflation rate.

t = time.

Bt = revenue from each year

TC = total cost

Trend of cost is on arithmetic progression increase at #5,000 increments in every five years, n making it #1000 rises in labour cost on yearly basis.

Cost for a particular given year will be expressed as:

Cost for year n = a + (n-1)d

Where

a = the first year cost

nth year= year in consideration

d = common difference or yearly rise

RESULT AND DISCUSSION

The table 1 below explain the socio-economic characteristics of the respondents, the result revealed that majority of the respondents of about 89% are male, average age of the citrus orange farmer is about 47 years, the average household size is 4 persons, the average farm size is four hectares and about 57% have post-secondary education experience and this revealed that the citrus production in Ibadan is predominant by educated people.

The table 3 below revealed that citrus production is a profitable enterprise as the BCR within the trend of times has value greater than 1. It can also be inferred from the table that the BCR is on the decline taking the cognisance of time factor of money into consideration. And the elasticity of citrus is inelastic.

Table 3: Benefit Cost Ratio between the years

Year	Discounted revenue	Total cost	BCR
2018	2689667	788092	3.412885
2019	2430391	884092	2.749025
2020	2196086	999592	2.196982
2021	1984354	1078092	1.840617
2022	1793017	1169092	1.533683

Source: 2023 survey

CONCLUSION

The result of the economy analysis of sweet orange production is profitable although the profit is on the decline as the time value of money makes the increasing nominal revenue to be on the decline while comparing the real ratio of income to cost. Time value of money is a key factor that needs to be considered in analysing the economics of horticultural crops especially the perennial ones. Instead of assuming the nominal value throughout the production cycle, it is very essential to consider the real worth so as to guide the decision making with reference to opportunity cost. Nevertheless, government policy has a key role in determining the inflation and interest rate which influences the time value of money. Recommendation is that people have to take into consideration time value of money while analysing their profitability nature of their orchard before announcing the nominal profit that has not been into existence.

ABSTRACT
This study investigated lead and cadmium concentration in African spinach 'Green' grown on Burnt Municipal Waste Residue and the implications on human health. This experiment was conducted at the Screen House in the Department of Agricultural Technology of the Federal Polytechnic, Ado-Ekiti in September, 2019. Thirty plastic buckets were each filled with Burnt Municipal Waste soil obtained from refuse dumpsites in the school yard and Top soil was also collected under fallow vegetation. Ten seeds of Amaranthus were planted per bucket and later thinned to five plants per pots and watered to saturation every two days. Data collection started three weeks after planting. Parameters measured were plant height, number of leaves, Root weight, Root length, days to first inflorescence and Total plant biomass. In this experiment, only two Heavy metals of Cadmium (Cd) and lead (Pb) of human concern were analyzed for each of stem, leaves and roots of African spinach. Using data obtained from chemical extractions, different parameters such as soil-to-plant transfer factor (Plant Concentration Factor), the Health Risk Index (HRI) and the Daily Tolerable Intake (DTI) of sampled heavy metals were employed to assess and/or predict metal uptake by Amaranthus species. From the result, the heavy metal concentration in amaranthus grown on Burnt Municipal waste residue is hazardous and therefore detrimental to human health. It was recommended that Farmers should be educated and encouraged not to cultivate in farmlands around dumpsites since such farms may be polluted by toxic heavy metals.
Keywords: *African Spinach, Burnt Waste Municipal Residue, Heavy metal Concentration*

INTRODUCTION

There is increasing concern about heavy metals in the soil for their high toxicity to crops and aquatic organisms (USEPA, 1986). Heavy metals like Zn, Pb, Cu, Cd and Fe are essential components of many alloys but the metal content of the soil is the results of inputs from organic waste, agro chemicals, parent materials, fertilizers and other sources of pollutants lost through up-take and harvest, leaching and volatilization. Evidence from various studies suggests that daily consumption of vegetables can prevent the development of cardiovascular diseases and some cancers, especially gastrointestinal cancers (Islam 2016). However, the consumption of vegetables grown on heavy metal-contaminated soils can lead to harmful metabolic and physiological effects on human body (Khan *et al* 2015). It is well known that lead (Pb) and cadmium (Cd) are very toxic heavy metals for human health (Nagajyoti, *et al,* 2010, Alam *et al* 2018) that directly or indirectly enter human body. In Nigeria, analysis on heavy metals is rarely carried out in monitoring of vegetable quality before supply despite the incessant contamination of the soil from refuse sites. These metals that are generated as a result of contamination are considered to be toxic and may accumulate gradually in soil sediments which are taken up by plants, animals and by man through food chain. With time, the level or trace elements may become higher than the acceptable limits in human body and may be responsible for some chronic diseases that affect the population that lives around the area (Mahmud *et al*, 2020**,** Mahmood *et al* 2019).

Most plants and animals depend on soil as a growth substrate for their sustained growth and development. In many instances, the sustenance of life in the soil matrix is adversely affected by the presence of deleterious substances or contaminants. The entry of the organic and inorganic form of contaminants results from disposal of industrial effluents (Gowd *et al*., 2010). The contamination of soils with heavy metals or micronutrients in phytotoxic concentrations generates adverse effects not only on plants but also poses risks to human health (Matthews-amune, *et al.,* 2018). Abandoned waste dumpsites have been used extensively as fertile grounds for cultivating vegetables, though research has indicated that the vegetables are capable of accumulating high levels of heavy metals from contaminated and polluted soils. Among the environmental pollutants, heavy metals represent a significant hazard to the environment, being both an ecological and health risk. Adiku, and Okoffo, (2015). These elements are highly persistent and not biodegradable contaminants, therefore, they accumulate in soil, then becoming accessible to plants or leaching to groundwater (Osma *et al*., 2012). The soil contamination by heavy metals can transfer to food and ultimately to consumers. For instance, plants accumulate heavy metals from contaminated soil without physical changes or visible indication, which could cause a potential risk for human and animal (Osma *et al*., 2012).

Based on its persistent and cumulative nature, as well as the probability of potential toxicity effects of heavy metals as a result of consumption of leafy vegetables and fruits, there is a need to test and analyse this food item to ensure that the levels of these trace elements meet the agreed international requirements. An index of metal phytoavailability frequently used in environmental monitoring is the degree to which an extractable solid-phase quantity is correlated with measured tissue concentration (Wang *et al*., 2011). Using data obtained from chemical extractions, different parameters such as soil-to-plant transfer factor, the translocation index, mobility factor and regression models have been used to assess and/or predict metal uptake by Amaranthus species (Chinyere and Madu, (2015). The present study was aimed at examining the effects of different heavy metals particularly Cd and Pb grown on Burnt Municipal Waste Residue as it affects the performance of African Spinach 'Green'.

METHODOLOGY

Site description

This experiment was conducted at the screen house in the Department of Agricultural Technology of the Federal Polytechnic, Ado-Ekiti in September, 2019 to examine the effect of Heavy Metal Concentration on performance of African Spinach 'Green' (Amaranthus hybridus) Grown on Burnt Municipal Waste Residue

Establishment of *Amaranthus hybridus*

Thirty plastic buckets were each filled with Burnt Municipal Waste soil obtained from refuse dumpsites in the school yard where household solid waste was dumped and Top soil was also collected under fallow vegetation. The total plastic buckets used were sixty and these were perforated at the bottom to allow for easy water percolation. The plastic containers were arranged in a randomized complete design with four replications. Seeds of African Spinach were obtained from Agricultural Development Programme. (ADP) at the Seed Processing Unit in the Ministry of Agriculture, Ado- Ekiti. Ten seeds of Amaranthus were planted per bucket and later thinned to five plants per pots and watered to saturation every two days.

Date collection

Data collection started three weeks after planting. Parameters measured were plant height, number of leaves, Root weight, Root length, days to first inflorescence and Total plant biomass. Three plants were randomly selected and tagged from each treatment and counted for data collection. The experiment was terminated at the eleventh week after planting after which the total plant biomass were harvested and weighed. In this experiment, only two Heavy metals of widespread concern to human health were analyzed for each of stem, leaves and roots of African spinach grown on top soil and burnt municipal waste residue**.** Leaf samples were collected from plants grown on top soil and soil obtained from burnt municipal waste residue and analyzed for elemental elements of Ph, N, P, Na, K, Ca, Mg and Organic carbon. Using data obtained from chemical extractions, different parameters such as soil-to-plant transfer factor (Plant Concentration Factor), the Health Risk Index (HRI) and the Daily Tolerable Intake (DTI) of some sampled heavy metals were employed to assess and/or predict metal uptake by Amaranthus species (Ahmad-Mahir *et al*., 2009).

Preparation of Soil and African Spinach samples

A. Digestion of soil sample

1g of soil sample each were weighed into a conical flask and digested in a fumed cupboard with a mixture of 25ml of HNO_3 (Conc) and 4ml of $HClO_4$ for 30min until white fumes were observed. This was filtered using filter paper and funnel into a 100ml volumetric flask and made up to the mark with distilled water. The metals where determined by Atomic absorption spectrophotometer.

B.Digestion of African Spinach sample

0.5g of fine powder of leaf, stem and root samples were weighed into conical flask and digested into 4ml per chloric acid, 25ml Nitric acid and 2ml Sulphuric acid under fume hood. The contents were mixed and heated at low temperature to medium heat on heating mantle. The heating was continued until dense white fumes appeared. The samples were then heated for 30 seconds on the same heating mantle at medium heat after which the solution was cooled and filtered completely in volumetric flasks. The solution was then stored and ready for the determination of metals using Atomic absorption spectrophotometer.

RESULT AND DISCUSSION

Pre-Soil Chemical Properties of Burnt Municipal soil and Top soil at Screen house

Table 1 shows the pre soil chemical properties of Burnt Municipal Waste Residue and Top soil at the screen house. Organic carbon and Nitrogen were higher in Top soil as shown in Table 1 while values of K, Ca, Mg and P were considerably greater in Municipal refuse soil. Organic matter may have been burnt up in Municipal refuse soil. This may have accounted for its low Nitrogen and Carbon content.

Effect of Municipal Waste Residue and Top soil on growth and yield of *Amaranthus hybridus*

The use of Municipal waste significantly increased plant height, root weight and total plant biomass. There was however no significant difference in the values of number of leaves and root length for amaranthus planted on Top soil and Burnt Municipal Waste Residue. Days to inflorescence were however shorter for amaranthus planted on Top soil over Municipal Waste Residue as presented in Table 2

Effect of Municipal Waste Residue and Top soil on Elemental Leaf Nutrient Composition *of Amaranthus hybridus*

The effect of treatments on elemental nutrient composition is presented in Table 3. The result shows that the leaf nutrient composition was significantly higher for P, Ca, Mg and Available P in amaranthus planted on Municipal Waste Residue while Nitrogen was significantly higher in Top soil.

Average Chemical Properties of some heavy metals present in leaf, stem and root of Amaranthus hybridus planted on Burnt Municipal Refuse Soil

Table 4 shows that the high concentration of heavy metals is located in the root region of the vegetable plant both for Cadmium (Cd) and Lead (Pb) respectively (1.725, 6.941). The concentration of heavy metals were however lower in the leaf region for both Cd and Pb. This is because heavy metals are more concentrated in the soil and are therefore easily absorbed into the root zone. These was however Not Detected in amaranthus planted on Top soil as presented in Table 5

Average levels of Cd and Pb present in the soil of Burnt Municipal Refuse Soil and Top soil

Table 6 indicate that the level of Cd and Pb in the soil of Burnt Waste Residue to be 1.604 and 4.887 respectively while these values were detected in Top soil

Tolerable intake value of Cadmium and Lead for Adult (WHO, 2007)

Table 7 shows the WHO (World Health Organization, 2007) provisional tolerance weekly intake (PTWI) of cadmium (0.007mg/kg) and Lead (0.025mg/kg) per body weight. This table was exacted from WHO (2007) fact sheet to compare and contrasts with the result in Table 4 and 5 to know how safe or hazardous is consumption of the leaf of amaranthus harvested from burnt municipal waste soil. The result shows that heavy metal concentration in burnt soil is detrimental to human health. Concentration of Cd and Pb has exceeded the safe level for human consumption in soil containing burnt municipal waste residue.

Provisional Tolerable Weekly Intake (PTWI) in mg/kg per body weight

Means the quantity of heavy metal intake for one kg body weight while mg content for Cd or Pb from this study shows that mg quantity of Cd or Pb that will be found in one kg weight of leaf which is one of the edible part of spinach. Therefore, from WHO, 2004 recommendation of at least 400g of fruit and vegetable intake per day, equivalent to (2800g/person/week), 2.8kg of leaf will be assumed to be the quantity by a person of 1kg body weight will be estimated as follows;

Cadmium leaf content obtained from Table 4 is 0.554, therefore,

Cadmium leaf content (0.4mg/kg) = 1.554 x 0.04 = 0.063mg/kgbw

Lead leaf content obtained from Table 4 is 4.20, therefore,

Lead leaf content (0.4mg/kg) = 4.20 x 0.04 = 0.168 mg/kgbw

Using these values of 0.063mg/kgbw and 0.168 mg/kgbw as probable intake value of cadmium and lead respectively, the values in Table 7 were obtained by dividing these values by the body weight of 10 to 1000kg.

Risk factor assessment

Transfer factor

Metal concentrations in the extracts of soils and plants were calculated on the basis of dry weight. The plant concentration factor (PCF) was calculated as follows:

From Table 4 and 7 values of concentration of cadmium and lead of amaranthus leaf and soil grown on burnt municipal waste residue,

$$PCF = \frac{\text{Concentration of (plant)}}{\text{Concentration of (Soil)}}$$

Where PCF is the plant concentration factor.

For cadmium =1.554/1.604 =0.969

For lead =4.200/4.887 = 0.859

The plant concentration factor for cadmium and lead is 0.969 and 0.859 respectively

(Wang *et al,* 2005)

Health risk index (HRI)

The health risk index (HRI) for the locals through the consumption of contaminated vegetables was assessed based on the food chain and the reference oral dose (RFD) by WHO/FAO standards for each metal. The HRI <1 means the exposed population is assumed to be safe.

Metals of Cd and Pb have been reported with high tendency of binding tenaciously to organic matter contained in the soil. Hence, the organic matter of soil is known to play a major role in determining the bioavailability of heavy metals. (Ahmed *et al.,* 2018). Alam *et al*. (2019) opined that the concentrations of Cd in this study were highly significant. Haque *et al*. (2018) studied on heavy metals in tomato and high concentration of Cu (43.10 mg/kg) was noticed (Ahmed *et al* 2018). Furthermore, the highest concentration of Cr was observed in tomato (380.20 mg/kg). These fruit vegetables were cultivated in industrial waste soil where the average value of Cr was found 79.43 mg/kg which was higher than the world safe limit (70 mg/kg) (Begum *et al.,* 2019). This value was above the safe limit (2.30 mg/kg) recommended by joint FAO/WHO due to the presence of higher concentration of DTPA (Diethylene triamine penta acetic acid) in soil Haque *et al*, 2018, Akram *et al.,* 2015, Rahman *et al*. (2020) determined the heavy metal concentrations in vegetable samples available in Bangladesh. The average value of Mn, Fe, Cu, Zn, Cd, and Pb were measured 30.83, 429.27, 9.91, 32.19, 0.58, and 8.88 mg/kg, respectively in vegetables. It was found that the mean concentrations of Zn (32.19 mg/kg), Cd (0.58 mg/kg), and Pb (8.88 mg/kg) were above the safe limit. Among these metals, the highest amount of Fe was found in red spinach (807.12 mg/kg).

This study also showed that Fe is more abundant in leafy vegetables. The content of Fe in leafy, fruit, and root vegetables were 659.14, 358.60, and 270.07 mg/kg, respectively Rahman and Rahman (2020). The lowest concentration was found for Cd (0.12 mg/kg). The level of all the metals was above the safe limit. As a result, long term exposure to these metals interrupts the biological processes in human body Ahmed *et al* (2018). Islam *et al*. (2015) assessed the heavy metals concentrations in vegetables in the vicinity of industries and observed that the mean concentrations of Ni (3.23 mg/kg), Cu (11.75 mg/kg), as (0.80 mg/kg), and Pb (0.83 mg/kg) were above the reference limits. Islam *et al*. (2016) concluded that the mean values of as (0.24 mg/kg) and Cd (0.06 mg/kg) exceeded the permissible limits

In this study, the average concentrations of the heavy metals were below the safe limit. However, Cd was non-essential element of human health with high biological toxicity which mainly accumulates in surface soil (Iqbal and Khan, 2019). Its concentration should be monitored. High concentration of heavy metals are present in the root of amaranthus hybridus based on Table 7 that showed the provisional Tolerable Weekly Intake (PTWI) of cadmium (0.007mg/kg) and lead (0.025mg/kg) per body weight. WHO (World Health Organization, 2007). From the result, the heavy metal concentration in amaranthus planted on Burnt Municipal waste residue is hazardous and therefore detrimental to human health (Adeyemi *et al*, 2019)

CONCLUSION AND RECOMMENDATIONS

The most adverse effect of heavy metals is that they can be introduced into the food chain and threaten human health. Agricultural products growing on soils with high metal concentrations are represented by metal accumulations at levels harmful to human and animal health as well as to the bio-environment. The concentration of lead and cadmium were high in burnt municipal waste residue. Also the health risk index (HRI) for the locals through the consumption of contaminated vegetables was assessed based on the food chain and the reference oral dose (RfD) by WHO/FAO standards for each metal calculated in the table above using USEPA model is less than 1 means the consumption of these vegetables as food may not pose immediate danger to humans but prolonged consumption could lead to bioaccumulation and adverse health implication especially for Cd and Pb. It is therefore recommended that monitoring of heavy metals in plant tissues is essential in order to prevent excessive build up of these metals in human food chain

It is also suggested that those wastes that pose greater health hazards be properly recycled in order to reduce environmental pollution and/or soil degradation. Sorting of wastes at source and statutory regulations of wastes managements should be encouraged. Farmers should also be educated and encouraged not to cultivate in farmlands around dumpsites since such farms may be polluted by toxic heavy metals.

ABSTRACT
The study provides an evaluation of the Nigerian Institute of Landscape Horticulturists as a professional body. The objective was to assess the Institute based on the parameters considered crucial for recognizing a profession. 145 respondents were selected. Data were collected with structured questionnaires; frequency and percentage analysis were used, while significant level ($p \leq 0.05$) was determined by tabulated Chi-square. Study revealed 5 types of the necessary parameters for recognizing a profession: knowledge and training (93.10%); autonomy (91.10%); effectiveness and utility (82.76%); ethical codes (82.07%) and legitimacy (83.45%). The Institute has challenges in area of professional identity and invasion of the profession by allied practitioners. An immediate implementation of the charter is required for the Institute.
***Keywords**: Profession, professionalism, practitioners, ethical codes and landscape horticulture*

INTRODUCTION
Professionalism is a character, spirit and methods that distinguish a profession from an amateur. Professionalism is associated with the development and use of a unique technical language by members. This language is acquired to distinguish it from any other form of activity (Hancock, 1974). A profession is said to be defined within a district body of knowledge which affords its members special and exclusive skills to rendering some societal services. The body of knowledge and skill must be distinct from existing ones. The members possess the special skill after attaining a prescribed level in training. Professionals are therefore adjudged to be capable of providing a certain service better than any other group and so constitute experts in their field (Artur, 2018).
Professional body is an institutionalized collection of practitioners or people, with a specialized skill, bounded together within some ethical codes designed to protect the public and perpetuate the social needs for the skill and services of its members (Fagbayide, 2002 Personal communications). Five parameters are considered crucial for recognizing a profession: knowledge and training, autonomy, legitimacy, ethical codes, effectiveness and social utility (Greenwood, 1957 and Storr, 2012). Rendering the history of an Institute such as that of the Nigerian Institute of Landscape Horticulturists is very vital to the great task of professionalism; the Nigerian Institute of Landscape Horticulturists was founded in 18th March, 1989 at Lagos State University (Durotola, 2000 Personal communications). Therefore, the assessment of the Institute such as the Nigerian Institute of Landscape Horticulturists based on the parameters considered crucial for recognizing a profession is very vital to an understanding of the present study.

METHODOLOGY
This consisted mainly of literature review; it encompassed review of the constitution of various professional bodies such as Nigerian Institute of Landscape Horticulturists, Nigerian Institute of Architects, Council of Registered Engineers of Nigeria, and Nigerian Institute of Town Planners. Journal article on the establishment of school ornamental horticulture, postharvest management of ornamental plants, books of the professional practice of landscape architecture, landscape principles and practices were also consulted (Rogers, 1997; Ingels, 2009 and Alabi, 2022). The data used in this research was obtained from the questionnaires administered around Ilorin metropolis. It also includes the gardens visited and its environs as well as personal interviews with workers and the professionals.
One hundred and forty-five (145) questionnaires were administered to people engaged in landscaping business. All the respondents were randomly selected form Ilorin metropolis; the questionnaires were

designed to gather information on the professionalism of landscape planning and development in Nigeria based on whether some parameters were necessary or not for recognizing a profession. The questionnaires were filled and retrieved on the spot. Data for the study were collected in two stages: primary data collection and secondary data collection. The primary data collection involved the observation of Ilorin metropolis for personal assessment, administration of questionnaires and interview of practitioners of landscape horticulture. The secondary data were obtained from published and unpublished sources. Frequency and percentage analysis were used, while significant level ($p \leq 0.05$) was determined by tabulated Chi-square (X^2).

RESULTS AND DISCUSSION

Assessment of professionalism based on knowledge and training

Table 1 shows that 93.10% of the respondents assessed the professionalism on the bases of knowledge and training as necessary, 5.52% as not necessary, and others like finance, management scores 1.38%. Therefore, the result shows that the Nigerian Institute of Landscape Horticulturists has not satisfied this parameter. Generally, for any professional body to qualify as a professional Institute, it must satisfy parameter such as knowledge and training. The extent to which this parameter is satisfied determines the professionalism of such body.

Table 1: Assessment of professionalism based on knowledge and training

Assessment	Frequency	Percentage (%)
Necessary	135	93.10
Not Necessary	8	5.52
Others	2	1.38
Total	145	100

Significant@X^2 ($p \leq 0.05$) = 5.99

Assessment of professionalism based on autonomy

Table 2 shows that 91.03% of the respondents support that autonomy is necessary for a profession to be recognized, while 8.28% says not necessary, others scored very low percentage. Professions are recognized on the degree of independence they possess in exercise of their professional expertise. Without being sentimental, no discipline is an Island to itself; every discipline has relatedness with others.

Table 2: Assessment of professionalism based on autonomy

Assessment	Frequency	Percentage (%)
Necessary	132	91.10
Not Necessary	12	8.28
Others	1	0.69
Total	145	100

Significant@X^2 ($p \leq 0.05$) = 5.99

Assessment of professionalism based on effectiveness and social utility

Table 3 shows that out of 145 respondents, 82.76% assessed the professionalism on the bases of effectiveness and social utility as necessary, while 15.86% says not necessary, 1.38% of the respondents have other criteria to be considered for recognizing a profession. Therefore, the Institute has to make a significant impact in this area by seeking a synergy with the Horticultural Society of Nigeria (HORTSON). Landscape horticulture as a profession, if not effective in some of places or sectors does not imply that it cannot be made effective. There is no profession that can claim perfect effectiveness. Given that landscape horticulture functions have social utility, what is required from the profession is to seek further for scientific techniques and methodologies apart from the design and planning techniques to make implementation more effective.

Table 3: Assessment of professionalism based on effectiveness and social utility

Assessment	Frequency	Percentage (%)
Necessary	120	82.76
Not Necessary	23	15.86
Others	2	1.38
Total	145	100

Significant@X^2 ($p \leq 0.05$) = 5.99

Assessment of professionalism based on ethical codes

Table 4 shows that 82.07% of the respondents considered ethical codes necessary for recognizing a profession, while those that considered it as not necessary amounts to 16.55% of the respondents. Therefore, for any profession to be recognized, ethical code is one of the crucial parameters to be considered. With regard to ethical codes, the Nigerian Institute of Landscape Horticulturists has a challenge with the effectiveness of this code because of lack of enactment by Federal Government of Nigeria to be chartered professional body.

Table 4: Assessment of professionalism based on ethical codes

Assessment	Frequency	Percentage (%)
Necessary	119	82.07
Not Necessary	24	16.55
Others	2	1.38
Total	145	100

Significant@X^2 ($p \leq 0.05$) = 5.99

Assessment of professionalism based on the legitimacy

Table 5 shows that 83.45% of the respondents confirmed that for any profession to be recognized the issue of legitimacy must be clearly stated and that is why the highest percentage of the respondents ascertained that legitimacy is one of the crucial parameter considered necessary for recognizing a profession, while 13.79% says not necessary, others considered administration, finance and non-chalant attitude as part of the parameters to be examined in professionalism of landscape horticulture. The Nigerian Institute of Landscape Horticulturists can be said to have satisfied this parameter, because they are registered by the Corporate Affair Commission (CAC) of Nigeria.

Table 5: Assessment of Professionalism based on the legitimacy

Assessment	Frequency	Percentage (%)
Necessary	121	83.45
Not Necessary	20	13.79
Others	4	2.76
Total	145	100

Significant@X^2 ($p \leq 0.05$) = 5.99

Assessment of the Invasion of landscape horticulture profession by other allied professionals

Table 6 shows that out of 145 respondents, 67.59% assessed the invasion of landscape horticulture profession by other allied professionals as significant and increasing, while 31.03% gave it significant and diminishing, 1.38% assessed it as not significant. However, in the history of any profession, invasion is customary hence the Nigerian Institute of Landscape Horticulturists is not unique in this sense. Therefore, the Institute has to make a significant impact in the area of reducing the rate of invasion by the other professional bodies.

Table 6: Assessment of the Invasion of landscape horticulture profession by other allied professional bodies

Assessment	Frequency	Percentage (%)
Significant & Increasing	98	67.59
Significant & Diminishing	45	31.03
Not Significant	2	1.38
Total	145	100

Significant@X^2 ($p \leq 0.05$) = 5.99

CONCLUSION

Research results revealed that some challenges are militating against the Nigerian Institute of Landscape Horticulturists. These problems include the problem of professional identity and the invasion of the profession by the allied practitioners such as architecture, engineering and town planning. Other identified problems are those of governmental policies and relatively young age of the Institute. From the findings, the future of the Institute is bright but it has a big task of strengthening its areas of weakness and intensifying its areas of strength. It is in the light of this that recommendations are made in the area of synergy with Horticultural Society of Nigeria in production and practices of horticulture, work towards professional identity, being chartered, application of plant architectural drafting and analysis, botanical science and artificial intelligence in the professionalism of the profession. An immediate implementation of the charter is required for the Institute to be renamed as Nigerian Chartered Institute of Landscape Horticulturists.

ABSTRACT
A field trial was conducted at the experimental farm site of Federal College of Forestry Mechanization, Afaka, Kaduna to determine the effect of weed control treatments and intra-row spacing on yield and yield components of okra (Abelmoschus esculentus L.). The treatments consisted of three rates of butachlor 1.5, 2.5 and 3.5 kg a.i./ha, supplementary hoe weeding at 6 weeks after sowing (WAS), hoe weeded control at 3 and 6 WAS, weedy check and three intra-row spacings (60 × 15cm), (60 × 30cm) and (60 × 45cm). The treatments were arranged in a randomized complete block design (RCBD), replicated three times. The result showed that weed dry weight, number of fresh okra per stand, weight of fresh okra per stand and yield per hectare responded significantly to weed control treatments. However, intra-row spacing had significant effect on number of fresh okra stand, weight of fresh okra per stand and on yield per hectare. Based on the result obtained, butachlor at 2.5kga.i./ha and hoe weeded control plots with intra-row spacing of 60 × 30cm were suggested for okra production in the study area.
Keywords: *Okra, Performance, Spacing, Weed and Yield*

INTRODUCTION

Okra is native of tropical Africa. It is widely distributed and cultivated in the tropics and subtropics of the world for its tender and delicious green fruits which are cooked, canned and consumed (Falusi *et al*., 2012). The world's greatest producer of okra is India, producing 70% of the total world's production estimated to be 6 million tons per year (FAOSTAT, 2012) followed by Nigeria and Sudan (Vermudy, 2011). In Nigeria, okra ranks third in terms of consumption and production area following tomato and pepper (Odeleye *et al*., 2005).In Nigeria, despite the increase in demand of okra, the yield of okra is still low (2.7t/ha) compared to other countries such as India (10.50t/ha), Sudan (10.2t/ha), Egypt (15.7t/ha), Pakistan (7.6t/ha), Sudan (11.5t/ha) (Oyelade, *et al*., 2003) .The control of weeds only through manual labour has become very expensive, due to high labour cost and their unavailability at critical times (Swardekar and Fugro, 2017). Weed competition caused substantial yield losses (40 – 80%) which depends upon the type of weed flora, their intensity and stages (Sharma and Patel, 2011). Weeds are generally controlled by physical and cultural methods and hand weeding is the most efficient method of weed control. However, these methods are tedious, time consuming and laborious. The easiest way to control weeds is through herbicides which is quicker and cheaper as compared to other methods (Shamla, *et al*., 2017). One of the cultural practices that farmers use in controlling weeds in okra is spacing. When adequate plant spacing is used for planting crops, it enables crops to have a high yield as water and nutrients will be made available to the crops. Ogbaji (2001) reported that plant population obtained by inter and intra – spacing Is one of the factors that determines efficient profitable crop yield and land use. This study is aimed at determining the influence of weed control treatments and intra – row spacing on yield and yield performance of okra.

MATERIALS AND METHODS

The field experiment was carried out at the experimental farm site of Federal College of Forestry Mechanization, located at Afaka, Kaduna at the Northern Guinea Savannah ecological zone of Nigeria (Latitude 10° 37 N and Longitude 7° 17 E). The physical and chemical properties of the soil profile (0 – 15cm) of the experimental site was taken for analysis, prior to land preparation. The treatments consisted of three rates of butachlor 1.5, 2.5 and 3.5 kg a.i./ha, supplementary hoe weeding at 6 weeks after sowing (WAS), hoe weeded control at 3 and 6 weeks after sowing (WAS), weedy check and three intra – row spacing (60 × 15cm), (60 × 30cm) and (60 × 45cm). Giving plant populations of 11.111111, 5.555555556 and 3.703703704 respectively. The treatments were arranged in a randomized complete block design (RCBD) replicated three times. The gross and net plot sizes were 4.05m^2 (1.8m × 2.25m) and 1.35m^2 (1.8m × 0.75m) respectively. The okra seeds were planted in situ according to the different intra – row spacings of (60 × 15cm), (60 × 30cm), (60 × 45cm) with two seeds per hole. The herbicide butachlor was applied pre-emergence (a day after planting) using a knapsack sprayer with a green deflector nozzle at a swath width of 75cm, kept at a pressure of 2.1kg/m^2 to give a spray volume of 250l/ha. Harvesting of okra started two months after planting when the pods were still soft for consumption. Harvesting was done every five days which helped to stimulate more pods.

Data collected includes, weed dry weight, number of fresh okra per stand, weight of fresh okra per stand and yield per hectare. Data collected were subjected to analysis of variance (ANOVA) as described by Snedecor and Cochran (1967). The treatment means were separated using Duncan multiple range test (DMRT) (Duncan, 1955). The most common weed species observed at the experimental site and their intensity of occurrence is shown on Table 2. Broadleaf weeds infested the okra plots more than grasses and sedges. This result is in line with the findings of Mohammed and Suhair (2012), who worked on okra and reported that the weed flora in the experimental site consisted of grassy and broad-leaved weeds, but broad-leaved weeds were predominant.

RESULTS AND DISCUSSION

The physico-chemical analysis of the soil indicated that the soil was a sandy loamy soil, with 0.028 % for total nitrogen, 0.65% for organic matter percent and 1.352 for C.E.C (Table 1).

Weed dry weight g/m^2

Weed control treatments had significant effect on weed dry weight and intra – row spacing had no significant effect on weed dry weight. Weedy check plots recorded significantly higher weed dry weight than all the other weed control treatments. Hoe weeded control plots recorded significantly lower weed dry weight than all the other weed control treatments that were statistically at par to each other. Intra-row spacing had no significant effect on weed dry weight. Adekpe (2006), reported similar findings on garlic (*Allium sativum* L.), that the weedy check plots resulted in significantly higher weed dry weight than the hoe weeded control plots and the other weed control treatments and also reported that intra-row spacing had no significant effect on weed dry weight (Table 3).

Number of fresh okra per plant

Number of fresh okra per plant was significantly influenced by weed control treatments and intra-row spacing. From table 3, butachlor at 2.5kga.i./ha recorded significantly higher number of fresh okra per plants. This was followed by butachlor at 3.0kga.i./ha and hoe weeded control. The rest of the treatments were statistically similar to each other. This result is in line with the findings of Muhhtar *et al*., 2018 on okra, who reported that the herbicide treatments and the weed free treated plots significantly increased fresh okra pod yield as compared to the weedy full-treated plots. Intra-row spacing of 60 × 15cm gave significantly higher number of fresh okra per plants than the other intra-row spacings that were statistically similar to each other. Mahadeen (2008) reported similar findings in his research work that narrow inter-row spacings produced higher yield.

Weight of fresh okra per plant

Weight of fresh okra per stand was significantly influenced by weed control treatments and intra-row spacing. Hoe weeded control plots produced significantly higher weight of fresh okra per plants than the other weed control treatments that were statistically similar to each other. Intra-row spacing of 60 × 15cm and 60 × 30cm gave significantly higher weight of fresh okra per plants than the other intra-row spacing. This result is still in line with the findings of Mahadeen (2008) who reported in his research work that narrow inter-row spacings produced higher yield. (Table 4).

Yield per hectare

Yield per hectare was significantly influenced by weed control treatments and intra-row spacing. Hoe weeded control plots recorded significantly higher yield per hectare than the other weed treatments that were statistically similar to each other. Intra-row spacing of 60 × 30cm recorded significantly higher yield per hectare than the other intra-row spacings that were statistically similar to each other. Similar findings from Moniruzzaman *et al*., 2001 indicated that at the spacing of 60 × 30cm the plants obtained increased seed yield per hectare (Table 4).

CONCLUSION

From the result obtained in the study carried out at the experimental farm site of Federal College of Forestry Mechanization, Afaka, Kaduna, on yield performance of okra (*Abelmoschus esculentus* L.) as influenced by weed control treatments and intra-row spacing, butachlor at 2.5kga.i./ha and hoe weeded control plots, with intra-row spacing of 60 × 30 cm should be suggested for okra production in the study area.

MARKET INTEGRATION OF MELON (*Cucumis melo)* IN RURAL AND URBAN MARKET OF KWARA STATE

Iliasu K.B, Adeoye I.B and Layade, A.A.
National Horticultural Research Institute, P.M.B 5432, Idi-Ishin, Ibadan

Corresponding author: iliasukamaldeenbiodun@gmail.com

ABSTRACT
The study assessed market integration between urban and rural markets of shelled and unshelled melon in Kwara state. Data on yearly retail price from 2010-2021 were collected from Kwara State Agricultural Development Programme and analyzed using trend analysis, augmented Dicker-Fuller, Johansen maximum likelihood test and Granger causality tests. Findings showed that rural and urban shelled melon prices were co-integrated, indicating some long-run relationship, while unshelled melon prices were not co-integrated. Granger causality test found no evidence of short-run price transmission between rural and urban of shelled and unshelled melon markets. Findings also showed that the shelled market has some spatial integration but the unshelled market remains weakly integrated, implying inefficiencies in price transmission from urban to rural market. The study recommends promotion of adequate market information for price updates to improve linkages and thus free flow of market prices.
Keywords: *Market integration, shelled melon, unshelled melon, market linkages, price transmission*

INTRODUCTION

Cucumis melo, a fruit vegetable of economic importance, is a rich source of vitamins and minerals, consequently improving nutrition (Manchali *et al*., 2021), high in demand in urban markets (Ibironke and Oyeleke, 2014). In many parts of the world, including Kwara State, Nigeria, melons are an essential agricultural commodity. Rural areas of Kwara produce both shelled and unshelled melons, which are sold in urban markets, significantly contributing to the livelihoods of smallholder farmers (Oladimeji *et al*., 2016). Thus, efficient marketing of the commodity is imperative. Market integration refers to the degree of interrelation of prices for a specific commodity, such as melons, across geographically distinct markets (Rapsomanikis, 2015). By analyzing the co-movement of melon prices and the speed of price transmission, it is possible to gauge the level of market integration and efficiency of the supply chain (Ogundari and Ojo, 2018). Despite the market-oriented reforms implemented in Nigeria since the 1980s, market integration between rural and urban areas remains limited (Arowosegbe and Adedeji, 2006). Various studies have identified high marketing costs, underdeveloped infrastructure, and institutional constraints as key hindrances to greater rural-urban market integration (Liverpool-Tasie *et al.*, 2017). In a study conducted by Adeoye *et al*. (2013) in South-western Nigeria, it was found out that there is quick transmission of prices between urban and rural markets for Amaranthus and Corchorus, whereas there is slow transmission of prices information between urban and rural markets for okra because the flow of information regarding okra is not efficient.

However, limited research inquiry has been directed towards scrutinizing the market linkages that exist between rural areas that produce melons and urban wholesale and retail markets in Nigeria. Evaluating the spatial integration of melon markets would offer valuable proof regarding the areas that suffer from information flow deficiencies or coordination issues between rural producers and urban purchasers. The study therefore assessed the level of market integration between rural melon-producing areas and urban markets in Kwara state to provide useful insights into the efficiency of price signals along the supply chain.

MATERIAL AND METHODS

The study was carried out in Kwara State, Nigeria. Data on average yearly retail prices of *Cucumis melo* from 2010 to 2021 were obtained from the Kwara State Agricultural Development Programme. The study made use of trend analysis, augmented Dickey-Fuller (ADF) statistics, co-integration and Granger causality procedures to analyze the data. Trend analysis was used to examine the movements of the prices based on the historical data; this can be used to predict the future price movements. The augmented Dickey-Fuller (ADF) statistics was used to test for stationarity; this is done to avoid the problem of spurious regression. Johansen maximum likelihood test was used to test for co-integration to determine the number of co-integrating vectors present and finally Granger causality test was used to know the direction of causality.

RESULTS AND DISCUSSION

Trend analysis of shelled melon and unshelled melon

Price trend analysis of shelled melon in (figure 1), shows that the highest price at the rural market was observed in 2019 (N394.08/kg), similar trend was also observed in the urban market for the same year (N428.93/kg). Lowest price in shelled melon was observed in 2010 for the urban and rural market prices. For the unshelled melon in (figure 2), highest price was also observed in 2019 at the rural and urban market. Generally, there is fluctuation in the market prices of shelled and unshelled melon in both the rural and urban market. The higher prices in 2019 may be due to reduced supply in the market.

Augmented Dickey-Fuller (ADF) statistics for stationarity test

Stationarity test in (Table 1) shows that rural and urban prices for unshelled melon were not stationary at level l (0) but stationary at first difference l(1). However, the prices for the shelled melon were stationary at level l (0). Therefore, the null hypothesis for non-stationarity were accepted for the unshelled melon prices while it was rejected for the shelled melon prices. These are in line with the findings of Yusuf *et al*. (2006), who reported that commodity prices are stationary at first difference. Chirwa (2000) emphasized that without spatial price analysis of markets, price signals will not be transmitted from food-deficit to food-surplus areas, prices will be more volatile, agricultural producers will fail to specialize according to the long-term comparative advantages and the gain from trade will not be realized. When a time series is stationary, it means that certain attributes of the data do not change over time. However, some time series are non-stationary, whereby values and associations between and among variables do vary with time.

Co-integration Test for Shelled and Unshelled melon

The co-integration results (Table 2) using the Johansen maximum likelihood test showed that here is co-integration between rural and urban shelled melon prices, therefore null hypothesis of no co-integration was rejected indicating that there is connection between the rural and urban shelled melon prices in the market. However, there is no co-integration between the rural and urban market prices for unshelled melon, therefore, null hypothesis of no co-integration was accepted meaning that there is no link between rural and urban market prices for unshelled melon.

Granger causality test for Shelled and Unshelled melon

The results in (Table 3) indicates that the null hypothesis of rural prices of shelled and unshelled melon does not Granger Cause urban and rural prices of shelled and unshelled melon respectively were accepted, indicating that there was no causal relationship between rural and urban market prices for shelled and unshelled melon, i.e. price changes in one market did not result to price response in the other market.

CONCLUSION AND RECOMMENDATION

Rural and urban shelled melon prices are co-integrated while the unshelled melon prices are not co-integrated implying no market linkages. There is no evidence of short-run Granger causality of price transmission between the rural and urban market for either shelled or unshelled melon. The shelled melon market exhibits some degree of spatial integration, the unshelled melon market remains weakly integrated. The study recommends promotion of adequate information for price updates to improve linkages and thus free flow of market prices.

ABSTRACT
Tomato is the world most highly consumed vegetable. In order to fulfill customer's demand, it is essential to enhance tomato fruit output. The experiment was conducted to determine the effect of plant resistance activators on growth and fruit yield of two varieties of tomato (Perfect Pee, Pp and Roma round, Rr). The experiment was conducted in the DELPHE research screen house and Teaching and Research Farm of Federal University of Agriculture, Abeokuta, Nigeria. The plant resistance activators (Acibenzilar – S – Methyl, ASM, β- Aminobutyric acid, BABA, Salicyclic acid, SA and Acetyl Salicyclic acid, ASA) were applied at four levels (0, 25, 50, 75 µg/ml) by foliar spraying. Results of the study revealed that Pp and Rr treated with ASA at 50 µg/ml had the tallest plant heights ***(133 and 152.2 cm)*** *and (145.3 and 156.7cm) as well as number of leaves* ***(39.5 and 45.2) and (40.4 and 46.5)*** *in the screen house and on the field respectively. Also, Pp and Rr treated with 50 µg/ml in the screen house and on the field produced significantly higher (103g/plant and 34.4 ton/ha) and (116g/plant and 38.7 ton/ha) yield respectively. The study concluded that application of ASA at 50 µg/ml improved the growth and fruit yield of tomato and is therefore recommended to the farmers.*
Keywords*: Acibenzilar – S – Methyl, β- Aminobutyric acid, Salicyclic acid and Acetyl Salicyclic acid*

INTRODUCTION

Tomato (*Solanum lycopersicum* L.) is native to tropical America, now grown all over the world (Arah *et al*., 2015). World annual production of tomato was 186.82 million metric tons (FAOSTAT, 2020). Nigeria is 14^{th} world and second largest producer of tomato in Africa with 3.69 million total tomato production after Egypt with 6.77 million metric tons (FAOSTAT, 2020). Tomato has become an important cash and industrial crop in many parts of the world (Ayandiji *et al*., 2011) not only because of its economic importance, but also due to its nutritional value to human health. (Popoola *et al.,* 2012).

Plant resistance activators (PRA_S) are agents that leads to improved protection against pathogen attacks by inducing the plant's own defense mechanism (Waiters *et al.,* 2013). PRA_S can be chemical compound as well as microbial or plant extracts. However, they seldom lead to full pathogen control (Waiter and Fountaine, 2009).

Poor yield resulting in low supply to meet the market demand, is a major constraint to tomato cultivation as a result of many factors which include increased incidence of microscopic phytopathogens such as bacteria, fungi and virus (Dennis, 2006). These microscopic organisms can be noticed in plants only when the symptoms manifest. However, there is dearth of information on the application of these chemical compounds in enhancing the performance of plants rather than a preventive measure against incidence of pathogens/diseases. Hence, the objective of this research work was to determine the performance and the appropriate concentration of plant resistance activator that will enhance growth and improve yield of tomato.

MATERIALS AND METHOD

Experimental sites

A screen house and field experiments were conducted at the DELPHE research screen house, Abeokuta and Federal University of Agriculture (FUNAAB) Teaching and Research Farm in Abeokuta, Ogun State, Nigeria respectively.

Experimental materials, treatments and experimental designs

The two tomato accessions, Roma round and Perfect pee, were obtained from the Plant Tissue Culture Laboratory, FUNAAB. Four Plant Resistance Activators; Acibenzilar – S- Methyl (ASM), Acetylsalicyclic acid (ASA), β- aminobutyric acid (BABA) and Salicyclic acid (SA) were sourced from Libertas store, Abeokuta, Nigeria.

Completely Randomized Design was used for the screen house experiment with three replications while Randomized Complete Block Design was used for the field experiment with three replications. The experiment consisted of two tomato accessions (Roma round and Perfect pee) at three levels (25, 50, 75 µg/ml) each of the four plant resistance activators (ASM, ASA, SA and BABA) and a control (where there was no application of PRAs)

Soil sterilization, Nursery establishment and Transplanting

A sandy loamy soil was collected and steam sterilized at 100 ºC for three hours. Before usage, the sterilized soil was placed inside sacks and allowed to cool for two weeks. Fifteen grams (15 g) of the sterilized soil was weighed and loaded in the nursery trays and tomato seedlings were grown and nurtured for four (4) weeks before transplanting. Four weeks old tomato seedlings were transplanted to plastic pots containing 9 kg sterilized soil and placed in the screen house. Two tomato seedlings were transplanted into each pot which was later thinned to one. There were seventy-eight pots altogether for the screen house experiment. Transplanting of tomato seedlings on the field was done on the already prepared land. The experimental plot size was 3 x 2 m^2 with 1 m border. Tomato seedlings were transplanted at 75 m x 50 cm spacing between and within rows. There are seventy-eight plots with sixteen plants per plot.

Preparation and application of plant activators

Each activator (ASM, ASA, SA and BABA) at three different concentrations of 25, 50 and 75 µg/ml was weighed and dissolved in sterile distilled water. Application of PRA_S was carried out at 4 days after transplanting and at weekly intervals for 4 weeks by foliar method. Control pots and plots received no treatment.

Data collection and analysis

Data collected on growth and yield parameters were subjected to analysis of variance (ANOVA), using Statistical Analysis System (SAS), 9.1 package. Means were separated using Duncan's Multiple Range Test ($p \leq 0.05$).

RESULTS

Effect of plant resistance activators on plant height of tomato

Table 1 shows the effect of plant resistance activator application on plant height of tomato in the screen house and on the field at six and eight weeks after transplanting (WAT). The screen house and field experiments' findings showed that tomato accession (Perfect pee) at concentration of 50 µg/ml of Acetyl Salicyclic Acid (ASA) were the tallest plants with the heights of (133 and 152.2 cm) which were significantly different ($P < 0.05$) from the control with the least plant heights (65.6 and 70.3 cm) in the screen house and field respectively at 8 WAT. Also, Roma round tomato variety treated with 50 µg/ml ASA has the highest plant heights (145.3 and 156.7 cm) which was significantly different ($P< 0.05$) from the least plant heights (72.9 and 79.3 cm) recorded for the control in the screen house and field respectively at 8 WAT.

Effect of plant resistance activators on number of leaves of tomato

Table 2 shows the effect of plant resistance activator application on number of leaves of tomato in the screen house and on the field at 6 and 8 WAT. The screen house and field experiment's findings revealed that Tomato accession Pp treated with50 µg/ml ASA gave the highest number of leaves (39.5 and 45.2) which was significantly different ($P < 0.05$) from the control with the least number of leaves in the screen house (19.2) and field (22.8) respectively at 8 WAT. Also, the Roma round tomato variety treated with ASA 50 µg/ml concentration had the highest number of leaves (40.4 and 46.5) which was significantly different ($P< 0.05$) from the least number of leaves (22.3 and 24.8) recorded for the control in the screen house and field respectively at 8 WAT.

Effect of plant resistance activators on fruit yield of tomato

Table 3 reveals the effect of plant resistance activator application on fruit yield of tomato in the screen house and on the field. The screen house and field experiment's findings revealed that Tomato accession Pp at 50 µg/ml ASA produced the highest fruit yield (103g/plant and 34.4 tons/ha) which was significantly higher ($P < 0.05$) compared to the least fruit yield (29.7g/plant and 16.6 tons/ha obtained from control in the screen house and field respectively. Similarly, Roma round (Rr) tomato variety treated with 50 µg/ml ASA produced significantly ($P< 0.05$) highest fruit yield (116 g/plant and 38.7

tons/ha) in comparison to the least fruit yield (38.9 g/plant and 19.6 tons/ha) recorded for the control in the screen house and field correspondingly.

DISCUSSION

The results obtained showed that all tested concentrations of ASM, BABA, SA and ASA have positive effect on tomato growth and fruit yield compared to the control experiment. However, 50 µg/ml ASA produced significantly higher ($P< 0.05$) growth and fruit yield compared to other activators used and the untreated experiment in both screen house and under the field condition correspondingly. This effect might be attributed to the fact that ASA diffuses more easily through the growth medium than others which are less water soluble. This supported the findings of Abd-El – Kareem (2002) who reported that spraying potato plant with ASA increased its growth and fruit yield. Similarly, El – Gamal *et al*. (2003) reported that foliar spray of bean with ASA at different concentrations resulted in a yield increase.

CONCLUSION AND RECOMMENDATION.

Application of 50 µg/ml Acetyl Salicyclic Acid (ASA) boosted tomato growth and yield more than any other PRAs. Therefore, application of 50 µg/ml ASA is recommended to farmers in order to boost tomato fruit yield and for farmers to meet the growing market demand of tomato fruits.

ABSTRACT
This study examines the perception of the use of Herbicides in cassava production in Kabba/Bunu Local Government Area of Kogi State, Nigeria. Data collected for the study were obtained from one hundred and twenty (120) respondents, the study employed the use of questionnaires to elicit information from respondents. Measure of central tendency such as mean, frequency and percentage as well as Likert scale analysis were used. Result from the analysis shows that the model age of the cassava farmers is between 41 – 50years (50%), with a mean age of 47years, majority (75.83%) of the cassava farmers sampled were literate holds certificates. Majority (75%) of the respondent had between 11 – 30years experience with a mean farming experience of 28years, more than half (62.50%) of the respondents had between 1-5 household size with a mean of 5 persons. Most (70.83%) of the respondents had between 1- 2ha farm size with a mean of 2ha. Access to credit distribution shows that majority (75%) of the respondents had no access. Most (70.83%) of the respondents had no contact with extension agents. Perception of farmers on the use of herbicides in cassava production revealed that majority (75%) of the respondent used herbicides and had perception on the use of herbicides and they do so as to increase output, control weed and control pests and diseases, etc. Major concerns or constraints of the cassava farmers on the use of herbicides includes inadequate credit, low technical knowledge due to extension contact, poor access to market in formation, price fluctuation, inadequate inputs, illiteracy, expensive and harmful chemical respectively and if addressed will enhance productivity of cassava production in the study area. It is therefore recommended that farmers should be sensitized on the need for them to farm more cooperative societies so that cassava farmers can use the opportunities it proffers to accesses farm inputs.
Keywords: *Herbicides, Cassava, Farmers, Kabba/Bunu, Kogi*

INTRODUCTION

Nigeria is said to be one of the largest producer of cassava, it is yet to meet the potential demand both in the local and international markets (olumide,2004). This is as a result of limiting factors in cassava production includes it cultivate by small scale, low resource farmers high cost of agro-chemical (herbicides), fertilizer, pests, and diseases, perception of farmers towards the use of herbicides, inadequate capital, weed management, unfavorable weather and climate, high costs of labour, land tenure, market constraints little or no extension contact, (Nweken,2004) fertility of the soil. Low technical know – how, inadequate land for cultivating among others. Stemming from the foregoing, the aim of this study is to access the use of herbicides in cassava product among small scale farmers in Kabba/Bunu Local Government Area of Kogi State, Nigeria. The following specific objectives describe the socio – economic characteristics of the cassava farmers in the study area; examine the perception of farmers on the use of herbicides in cassava production in the study area identify the constraint associated with cassava production in the study area and solution to constraints associated with herbicides in cassava production in the study area.

MATERIAL AND METHOD

Study Area

This is being conducted in Kabba/Bunu Local Government Area of Kogi State. The study is within the northern Guinea Savannah Ecological zone of Nigeria. It lies between latitude $7^{0}49^{1}$N and 37.88^{11}N and longitude of $6^{0}04^{1}$E and 30.07^{11}E of the equator within area of 2.70km2 and a population of 145,446 (NPC, 2006), they have two distinct seasons in a year, the wet and dry seasons. The wet season spans between middle of March to October, while the dry season is between the months of November to

March, the area has an average maximum temperature of 210c with annual rainfall between 1,100mm and 1, 300mm. The main crops grown in the area are cassava, oil palm, maize, Yam, Melon, Plantation, and Vegetable. Animal husbandry is also practiced in the area. In terms of sampling size and procedure, ten (10) villagers were selected using convenience sampling from Kabba and Bunu districts (Five from each district). Based on their predominance of cassava farming in the area, with three hundred and twenty-five (325) members. Taro Yamani's formula was used to determine the number of respondents to a total of 120 respondent's primary data for analysis was generated through the administration of structured questionnaire while secondary information was obtained via journals, newspapers, Internet, Literature, and State Official website. Generated data were analyzed with descriptive statistics,and 4-point Likert scale rating were used to achieved the objectives of the study.

Two Yamani's Formula

Formula: - n = s/1 + N^2 where: - N = 668,5 = 325,

e = 0.05, n = 325 / 1 +668 $(0.05)^2$ = 325/2.70

= 120.37. With the above calculation one hundred and two (120) questionnaires distributed.

To get a true representative sample of the target population, the Taro Yamane (1964) formula for sample size determination was used thus:

$$N = \frac{S}{1 + N(e)^2}$$

Where:

S = Sample Size

I = Constant

N = Population Size

e = Margin of Error, usually 5% (0.05)

In applying the formula, these figures were obtained as follows:

N = 668

S = 325

$1 + 668\,(0.05)^2$

Therefore, the sample size is 120

RESULTS AND DISCUSSION

Socio – Economic Characteristics of the cassava farmers in the study area;

Table 1: Show that (75%) of the respondent were males while 25% were females. The model age of the cassava farmers is between 41 – 50 years (50%), with a mean age of 47years. (77%) of the respondents were married, (22%) were single, widow/widower and divorced. (75%) of the cassava farmers were literate, (62%) of the respondents had between 1 – 5 household size with a mean of 5 persons. (70%) had between 1 – 2 farm size with a mean of 1 – 5ha. (62%) had between 100,000 – 200,000 with a mean annual cassava production income of 197,000. (75%) had no access to credit while (25%) has access to credit. (70%) had no contact with extension agents while (29%) had contacts.

Perception of farmers on the use of Herbicides in Cassava Production in the study area:

Table 2: Shows that (66%) of the respondents used family labour, (8% usedhired labour while (25%) used both labour. (75%) used herbicides while (25%) do not used herbicides. (91%) had good perception on the use of herbicides while (8%) had perception on the use of herbicides in cassava production in the study area. The result of the mean ratings of the responses by the cassava farmers on the extent why they use herbicides in study area showed that the three (3) items had mean value that ranged between 3.54 to 3.81 which are greater than the cut – off point value of 2.50 on 4 – point rating scale. This indicated that the cassava farmers agreed that the three identified items in the table are the reasons why they use herbicides in the study area.

Constraints Associated with Herbicides in Cassava production in the study area.

Table 3 show that the mean rating of the responses by the cassava farmers on the constraints associated with the used of herbicides in cassava production in the study area showed that the eight (8) constraining items had mean values that ranged between 2.61 to 3.54 which are greater than the cut – off point value of 2.50 on 4 – point rating scale. This indicated that the cassava farmers agreed that the eight (8) identified items in the table are constraints facing the usage of herbicides in cassava production in the study area.

Solution to constraints associated with Herbicides in cassava production in the study area.

Table 4: Show that the mean ratings of the responses by the cassava farmers on the possible solutions on the constraints associated with the used of herbicides in cassava production in the study area showed that the eight (8) possible solution items had mean values that ranged between 2.61 to 3.54. this indicated that the cassava farmers agreed that the eight identified items in the table are the possible solution facing the usage of herbicides in cassava production in the study area.

CONCLUSIONS

Based on the findings, it was concluded that majority of the respondents used herbicides in cassava production and had a possible perception on the use of herbicides. Major concerns of the cassava farmers on the use of herbicides include inadequate credit, low technical knowledge due to no extension contact, poor access to market information, prize fluctuation, inadequate inputs, illiteracy, expensive and harmful respective and harmful respectively and if addressed will enhance productivity of cassava production in the study area.

RECOMMENDATION

Based on the conclusion, it was recommended that the Agricultural Development Project (ADP) should ensure regular contact with farmers to expose them with relevant information on improve agricultural practices especially on agro – chemicals in order to increase the farmer's productivity level. Farmers should be enlightened on how to apply herbicides and the importance of herbicides application to crops basically cassava. This will assist farmers to meet up with their production target without much labour and capital.

ABSTRACT
Majority of the soils in Nigeria are exposed to leaching effects due to incessant rainfall that leads to low organic matter and nutrients contents. The importance of cocoa nutrition cannot be exaggerated because nutrition affects the size and cocoa bean quality. This study was carried out to review nutritional conditions and fertility status of soils for cocoa production in Nigeria. It was revealed that most soils under cocoa production in Nigeria are moderate to marginally suitable in fertility status. However, some of the soil contents for the nutrients needed for high cocoa yield were below critical levels. Therefore, good management practices that would replenish lost nutrient elements in the soil were considered necessary. Recommended rates of organic and inorganic fertilizers for cocoa cultivation are highlighted in this paper.

INTRODUCTION

Still called the "food of the gods", the cocoa tree (*Theobroma cacao* L.), of the Malvaceae family, is a tropical plant cultivated for its beans, from which cocoa powder and butter are extracted. There are three varieties of cocoa: "Forastero", usually yellow but occasionally red when the pod is ripe, "Criollo", more sought after and more expensive, whose pods are red-orange when mature, and "Trinitario", which is hybrid of the two preceding varieties. "Forastero" is the most commonly grown variety in West and Central Africa, but its flavour is not as good, as that of the other two varieties (Kokou Edoh Adabe and Lionelle Ngo-Samnick, 2014). Cocoa is a major source of income for about 5 million small-scale farmers (Poelmans and Swinnen 2016). Cocoa is produced within 10^o N and 10^o S of the equator where the climate is suitable for growing cocoa trees. West Africa has been the centre of cocoa cultivation for many decades, as two-thirds of the world's cocoa is produced in West Africa. Approximately 74% of the global production originates from four countries in West and Central Africa: Côte d'Ivoire, Ghana, Cameroon and Nigeria (ICCO 2020), where the cocoa plantations are among the least productive in the world (Oomes *et al.,* 2016). This is less than one-tenth of the potential yield of cocoa in West Africa (Zuidema *et al*., 2005). A considerable part of the cocoa in the world is produced by smallholders, and the International Cocoa Organization (ICCO) estimates that approximately 14 million people are directly involved in cocoa production.

Cocoa ranked first amongst agricultural export crops in its contribution to foreign earnings (Tijani *et al*. 2001). It is a crop of economic importance with more than 650,000 ha being cultivated in Nigeria (Sanusi and Oluyole 2005) Cocoa has generally enhanced the economy of Nigeria over the years. It is exported either as raw cocoa beans or cocoa products. Some 70% of Nigeria's annual cocoa exports are to Europe with a further 10% to the United States of America and up to 15% to Eastern Europe. Nigeria is currently the 4th largest producer of cocoa in the world. However, the gross production of cocoa has decreased since 2010 because of declining yields per hectare that started in the early 1990s (FAOSTAT, 2020). Because of the limited availability of land, productivity per hectare will need to increase if Nigeria is to contribute to the increasing global demand for cocoa. In Nigeria, most of the Cocoa plantations are old and less productive (Ayoola 2000). Most soils under Cocoa plantations and adaptable areas in Nigeria are marginal to moderately suitable in fertility status. The soils are well drained, thoroughly leached and deeply weathered. Cocoa is exceptionally demanding in its soil requirement (Smith, 1975). Wessel (1971) showed steady decline in almost all nutrients with length of cultivation. Omotoso (1975) reported that a crop of 1000 kg dry Cocoa beans removed about 20 kg N, 41 kg P and 10 kg K from the soil. It has been reported by Ogunlade *et al*. (2009) that most Nigerian Cocoa farmers don't use fertilizers on their farm.

Soil fertility often deteriorates on cocoa farms (Adeniyi *et al*., 2017). Typically, cocoa trees planted on a freshly cleared forest initially benefit from high fertility due to high organic matter levels and well-developed soil structure. However, the subsequent removal of the harvested pods and beans can reduce nutrient levels (Boyer, 1973; Fassbender *et al.,* 1988; Hartemink, 2005; Thong & Ng, 1978; Van Vliet *et al.,* 2015), and soil fertility declines if they are not replenished with organic or mineral/inorganic fertilizers (Aikpokpodion, 2010; Hartemink, 2005). Degradation can also occur due to the acidification of the soil from the use of acidifying fertilizers, like urea, organic matter decay, the removal and leaching of basic cations (Goulding, 2016), and an increased availability of toxic elements (Lal *et al*., 1989). To maintain soil fertility, farmers typically apply amendments and fertilizers to replenish nutrients stocks and correct soil acidity. Few peer-reviewed studies have evaluated their effects both on cocoa productivity and soil properties, and where there is research, it often focuses on short-term effects on seedlings or young cocoa trees (Ahenkorah *et al.,* 1987; Van Vliet *et al*., 2015; Wessel, 1971). Verlière (1981) reported that only a few fertilizer experiments with cocoa had provided significant results, and there was a need to determine the interactions between shade management, cocoa nutritional needs, and productivity. Low levels of adoption of good cocoa farming practices, pest and disease attacks, ageing plantations, and poor and decreasing soil fertility contribute to poor average yields (Wessel and Quist-Wessel 2015). Whereas reported yields at farm level vary from 300–400 kg ha^{-1} (Beg *et al*. 2017; Wessel and Quist-Wessel 2015) to 700–900 kg ha^{-1} (Jagoret *et al*. 2017; Jagoret *et al*. 2018), cocoa yields can reach >3000 kg ha^{-1} (Van Vliet and Giller 2017; Yin 2004) in on-station trials.

Crop simulation models suggest that the potential yield of cocoa exceeds 4000 kg ha^{-1} (Zuidema *et al*. 2005). Poor soil fertility is considered to be an important cause of the prevailing cocoa yield gap in Africa (Van Vliet and Giller 2017). Soil fertility refers to the degree to which soils support plant growth. When forests are initially cleared for cocoa plantations, the soils are fertile and can sustain cocoa production for several years, referred to by Ruf and Zadi (1998) as the 'forest rent.' Continuous harvesting of cocoa with no additional fertilisers leads to a decline in soil fertility (Appiah *et al.* 2000; Van Vliet and Giller 2017). The decline of cocoa yields (WCF 2018) contributes to deforestation due to expansion of cocoa farming (Ruf and Zadi 1998). Maintenance and enhancement of soil fertility are essential to increase cocoa production with minimum negative environmental impact (Liniger *et al*. 2011; Vanlauwe *et al*. 2010; Vanlauwe *et al.* 2015). Several scholars cited by van Vliet and Giller (2017) have reported increased cocoa yields in response to fertilisation. For instance, in Ghana, the gross yield of fertilised plots was 61% to 116% higher compared with unfertilised plots (Appiah *et al*. 2000). During fertiliser experiments, yield response was stronger when cocoa was cultivated without shade (Van Vliet and Giller 2017). Besides mineral fertilisation, soil fertility enhancement can be achieved through the application of organic fertilisers or lime, and inclusion of legumes in the cropping system, or a combination of these (Hartemink 2006; MINADER 2018; Vos *et al*. 2003). The implementation of these practices requires farmers' recognition that declining soil fertility is a problem. Understanding the logic and rationale that underpin current farmers' management of soil fertility is essential for designing interventions to enhance yields. The paper reviewed nutritional conditions and fertility status of soils for cocoa production in Nigeria.

SOIL AND LAND REQUIREMENTS

Cocoa requires deep and well-drained soil for easy penetration of the roots. Poorly drained soil is inimical to this crop. It is predominantly grown on clay loam and sandy loam soils. It thrives well on wide range of soil types with pH ranging from 4.5-8.0 with optimum being 6.5-7.0 (CPCRI, 2006). To achieve high productivity, cocoa requires a soil abundant in nutrients (Wessel 1971). The importance of other soil characteristics, such as pH, is largely due to their influence on the availability of nutrients. Cocoa needs a soil containing coarse particles and with a reasonable quantity of nutrients, to a depth of 1.5m to allow the development of a good root system. Below that level it is desirable not to have impermeable material, so that excess water can drain away. Cocoa will withstand waterlogging for short periods, but excess water should not linger. The cocoa tree is sensitive to a lack of water, so the soil must have both water retention properties and good drainage. The chemical properties of the topsoil are most important, as the plant has a large number of roots for absorbing nutrients. Cocoa can grow in soils with a pH in the range of 5.0-7.5. It can therefore cope with both acid and alkaline soil, but excessive acidity (pH 4.0 and below) or alkalinity (pH 8.0 and above) must be avoided. Cocoa is tolerant of acid soils, provided the nutrient content is high enough. The soil should also have a high content of organic matter: 3.5% in the top 15 centimetres of soil. Soils for cocoa must have certain anionic and cationic balances. Exchangeable bases in the soil should amount to at least 35% of the total cation exchange capacity (CEC), otherwise nutritional problems are likely. The optimum total nitrogen|total phosphorus ratio should be around 1.5 (International Cocoa Organization, 2020). In Nigeria, most of the Cocoa plantations are old and less productive (Ayoola 2000). Most soils under Cocoa plantations and adaptable areas in Nigeria are marginal to moderately suitable in fertility status. Cocoa can be grown in arecanut and coconut gardens as a mixed crop. It can also be planted in forest lands by thinning and regulating the shade suitably (Hamzat, 2005; Aroyeun *et al*., 2006).

COCOA NUTRITION

Cocoa plant requires adequate nutrients for optimum production. Both macro and micro nutrients are needed. Nitrogen (N), Phosphorus (P) and Potassium (K), Magnesium (Mg), Calcium (Ca), are required in large quantities while Zinc (Zn), Copper (Cu), Boron (B), Iron (Fe), Manganese (Mn), Molybdenum (Mo), Sulphur (S) and Chlorine (Cl) are required in small quantities. Quantities of these elements in the soil and plants are determined through soil and leaf sample analysis. Nutrients application is done to replenish those that are lost. Thus, fertilizers are needed to be applied in the necessary amount. UCDA, (2019) suggested that for proper and effective use of fertilizer, both soil and cocoa leaves should be sampled and analysed once in a year to determine the present status of nutrients and pH of such cocoa plantation. This would make for proper understanding of the nutrient recycling and management of fertilizer for optimum production of cocoa. Adejobi *et al*., (2011) reported from a research carried out in Ibadan, Nigeria that the use of both chemical (NPK, Ca and Mg) and organic fertilizers significantly enhanced cocoa growth parameters, fresh, dry matter and dry cocoa bean yield.

The need to fertilize cacao (*Theobroma cacao* L.) emerged at the very beginning of the establishment of high-yielding commercial cacao plantations. Results of fertilizer trials were first published in a study conducted in Cameroon in 1910, quickly followed by Java, Trinidad and Ghana, among others (Verlière, 1981). The objective of these studies was to evaluate the effect of each nutrient supplied separately on cocoa yields. The results showed that phosphorus (P) and potassium (K) have always had positive effects on cacao yields. Although calcium (Ca) and magnesium (Mg) have also had positive effects on yields, the responses were much more variable and the quantities were dependent on the environmental condition. The variability of yield responses to nutrients pointed to the need to link the nutrients with each other or with other factors, in particular with soil, climate and topography. In the case of nitrogen (N), a significant effect on yields was rarely observed, except when the intensity of shading is reduced (Evans and Murray, 1953). There are three reasons for the contrasting effects of N (positive, neutral or negative) and its relationship to shading. First, due to the high vigor of the hybrid cacaos, the supply of nitrogen promotes vegetative growth at the expense of the production of pods (Alvim, 1977; Bastide *et al*., 2003). Consequently, the positive effect of N on yields is only visible when the yield of pods is high and nutrient requirements are consequently high, which is more frequently the case when cacao is grown without shade.

Second, since cacao is cauliflorous, the fruits grow directly on the trunk and primary branches (at the base of the tree), while leaf production is concentrated in the apical branches (at the top of the tree). As N promotes vegetative growth, cacao uses the products of photosynthesis to produce more branches at the expense of flowering and fruiting. By increasing the amount of shade over the fruiting area, N can thus have a rather negative effect on production unless shading is controlled (Wessel, 1985).Third, when nitrogen deficiency occurs in the soil, the need for N may emerge and it becomes a limiting factor for other nutrients, which is quite a common phenomenon in soils with low organic matter content (Snoeck *et al.*, 2016). However, our study also showed that when cacao is grown under shade trees, recycling of organic matter increases soil N content, which improves soil quality with age, thus reducing the need for N in older plots. Nitrogen management should therefore aim for a balance between soil poverty and shade intensity. Based on the findings that P and K are always important and most often the only nutrients required, many governments recommend only one P–K–Ca–Mg-based fertilizer formula for their countries. The same formula may even be recommended in several other countries (e.g. Côte d'Ivoire, Ghana, Togo and Cameroon). Only a few countries (particularly, Brazil and Malaysia) have more specific recommendations, where fertilizer formulas are calculated based on critical N, P and K levels in the soil (Chepote *et al.,* 2013; Ling, 1984; Malavolta, 1997). This simplification, which consists in using very few formulations or even only one for a whole country, goes against the principle of nutrient management of the soil–plant system, which is based on two observations:

Each species has unique nutritional requirements and its own mechanisms underlying soil nutrient absorption. The specific nutrient requirements of cacao were deduced from the results of many trials conducted in many countries (Jadin and Snoeck, 1985).

Each soil can only supply what it contains, and the availability of each nutrient in the soil varies with the type of soil in interaction and with the properties of the soil–root interface. In particular, pH may be a determining factor for P (retrograded forms) content and cations.

Thus, the objective of nutrition management is to correct the soil so that the cacao plant can find the nutrients it needs in optimal quantities and ratios. The fertilizer formula is determined by physical-chemical analyses of a sample of soil taken from each plot to be corrected. A plot corresponds to a map unit with the same soil and climatic conditions and homogeneous farming practices.

FERTILIZER MANAGEMENT

Nigerian soils are generally low in quite a number of essential nutrients due to various factors such as erosion, leaching, bush burning, low activity clay among others, hence, these must be provided to foster good and optimum cocoa yield. Large quantities of human, agricultural, forestry and industrial wastes are produced annually which are not being effectively utilized. However, because of increasing costs of chemical fertilizers coupled with disposal problems posed by these wastes, their use as means of maintaining organic matter level and boosting agricultural productivity has become an economic proposition. Studies have shown that ash derived from wood, cocoa pod husk, saw dust, oil palm bunch and other plant sources increased availability of nutrients in the soil and crop respectively thereby causing a significant increase in yield of food crops such as vegetables, maize, yam, cassava e .t .c (Olomilua, *et al*., 2007; Ojeniyi *et al.*, 2007; 2010; Ezekiel *et al.,* 2009b and Ayeni *et al*., 2008a).

Akanbi *et al*., (2014) reported from there trial that Oil palm bunch ash (OPA) contained Ca, Mg and other essential micro nutrients in addition to N, P, K. Similarly, its addition enhanced cocoa seedling growth, dry matter accumulation and improved the soil nutrient status. Therefore, it could be recommended as soil amendment for a depleted soil.

Ogunlade *et al*. (2004) reported a superior performance of neem leaf, its availability all year round unlike the seasonal nature of neem seed production, neem leaf can be considered for organic fertilizer amendment towards the up-grading their N contents.

Ogunlade and Adeoye (2006) reported that the fortification of cocoa pod husk with neem is a release precursor for nitrogen and correction of soil acidification, which are critical factors in soil fertility and plant nutrition evaluation in low acidity clay soils. They also report a higher soil pH of the amended soil which was probably due to supply of basic cations into the soil system by mineralization of the organic materials. Cocoa pod husk fortified or not fortified with neem seed or neem leaf and NPK gave similar values of height, number of leaves and stem diameter of cocoa seedlings. Fertilizer rates have significant effect on the growth and dry matter yield (DMY) of cocoa seedling. Both organic fertilizer and NPK applied at 10 kg N ha^{-1} significantly enhanced the height, number of leaves, stem diameter and dry matter of cocoa in Ibadan, South West Nigeria. Ipinmoroti *et al.* (2005) reported that manures were better nutrient sources than NPK fertilizers for cocoa seedlings, while formulation from urea + rock phosphate + mutilate of potash mixture was better than other NPK mixtures.

Available phosphorus in Nigeria cocoa soils is low and considered inadequate for good growth and production of cocoa, nutrient imbalance also exists. Low yield of cocoa in Nigeria can be attributed to soil fertility problems among others as clearly shown in an experiment carried out by Ogunlade and Aikpokpodion (2006). The main achievement of the third Nigerian breeding programme are the selection of 10 Nanay and 4 Parinary hybrids and the subsequent development and testing of the new CRIN varieties, all from among the Trinidad introduction population (Ojo and Sanwo, 1981). Amazon cultivars have been shown to respond very favourably to boron fertilizer and foliar applications, increasing the yield by about 30% (Ojeniyi, Egbe and Omotoso, 1981; Olaiya, 2005a). Ojeniyi (1981) reported a response to N (31-35 kg ha^{-1}) and P (36-207 kg ha^{-1}) in a N^4, P^2, K^2, B^2 fertilizer trial on 12-year Amazon cocoa. This result confirmed that phosphorus is the most limiting of all nutrient elements for cocoa production in Nigeria. The micronutrients requirements of cocoa have received considerable attention and of various micronutrients, boron, zinc and copper deficiencies have been found in both cocoa nurseries as well as in matured plantations (Olatoye *et al*., 1987). Chude and Obigbesan (1983) detected that 5 ppm B applied, as solubor, was required to raise the leaf B level of six-month-old cocoa seedlings from deficiency to sufficiency level. Foliar application of boron was also recommended to reduce cherelle wilt in old cocoa plantation (Olaiya, 2005a).

Ogunlade *et al*. (2008) reported that the soil pH of their selected site (Ikoromaja cocoa farming community), Osun State was 5.8 fell within the ideal pH range of cocoa. While available P and exchangeable K, Ca and Mg were below the critical values of 10 mg kg ha^{-1}, 0.3, 5.0 and 0.9 cmol kg ha^{-1} soil respectively required by cocoa, the nitrogen, phosphorus and potassium contents of the organic materials indicated similar nitrogen content for both neem leaf and *Chromolena odorata*. All the fertilizers used in the experiment increased dry bean yield compared with control, pod yield was highest (though not significantly) under NPK fertilizer treatment probably due to higher rate of nutrient release compared to other fertilizers (cocoa pod husk based organic fertilizer and organ mineral fertilizer). In another study it was reported that cocoa pod husk compared favourably with the inorganic fertilizer (NPK) on growth parameter such as plant height at 3 and 4 months after transplanting (MAT). This could be an indication that cocoa pod husk could serve as an alternative nutrient source for cocoa seedlings.

Soils of moribund cocoa plantation or previously cropped lands with low soil available phosphorus 16 kg P (37 kgP_20_5) ha^{-1} could be applied. The use of Sokoto rock phosphate could be beneficial for longer period on the field for tree crops such as cocoa (Iloyanomon, 2008).

A trial was conducted at the experimental plot of cocoa research institute of Nigeria Ibadan to study the comparative effect of organically sourced cocoa pod husk ash (CPHA) and urea fertilizer application on soil properties and growth performance of cocoa seedlings in 2010 where the final results of the trial indicated that 25 t ha^{-1}, 30 t $ha^{-1}$and 20 t ha^{-1} of CPHA applications increased the soil, leaf N, P, K, Ca, Mg, soil pH, organic matter and also plant height, stem diameter, number of leaves, leaf area, fresh and dry shoot weights of cocoa seedlings. It was concluded from the experiment that CPHA could serve as a good fertilizer and liming material for the cocoa seedlings (Adejobi *et al*., 2010).

Adejobi *et al.,* (2011) reported that the different combinations of organo-mineral fertilizer and cocoa pod husk ash are effective sources of organic matter, N, P, K, Mg and Ca for cocoa seedlings. Their application to soil increased growth or cocoa seedlings and uptake of nutrients. Cocoa pod husk can therefore be utilized to the maximum as organic fertilizer supplement and its combination with organo-mineral fertilizer enhance its performance to increase the growth of cocoa seedlings and nutrient uptake.

Having reviewed the beneficial effects of applying the different sources of organic and inorganic fertilizers in the cultivation of cocoa in Nigeria. Agbeniyi *et al*., (2010) reported a Lacuna on the usage of fertilizers in cocoa production where they found out from their study that majority of cocoa farmers are not using fertilizer for cocoa production in the study area. They are doing this with the view that their soil is rich enough forgetting that there is a need to replenish the lost nutrients due to pod harvest from time to time.

CONCLUSION AND RECOMMENDATIONS

They study reviewed nutritional conditions and fertility status of soils for cocoa production in Nigeria. It was revealed that Nigerian soils are moderate to marginally suitable for cocoa production and will require good management practices to obtain optimum productivity. Therefore, deficient nutrients should be supplied through the use of appropriate organic and inorganic fertilizers which has been reported to increase cocoa productivity. In another twist, majority of cocoa farmers are not using fertilizer for cocoa production in Nigeria. They are doing this with a view that their soil is rich enough forgetting that there is a need to replenish the lost nutrients due to pod harvest from time to time. Due to this problem, the following recommendations are made:

a) Farmers should be trained on the relevance of soil test to know the fertility status of their cocoa farms. This is very important in view of the fact that some farmers were claiming that their farms were fertile enough and did not require fertilizers application.

b) Government and other stakeholders should encourage the production of cocoa pod husk fertilizer in as much that cocoa farmers are ready to use it to grow their crops. Apart from the fact that the fertilizer will boost cocoa production, it will also reduce the disease infestation that is likely to result due to compilation of cocoa pod husk constituting nuisance on farms.

c) Farmers should be encouraged to improve their level of education. This is quite imperative in as much that level of education was found to have affected the use of fertilizer for cocoa production. Illiterate farmers could be encouraged to undergo adult literacy programme.

ABSTRACT
The medicinal and economic benefits of tea beverage make it the most consumed beverage worldwide. Tea production is however, limited by high light intensity which can be mitigated with shading. Therefore, a field experiment was conducted in Ibadan and Owena, southwest Nigeria to evaluate the response of tea plant to three levels of light intensity (45%-4.57x10^4lux, 65%-6.75x10^4lux and 100%-1.04x10^5lux) using different layers of palm fronds. The treatments were applied under randomized complete block design in four replicates. Data were obtained on number of leaves (NL), number of branches (NB) and leaf area (LA) as well as Nitrogen, Magnesium and Iron uptakes. Data were analyzed with Analysis of Variance at $\alpha_{0.05}$. The 45% light enhanced the highest NL, NB and LA in Ibadan and Owena; while the least values were caused by 100% light. The N, Mg and Fe contents were 43.53, 3.63 and 0.64 (mg/g), respectively under 100% light and 108.73, 9.26 and 1.77 (mg/g), respectively under 45% light at Ibadan. The highest N, Mg and Fe contents were obtained under 45% light, and the least nutrient uptake was obtained under 100% light in Owena. In conclusion, 45% light enhanced the growth and nutrient uptake of tea plant in Ibadan and Owena.
***Keywords**: Growth, Light intensity, Nutrient uptake, Tea plant*

INTRODUCTION

Consumption of tea beverage is popular in many countries of the world due to its medicinal and nutritional properties. Research has shown that tea beverage possesses powerful antioxidants which help to prevent heart diseases and cancer (Aroyeun *et al*., 2013; Pen Medicine, 2023). Besides, tea production is the economy mainstay of many countries of the world. Its cultivation has contributed to the foreign exchange and rural development of many countries (Hajiboland, 2017). Tea beverage is made from tea plant after infusion of its leaves in hot water. Tea plant (*Camellia sinensis* (L.) O. Kuntze) is cultivated in many countries. After its discovery in China in 1700BC (Oi, 2004; Famaye *et al*., 2006), its cultivation has spread to 50 countries in all the five continents of the world with major producers being China, India, Kenya, Sri Lanka, Vietnam, Turkey, Indonesia and Iran (FAO, 2014).

Light is an absolute requirement for plant growth and ultimate energy source for photosynthesis (Yue *et al*., 2021). It is the most imperative factor among all the ecological factors (Ghasemzadeh and Ghasemzadeh, 2011). Light intensity exerts direct and indirect effect on guard cells that control the opening and closing of stomata. According to Janendra *et al*. (2007), stomata conductance is affected by light intensity as its opening is sensitive to light intensity. When excessive light intensity is incident on leaf surface, it precipitates photo-inhibition; it increases leaf temperature and transpiration rate which precipitates low leaf water potential, making the guard cells to lose turgor and collapse. The collapse of the guard cells implies stomata closure which leads to poor stomata conductance and consequent blocking of CO_2 diffusion into the leaf.

Tea is a light sensitive plant. Light is one of the important abiotic factors affecting tea production around the world. Photosynthesis, respiration, transpiration, translocation of photo assimilate and development are some of the important physiological processes in *Camellia sinensis* affected by light intensity (Janendra *et al*., 2007; Too *et al.,* 2015). Various trials around the world have shown the beneficial effect of reduced light intensity for enhanced tea production (Sysoever *et al.*, 2010). Shading, either natural or artificial, has been used severally in many tea ecologies of the world to reduce light intensity for optimum tea production.

Shade reduced photo inhibition by increasing stomata conductance and thereby channeling a greater proportion of excited energy towards carboxylation when sunlight is excessive (Janendra *et al*., 2007). Mohotti and Lawlor (2002) have shown that seedlings of tea were consistently taller under shade as compared to un-shaded ones. Iremiren *et al*. (2010) reported that extra shade from erected palm fronds and plantain resulted in higher survival count of tea cuttings. However, determination of the optimum light reduction by shading that could enhance tea growth and nutrient uptake by tea plant is a challenge in southwest Nigeria. Therefore, this trial evaluated the effects of varied light intensities on the growth and nutrient uptake of tea.

MATERIALS AND METHODS

This field trial was undertaken at the experimental plots of the Cocoa Research Institute of Nigeria stations in Ibadan, Oyo State, (Latitude 07º 10' N and Longitude 03º 52' E) and Owena, Ondo State, Latitude (07º N and longitude 05º 7'E). Both locations are in the tropical rain forest belt of Southwest Nigeria. The treatments comprised three levels of light intensity, 45%, 65% and 100% lights determined by sheds of different layers of palm fronds (Adeosun *et al*., 2019) laid out in randomized complete block design with four replicates. The light intensities (lux) were predetermined using Lux meter, model LX1010BS. Each block of the experiment contained two sheds of 8 x 3 x 2 m dimension. The sheds were erected with bamboo poles and palm fronds covering the top and sides of the sheds. The 65 and 45% light intensities ($6.75x10^4$ and $4.57x10^4$ lux, respectively) were achieved with 2 and 1 palm fronds layers, respectively. The 100% light intensity ($1.04x10^5$lux) plot had no shed cover.

The experimental site was cleared of all vegetation manually. After land clearing, the plot was demarcated into four blocks. Each block was 24 m long and 3 m wide. A gap of 2 m was allowed between the blocks and between the plots in each block. Clonal materials (14 months old) of tea cultivar 143, obtained from CRIN Station in Mambilla, Taraba State were transplanted. Planting holes (20 cm long, 20 cm wide and 25 cm deep) were dug. The tea plants were planted in the dug holes at a spacing of 100 x 60 cm. For the plants inside the sheds, a space of 1 m was allowed between the shed wall and the tea plants.

At 3 MAT (months after transplanting), two tea plants per treatment per replicate were randomly tagged in each row of tea plants for data collection. Morphological parameters: number of leaves, number of branches and leaf area were measured on monthly basis. At 15 MAT, plant samples used for morphological data were uprooted. The uprooted plants were partitioned into root, stem and leaves. The roots were washed in clean water to remove soil particles. The fresh weight of the plant parts was measured. The plant parts were packaged in paper envelopes, oven dried at 70ºC for 48 hours to constant weights and their dry weights measured. Both the fresh and dry weights were measured with the KERRO Electronic Compact Scale. The dried leaf samples were assayed for determination of N, P, K, Mg and Fe in the Soil and Plant Nutrition Laboratory of CRIN following standard procedures. Data were analyzed with Analysis of Variance (ANOVA) and significant means were separated with Tukey's Honest Significant Difference (HSD) Test (P=0.05)

RESULTS AND DISCUSSION

In Ibadan, 45% light intensity increased number of leaves from 29 to 84, 65% light from 27 to 67, and 100% light from 36 to 57.; while the number leaves under 45% and 65% lights were significantly higher than that under 100% light. Similarly, at Owena, number of leaves under 45 – 100% lights increased from 3 MAT to 12 MAT. However, number of leaves under 45% and 65% lights were significantly higher than that under 100% light (Table 1). Similar trend was observed for number of branches in both locations especially at 12 MAT. However, the light intensities were not significantly different except at Owena (9 – 12 MAT) where 45 and 65% lights were significantly better than 100% light in enhancing branching in tea plants (Table 2). The different light intensities significantly influenced the leaf area of tea plants in Ibadan and Owena. In both locations, 45% light caused the highest leaf area throughout the sampling periods. At Ibadan, the highest leaf area was caused by 45% light (2885.75), followed by 65% light (1660.59) and 100% light (660.38). However, at Owena, both 45 and 65% light were not significantly different; but both engendered significantly higher leaf area than 100% light (Table 3).

The better performance of 45% light in enhancing number of leaves, number of branches and leaf area of tea plants might probably be as a result of subdued light precipitating optimal condition for photosynthesis by regulating leaf and canopy temperature (Janendra *et al*., 2007). This is in consonance with Sadgheti *et al.* (2018) who reported an increased leaf size of Sage (*Salvia officinalis* L.) under 50% light intensity, and Yue *et al*. (2021) who posited that under shade, tea plants produce large leaves. The 45% light was superior to 65 and 100% lights in enhancing nutrient uptake of tea plants (Table 4). In both locations, 45 and 65% lights were better than 100% light in enhancing the nutrient uptake. The highest N, P, K, Mg and Fe were caused by 45% light while the least were found in tea plants under

100% light. The P and K uptake at Ibadan as well as P and Fe uptake at Owena enhanced by 45% light was significantly higher (P=0.05) than that of 65 and 100% lights. The 45 and 65% lights were not significantly (P>0.05) different in enhancing N, Mg and Fe at Ibadan, and N, K, and Mg at Owena; but both were significantly (P=0.05) better than 100% light in the uptake of these nutrients. This might be because reduced lights precipitated conducive edaphic environment for easy absorption of this nutrients. This corroborates the work of Ogawa *et al.* (2010) who submitted that reduced light intensity enhanced the accumulation of amino acids in tea leaves.

CONCLUSION

Tea grown under 45 and 65% light intensities performed better than those grown in 100% light. However, the best performance was observed in tea grown under 45% light intensity. Therefore, it could be concluded that tea can be successfully grown in Ibadan and Owena, Southwest Nigeria under reduced light intensity of 45%.

SELECTION OF SUITABLE CULTIVARS FOR HIGH TUNNEL TOMATO PRODUCTION IN IWOLLO, USING RANK SUMMATION INDEX

Adinde, J. O. and Odom, I. C.
Department of Horticultural Technology, Enugu State Polytechnic Iwollo, Southeast, Nigeria

ABSTRACT
Tomato is a highly valued horticultural crop that has high nutritional and economic benefits. It's production in Iwollo, Southeast Nigeria is low. High Tunnel is a less expensive greenhouse-like structure that is used to improve tomato production. A study to determine the cultivar best suitable for high tunnel tomato production in Iwollo was carried out at the Teaching and Research Garden of the Department of Horticultural Technology, Enugu State Polytechnic, Iwollo, Southeast Nigeria. High yielding tomato cultivars viz; Roma VF, BHN-1021, Supremo, Pomodro, Money maker and Iwollo local were evaluated. Completely Randomized Design with three replications was used for the study. Data were collected on some agronomic characters of interest and were analyzed using Analysis of Variance at 5% level of probability. The characters that showed significant differences among the cultivars were ranked and summed up to get the Rank Summation Index of the cultivars. The results showed that there were significant differences (p<0.05) among the cultivars in plant height, number of leaves per plant, number of branches per plant, days to maturity, number of fruits per plant, average fruit weight and fruit weight per plant. The Rank Summation Index showed that Supremo cultivar had the best score (18) and could be selected for high tunnel tomato production in Iwollo, Southeast Nigeria.

INTRODUCTION

Tomato (*Lycopersicon esculentum* Mill.) belongs to the family *Solanaceae*. It originated in Mexico and it is widely grown all over the world as a garden or field crop (Rogers and Wszelaki, 2012). It is an important horticultural crop that is grown for both nutritional and economic benefits in Nigeria. It is palatable and succulent and used in preparing various types of dishes in Nigeria. Tomato is rich in vitamins, minerals, sugar, essential amino acids, dietary fibers and antioxidants (Enujeke, 2013). Despite the nutritional and economic benefits of tomato, production in Nigeria is low especially in South East Nigeria where yield is low due to unfavourable climatic factors that affect its yield in open field rain-fed production, among other factors. The bulk of the tomatoes consumed in the study area are from Northern Nigeria and they are expensive because of high cost of transportation and spoilage in the process.

The reliable way of controlling unfavourable environmental conditions in tomato production is through close production system. The well documented close production system in Nigeria is the use of greenhouse. However, greenhouse is very expensive making it unaffordable by most of the farmers in Southeast Nigeria. High tunnel is a greenhouse-like structure that creates micro-climate that impact biotic and abiotic factors and influences plant growth and development (Rogers and Wszelaki, 2012). It is a less expensive alternative to a true greenhouse and can be constructed with improvised material like bamboo making it even less expensive and affordable by small-holders farmers who contribute more to the production and availability of horticultural produce in the Nigerian food market. High Tunnel provides controlled environment against adverse climatic condition. It improves yield and fruit quality by reducing wind damage and injury from insects, diseases, birds, and rodents (Rogers and Wszelaki, 2012; O'Connell *et al.*, 2012; Martinez-Blanco *et al.*, 2011). Hunter *et al.*, (2012) noted that high tunnel can be used to extend growing season in tomato farming thereby increasing production.

Tomato cultivars have varied responses to environment in expression of the traits they possess. Mesbah *et al.* (2014) reported varied performance of some tomato varieties grown under high tunnel conditions. Schonbeck *et al.*, (2006) noted that decision on the choice of tomato cultivars to plant is a complex one. Warren *et al.* (2015) stated that cultivar selection remains a critical component to successful tomato production, and many important traits contribute to cultivar performance in all growing environments, including high tunnels. According to Bertini *et al.*, (2010), cultivars selection should not be based on single factor as cultivars with economic potential have multiple traits that control productive performance; adaptability and stability.

Rank Summation Index proposed by Mulamba and Mock (1978) is a widely used multiple-trait selection tool that allows superior and adaptive cultivars to be selected by combining several attributes (Coutinho *et al*., 2019). It involves ranking the performance of cultivars in respect to the desired agronomic characters and summing the ranks of several characters for each cultivar, with lower score suggesting better performance (Teixeira *et al*., 2012; Coutinho *et al*., 2019). Rank Summation Index has been applied by Okoli (2021) and Onwubiko *et al.* (2018) for the selection of superior genotypes in maize and bambara groundnut, respectively. There is dearth of information on the suitable tomato cultivars for high tunnel production in the study area; hence, evaluation of tomato cultivars with high horticultural potential for high tunnel production using Rank Summation Index that factors multiple traits became necessary to improve tomato production in Iwollo, Southeast Nigeria. The study was therefore aimed at evaluating some high yielding tomato cultivars namely; Roma VF, Supremo, Pomodro, Money maker, BHN-1021 and Iwollo local using Rank Summation Index to determine the best suitable cultivars under high tunnel conditions for improved tomato production in Iwollo, Southeast Nigeria.

MATERIALS AND METHODS

The experiment was carried out at the Research and Teaching Garden of the Department of Horticultural Technology, Enugu State Polytechnic, Iwollo, Southeast, Nigeria, located within Latitude 06016.834' N and longitude 007016.834' E. A high tunnel of 7m high by 5m wide by 9m long was constructed using bamboo sticks. The high tunnel was covered with a blue polyethylene film. High yielding tomato cultivars *viz*; Supremo, BHN-1021, Roma VF, Money maker, Pomodro and Iwollo local were used for the experiment and were sourced from the Department of Horticultural Technology, Enugu State Polytechnic, Iwollo. The experiment was carried out in a Completely Randomized Design (CRD) having three replications. The six tomato cultivars which served as treatments were randomly assigned to the experimental unit. Wooden boxes of 0.25m high, 1.5m long and 0.5m wide, each filled with top soil mixed with 1kg of poultry manure were used as growth media. Healthy tomato seedlings from the nursery for each cultivar were transplanted into the wooden boxes four weeks after sowing in a single row using a spacing of 0.5m between plants giving a total of 3 plants per box. The plants were watered as at when due. Weeding was done manually using small hoe. The plants were protected against nematodes using Carbofuran (5G) incorporated into the soil one week before transplanting. Lambda cyhalothrin was used to control insect pest while Cabendazem and Mancozeb were used to control fungal diseases.

Observations were made on number of leaves per plant, number of branches per plant, plant height, days to 50% flowering, disease severity, days to fruit maturity, number of fruits per plant, average fresh fruit weight and fresh fruit weight per plant using the procedures described by Adinde *et al.* (2016). The data collected were subjected to Analysis of Variance (ANOVA) at 5% level of probability using Genstat Release 10.3DE software (GenStat, 2011). Rank Summation Index was used to rank the cultivars for their overall performance with respect to characters that varied significantly ($p<0.05$) among the cultivars, using the Rank Summation Index model:

$Ij = \sum nij$, where Ij is the index for cultivar j and nij is the ranking number of character i for cultivar j. The cultivars were first ranked for each of the characters they showed significant difference using the mean values and the ranks were summed up to get the Rank Summation Index score for each of the cultivars.

RESULTS AND DISCUSSION

The results of the analysis of variance of some agronomic characters of the tomato cultivars evaluated showed that there were significant differences ($p<0.05$) among the cultivars in plant height, number of leaves per plant, number of branches per plant, days to fruit maturity, number of fruits per plant, average fruit weight and fruit weight per plant (Table 1). This was in agreement with Mesbah *et al.* (2014) who reported varied growth and yield performance of some tomato cultivars grown under High Tunnel. Bento (2008) also noted that tomato cultivars available today have a wide range of characteristics and observed that tomato cultivars are specifically adapted to a particular environment. There was non- significant difference among the cultivars in disease severity. This probably suggest that High Tunnel provides protection against disease by wading off insect and protecting the crop against rain splashes that aid spread of fungi disease in tomato farms. Orzolek *et al.* (2002) opined that Tomato Production under High Tunnel could provide more economic return compared to field production.

Determining the performance of the cultivars through ranking using parameters that varied significantly among the cultivars namely: plant height, number of branches per plant, number of leaves per plant, days to fruit maturity, number of fruits per plant, average fruit weight and fruit weight per plant, the results showed that the lowest Rank Summation Index value was obtained in Supremo tomato cultivar (18) followed by Money maker cultivar (22); Roma VF (25) and the highest was in Iwollo local cultivar (34) (Table 2). The lower the Rank Summation Index score the better the performance. Thus, Supremo cultivar was the best performer under High Tunnel conditions followed by Money maker and the least was Iwollo local. Supremo cultivar probably has superior multiple traits that control productive performance, adaptability and stability for high tunnel production. Clark *et al*. (1997) attributed differences in varietal performances to variations in genetic structure, mineral concentration and potentials to transport photosynthetic materials. Elings (1999) noted that crop performance is determined by the interaction between it's genetic makeup and the environment where it is grown. A cultivar can express its genetic potential under optimal environmental conditions. Supremo cultivar probably had superior productive genotype and environmental interaction under High-tunnel compared to the other cultivars evaluated.

Table 1: Mean values of some agronomic characters of the tomato cultivars

Cultivars	PHT (cm)	NLVS	Number of branches	D50% F	DS	DFM	NFRPP	AFW (g)	FWTPP (kg)
Roma VF	55.00	58.33	8.83	45.67	1.33	95.20	14.83	50.74	0.75
Supremo	67.00	58.03	7.17	44.67	2.33	68.10	8.33	119.86	1.00
BHN -1021	76.19	58.20	5.33	43.67	2.00	72.00	8.17	102.50	0.84
Iwollo local	64.10	49.50	7.33	41.00	1.33	96.00.	14.67	40.02	0.58
Pomodro	66.19	48.20	7.20	42.67	2.33	78.20	12.42	97.50	0.81
Money maker	65.20	49.80	7.54	43.00	2.00	75.10	14.92	60.20	0.77
	P<0.05	P<0.05	P<0.05	ns	Ns	P<0.05	P<0.05	P<0.05	P<0.05

P<0.05= probability value is less than 0.05. ns =non-significant. PHT=Plant height (cm); NLVS=Number of leaves; NBR=Number of branches; D50%F= Days to 50 percent flowering. DS= Disease severity; NFRPP=Number of fruits per plant; AFW= average fruit weight(kg); DFM= Days to fruit maturity and FWTPP=Fruits weight per plant (kg)

Table 2: Rank Summation Index of the tomato cultivars

Cultivar	Plant height (cm)	Number of leaves	Number of branches	Days to fruit maturity	Average fruit weight (g)	Fruit weight per plant (kg)	Rank summation index
Roma VF	6	1	1	5	2	5	25
Supremo	2	3	5	1	5	1	18
BHN-1021	1	2	6	2	6	2	21
Iwollo Local	5	5	3	6	3	6	34
Pomodro	3	6	4	4	4	3	27
Money Maker	4	4	2	3	1	4	22

CONCLUSION

The findings of the study showed that there were significant variations on some agronomic characters among the cultivars under High Tunnel conditions. Rank Summation Index of the cultivars showed that Supremo cultivar had the best score and could be best suited for high tunnel tomato production in Iwollo, Southeast Nigeria. Other cultivars especially BHN-1021 and Money maker could be considered for selection for improvement using High Tunnel Tomato Production. Further studies should consider widening the number of tomato cultivars for evaluation and study areas to develop a horticultural protocol for High Tunnel Tomato Production in Southeast Nigeria towards improving tomato production in the zone.

ABSTRACT
Field trials were conducted during 2020/2021 dry season at Research Farm of Faculty of Agriculture and Agricultural Technology, Kano University of Science and Technology Wudil (110 58'N, 80 25'E and 450m above seas level) and Institute for Agricultural Research, Kadawa (110 39'N, 80 27'E and 500m above seas level). The experiments were laid out to investigate the effect of different rates of organic manure (Poultry Manure) 4 t/ha (3.6 kg/plot), 6 t/ha (5.4 kg/plot), control (0 t/ha/plot) on growth and yield of three okra varieties (Jokoso, NHAe-47-4 and local variety yarballe). Treatments were allocated in a randomized complete block design (RCBD) in three replications. Data were collected on growth parameters (Plant height, number of leaves per plant, leave area index, seedling vigor, days to 50% flowering). Results obtained indicated that poultry manure positively influenced growth and yield of okra. Poultry manure positively increased Plant height, number of leaves per plant, leaf area index, seedling vigor, days to 50% flowering. Based on the findings of the experiments it could be deduced that poultry manure seems to promote higher growth of okra, hence, application of poultry manure of 6 t/ha and 4 t/ha significantly influenced better growth and development of okra compared to control by supplying adequate nutrients which increased its growth and development. Jokoso and NHAe47-4 were improved varieties that performed better than the local variety of yarballe in the study areas.

INTRODUCTION

Okra (*Abelmoschus esculentus* L. moench) is a fruit vegetable belonging to the family malvaceae. (Awurum and korie, 2011). It is an important vegetable cultivated in the tropical and subtropical region of the world. It can be found in almost every market in Africa (Schippers 2000). It is a good source of minerals, calories and amino acid found in seeds and compared favorably with those in poultry, egg and soybean. (Thompson 1949; and scippers, 2000). The crop is used as soup thickener which may also be served with rice and other food types (Eke *et al*, 2008). Okra is a perennial often cultivated as annual in temperate climates and often grows to around 2 m tall. It is related to such species as cotton, cocoa and hibiscus. The leaves are 10 cm -20 cm long and broad, palmately lobed with 5-7 lobes. The flowers are 4-8 cm in diameter, with a red or purple spot at the base of each petal. The fruit is a capsule up to 18 cm long with pentagonal cross-section containing numerous seed. Abelmoschus esculentus is cultivated throughout the tropical and warm temperature of the world for it fibrous fruits or pods containing round white seeds, it is among the most heat and drought-tolerant. It is now widely distributed in the tropics including Nigeria. It is an important vegetable crop occupying a land area of 277,000 hectares with a production of 731,000 metric tons worldwide and productivity of 2.63 t ha-1 in Nigeria.

Use of organic manures as a means of maintaining and increasing soil fertility has been advocated (Rodale, 1984; Smil, 2000). Poultry manures, when efficiently and effectively used, ensure sustainable crop productivity by immobilizing nutrients that are susceptible to leaching. Poultry manure is an excellent organic fertilizer, as it contains high nitrogen, phosphorus, potassium and other essential nutrients (Oyewole and Oyewole, 2011). Nutrients contained in manures are released more slowly and are stored for a longer time in the soil ensuring longer residual effects, improved root development and higher crop yields (Sharma and Mittra, 1991; Abou El Magd *et al.*, 2006). Manures are usually applied at higher rates, relative to inorganic fertilizers. When applied at high rates, they give residual effects on the growth and yield of succeeding crops (Makinde and Ayoola, 2008) Improvements of environmental conditions as well as the need to reduce cost of fertilizing crops are reasons for advocating use of organic materials (Bayu *et al*., 2006). Organic manures improve soil fertility by activating soil microbial biomass (Ayuso et al., 2008). Application of manures sustains cropping system through better nutrient recycling (El-Shakweer *et al*., 2009). Manures provide a source of all necessary macro- and micro-nutrients in available forms, thereby improving the physical and biological properties of the soil (Abou El-Magd *et al*., 2006). Chemical fertilizer could cause problems not only to the soil health but also to the human health and physical environment.

In spite of the potential of okra as a food security vegetable crop, yields are generally low in the tropics due to growing population and attendant pressure on land resulting in more intensive agriculture and declining soil fertility (Mbagwu and Skwealor 2006). The scarcity of inorganic fertilizer associated with high cost has created a lot of problem in arable crop production in Nigeria. In the past, farm yard manure has been used to improve and supplement soil nutrient (Adeyele *et al* 2010). This research was conducted to assess the effect of poultry manure on growth parameters of okra.

MATERIALS AND METHODS

Study Area

Field trials were conducted at Research Farm of Faculty of Agriculture and Agricultural Technology, Kano University of Science and Technology Wudil (110 58'N, 80 25'E and 450m above seas level) and institute for Agricultural Research, Kadawa (110 39'N, 80 27'E and 500m above seas level).

Treatment and experimental design

The experiments were laid out in a randomized complete block design (RCBD) with nine treatments combination and replicated three times. The treatments were three levels of poultry manure 4 t/ha (3.6 kg/plot) and 6 t/ha (5.4 kg/plot), control 0 t/ha and three varieties of okra (Jokoso, NHAe47-4 and local variety yarballe.

Experimental Materials

Three (3) varieties of okra (Jokoso, NHAe47-4 and local variety yarballe obtained from Department of Agronomy, Faculty of Agric., ABU Zaria was used to determine their response to different levels of poultry manure i.e 3.4 kg/plot (4 t/ha), 5.4 kg/plot (6 t/ha) and control (0 t/ha). Ploughing and harrowing was done to obtain a fine tilth soil and ridges of 75 cm apart was made. Three seeds of okra per hole was sown with inter and intra row spacing of 75 cm × 25 cm respectively. Organic fertilizer application was done two weeks before planting using drilling method at the rate of 3.6 kg and 5.4 kg where by the ridges was drilled open at the centre and the organic manure applied based on the experimental rate and covered with soil. Weeding was carried out three times, at three (3) and six (6) weeks after planting using hoe and one supplementary hand weeding. Fruits were harvested after its maturity by cutting off the fresh fruit with knife from the plant, harvesting was done at the interval of four days.

Data Collection

Data were collected for the following parameters

Plant Height (cm), Number of Leaves, Number of Days to 50% Flowering, Number of Days to maturity, Leaf Area (cm2), Number of Fruit/Plant, Fruit Length (cm), Fruit Diameter (cm), Number of Flowers per Plant and fruit yield (kg/ha)

Data Analysis

Data recorded were subjected to analysis of variance (ANOVA) using GENSTAT (17 edition), the treatment means that were significantly different were compared using fisher's LSD

RESULTS AND DISCUSSION

Plant Height

The effect of rate of organic fertilizer on plant height of okra varieties at Wudil and Kadawa during 2021 dry season is presented in table 1. The result shows that Plant height was significantly ($P<0.05$) affected by different rate of poultry organic manure in both locations across 3, 6 and 9 weeks. At Wudil 6 t/ha and 4 t/ha were significantly the same and produced the tallest plants across the period of sampling compared to control. Likewise, at Kadawa the same trend was observed at 3, 6 and 9 wap. The positive effect of organic manure on plant height could be due to the contribution made by manure to fertility status of the soils. Manure when decomposed increases both macro and micro nutrients as well as enhances the physico-chemical properties of the soil. This could have led to its high vegetative growth. Aniefiok et al. (2013) agrees with this finding in which they reported that organic manure, especially poultry droppings could increase plant height and number of leaves. Also from the Table 1, it was observed that the effect of poultry manure rate significantly affected the variety of okra with improved varieties of Jokoso and NHAe47-4 having significantly (P≥0.05) similar performance across 3 and 9 wap performed better than the local variety of yarballe, while there was no significant difference at 3wap among the varieties tested. The reason for this might be that the yield potential of these varieties were genetically improved since genetic makeup of an individual affects its performance generally, report from IAR (1985) indicated that plant height of okra is genetically determined. The interaction of variety and poultry manure rates was not significant (P≥0.05) in both locations.

Number of Leaves

The effect of rate of organic fertilizer on number of leaves of okra varieties at Wudil and Kadawa during 2021 dry season is presented in table 2. The poultry manure rates at Wudil location significantly (P≥0.05) affected number of leaves of okra at 6 wap only where 6 t/ha and 4 t/ha have statistically the highest number of leaves compared with control treatment while at Kadawa there were significant difference (P≥0.05) among the poultry rates at 6 and 9 wap only where 6 t/ha and 4 t/ha were statistically the same and have the highest mean values compared to control rates that possess the lowest mean values. This may be attributed to the increase rate of poultry manure which resulted in a corresponding increase in both vegetative traits in okra compared to control, this indicates that an increase in nitrogen promotes vigorous plant growth. The increase in number of leaves per plant with organic fertilizer application stressed its importance during the vegetative growth of crop plants (Tindall, 1992). This agrees with the study of John et al. (2004) who reported that poultry manure contains essential nutrients which are associated with high photosynthetic activities that promote root and vegetable growth. This agrees with the work of Dauda et al. (2008). Table 2 also shows that varieties of okra significantly influenced (P≥0.05) number of leaves across the two locations, at Wudil, there was no significant difference between varieties at 3wap, but significant difference (P≥0.05) at 6 and 9wap with improved variety Jokoso having the highest number of leaves compared to local variety of Yarballe that possessed the least number of leaves. While at Kadawa there were also no significant difference at 3wap, but significant difference existed at 6 and 9wap where the two improved varieties (Jokoso and NHAe47-4.) possessed the highest mean values of number of leaves and are statistically similar compared to local variety of Yarballe that possessed the lowest number of leaves. Significant difference (P≥0.05) does not exist between the interaction of variety and poultry manure rates in both locations.

Days to 50% Flowering, Leaf Area Index and Seedling Vigor

The effect of rate of organic fertilizer on Days to 50% flowering, leaf area index and seedling vigor of okra varieties at Wudil and Kadawa during 2021 dry season are presented in Table 3. Days to 50% flowering of okra was significantly affected by different rate of poultry manure across the locations, at Wudil, application of 6 t/ha of poultry manure exhibited the earliest date to flowering compared to the 4 t/ha and control application that were statistically the same and produced the longest date to flowering. Also, Application of 6 t/ha of poultry manure at Kadawa exhibited the earliest date to flowering compared to control that delayed the flowering period. Earlier production of flower and fruit may be due to excellent release of macro and micro-nutrients from the poultry manure. This finding agrees with Garge and Bahla (2008) who reported that poultry manure readily supply phosphorous to plants than other organic sources. Also similar observation was made by Tu et al. (2006) and Ayuso et al., (2008) that microbial biomass and activities were higher in organically managed soils compared to conventional soil amendment with synthetic inorganic fertilizer.

There were significant influences among the varieties on the date to 50% flowering at both locations. At Wudil, Jokoso and NHAe47-4 were found to be statistically the same and exhibited the least days to 50% flowering compared to local variety of yarballe that had a prolong days to 50% flowering. While at Bagauda, Jokoso variety possessed the least days to 50% flowering compared to local variety of yarballe that bear the longest days to 50% flowering. There was no interaction between variety and poultry manure rates that was significant (P≥0.05) in both locations. The result of this study as presented in table 3 revealed that there was significant difference (P≥0.05) among the different rates of poultry manure applied with regard to leaf area index at both locations, at Wudil. The rates of 6 t/ha and 4 t/ha were statistically similar and produced the highest leaf area index compared to the control that produced the lowest leaf area index. While at Kadawa, the rate of 6 t/ha influence the highest leaf area index compared to control rate that has the lowest leaf area index. There was no significant difference among the varieties tested across the locations. The interaction of variety and poultry manure rates was not significant (P≥0.05) in both locations.

Table 3 also indicated that seedling vigor was significantly affected (P≥0.05) by different rates of poultry manure at both locations. The rates of 6 t/ha and 4 t/ha were statistically similar and were found to possessed the highest seedling vigor compared to control treatment which possessed the lowest seedling vigor This could also be related to low C:N ratio, lignin and lignin/N values These attributes of poultry manure will lead to fast mineralization and early release of nutrients to a short gestation crop like okra, hence there was a boost in the morphological growth of the plant which translate to greater yield (Aruna O. A. *et. al,* 2020). There was no any significant difference among the varieties tested across the locations also the interaction of variety and poultry manure rates was not significant (P≥0.05) in both locations.

CONCLUSION

Based on the finding from this study, it can be concluded that application of poultry manure at 6 t/ha and 4 t/ha significantly influenced better growth and development of okra compared to control by supplying adequate nutrients which increased its growth and development. Jokoso and NHAe47-4 were improved varieties that performed better than the local variety of yarballe in the study areas.

ABSTRACT
The constraints of cashew farmers in the production of cashew were analysed in this study. Data were collected using a well-structured questionnaire administered to sixty (60) respondents selected through a multi-stage sampling techniques. The data collected were analyzed with descriptive statistics and multiple linear regression. The result revealed that the age of cashew farmers and the cost of weeding significantly (P<0.05) affect cashew production positively while household size and cost of chemicals (P<0.05) have a negative effect on cashew production. Also, all the respondents (100%) in the study area ranked inadequate credit (finance) and unstable price of produce as the most severe constraints. Incentives such as soft loan should be provided for cashew farmers to alleviate the constraints of inadequate credit in order to increase their level of income which will thereby promote cashew production.

INTRODUCTION

Cashew is one of the most important agricultural commodities in Africa. It has contributed to Gross Domestic Product (GDP), National Income (NI) and foreign exchange earning of many cashew producing States in Africa (Oluyole et al, 2015). The studies at Cocoa Research Institute of Nigeria (CRIN) have created the capabilities of exploiting the apple to produce juice, wine, vinegar, jam and so on while whole cashew kernels when roasted plain or salted are eaten up as desert fruit. However, cashew kernels grounded are mixed with cocoa to produce cashew chocolate and the cracked ones are made into cashew butter (Olunloyo, 1999). Most of the constraints militating against cashew production results from damages from different stages of production thereby leading to high loss of yield. Therefore, considering the effects the various constraints are having on farmers' productivity, it is quite imperative that this study which investigates the constraints in cashew production among cashew farmers in the study area is carried out.

Cashew production in Nigeria, most especially in Oyo State are faced with many constraints. Akinwale and Ayodele (1999) identified some constraints of cashew production as land acquisition (about 60% of Nigeria cashew nut production are small-scale farmers who used between 2-4ha of cashew farm), unavailability of labour, lack of processing technology, high cost of production, unstable market system, high interest rate, low funding, inadequate infrastructural facilities such as rural roads, electricity, water supply and poor exit services. Inadequate availability of good planting material and prevalence of Powdery Mildew Disease (PMD) are also major constraints to cashew production. Although recent studies by Oluyole et al (2015) have identified various constraints militating against cashew production which varies from one place to the other in Southwestern Nigeria, it is necessary to carry out similar study in Oriire and Surulere local government areas to corroborate existing research findings. This necessitates this research work on the constraints of cashew production among farmers in Oyo State.

The main objectives of the study are to:

(i) describe the socio-economic characteristics of cashew farmers in the study area;
(ii) examine the farm inputs affecting cashew production in the study area;
(iii) analyze the constraints affecting cashew production in the study area; and

MATERIALS AND METHODS

Sampling Procedures or Techniques

Multi-stage sampling procedure was used to sample the respondents from the agricultural zones in Oyo state. Oyo state has four (4) agricultural zones, namely Ibadan/Ibarapa zone, Oyo zone, Ogbomoso zone and Saki zone. In the first stage, Ogbomoso zone was purposively selected based on the intensity of cashew production. The second stage involved purposive selection of two local government areas (Surulere and Oriire) from Ogbomoso zone. The last stage involved the random selection of thirty cashew farmers from each of the local government areas giving a total of sixty (60) respondents that was used for the study. Well-structured questionnaires were administered to the respondents in the study area. Data collected were analysed with descriptive statistics and multiple linear regression.

Method of Data Analysis

Multiple Linear Regression

The multiple linear regression model for the factors affecting cashew production are presented in equation (1). The result of the analysis is shown in Table 2. Also, Thusyanthini et al (2019) used multiple linear regression to achieve the objectives of the factors affecting cashew production.

$Yi = \beta o + \beta 1x1i + \beta 2x2i + \dots\dots\dots + \beta nxni + ei$ ……………………………… (1)

Where: Yi = Total cashew output of the farmer in kilogram per hectare (kg/ha)

β1 to βn = coefficients relating the n explanatory variables to the variables of interest

X1 = Age of cashew farmers, X2 = Years of farming experience

X3 = Level of education, X4 = Household size, β0 = Constant term

X5 = Farm size, X6 = Cost of weeding, X7 = Cost of chemical

ei = Random error which are assumed to be independently and identically distributed.

RESULTS AND DISCUSSION

Table 1 below shows the socio economic characteristics of the cashew farmers in the study area. The results revealed that 68.30% which constitute the majority are male cashew farmers with females being 31.70%. This corroborate with what was reported by Uwagboe et al. (2010) that there is male dominance in cashew farming in Oyo State probably because females were allowed to cultivate arable crops on their husband's farm plots while access to permanent crop production is usually restricted to men (Abubakar, 2003). Majority of them (36.70%) have primary education while 15.00% were university graduates indicating that the farmers are fairly educated which would enhance their farming activities and level of awareness of new technology as well as the ability to quickly adopt new technology. Further analysis shows that the mean age of the farmers was 56 years and its standard deviation was 12.24, this implied that cashew farming is being practiced by middle age farmers who are still strong to carry out farming activities. The mean year of cashew farming experience was at 26 years and its standard deviation was 12.02. Most (96.70%) of the farmers were married. This indicates a higher chance of involving family labour in cashew production. The mean household size is at 8.00 while its standard deviation was 3.49. Most (97.00%) of the farmers have between 1 - 10 hectares or more of cashew farm size while 3.30% of the farmers have less than 1 hectare of cashew farm size and its mean is 4.00.

Table 1: Socio-economic characteristics of cashew farmers in Oyo State

Variables	Frequency	Percentage (%)	Mean	Standard Deviation
Gender				
Male	41	68.30		
Female	19	31.70

Source: Field survey, 2022

The results presented in table 2 shows the various constraints affecting cashew production in the study area. The result analysis shows that the coefficient of determination - R2 is 0.9734 which indicated that 97.34% of the variation in the dependent variable is explained by the independent variables included in the model. The result further shows an F- statistical value which is significant at 1% level. This indicates that the model used for the analysis is of a good fit. Also, the result in table 2 shows that the age of the farmers, household size and the cost of weeding are significant at 5% level of probability. These are critical variables affecting cashew production. Age of the cashew farmers has a positive effect indicating that the mean age of the farmers (56 years) has a positive effect on cashew production. Household size has an inverse relationship with cashew production, this is however against the a priori expectation, however, this could be as a result of the fact that majority in the household are juvenile who cannot be used for labour work on the cashew farm. Furthermore, the cost of weeding has a direct impact on the production of cashew showing that the more cost incurred on weeding the better the cashew production. Cost of chemicals was found to have an inverse relationship with cashew production indicating that a unit increase in the cost of chemical will give a corresponding decrease of 22% in cashew production.

Table 2: Farm Inputs affecting cashew production in Oyo State

Farm Inputs	Coefficient	Standard Error	T	P>|t|	[95% Confidence	Interval]
Age	25.162	8.112	3.100	0.021**	5.313	45.011
Years of farming experience	-2.121	8.086	-0.260	0.802	-21.906	17.663

Cost of chemical	-0.220	0.094	-2.340	0.058***	-0.450	0.010

R^2 = 97.34 Prob > F = 0.0003

Note: *, ** and *** denote t-test significant at 1%, 5% and 10% levels respectively.

Source: Field Survey, 2022

Constraints experienced by cashew farmers

Table 3 reveals that all the respondents ranked inadequate credit and unstable price of produce as the most severe constraints while land tenure problem and inadequate rainfall were ranked as the least constraints (60%). This implies that cashew farmers in the study area find it difficult to obtain loan from banks due to collateral needed to enhance increase in their cashew production which would increase their level of income. This finding is in consonance with Uwagboe et al (2010) study which revealed that inadequate capital was ranked the most severe constraints faced by cashew farmers in Oyo State. Land tenure problem and inadequate rainfall are seen to be the least constraints due to the fact that land could easily be accessible by the cashew farmers. Also, cashew is drought tolerant so rainfall may not be a major constraint.

Table 3: Constraints Faced by Cashew Farmers in Oyo State

Constraints	Frequency	Percentages	Ranking (%)
Inadequate credit	60	100.00	1
Unstable price of produce	60	100.00	2
High cost of labour	57	95.00	3
Lack of improved planting materials	55	91.70	4
Skill acquisition	54	90.00	5
Difficulty in accessing extension services	52	86.70	6
High cost of transportation	51	85.00	7
Poor road network	48	80.00	8
High cost of fertilizer	38	63.30	9
Land tenure problems	36	60.00	10
Inadequate rainfall	36	60.00	11

Source: Field survey, 2022

CONCLUSION AND RECOMMENDATION

This study concludes that the major constraints affecting cashew production are age of the cashew farmers, household size of the farmers, cost of weeding as well as the cost of chemicals. Inadequate access to credit facilities and unstable price of cashew are also major constraints to cashew production in the study area. It is recommended that government should provide loan to the cashew farmers to enable them to acquire the necessary farm inputs in order to alleviate the constraints of inadequate credit (finance).

ABSTRACT
This research investigates consumers' perception and preference for dried pineapple slices as a value-added agricultural product. Drying fruits, including pineapples, is a popular preservation method that enhances shelf-life and nutritional value. Understanding consumers' perceptions and preferences regarding dried pineapple slices can provide valuable insights for producers, marketers, and policymakers in the agricultural sector. The study utilizes a combination of quantitative surveys and qualitative interviews to explore factors influencing consumers' attitudes towards the product, such as colour, texture, aroma and general appearance, which were found to significantly affect consumers' preference, suggesting improving sensory attributes could increase consumer acceptance. A survey of 60 consumers found 68.3% preferred dried to fresh pineapple. Over 85% felt drying could reduce perishability and off-season scarcity. Respondents perceived dried pineapple as nutritious and were willing to purchase it off-season. Dried pineapple chips have good market potential. The study recommends further research on processing perishable fruits to enhance shelf life and meet consumer demand. In summary, drying pineapples into slices could curb postharvest losses, satisfy consumer preferences, and provide off-season availability through superior texture, color, aroma and appearance.
Keywords*: Dried pineapple slices, Fruits, Consumers' perception, Food preference, Preservation.*

INTRODUCTION

Pineapple, a tropical fruit, has been identified as the third most valuable fruit globally, following bananas and citruses such as grapefruit, limes, lemons, and oranges (Olayinka, 2013 and Esiobu *et al*., 2014). In Nigeria, pineapple farming is a significant source of income for a considerable number of farmers. However, Nigeria's pineapple production is relatively low compared to other producing countries, with a productivity rate of 7.9 tons/ha (Adegbite and Adeoye, 2015). Pineapple, apart from being a delicious fruit with an excellent flavor, is a rich source of dietary fiber, vitamins A, B, B6, C, E, and sugar (15%) (Portia *et al*., 2017; Iwuchukwu *et al*., 2017; Enibe *et al*., 2018). Nigeria ranks seventh globally as a pineapple producer, accounting for 1.42 million metric tons or 5.8% of the world's output at 7,778T/ha (Akhilomen *et al*., 2015).

Pineapple is regarded as an excellent source of vitamins A, B, C, along with calcium, magnesium, potassium, and iron. Additionally, it is a valuable source of bromelin, a digestive enzyme. Pineapple can be consumed either fresh or in the form of juice, jam, squash, saturated fats, and cholesterol, all while providing a rich source of fiber (Wilcox *et al*., 2015). According to Hossain (2016), pineapple production is carried out on more than 2.1 million acres in over 82 countries worldwide, including Thailand, Brazil, Costa Rica, India, Nigeria, Kenya, Indonesia, Mexico, Hawaii, Philippines, Australia, South Africa, Puerto Rico, Cuba, and Formosa. Among these countries, Nigeria ranks seventh globally and first in Africa in pineapple production. Enibe *et al*. (2018) conducted a study on pineapple marketing in Anambra State and found it to be profitable, recommending its exploration by potential traders and entrepreneurs. Iwuchukwu *et al*. (2017) investigated the problems and prospects associated with pineapple production in Enugu State. However, there still exist research gaps on the crop that warrant further investigation.

The marketing of pineapples is primarily distinguished by the challenge of perishability, among other factors. In many instances, marketers find themselves obligated, if not coerced, to sell their produce at a significantly reduced price in order to prevent substantial wastage or complete loss, thereby diminishing their marketing margins and efficacy (Ugwu, 2018). A comprehensive examination of the National Health and Nutrition Examination Survey (NHANES) in the United States has revealed that the consumption of dried fruits has been linked with increased intake of essential but under-consumed nutrients, heightened overall energy intake, and enhanced diet quality among adults. This finding suggests that dried fruits can potentially aid in the fulfillment of nutritional requirements and the promotion of overall dietary health. In light of this, the present study aims to conduct a consumers' preference for pineapple chips as this may be a way to reduce the post-harvest losses incurred by the farmers during the period when the fruit is in season and also create for an avenue to have the fruit available even during the off-season of the fruit.

MATERIALS AND METHODS

Study Area

The study area was Ibadan North West Local Government area of Oyo state. Ibadan North West has an average population of 153,000 people according to the 2006 National Population Census. The major occupation of the people is trading where two-third of the population are engaged while others are engaged in public service like teaching, manufacturing, publishing, etc.

Sampling Procedure and Sample Size

A two-stage sampling technique was used to select the respondents for this study. The first stage of the sampling involved a purposive selection of Ibadan-North East Local government of Oyo state because there was a training program at the National Horticultural Research Institue which had in attendance 80 trainees, from which there was a random selection of 60 pineapple consumers.

Methods of Data Analysis

Descriptive statistics was used to analyze the socio-economic characteristics of the respondents and to know consumers' preference and perception of dried Pineapple slices. Probit regression analysis was used to analyze the factors that determine the consumers' preference for the dried pineapple chips.

RESULTS AND DISCUSSION

This section presents the findings of the research. It describes the socio-economic characteristics of the respondents, their preference, perception and factors that determine their preference for dried Pineapple slices.

Table 1: Socio-economic characteristics of the respondents.

Variables	Category	Frequency	Percentage	Mean
Gender	Male	19	31.7	
	Female	41	68.3	
Marital status	Single	15	25.0	
	Married	42	70.0	
	Divorced	1	1.7	
	Widow	2	3.3	
Age	≤ 30	9	15.0	
	31-40	19	31.6	44
	41-50	13	21.7	
	51-60	16	26.7	
	> 60	3	5.0	
Household size	1-6	48	80.0	
	7-12	10	16.7	6
	≥13	2	3.3	
Education level	No formal education	2	3.3	
	Secondary education	11	18.3	
	Tertiary education	47	78.3	

Source: Field survey, 2023

The result revealed that most of the respondents were female (68.3%), married (70%), and of age group 31-40 years (31.6%). The mean age of the respondent was 44 which signifies that they are in active age group and may be willing to try a new product. The study by Hettich *et al*. (2019) which stated that older consumers tend to resist innovation due to reduced product-related information processing was however not in line with this finding. The household has a mean size of 6 persons. Majority of the respondents had tertiary education level (78.3%) which could be of a great factor to their preference for dried pineapple chips.

Table 2: Consumers' preference for dried pineapple slices

Prefer processed to fresh	Frequency	Percentage
No	19	31.7
Yes	41	68.3
Total	60	100.0

Source: Field survey, 2023

Majority of the respondents (68.3%) preferred dried pineapple slices to the fresh. This is a good indicator as more consumers preferred dried pineapple slices which has a great potential of being acceptable and surviving in the market, especially during the off-season production and thus create market for value addition actors in pineapple production chain.

Table 3: Consumers' perception for the dried Pineapple chips

Respondents' Perception	**Yes (percentage)**	**No (percentage)**
Reduce perishability Problem	86.7	13.3
Reduce scarcity problem during off-season	90.0	10.0
Will buy during off-season	86.7	13.3
Dried pineapple is nutritious than fresh pineapple	45.0	55.0

Source: Field survey, 2023

The results showed that respondents' perception in reducing perishability during production season and scarcity problem during off-season had higher percentage of 86.7 and 90.0 respectively, which revealed that the respondents believed that the problem of pineapple perishability will reduce through processing into dried slices, thus reduce post-harvest losses and be made available and accessible to consumers all year round. 86.7% of the respondents would be willing to buy dried pineapple chips during the off-season if available and finally, 45.0% of the respondents recorded that dried pineapple slices is nutritious than the fresh which is an indicator of consumers' positive review in the value addition of pineapple into dried slices.

Table 4: Factors that determined the Consumers' preference for dried Pineapple slices

Consumers' pref.	Coef.	Std. Err.	z	P>z	[95% Conf.	Interval]

Prob > chi^2 = 0.2028
Pseudo R^2 = 0.1787
Log likelihood = -30.765758

An examination of the regression analysis yields various significant findings concerning the determinants that impact consumer preferences. The demographic factors such as gender, marital status, age, and educational attainment did not exhibit a substantial correlation with preferences in this particular sample, as the p-values for these coefficients were all greater than 0.05. Additionally, the frequency of product consumption did not emerge as a significant predictor in the model. Nevertheless, numerous sensory and aesthetic attributes of the products displayed noteworthy associations with overall consumer preferences. Notably, taste preferences displayed a positive correlation with preferences at the $p<0.15$ level, implying that taste strongly influences preference. Furthermore, texture exhibited a highly significant positive association with preference ($p=0.049$), indicating that consumers tend to favor products with smoother, finer textures. The relationship between aroma and preference was found to be positive and marginally significant at a significance level of $p<0.10$. This suggests that consumers have a tendency to prefer products that possess more alluring scents and fragrances. On the other hand, color showed a negative association with preferences, indicating that consumers have a preference for options with lighter hues. Additionally, the coefficient for general appearance was negative, implying that consumers have a preference for products that have a visually pleasing appearance. These sensory factors, such as texture, aroma, color, and appearance, appear to have a stronger influence on consumer preferences compared to demographic factors in this particular sample. Notably, taste and texture emerge as attributes that could significantly enhance preferences. Consequently, the marketer should concentrate on emphasizing the texture, fragrance, taste, and aesthetic appeal of the products in order to better cater to consumer preferences. By enhancing these sensory and visual elements, there is the potential to increase the favorability of the product.

CONCLUSION

Finding reveals that consumers' preference for dried pineapple slices is high and their perception about the problem of pineapple slices ability to address a problem of perishability and scarcity are also high. 86.7% of the respondents will buy dried pineapple slices during off season if made available. A probit regression analysis of the preference determining factors indicates that color, texture, aroma and general appearance influence consumers' preference for the dried pineapple slices. Further improvement on these attributes will increase its attractiveness to the consumers.

RECOMMENDATION

Based on empirical findings of this study, it is recommended that further studies should be conducted on value addition on other perishable fruits and vegetables in order to increase their shelf life and acceptability by consumers.

ABSTRACT
Field experiment was conducted during 2019/2020 rainy season at the Teaching and Research Farm of the Federal University of Agriculture, Zuru (Lat, 11^0 35'N; Long, 4^0 45' E;) 394 meters above sea level. The study aimed to determined appropriate plant population density on and yield components of two coleus potato land races in study area. Factorial combination of four intra-row spacings (15, 20, 45, and 60 cm), giving rise to 89,285, 66,666, 29,673 and 22,222 plants/ha^{-1} respectively) and two land races of Coleus Potato (ex-Zuru Black and ex-Zuru Brown respectively) Treatments were laid out in a randomized complete block design (RCBD) replicated three times. The results showed that land race Ex-Zuru Black recoded highest yield and yield components than Ex-Zuru Brown. On the other hand widest population density of 60cm x75cm recorded highest mean tuber number per stand, tuber diameter, tuber weight, tuber weight per stand, marketable yield, and unmarketable yield and yield ha^{-1} than the other plant population densities. The study therefore concludes by recommending 60cmx70cm population density and variety Ex-Zuru Black for higher yield.
Keywords- *Population Density, Coleus Potato land races, Ex- Zuru Black, Ex-Zuru Brown*

INTRODUCTION

Coleus Potato (*Coleus rotundifolius* P.), closely related to the Coleus plants widely cultivated as ornamentals and is now again placed in the genus *Coleus*, after being placed in the defunct genus *Solenostemon* and in *Plectranthus*. (Paton *et al.*, 2019). Coleus Potato, popularly known as *Hausa Potato, Tumuku or Somo (C'Lela)* is a tropical, multipurpose minor tuber crop. It has been reported to be one of the best staple tuber crops in terms of its distinctive fragrance, peculiar taste, medicinal, nutritional and economic values (Namena *et al.,* 2009). The crop is a perennial herbaceous plant of the mint family (Lamiaceae) native to tropical Africa [National Research Council (NRC, 1983)]. Coleus Potato is cultivated for its edible tubers primarily in West Africa as well as more recently in parts of Asia, especially India, Sri lanka, Malaysia and Indonesia *(Blanch, 2006)*. Although it is not widely cultivated as food crop in Africa. However, it is still popular in Nigeria especially on Jos Plateau, Kaduna, Borno and Adamawa States (Aniedu and Agugo, 2010). The plant is a perennial herb with prostrate or ascending habits and can grow as tall as 30 cm. The distinctive fragrant or pungent aroma is due to volatile oils contained in the glands or sacs found in the leaves and other parts. The stem is succulent and it has thick leaves with serrated margins (Enyiukwu *et al.,* 2011). Coleus Potato is one of the tuber crops grown in the guinea savanna region of Nigeria especially in Jos Plateau, Kaduna, Borno and Adamawa States (Aniedu and Agugo, 2010).

Coleus Potato is grown by smallholder farmers, most especially women. It is regarded as food security crop because of its ability to provide a higher yield per unit area. Its production could be extended to other agro -ecological zones ranging from forest to the northern guinea savanna regions, thereby contributing sources of income, food security, solving malnutrition problem and diversification of the local food base and sustaining livelihoods. Information on the economic importance and agronomic practices of Coleus Potato is limited and has suffered research neglect for several years (Enyiukwu *et al*., 2014). Concerted efforts of conserving, documenting and promoting the dynamic use of Coleus Potato is now required (Olojede *et al.,* 2005). Evidently, agronomic researches on Coleus Potato are scanty and more are needed before any meaningful advancement of the crop can be made. Although there are coordinated efforts by the National Root Crops Research Institute (NRCRI), Nigeria, to improve the cultural and agronomic production, therefore more research is required in multiple locations and with different experimental treatments. Despite the important benefits of Coleus Potato, average yield in

Nigeria is relatively low (3-5 t/ha^{-1}) compared to Ghana (10 t/ha) and South Africa (19 t/ha^{-1}) (Nkansah, 2004).

The reason for low yield in Nigeria has been attributed to research neglect as the crop is often considered among the neglected tropical crops, low yielding varieties and poor agronomic practices such as nutrients supplies, spacing (Akinpelu *et al.*, 2011). Coleus Potato production could be increased by improving the inherent genetic potential of the crop coupled with adoption of better agronomic management, such as use of optimum plant population density. Most farmers that grow Coleus Potato give less regard to optimal plant population density and fertilizer application (Bayorbor and Gumah, 2007; Akinpelu *et al*. 2011). Farmers in Nigeria most often use spacing below the recommendation and sometimes under dose or over dose the crop with nutrients. Inappropriate plants density affects growth and yield because of competition among plants for growth resources. The most common population density for Coleus Potato in Nigeria ranges from 33,333 - 66,000 plants per hectare (NRC, 2006; Ogedebe *et al.* 2015). Adequate population density and soil fertility influence dry matter production, leaf area index and increase yield (Carl, 2003). The study aimed to determined appropriate plant population density on yield and yield components of two coleus potato land races and to recommend the best plant population density and coleus potato land race for higher yield in the study area.

MATERIALS AND METHODS

Field experiment was conducted during 2019/2020 rainy season at the Teaching and Research Farm of the Federal University of Agriculture, Zuru (Lat, 11^0 35'N; Long, 4^0 45' E; 394 meters above sea level (masl) in the Guinea Savanna Zone of Nigeria (field data). Rainfall ranged from 690-885 mm per annum, distributed over a period of 4-6 months (April-October) Minimum and maximum temperature ranges were 18-29^{0}C and 30-38^{0}C, respectively Minimum and maximum solar radiation ranges were 3.52wm^{-2} – 4.46wm^{-2} and 844.17wm^{-2} - 976.840wm^{-2}, respectively. The relative humidity ranged from 26% to 39% and wind speed ranged between 1.9 to 5 ms^{-1}. (Field data, 2019). Random soil samples was collected from the experimental site, using auger before land preparations at depths of 0-20cm and 20-40cm. Factorial combination of four intra-row spacings (15, 20, 45, and 60 cm), giving rise to 89,285, and 66P,666, 29,673 and 22,222 plants/ha^{-1}) and two lands race of Coleus Potato (ex-Zuru Black and ex-Zuru Brown).

Treatments were laid out in a randomized complete block design (RCBD) replicated three times. Seed tubers for two local land races of Coleus Potato (named after their skin colour) were sourced from farmers (ex-Zuru Black) in Dongo area and (ex-Zuru Brown) in Ribah and Girmache areas, spread across Zuru communities in Kebbi State. The ex-Zuru Brown belongs to early maturity (95-110 days) while ex-Zuru Black belongs to late maturity of (110-125 days). Glyphosate (phosphonomethyl) glycine) was sprayed at 20ML^{-1} of water against weed and allowed for 3 weeks before ~~to~~ ploughing. The land was ploughed and ridged using oxen. Gross plots measuring 6 m x 4.5 m (27.0 m^2) consisted of six (6) ridges 75 cm apart and about 40 cm high was ~~was~~ manually constructed. The net plots measuring 6 m x 2.5 m (12.5 m^2) consist of two middle rows. Fresh and healthy tubers were selected for planting. The seed-tubers were dressed with fungicide (dithiocarbamate) powder at 2.0 g kg^{-1}) a day to planting and the latter were done at the depth of about 5 cm as per the intra-row spacing treatment. Compound fertilizer (NPK 15:15:15) was used ~~as~~ per treatment at the rates of 300 kg NPK ha^{-1}.

The fertilizer was applied in two equal splits doses; the first dose was applied 4WAP and second split doses were applied 8WAP. The fertilizer was applied 10cm away from stand and 5cm deep and covered. The plots were weeded manually at 5, 9, and 13 WAP ~~9~~ after planting to control weeds. They were earth up at 3 weeks after planting to keep the tubers from being exposed to sunlight. Karate (Lamdacyhalothrin) was spray at 4ML^{-1} of water against insect pests. Harvesting was done manually using hoe from the net plot at physiological maturity by uprooting the whole plant. Data collected on number of tuber per stand, tuber weight per stand (g), mean tuber diameter (cm), mean tuber weight (g), tuber yield and percent marketable and unmarketable yield (%) were subjected to Analysis of Variance (ANOVA) using Statistical Analysis System package, version 9.3 (SAS 2012), treatment means were separated using Duncan's new Multiple Range Test (DMRT) at 5% Probability.

RESULTS

Results on table 2 revealed significant effect ($P<0.05$) on two tested land races of coleus potato significantly differed in tuber number per stand and Mean tuber diameter (cm). Variety Ex-Zuru Black produced more tuber Number per stand and mean tuber diameter than Ex-Zuru Brown. On the other hand, significant difference was also recorded amongst the plant population densities. Plant population density of (75cm x 60cm) and (45cm x 60cm) recorded the highest tuber number per stand and mean tuber diameter (cm) than the other population densities.

Results in table 3 Showed significant difference ($P<0.05$) was observed among the two tested land races of coleus potato significantly. Ex-Zuru Black produced the highest mean tuber weight (g) and tuber weight per stand (g) than Ex-Zuru Brown. On the other hand, significant differences were also recorded amongst the plant population densities. Widest plant population density (75cm x 60cm) produced the highest mean tuber weight (g) and tuber weight per stand (g) than the other population densities.

Results in table 4 Showed significant difference ($P<0.05$) was observed among the two tested land races of coleus potato significantly. Variety Ex-Zuru Black produced the highest marketable yield, unmarketable yield and yield ha^{-1} than Ex-Zuru Brown. On the other hand, significant differences was also recorded amongst the plant population densities. Widest plant population density (75cm x 60cm) and (45cm x 60cm) produces more marketable yield, unmarketable yield and yield ha^{-1} than the other population densities.

DISCUSSION

The yield of potatoes and many crops is dependent on many factors like the amount of minerals in the soil, plant spacing, cultivars etc (Beukema & Vanderzaag,1990). Increasing the plant population density can increase the yield in three ways. First, the green leaves will cover the soil earlier and will absorb more sunlight which will lead to more assimilation. Second, few lateral shoots will grow and the third is growth of tubers will start earlier (Beukema & Vanderzaag, 1990). The Potato variety influences yield through the size of the foliage, its time of tuber initiation, length of time of foliage remains alive and photosynthesis after tuber initiation, maturity regime and response to environmental conditions (Okonkwo *et al.,* 1995).The significant differences amongst the coleus potato land races is an indication these land races possessed inherent genetic qualities that enhance development than the other land races Ogedengbe et al. (2015). The greater mean tuber diameter of Ex- Zuru Black over Ex- Zuru Brown was due to the variation in tuber shape. The tubers of Ex-Zuru Black are morphologically rounded while the tubers of Ex-Zuru Brown are oblong or oval is shape. This has agreed with Keneth and Brain (2000), who reported potato variety, is genetically controlled, but can be influenced by other external factors such as fertilizer, water, spacing, pest and diseases. The higher mean tuber weight and tuber weight per stand recorded in Ex-Zuru Black than Ex-Zuru Brown could be link to their SDW and CGR which enhanced their rate of tuber bulking, hence dry matter content which consequently attributed to heavier tubers. Generally, low yield and other yield components in this study confirms poor yield in the coleus potato. Many tubers are produced per plant, but are small in size perhaps, this has indicated poor translocation of assimilates from the source to the sink.

Plant response to spacing varies from species to species and is highly dependent on environmental condition as well as soil characteristic and climatic condition of the site (Chopra and Chopra, 2004). It was also observed that the population density has significant influence on coleus potato land races, the widest population of 60cm x75cm record the highest yield components of the coleus amongst the parameters measured this could be attributed to less competition for available resources between the plants in the wider spaced plots, this results in efficient utilization of water, and light interception which collectively enhance effective photosynthesis and consequently translocation hence higher yield component. This has agreed with Squire (1990) appropriate plant population density increase light interception by the plant chloroplast which enhances photosynthesis upon which yield of the crop is totally and directly controlled. Adequate population density and soil fertility influence dry matter production, leaf area index and increase yield (Carl, 2003). Hailu and Sue (2011) reported planting with spaces between each plant develop root and shoot of tuber plant. Total tuber yield was generally low in all the land races, contrary to the findings of Enyiukwu et al. (2014) and Nkansa (2004) who reported average tuber yields of between 5 and 19 ha^{-1} It has been observed that more dry matter could be left in the above- ground portion (leaves and stems) than in the roots at the end of the cropping season, suggesting, perhaps, a lack of balance between the source potential and sink capacity. Namo et al., (2005)

CONCLUSION

From the findings of the study coleus potato land race variety (Ex-Zuru Black) proved to be robust in terms of yield and yield components than varieties (Ex-Zuru Brown). The findings further show that planting at the widest plant population density of 60cmx75cm produced the highest yield component in the two land races varieties and will be recommended to the farmers. Further research is ongoing to determine effects of Plant Population Density, Npk Nutrition and Variety on Growth and Tuber Yield of Coleus Potato (*Coleus Rotundifolius* P. A. Chev & Perrot) In Northern Guinea Savannah Zone of Nigeria.

EFFECT OF DIFFERENT MULCH MATERIALS AND DENSITIES ON THE GROWTH OF *Cleopatra mandarin* ROOTSTOCK IN A CITRUS NURSERY

***[1]Egberongbe R. K., [1]Alamu O.O, [1]Adeoye P.O., [1] Okafor B.N**

ABSTRACT
A pot experiment was conducted at the screen house of National Horticultural Research Institute (NIHORT), Ibadan, to evaluate the impact of different mulch materials and densities on growth of Cleopatra mandarin. The treatments consisted of Sesbania pachycarpa mulch (2cm depth; 4cm depth), Panicum maximum mulch (2cm depth; 4cm depth), Sawdust mulch at 2cm depth and no mulch as control. The experiment was laid in completely randomized design in 5 replications. Four months old Cleopatra mandarin were transplanted into containers 18 cm height and a diameter of 16 cm containing 3kg each dry soil. Data such as number of leaves, plant height (cm) and stem diameter (cm) were taken on the Cleopatra mandarin seedlings, weed densities and frequencies were also obtained to compute Relative Importance Value (RIV) of the emerged weeds. Results obtained revealed that plants mulched with Sesbania pachycarpa clippings to a 4cm depth had a significantly (p<0.05) higher plant height of 53.4 cm. The control treatment recorded more diverse weed species number. Plant-based mulches, are effective in improving crop growth and weed control.
Keywords: *Cleopatra mandarin, Plant height, Mulch materials, Weed control*

INTRODUCTION
Mulching can be classified as organic mulch (cover crop, inter-crop, green manure crop, compost, etc.) and in-organic mulch (polyethylene, paper, etc). The use of biodegradable mulches (organic mulch) is a widespread and common practice for weed control on organic farms, though it is usually considered to be economical only for high value or perennial crops or on small acreages (Runham and Town, 1995). Biodegradable mulches such as straw, leaves, wood chips or compost have been documented to offer advantages such as conservation of soil moisture, reduced soil erosion, weed and disease suppression (Singh, 1992). For example, Mbagwu (2000) recorded 40% increase in maize grain yield when 2 t/ha film mulch were added and of 80% when 4 t/ha mulch were placed on an Ultisol in Nigeria. Mulching in agriculture provides a safe yet equally profitable method of enriching and fertilizing the soil planted with crops. Unlike synthetic fertilizers and herbicides, these organic mulches pose little damage to the soil and crops. Usually defined as the use of organic and biodegradable materials to give plants the nutrients they need. Therefore, the study was set up to assess the advantages of mulching of *Cleopatra mandarin*.

MATERIALS AND METHODS
The pot experiment was carried out at National Horticultural Research Institute screen house in Ibadan. The treatments were: *Sesbania pachycarpa* mulch (2cm depth), *Sesbania pachycarpa* mulch (4cm depth) *Panicum maximum* mulch (2cm depth) *Panicum maximum* mulch (4cm depth) Sawdust mulch (2cm depth) and the Control (no mulch). Four months old *Cleopatra mandarin* seedlings were tested with the six treatments above and replicated five times in a completely randomized design. The treatments were applied 4 weeks after transplanting. Data were taken every 4 weeks for a period of 12 weeks on growth parameters like number of leaves, plant height (cm), stem diameter (cm). The effect of the mulches on weed suppression was also studied. Weed samples that emerged from the pots were collected for assessment; this is to study the effects of the various treatments on weed species diversity and abundance, this was used to compute Relative Importance Value (RIV). The number of plants of each species recorded in each pot was used to calculate the (RIV) as:
$[(RD + RF)/2] \times 100$ (Kent and Coker, 1992)
where RD=Relative Density and RF= Relative Frequency
Absolute Density (D) is the number of individuals of a particular species per unit area.
Relative Density (RD) is the percentage value of density of a weed species relative to the total density of all species.

RD=d/D X 100. where d = the density of species; D = total density of all species.

Absolute Frequency (F) is the measure of the chance of finding a species within a pot. That is, the number of pots that has a particular species in relation to the total number of pots sampled.

Relative Frequency (RF): The frequency of a species relative to the total frequency of all species.

RF=f/F X 100, where f = frequency of a species and F = total frequency of all species.

RESULTS AND DISCUSSION

Growth parameters of *Cleopatra mandarin* rootstock

The results revealed that different types of mulching materials influenced the growth parameters of the citrus plants. At 4 WAT, sawdust mulch at 2 cm had the highest plant height though it was not significantly different from, *Sesbania pachycarpa* mulch at 2 cm, *Panicum maximum* mulch at 2cm depth and control, but was significantly higher ($p<0.05$) than *Sesbania pachycarpa* mulch at 4 cm and *Panicum maximum* mulch at 4 cm. This may be attributed to the mulch decomposition. As the mulch decomposes, carbon levels gradually decline and the microbes release or mineralize nitrogen back to the soil, making it available again for plants uptake. *Sesbania pachycarpa* mulch at 2 cm had the highest number of leaves but was significantly different from all other treatments except *Sesbania pachycarpa* mulch at 4 cm. *Panicum maximum* mulch at 4 cm had the highest stem diameter but was not significantly different from all other treatments.

At 8 WAT, no significant difference was recorded for stem diameter and number of leaves though saw dust mulch recorded bigger stem diameter. At 12 WAT, the *Sesbania pachycarpa* mulch at 4 cm had the highest plant height and this was significantly higher than the control. *Sesbania pachycarpa* mulch at 4 cm and *Panicum maximum* mulch at 2cm depth, had the highest number of leaves but was not significantly different from other treatments. *Panicum maximum* mulch at 2cm depth and *Panicum maximum* mulch at 4cm depth had the highest stem diameter but was not significantly different from other treatments. Since organic mulches decompose under appropriate water and temperature levels, nutrients are released to the soil and become available for root uptake suggesting that soil mulching stimulates plant growth. Scharenbroch, (2009) also reported that organic material could be beneficial for tree establishment, weed control, and root decay. However, Iles and Dosmann, (1999) reported that tree height and stem diameter of red maple trees (*Acer rubrum* L.) were not affected after two years of mulching. Mulching materials can be successfully used as an alternative to chemical weed control. The mulching materials tested provided a similar weed control, while un-mulched pots had the highest number of weeds. Weed species diversity and abundance were the highest in the control pots that had no mulch. There were 7 broad leaves,1 grass species and 1 sedge encountered during the study. Also, there were less weed species in pots mulched up to 4 cm depth.

CONCLUSION

Sesbania pachycarpa mulch up to 4cm depth gave the best growth performance of the *Cleopatra mandarin* rootstock. Mulching up to 4 cm depth reduced the emergence of weeds.

ABSTRACT
In order to obtain high yield in Golden melon production, there is need to augment the soil constantly with nutrients to meet the crops need and thus maintain soil fertility. This study was carried out at the Federal University of Agriculture, Abeokuta, Ogun State, Nigeria, to determine the rate of poultry manure that will enhances optimum growth and proximate composition of Golden melon. Poultry manure was applied at rates of 0, 5, 10, 15 or 20 t·ha^{-1} in 4 replicates and arranged in a randomized complete block design. Growth and proximate composition of the melon plants were assessed. Data collected were subjected to analysis of variance using GENSTAT Mean differences were separated using Least Significant Difference at 5% probability level. Results showed that vegetative growth increased as the rate of poultry manure increased. The number of leaves and stem girth of Golden melon cultivated with 10 t/ha poultry manure had higher number of leaves, larger girth and wider leaf area. Proximate composition increased as the rate of poultry manure increased from zero to 15 t/ha while the values declined with when the rate increased to 20 t/ha with respect to the fat, ash and protein composition. For optimum growth and better proximate composition of Golden melon, soil fertility enhancement with 10 t/ha poultry manure is efficient.

INTRODUCTION

Melon (*Cucumis melo*) originated from the Middle East to the Mediterranean and it belongs to the family Cucurbitaceae (Maynard *et al*., 2001). Melons are consumed as desserts, fresh-cut fruits and as juice (Saftner and Lester, 2009). The refreshing pulp, high nutritional, sweet pleasant aroma, bright color, firm flesh texture, high sugar content of above 10% and proper fruit shape are important traits which make melons unique and a relish for the imperial family in Japan (Gusmimi and Whener, 2005). According to FAOSTAT (2019), melon production in the world was 27,501,360 tons with a total area harvested of 1,039,691 ha. China is the leading country in the production of melon (13,541,452 ton), followed by Turkey (1,777,059 ton) and Iran (854,090 ton). It is an important commercial crop in many countries and mostly cultivated in the temperate regions of the world due to its good adaptation to temperate soils and climate (Zulkarami *et al*, 2010). In Nigeria, it is mostly grown in the Northern part of the country where it is popular because of its sweet pulp and the pleasant aroma (Villanueva *et al*., 2004). The edible portion of a matured melon fruit is 45–80%. Raw peeled fruits per 100 g edible portion contains: 90.2 g water, 142 kJ (34 kcal) energy, 0.8 g protein, 0.2 g fat, 8.2 g carbohydrate, 0.9 g fibre, 9 mg Ca, 12 mg Mg, 15 mg P, 0.2 mg Fe, 0.2 mg Zn, 3382 IU vitamin A, 0.04 mg thiamin, 0.02 mg riboflavin, 0.7 mg niacin, 21 µg folate and 37 mg ascorbic acid (USDA, 2002). Comparatively, the nutritional composition of snake melon per 100 g edible portion is: 94.5 g water, 75 kJ (18 kcal) energy, 0.6 g protein, 0.1 g fat, 4.4 g carbohydrate, 0.3 g fibre and 13 mg ascorbic acid (Polacchi *et al*., 1982). In order to obtain high yield in golden melon production, there is need to augment the nutrient status of the soil to meet the crop's need and thereby maintaining soil fertility and increasing production. Therefore, this study was conducted to determine the effects of poultry manure on the growth and proximate composition of golden melon in Abeokuta area of Ogun State, Nigeria

MATERIALS AND METHODS

The experiment was conducted at the Directorate of University Farms, DUFARMS site of the Federal University of Agriculture, Abeokuta, Ogun State in August, 2021. Golden melon seeds (Uranus F1) were purchased from East West Company at Abeokuta, Ogun state. Poultry manure was collected from the Directorate of University Farms (DUFARMS) at Federal University of Agriculture. The treatments consisted of five poultry manure rates 0, 5, 10, 15 and 20 t/ha and the experiment was laid out in a

Randomized Complete Block Design (RCBD) with four replicates. The experimental field 19 m × 15 m was marked out, ploughed, harrowed and carved into twenty raised beds of 3 m ×3 m with 1m spacing between the beds.

The poultry manure collected was air-dried and broadcast on the plot according to the treatment rates and was left to mineralize in the soil for two weeks before planting. Samples of the manure were subjected to routine analysis to determine its nutrient status. Soil samples were taken at random at a depth of 15 cm and composite samples were taken to the Laboratory for routine analysis to determine the soil physio-chemical properties. Golden melon seeds were planted by drilling at a spacing of 100 cm by 60 cm (16,666 plants/ha) according to Ayeni, *et al.*, (2021). Data were collected on the number of leaves, vine length, stem girth, flowering and proximate composition which includes the dry matter, fat, ash, crude protein, crude fibre and carbohydrate contents using standard procedures. Data collected were subjected to Analysis of Variance (ANOVA) using GENSTAT Significant mean differences were separated using the Least Significant Difference at 5 % probability level.

RESULTS

The manure used had a near neutral pH (7.3) and contained nitrogen (3.42%), organic carbon (20.86%), available phosphorus (1.73%), potassium (1.58%), calcium (6.16%), and magnesium (1.92%). The experimental site soils had a near neutral pH (6.8) with nitrogen (0.14%), organic carbon (0.54%), available phosphorus (14.11mg/kg), potassium (0.47cmol/kg), calcium (0.25 cmol/kg), and magnesium (0.37 cmol/kg) while the textural class of the soil was sandy loam (Table 1). Total rainfall during the experimental period (September to December) was 285.1mm. The peak of the rainfall was in October (139.0mm). Mean temperature range during the period of experiment was 26-28 ^{0}C. The relative humidity ranged between 75 and 90% (Table 2). There were no significant differences in the number of leaves produced at 3 and 4 weeks after planting but there was a significant difference in the mean number of leaves produced at 5 WAP as influenced by the poultry manure rates (Table 3). At 3 WAP, the unfertilized golden melon produced more leaves which were similar when compared with the fertilized stands. At 4 WAP, golden melon cultivated with 10 t/ha poultry manure produced more leaves which were similar compared with other rates. At 5 WAP, golden melon cultivated with 10 t/ha poultry manure produced more leaves which were significantly higher compared with other rates (Table 3).

There were no significant differences in the vine lengths produced at 3 and 4 weeks after planting but there was a significant difference in the vine lengths produced at 5 WAP as influenced by poultry manure rates (Table 4). At 3 WAP, golden melon cultivated with 20 t/ha poultry manure produced longer vines which were similar when compared with other rates. At 4 WAP, unfertilized golden melon produced longer vines which were similar when compared with the fertilized golden melon. At 5 WAP, golden melon cultivated with 10 t/ha poultry manure produced longer vines which were significantly higher when compared with those cultivated with 15 t/ha manure but similar when compared with those cultivated with unfertilized, 5 and 20 t/ha poultry manure (Table 4). There were no significant differences in the stem girth produced at 3 and 4 weeks after planting but there was a significant difference in the stem girth produced at 5 WAP as influenced by poultry manure rates (Table 5). At 3 WAP, golden melon cultivated with 5and 10 t/ha poultry manure produced wider girths which were similar when compared with other rates. At 4 WAP, fertilized golden melon produced wider girths which were similar when compared with the unfertilized golden melon. At 5 WAP, golden melon cultivated with 5 t/ha poultry manure produced wider girth which were significantly higher when compared with unfertilized those cultivated with 10 t/ha manure but similar when compared with those cultivated with unfertilized, 15 and 20 t/ha poultry manure (Table 5)

There were significant differences in the proximate contents of golden melon as influenced by poultry manure rates (Table 6). Unfertilized golden melon had significantly higher moisture content when compared with those cultivated with 10 and 20 t/ha poultry manure but similar when compared with those cropped with 5 and 15 t/ha manure. Golden melon cultivated with 10 t/ha manure had significantly higher dry matter content when compared with the unfertilized melon but similar when compared with those cultivated with 5, 15 and 20 t/ha manure. Golden melon cultivated with 10 t/ha manure had significantly higher fat content when compared with those cultivated with 15 and 20 t/ha manure but similar when compared with unfertilized melon and those cultivated with 5 t/ha manure. Golden melon cultivated with 10 t/ha manure had significantly higher ash content when compared with the unfertilized and those cultivated with 5, 15 and 20 t/ha manure. Unfertilized golden melon had significantly higher crude fibre content when compared with those cultivated with 5, 15 and 20 t/ha poultry manure but similar when compared with those cropped with 10 t/ha manure. Golden melon cultivated with 10 t/ha manure had significantly higher crude protein content when compared with the unfertilized and those cultivated with 5, 15 and 20 t/ha manure. Golden melon cultivated with 15 t/ha manure had significantly higher carbohydrate content when compared with the unfertilized but similar when compared with those cultivated with 5, 10 and 20 t/ha poultry manure (Table 6).

DISCUSSION

The soil pH of the experimental site was near neutral and was within the favourable range for crop cultivation. (Van der Vossen, *et al*., 2004). The organic carbon was low but the Total N was just adequate, with the critical level of 1.5 g/kg reported by Aduayi et al. (2002). Available P was high based on the 8-12 mg/kg critical level reported by Udo et al. (2009). The soil had a high content of sand, medium silt content and a low clay content making the soil adequate for the cultivation of golden melon. The observed rainfall pattern was irregular while the observed range of air temperature during the vegetative and reproductive phase was within a permissible range of 10 to 45ºC according to Baker and Reddy (2001). Poultry manure rates affected the growth and proximate composition of Golden melon in the tropical rainforest/savannah transition zone of southwestern Nigeria. Vegetative growth was observed to increase as the rate of poultry manure increased from zero to 10 t/ha while a decline was observed as the rate increased from 15 to 20 t/ha with respect to the number of leaves, vine length and leaf area of Golden melon. This may be due to toxicity of nutrients resulting to the deposition of excess nutrients on the soil surface made available to the plant.

Proximate composition of harvested fruits was observed to be greatly influenced by the weather condition, especially rainfall. Moisture content determination is an integral part of the proximate n analysis of food. The high moisture content in Golden melon is in agreement with the finding of Falodun and Ogedegbe (2019) in their study on performance and Quality of Golden melon. Lower poultry manure rates produced fruits with higher moisture content and reduced dry matter content while higher manure rates produced fruits with more dry matter content with reduced moisture content, which may be due to the low weed competition which allows the plant more space available for the plants to grow and access more manure thereby aiding the production of more assimilate. Proximate composition of golden melon as influenced by poultry manure rate was observed to increase with the rate of manure from zero to 10 t/ha with respect to the fat, ash, fibre and protein contents while a decline was observed as the manure rates increased from 15 to 20 t/ha poultry manure. It is therefore concluded that cultivating golden melon with 10 t/ha poultry manure was sufficient for its optimum growth and proximate composition.

ABSTRACT
Type of fertilizers used in vegetable production influences quality of the crop and safety of the consumers. Presence of heavy metals in vegetables above the FAO/WHO permissible value is detrimental to human health. Treatments consisted of fertilizer types (control, 5 t ha^{-1} of cow dung, 5 t ha^{-1} of compost, 400 kg ha^{-1} of NPK fertilizer 20-10-10 and 400 kg ha^{-1} of urea). Heavy metal contents of scent leaf harvested one month after treatment application and analyzed in the laboratory showed the following trend: Fe (Control > urea > Cow dung > compost > NPK), Zn (Control > urea > compost > NPK > Cow dung), Cu (Control > urea > compost > cow dung > NPK), Ni (control > urea, NPK > compost > cow dung), Pb (control > urea > cow dung > compost > NPK) and Cd (Compost > NPK > control > urea > cow dung). Heavy metals in scent leaf produced with compost, cow dung and NPK fertilizer were below FAO/WHO permissible values. Therefore, the use of cow dung, compost and NPK fertilizer produced quality and safe scent leaf and is recommended for potted scent leaf production in Ifite Ogwari, Anambra State.
Keywords: *Compost, cow dung, inorganic manure, heavy metals, food safety*

INTRODUCTION
Scent leaf (*Ocimum gratissimum*) belongs to the group of plants known as spices, which belongs to the family Labiatae and is the most abundant of the genus *Ocimum*. Scent leaf is an aromatic plant that grows as a wild plant and also cultivated for culinary, medicinal and ornamental purposes. The proximate composition of scent leaf as reported by Anjili *et al.* (2018) shows that scent leaf contains crude protein of 7.61%, 32.00% crude fibre, and crude fat content of 18.66% and ash content of 15.33%. Scent leaf is rich in alkaloids, tannins, phytates, flavonoids, oligosaccharides, terpenoids, thymol and saponin, with tolerable cyanogenic contents (Alexander 2016). Agricultural and food wastes can be harnessed by farmers as compost for soil amendment and thereby reduce environmental pollution. A lot of research work on the use of different agricultural and food wastes for compost and their effect on crops abound. Oyeyemi *et al*., (2017) reported that the application of compost to nutrient deficient soil promoted growth, fresh shoot and dry matter yield of *A. cruentus*. Kumngen *et al*., (2023) stated that the use of BA compost promoted growth, chlorophyll content, phytochemicals and chemical contents of lettuce.
The type of fertilizer used in soil amendment will influence the quality of nutrient elements and the phyto-availability of heavy metals and thus influence the safety of the vegetable for human consumption. Cow dung is known for containing heavy metals which come from feed additives and even when composted or used it is original form can still be a significant source of heavy metal (Vukobratovic *et al*., 2014). The range of heavy metals above the safe limit set by WHO is very harmful to the human health and heavy metal concentration in the soil can lead to soil pollution, negative effect on organisms and crops (Iyama *et al.,* 2021). The FAO/WHO (2017) maximum permissible values (mg/kg) in vegetables are Cd (1), Pb (2), Ni (0), Fe (48), Cu (30) and Zn (60) (Olayiwola *et al.,* 2017). Above the FAO/WHO permissible values, heavy metals such as Cd cause artery problems (Khan *et al*., 2013: Nordberg *et al*., 2022; Turkdogan *et al*., 2003), Ni causes cardiac arrest, fatigue, heart problems and respiratory diseases (Muhammad *et al*., 2011), Pb and Cd can cause heart, kidney and bone diseases (Iyama *et al*., 2021). Therefore, this experiment aimed at determining the effect of fertilizer types on heavy metal concentration on the leaves of scent leaf and the safety of scent leaf produced using each fertilizer type.

MATERIALS AND METHODS
Experimental site
Experiment was conducted in the Teaching and Research Farm of the Department of Crop Science and Horticulture, Nnamdi Azikiwe University, Ifite Ogwari Annex, Nigeria. The research farm lies at the

latitude of 06 °15 N and longitude 07 °08 E, with an average annual rainfall of 1810.3 mm and relative humidity of 72.3%. The average minimum and maximum temperatures of the field were 28.74 °C and 28.96 °C with average relative humidity of 63.48% during the experiment.

Experimental design

Treatments consisted of five fertilizer typees (control (zero application of fertilizer sources), cow dung, compost, urea and NPK 20-10-10). Compost and cow dung were applied at 5 t ha^{-1} while NPK fertilizer and urea were applied at 400 kg ha^{-1}. Mid stem cuttings with five nodes were used for planting and. The scent leaf cultivar used for this experiment has adapted to Ifite Ogwari environment and are commonly used by the farmers.

The experimental design was a completely randomized design and treatments were replicated four times in both field and laboratory analysis.

Composting process

Food wastes were gotten from Madonna Eatery at Nnamdi Azikiwe University, Awka Annex. Cowdung, wood ash and dried grasses were obtained from Nnamdi Azikiwe University, Ifite Ogwari Annex. Compost pile was produced by placing the food wastes, followed by grasses and cow dung till the bucket was filled in the ratio of 3:2:1, wood ash of 1 kg sprinkled on top of the each compost pile and 1 litre of water was sprinkled on the compost pile. Four buckets of compost pile were made for the experiment. The piles were turned every evening for four weeks and were dried to 10% moisture content under shade by spreading them a clean poly sheet.

Fig 1: Compost pile

Fig 2: Four weeks old compost

Agronomic operations

Top soils of 0 – 20 cm depth were excavated, mixed together and solarized using black polythene nylon. Bags of 20 x 30 cm contained 15 kg of sand. The bags were perforated at the bottom and used for the experiment. Stem cuttings of 20 cm length were planted by inserting 5cm portion of the stem cutting inside the soil. NPK 20-10-10 and urea were bought from fertilizer market. Soils were irrigated before and after planting of the stem cuttings. Four Stem cuttings of 20cm length were planted per bag and were thinned to two stands per bag after two weeks of planting. Cow dung and compost of 110 g each per plant and NPK fertilizers of 140 g per plant each were applied to scent leaf stem cuttings at two weeks after planting using ring method at 10 cm away from the stem cuttings. Stem cuttings were planted in late February and irrigated till rain became steady and harvested at 73 days after planting. The surrounding and in between the bags were weeded as the weeds come up.

Laboratory analysis of food waste, compost, grass, wood ash, top soil and cow dung

Five soil samples were collected randomly from the experimental site at 0 - 20 cm depth before bagging in the bags. Soil pH was analyzed by the use of pH meter (Hendershot *et al.,* 1993), organic carbon was determined by Nelson and Sommers, (1982), organic matter values were obtained by multiplying total carbon with 1.724 (Van Bemmelen's correlation factor) (Nelson and Sommers, 1982), available phosphorus was determined according to the procedure of Olsen and Sommers (1990), total nitrogen was done by microkjeldahl digestion technique (Bremner and Mulvaney, 1982), calcium and magnesium by

Versenate titration method and potassium by flame photometer method. Cowdung, wood ash and compost were analyzed for their nutrient status using the same procedures in the soil analysis.

Methods for the Heavy Metal Analysis

Heavy metal analysis was conducted using Varian AA240 Atomic Absorption Spectrophometer according to the method of APHA 1995 (American Public Health Association)

Working principle: Atomic absorption spectrometer's working principle is based on the sample being aspirated into the flame and atomized when the AAS's light beam is directed through the flame into the monochromator, and onto the detector that measures the amount of light absorbed by the atomized element in the flame. Since metals have their own characteristic absorption wavelength, a source lamp composed of that element is used, making the method relatively free from spectral or radiational interferences. The amount of energy of the characteristic wavelength absorbed in the flame is proportional to the concentration of the element in the sample.

Dry Digestion

2g of the sample was weighed into a crucible and put into a muffle furnance for ashing at a temperature of 450^0c for 2hours. The sample was removed from the furnance and allowed to cool. The dry ash was emptied into a 250ml beaker 20ml of 20% H_2SO_4 was added, heated in a water bath for 20mins, filtered and made up to 50ml with distilled water and stored in a sample bottle for AAS macro and micro nutrient analysis.

Preparation of Reference Solution:

A series of standard metal solutions in the optimum concentration range was prepared, the reference solutions were prepared daily by diluting the single stock element solutions with water containing 1.5ml concentrated nitric acid/litre. A calibration blank was prepared using all the reagents except for the metal stock solutions. Calibration curve for each metal was prepared by plotting the absorbance of standards versus their concentrations

Analysis of data

All data measured were subjected to analysis of variance using Genstat 2019 and means were separated using Least Significant Difference at 5% level of probability.

RESULTS

Table 1: Chemical properties of the soil, grass, food waste, cow dung and compost used in the experiment

Nutrient contents	Soil	Grass	Food waste	Cow dung	Wood ash	Compost	Testing method
Lead (mg/kg)	0.42	-	2.18	2.35	0.91	2.93	APHA (1995)

Effect of fertilizer types on heavy metal contents of the scent leaves

Effect of fertilizer types on heavy metal contents of the scent leaves is shown on Table 2. Fertilizer types significantly ($p \leq 0.05$) affected iron (Fe) content of the scent leaf. Fe was highest in control scent leaf (63.73± 0.58 mg/kg) and was least in scent leaf produced with NPK fertilizer (32.86 ± 0.11 mg/kg). Scent leaf produced with compost and cow dung had 41.33 ± 0.14 and 46.84 ± 0.09 mg/kg of Fe respectively while soil amended with NPK and urea produced scent leaves with 32.86 ± 0.11 and 51.79 ± 0.16 mg/kg of Fe respectively. Organic amendment showed a decreased and less variable Fe content in scent leaf than the inorganic manures. Zinc (Zn) was highest in scent leaf produced without soil amendment (31.89 ± 0.123 mg/kg) and lowest in scent leaf produced with cow dung (22.33 ± 0.38

mg/kg). Soil amendment reduced Zn content in scent leaf, however, scent leaf produced with urea had highest Zn content (26.53 ± 0.14 mg/kg). Copper (Cu) was highest in control (9.62 ± 0.10 mg/kg) and lowest in scent leaf produced with NPK fertilizer (3.89 ± 0.08 mg/kg). Soil amendment reduced Cu content in scent leaf, however, scent leaf produced with urea had highest Cu content (6.63 ± 0.11 mg/kg). Nickel (Ni) was highest in scent leaf produced without soil amendment (2.07 ± 0.08 mg/kg) and lowest in scent leaf produced with urea (0.03 ± 0.04 mg/kg). Soil amendment reduced Ni content in scent leaf, however, scent leaf produced with urea had highest Ni content (0.97 ± 0.04 mg/kg). Lead (Pb) was highest in control (6.23 ± 8.03 mg/kg) and lowest in scent leaf produced with NPK fertilizer (0.11 ± 0.06 mg/kg). Soil amendment reduced Pb content in scent leaf; however, scent leaf produced with urea had highest Pb content (2.06 ± 0.04 mg/kg). Cadmium (Cd) was highest in scent leaf produced soil amended with compost (0.61 ± 0.04 mg/kg) and lowest in scent leaf produced with cow dung (0.26 ± 0.09 mg/kg). There was no significant difference in Cd contents of scent leaf produced without soil amendment (0.56 ± 0.09 mg/kg), compost (0.61 ± 0.04 mg/kg) and NPK fertilizer (0.58 ± 0.08 mg/kg).

Inorganic fertilizer and organic manures are used in reducing heavy metals in soil. The use of inorganic fertilizers reduce the bioavailability of metals, due to production of binding sites (Puschenreiter *et al*., 2005) and through the addition of nitrogen and phosphorus which affect the remediation of heavy metals through the promotion of metabolism of plants and changing the forms of metals (Sun *et al*., 2007). Organic manures such as cow dung and composts made from are also used to reduce heavy metal availability in soil because organic manures have high content of organic matter, phosphorus and iron and can form chelates in soil (Brown *et al*., 2003). Cow dung and compost made from cow dung are high in heavy metals because of feed additives used in rearing cows and this raises the heavy content of the manure and increases heavy metal content of the soil during soil amendment and increases the absorption of these heavy metals by the plants. However, organic matter contents and chelation of organic manures help to reduce phyto-availability of heavy metals in plant tissues.

Cultivation of scent leaf without soil amendment increased heavy metal contents in the leaves in comparison with scent leaf produced with organic and inorganic manure. Wang *et al.,* 2020 and Nkoh *et al.* 2022 independently reported the effectiveness of organic manure in reduction of heavy metals absorption by crops, promoting plant growth and producing safe crops. Soil amendment using urea did not reduce phyto-availability of heavy metals in comparison with NPK fertilizer. This could be attributed to the ability of urea to supply only nitrogen element to the soil and supports the report of Puschenreiter *et al*., (2005) which stated that complete inorganic fertilizers are used in heavy metal remediation through the actions of N and P which form binding sites in the soil.

Cow dung reduced the phyto-availability of Zn, Cu. Ni and Cd in comparison with compost. Compost had higher heavy metals than the cow dung and thus, contributed to higher heavy metals presence in scent leaf leaves (Table 1). Cd content of scent leaf was higher in NPK fertilizer than in control. This agrees with the reported of Singh *et al*., (2010) in Beta vulgaris L. which stated that phyto-availability of Cd, Cu, Pb, Zn, Mn, Ni and Cr was least in Beta vulgaris L. produced with farmyard manure and highest in soil treated with NPK fertilizer compared to control. Control had highest heavy metals above FAO/WHO (2017) permissible values in crops, while scent leaf produced in soils amended with cow dung, compost and NPK fertilizer had heavy metals values below the FAO/WHO permissible values than urea. This disagrees with the report of Alromian (2020) who stated that the use of different rates of compost made from residues of chicken, animal and mixed organic residues increased the heavy metal concentration in lettuce tissues and were above permissible values and thus, made the lettuce unsafe for human consumption.

Table 2: Effect of fertilizer types on heavy metal contents of the scent leaf

Fertilizer types	Iron (mg/kg)	Zinc (mg/kg)	Copper (mg/kg)	Nickel (mg/kg)	Lead (mg/kg)	Cadmium (mg/kg)
Control	63.73± 0.58a	31.89± 0.123a	9.62 ± 0.10a	2.07 ± 0.08a	6.23 ± 8.03a	0.56 ± 0.09a
Compost (t ha^{-1})	41.33 ± 0.14d	23.89 ± 0.07b	4.82 ± 0.06c	0.66 ± 0.01d	0.48 ± 0.09a	0.61 ± 0.04a
Cow dung (t ha^{-1})	46.84 ± 0.09c	22.33 ± 0.38e	4.16 ± 0.05d	0.03 ± 0.04e	0.85 ± 0.05a	0.26 ± 0.09c
NPK 20:10:10 (kg ha^{-1})	32.86 ± 0.11e	23.15 ± 0.07d	3.89 ± 0.08e	0.84 ± 0.10c	0.11 ± 0.06a	0.58 ± 0.08a
Urea (kg ha^{-1})	51.79 ± 0.16b	26.53 ± 0.14c	6.63 ± 0.11b	0.97 ± 0.04b	2.06 ± 0.04a	0.40 ± 0.05b
LSD $_{(0.05)}$	0.51	0.35	0.15	0.11	6.53	0.12
Significant level	**	**	**	**	NS	**

NS = Non significant, ** = Highly significant, * = Significant

CONCLUSION

Scent leaf produced with cow dung and compost had reduced heavy metal contents than scent leaf produced with urea and NPK fertilizer. Scent leaf produced with urea showed higher heavy metal accumulation than scent leaf produced with NPK fertilizer. Soil amended with urea produced scent leaf with higher contents of Fe and Pb. Control had highest Fe, Cd, Ni. Cu, Mn, Pb and Zn contents. Therefore, the use of cow dung, compost and NPK fertilizer produced quality and safe scent leaf with heavy metal presence below FAO/WHO permissible values and is recommended for potted scent leaf production in Ifite Ogwari, Anambra State.

EVALUATION OF COCOA POD HUSK AND CASHEW DRY LEAVES AS ORGANIC SOIL AMENDMENT ON CASHEW (*Anacardium occidentale L.*) SEEDLING GROWTH IN THE NURSERY

Ogbeide, C.E., Aremu-Dele, O., Nduka, B.A and Akanbi, O.S.O
Agronomy & Soil Division, Cocoa Research Institute of Nigeria, P.M.B.5244, Ibadan, Oyo State, Nigeria.

Corresponding author: ogbeidechristerbeth@yahoo.com

ABSTRACT
A nursery experiment was conducted at the Cocoa Research Institute of Nigeria to evaluate the impact of cocoa pod husk and dry cashew leaves on young cashew seedling growth. Medium cashew biotype was used. The treatments were applied at the rate of 0g (NF), 4g cashew leaf (CL4g), 6g of cashew leaf (CL6g), 4g of cocoa pod husk (CPH4g), 6g of cocoa pod husk (CPH6g), 2g each of cocoa pod husk +cashew leave (CPHCL4g) and 3g each of cocoa pod husk +cashew leave (CPHCL6g). The trial was laid out in a Completely Randomized Design (CRD). The physio-chemical properties of the soil were determined before the establishment of the experiment. Data on morphological parameters collected at two-week intervals for two months include plant height (cm), number of leaves, stem diameter (mm), and leaf area (cm^2). Data collected was subjected to Analysis of Variance (ANOVA) using GENSTAT (2012) statistical software. The result of the physio-chemical properties revealed that the soil was acidic and belongs to the sandy clay loam textural class. The application of CL4g gave a superior improvement of young cashew seedling growth while CPH4g gave considerable improvement. The application of CPH6g, CL6g, and CPHCL6g all gave a fair improvement in young cashew seedling growth.

INTRODUCTION
Cashew is a very important horticultural crop in Nigeria and other tropical countries, contributing significantly to their economies and ranked third globally in edible nut production (Akanni, 2011). Cashew trees are adapted to many different agro-ecosystems (Olubode *et al.*, 2018), but are grown economically in the savannah and tropical forest agro-ecological zones of Nigeria. Aliyu *et al.* (2014) highlighted some savannah areas such as Kwara State and north-central Nigeria such as Kogi State, where cashew nuts are commercially produced. Falade (1978) reported that cultivation had spread to other agroecological zones of Nigeria as well as Oyo, Enugu, Abia, Anambra, Ekiti, and Imo. The cashew tree, a resilient fruit tree, thrives in degraded lands, particularly on sandy soils (Ohler, 1979). Its modest soil requirements allow it to adapt without affecting productivity. However, it requires a continuous nutrient supply for fruit development and seed growth.

Plant growth is maintained by organic matter recycling, but chemical fertilizers introduce toxicity, nutrient leaching, and soil degradation (Nottidge *et al,* 2005). To maintain productivity levels, it is mandatory to adopt the use of organic nutrient sources such as wood ash, manure and compost (Northwood, 1996, Moyin - Jesu and Atoyosoye, 2002). Organic agricultural production in Nigeria is gaining interest due to the use of plant residues, animal manures, and compost (Hugo *et al.* 2001). These residues, including cocoa pods, cashew leaves, livestock manure, Oil palm waste, tea waste, rice bran, and other plant wastes are combined with controlled chemical fertilizers for growing cashew trees. Further research is needed (Moyin-Jesu, 1999 and Hugo *et al.* 2001).

Cashew and cocoa plantations have huge organic biomass potential for recycling. The amount of cashew leaf waste available from plantations in different age groups (10 to 40 years old) ranged from 1.38 to 5.20 tons/ha. About 5.5 tons of available cashew biomass waste per hectare can be converted into 3.5 tons of organic fertilizer or vermin-compost, thereby meeting 50% of the nutritional needs of cashew trees. It is estimated that 8,000,000 tons of cocoa pods are discarded during harvesting, providing between 64,000 and 94,000 tons of K, Ca, and P (Egunjobi, 1975). There are many suggestions for the use of CPH as a prerequisite for adding fertilizer to rice crops (Eegunjobi and Larinde, 1975; Adv Dappah *et al.,* 1994); Moyinjesu and Atoyosoye, 2002). Most of the fallen cashew nuts and cocoa leaves are wasted on plantations because they are not collected for fertilizer due to their difficulty in decomposing on-site in open conditions due to high lignin content and unfavorable decomposition conditions. Farmers often burn the land with leaves, which is not a healthy practice. During the dry season, fallen leaves can cause problems such as forest fires in cashew and cocoa plantations. Therefore, collecting fallen leaves not only keeps the plantation safe from fire hazards and allows adequate composting but also keeps the plantation clean for ease of harvesting of fallen nuts. This study was conducted to evaluate the use of cocoa pods and cashew leaves as organic soil amendments for the growth of cashew nuts in nurseries.

MATERIALS AND METHODS

The experiment was conducted at the screen house of the Cocoa Research Institute of Nigeria (CRIN), Ibadan, in the Southwestern belt of the Nigerian agro-ecological zone, from February to April 2023. Before the commencement of the experiment, surface soil samples were collected. (0-20 cm) taken from the Institute estate. Soil samples were air-dried, sieved through a 2-mm sieve, and analyzed for their physicochemical properties. Cocoa pods (CPH) were sourced from the CRIN area while dried cashew leaves were sourced from the Institute's plantations. The dried cashew leaves have been crushed for ease of use and to facilitate the mineralization process. The topsoil (0-20 cm) collected from the Institute campus was air-dried, sieved, thoroughly mixed, and poured into 25 cm x 12.5 cm perforated polyethylene bags. Each polyethylene bag is filled with 0.8 kg of topsoil. The polythene bags were watered to capacity in the field and placed on a raised platform in the greenhouse. Watering was carried out twice a week throughout the experimental period.

Treatment Application

The treatments involve cashew leaf (CL), cocoa pod husk (CPH), and their combinations (CL+CPH) at two rates, with six treatment combinations and a control, laid out in a Completely Randomized Design (CRD) replicated three times. Agronomic parameters measured include plant height (cm), number of leaves, stem diameter (mm), and leaf area (cm^2). They were measured fortnightly for two months and data collected therein were analysed using ANOVA and Duncan Multiple Range Test.

RESULT AND DISCUSSION

Table 1 shows the result of the chemical properties of soil before planting. The soil pH value 4.12 was acidic, suitable for cashew crops, hence cashew crops with a tolerant range of pH 4.5-8.5, as optimum values are within 5.2-7.5 (Dedoe *et al*., 2001). The organic carbon content of the soil (1.13g/kg) was below the critical value of >2% considered suitable for cashew cultivation (Aikpokpodion *et al*., 2010). The soil nitrogen is below 0.1% N required for cashew cultivation (Egbe *et al*., 1989). Possibly due to the low organic matter content of the soil. Hence it is expected that the application of cashew leaf and cocoa pod husk would enhance soil fertility and the performance of cashew crops. However, available P 2.49cmol/kg is low compared to the 3.7 cmol/kg recommended for optimal growth of cashews (Egbe *et al*., 1989). The soil K value of 0.12 cmol/kg on the other hand is higher than the critical value of 0.81 cmol/kg (Egbe *et al.,* 1989).

Table 2 shows the impact of cocoa pod husk and cashew leaves on cashew nuts' growth index after 8 weeks of sowing (WAS). No significant difference was observed between NF (24.77 cm), CPH4g (25.83 cm), CL4g (25.67 cm), CPHCL4g (19.9 cm), and CPHCL6g (25.07 cm). CL6g however, recorded the highest plant height value (29.60m). This result could be as a result of the higher nutrient supply in 6g of dry cashew leaves which were accessible for the cashew seedling root for utilization (Brady, 1990). This confirms the suggestion by Janick (1986) that higher availability of nutrients increases the succulent growth of plants. The result supports the findings of Nanjundappa *et, al* (2001) who reported improvement in the general performance of crops that received a combination of the different nutrient sources. The outstanding performance of 6g of cashew leaf over others could be due to higher levels of N, P, and K that are contained in the leave compared to others.

This assumption supports Abhijit (2015) who reported that considerable levels of macro-nutrients and secondary nutrients indicate the efficacy of the cashew leaves as the ingredients of organic fertilizer. The treatments did not significantly differ in leaf and stem diameter, but CPH4g (12), CL4g (11.67), and CPH6g (10.33) had more leaves and thinner stem diameters than NF (9.50). The control NF (40.73 cm2) treatment did not significantly affect leaf area, but CPHCL6g (48.56 cm^2) and CL4g (44.74 cm^2) improved the stem diameter of cashew seedlings. The leaf area differences between treatments were only observed between CPHCL6g (48.56 $cm^{2)}$ and CPH 4g (27.77 cm^2), with the latter having the smallest leaf area. The study confirms earlier research work of Akanbi, (2016) on the impact of cocoa pod husk and oil palm bunch ash on cocoa performance, revealing enhanced agronomic parameters.

CONCLUSION

To reduce the cost of purchasing inorganic fertilizers and maintain good soil quality, it becomes imperative to use plant materials as a source of organic manure. All organic materials used in this study, except CPHCL4g, showed various potentials to improve cashew growth when used. However, applying CL4g brought outstanding improvement in the growth rate of cashew trees, while CPH4g showed significant improvement. The application of CPH6g, CL6g and CPHCL6g all brought about a significant improvement in the growth rate of cashew trees.

ABSTRACT

The study analysed the economic analysis of date palm fruit marketing in Kiyawa local government area of Jigawa state Nigeria. The data were to describe the socioeconomic characteristics, profitability, efficiency and finally the major constraints. Primary data were used for the study through the distribution of a structured questionnaire. There were 800 date palm fruit marketers according to their association record. Ten percent (10%) were selected at random to give the sample size of 80 respondents. Descriptive statistics, marketing margin, net margin, and efficiency. The results indicated sex, 84.8% were male and 15.2% were female. age, the mean age was 37.9 years, which implies that marketing is profitable, 63.3% were married, non-formal education was the highest 39.3% and the mean household size was 8.10 people. The results of profitability marketing margin and net margin 0.10 and 362370 in 100kg per bags of total the respondents and had constraints, such as unstable price, irregular supply, poor road network, and pest. It was recommended that financial institutions such as microfinance banks and BOA should ensure provision of soft credit facilities for agriculture to date palm fruit marketers at very low interest rates, to block the constraint of inadequate capital, to expand their date palm fruit marketing.

Keywords: *date palm, economic analysis*

INTRODUCTION

Date Palm fruit (*phoenix dactylifera L,*) is considered a symbol of life in the desert because it tolerates high temperature, drought and salinity more than many other fruit crop plant species. It is a popular food in the Middle East, found in abundance in the desert and around oases. Hays J, (2009) stated that many parts of the Middle East would be uninhabitable were it not for date palms, one of the few crops that grow in the desert. It has been described as the "tree of life." Botes and Zaid (2001) opined that date palm fruit (dates) is marketed all over the world as a high-value confectionary and fruit crop, and remains an extremely important subsistence crop in most of the desert regions. Thus, the heavenly religions honoured the date palm fruit and showed concern for its cultivation and care (El-juhany, 2010).

Date palm fruit is grown extensively in the arid region of the northern parts of Nigeria from latitude 10^0N in the Sudan savannah to the Sahel regions. These parts include Jigawa, Katsina, Kaduna and Kano State etc. It is generally believed that the date palm fruit was introduced into Nigeria in the early 17^{th} century by traders and Muslim pilgrims on pilgrimage to the holy cities of Mecca and Madina through the Tran Saharan trade route from North Africa and Middle East (Omoti & Okolo, 2000)

The date palm fruit is a multipurpose tree, providing food, timber products, and shelter. The date palm fruit is a good source of food, provides carbohydrates, minerals vitamins and fibre.In Arab countries, the date palm fruit is considered one of the main fruit crops. The major producers of date in the world are situated in the Arabia Gulf and north. Kader and Hussein (2009) reported that in 2006, world production of date palm fruit was about 7 million tons; there are thousands of date palm cultivars, including those with soft, dry and semi-dry fruit depending on their water and types of sugar content at harvest when full-ripe, grown in these countries (Kader & Hussein,2009).

According to (folayan, 2005). Agricultural marketing can be defined as comprising all the activities or operations that are involved in the movement of goods and raw materials from farm production to the final consumer of consumption. Efficiency in marketing can only be achieved through services such as transportation, storage, packaging, financing, grading, risk bearing, price determination and distribution of market information. Dates palm fruit lend themselves to a wide variety of value-added food products, including date paste, date sugar, date syrup and date vinegar. The high nutritional composition, profitability as well as environmental advantages make date palm fruit an excellent choice for farmers

(Al-shahib& Mashall, 2003). Its cultivation and marketing is a good alternatives to improve the food and economic status of the people (Hassan et al, 2006) agricultural holdings and supplies are very small and scattered as a result of which the marketable surplus generated is very meagre which subsequently results in low supply of commodities in the market (Reddy and Devi, 2004). This study thereforedescribe the socio-economic characteristics of the date palm fruit marketers in the study, analyse the profitability of date palm fruit in the study area, determine the marketing efficiency in the study area, and describe the major constraints militating against effective date palm fruit marketing in the study area.

MATERIALS AND METHODOLOGY

Study Area

Kiyawa Local Government Area (LGA) is situated in the south-eastern part of Jigawa state, between latitude 11.42ºN and longitude 9.40ºE. Its landform is characterized by undulating land with sand dunes of variable sizes spanning across the northern part of the LGA. The south-eastern part consist of fine textured clay to sandy loam soil that is greyed and have some humus content that favoured arable agricultural practices in the area. It has an average annual rainfall of about 550mm. Mean annual temperature of 23.75ºC and average relative humidity of about 45% has been recorded. The area lies within the Sudan savannah type of vegetation, Kiyawa has an estimate population of 17,704 according to 2006 National Population Census, of which Hausa/Fulani dialect is predominant and their major occupation is farming. (J.SDSD, 2005).

Sampling Technique

Shuwarin market was purposively selected based on the concentration of date palm marketers. Then, a list of 800 date palm marketers was collected from their association found in the market out of which, 10% of them were selected at random to give the sample size of 80 respondents were interviewed.

Data Analysis

The analytical tools used for this research included descriptive statistics, marketing margin, net margin and Efficiency was used to achieve objectives.

Marketing Margin Analysis

Marketing margin is the difference in price of a commodity at different stages of time, place, and possession as it moves from producer to the ultimate consumer, (olukosi and isitor, 1999). Part of objective3 was analysed and achieved used this particular model. It is specified as follow, where MM= marketing margin wereMM $= \frac{SP-PP}{SP}$.SP= selling prices.

PP= purchasing price or Supply price.

Net Margin= SP-MC. SP= selling price. MC= marketing cost.

RESULTS AND DISCUSSION

The results obtained from the tests conducted on the data collected for the study based on the stated objectives. The result showed that 84.8% of the Date palm marketers were male while 12.2% were female.The age range from 18-60 with Mean of37.9, the result show that majority of the Date palm fruit Marketers were within age of 36-44. The result revealed majority of the date palm marketers were married 63.3%. Therefore, house hold size is the total number of individuals who live and feed in the particular pot, adekanye (1998) Minimum = 1, Maximum = 20, Mean = 8.10. Educational levels indicate that 29.1% have primary certificate and 25.3% have secondary school certificate while 39.3% have no formal education and 6.3% have Tertiary certificate. Were found that majority of the respondents have no formal education. Marketing experiences is an important variable to determining the quality of the commodity and experience as the major factor that increases the traders' profit

Income, the marketing experience were range from 1-20 with mean 7.8. This is in line with the finding of Ali et al, (2008).

Table 1: Socioeconomic Characteristics of the Respondent

Variable	Range	Frequency(f)	Percentage (%)
Sex	Male	67	84.8
	Female	12	15.2
Age	18-26	13	16.5
	27-35	19	24.1
	36-44	27	34.2

Total Marketing Service	31630		
Selling Price	4002000		
Marketing Margin	0.10		
Net Margin	362370		
Marketing Efficiency	109.96%		

Source: Field Survey 2017

Profitability Analysis

The results in Table 2 were profitability analysis of 100kg/ bag of date palm fruits marketing in the study area was presented in Table 2. The purchase price of total respondents was ₦3608000. Total marketing service was ₦ 31630. The total cost incurred in date palm fruits marketing was obtained from the addition of the total marketing costs and the purchase price of date palm. This was found to be ₦

3639630. The total Selling price was found to be 4002000. The average purchase price was ₦ 45670.89, while the average total marketing cost was ₦ 46071.27. The result in table 2 also shows that the total cost of marketing in 100kg was ₦ 363930 of total Date palm fruit respondents, more so, the total return of ₦ 4002000 was realized which gives a net marketing margin of ₦ 362370. This implies that Date palm fruit marketing is profitable in the study area,

Marketing Margin, Net Margin and Efficiency Analysis

Marketing margin is the difference in prices of the commodity at different stages of time, place, form and possession as it moves from producer to the ultimate consumer. The lower the marketing margin the profitability becomes higher. The marketing margin from results of table 2 was found 0.10. The result indicated that the marketing efficiency was 109.96%.

Table 3: Constraints of Data palm fruit marketers in the Study Area

Purchasing Constraints	Frequency (f)	Percentage (%)
Poor road network	8	10.1
Unstable price	27	34.2
Activities of middle men	16	20.3
Lack of marketing information	8	10.1
Insecurity on the road	3	3.8
Irregular supply	9	11.4
Pest	8	10.1
Total	**79**	**100**

Source: Field Survey 2017

The results in table 3 showed that 10.1% were facing constraints of poor road network and 34.2% are facing the constraints of unstable price and 20.3% were facing the problem of activities of middlemen while 10.1% were facing the constraints of lack of marketing information and 3.8% are facing the constraints of insecurity on the road and 11.4% are facing the problem of irregular supply and 10.1% are facing pest constraints. The finding here shows that majority of the date palm fruit marketers are facing the constraint of unstable price

CONCLUSION AND RECOMMENDATIONS

It is clear that, Date palm fruit marketing is dominated by middle aged of marketers, with middle number of household size. The date palm fruit marketing is a profitable, the marketing margin, net margin indicated that the cost of providing those market functions is reflected in the profit. It was recommended that financial institution such as microfinance bank and BOA should ensure provision of soft credit facilities for agriculture to date palm fruit marketers at very low interest rate, so as to block the constraint of in adequate capital, in order to expand their date palm fruit marketing. Government should take appropriate policy measures to guard against price fluctuation / uncertainties of agricultural commodities so as to aid both the producer (farmer) and the marketers.

ABSTRACT

Roses are ornamental plants of economic value with high demand for domestic and exports markets. They are known for their beauty, fragrance and bright colours. Rose plants are susceptible to insect pests which affect flower yield, flower quality and reduce aesthetic value of the plant. Grasshopper (Zonocerus variegatus), mealybug (Maconellicoccus hirsutus), aphids (Macrosiphum rosae), cotton stainer (Dysdercus spp) and stink bug (Nezera viridula) were major insect observed on the rose field in this study. Grasshoppers were the most abundant (42.80%) on the field and its occurrence was observed throughout the vegetative, flowering and post flowering stages of the plant while cotton stainer recorded the lowest (5.20%) population density. Damage to rose plants included defoliation, sap sucking, petals and flower buds deformation. Adequate knowledge of pests and associated damage on the host is essential for the development of efficient and sustainable management package for the pest.

Keywords: *Rosa spp, insect spectrum, damage, aesthetic value, ornamental plant*

INTRODUCTION

Rose (*Rosa* spp) is one of the most important and cherished plant in the ornamental industry (Horibe and Yamada, 2017). It ranked first among the top cut flowers in the international flower market (Hegde, 2010). Rose is native to Asia and belongs to the family Rosaceae (Chaudhari and Kumar, 2020). The plant is known as "Queen of Flowers" due to its beauty, fragrance, varied colours and size of its flowers (Hegde, *et al*., 2020). Rose flower is a symbol of love and adoration, it attracts both pollinators and human admirers (Horibe and Yamada, 2017; Hegde *et al*., 2020). Its uses range from cut flowers and landscape beautification to being used as raw material in agro and floriculture industries especially in the production of cosmetics, soaps and perfumes (Chaudhari and Kumar, 2020).

Roses also play important roles in medicine and nutrition. It is used as a medicinal herb against nephritis and hemorrhoids (Bitis *et al*., 2017). The essential oil from rose petals is incorporated in ayurvedic medicines, flavoring soft drinks, and alcoholic beverages (Hegde *et al*., 2020). Among the various factors affecting rose cultivation and quality of flowers produced, insect pests are paramount. Insects attack on rose plants may stunt or kill plant parts, affect flowering, reduce yield and flower quality or cause aesthetic damage (Hegde *et al*., 2020). Rose plants are vulnerable to the attack by many insect pests among which are; aphids, *Macrosiphum rosae* (Linnaeus) (Hemiptera: Aphididae); thrips, *Frankliniella schultzei* (Pergande) (Thysanoptera: Thripidae), whitefly, *Trialeurodes vaporariorum* (Westwood) (Hemiptera: Aleyrodidae); mealybug, *Planococcus citri* (Risso) (Hemiptera: Pseudococcidae); foliage feeders and bud borers, *Helicoverpa armigera* (Hubner); *Spodoptera litura* (Fabricius) (Lepidoptera: Noctuidae) (Dreistadt, 2001; Rajkumar *et al*., 2004). The aim of this study however, is to identify the spectrum of insect pests on rose plants and their associated damage in the floriculture garden of the National Horticulture Research Institute (NIHORT), Ibadan, Nigeria.

MATERIALS AND METHOD

The study was conducted in the Floriculture garden of the National Horticultural Research Institute Ibadan, (Latitude 7° 54′ N and Longitude 3° 54′ E, 213 m above the sea level). Rose seedlings were transplanted on the field 644m^2 and spaced 2m x 2m apart. A total of 103 rose stands were established and maintained. At full establishment and stability (4 weeks after transplanting), 30 rose plants were selected at random and tagged for the study. Insect population was assessed and counted visually on the randomly selected plants on a weekly basis in the early hours of the morning between 07:30 and 09:00 am (when the insects were usually inactive) till flower maturity. The plants were categorized into damage and undamaged. Damaged (when leaves and flowers show signs of insect feeding or as undamaged when signs are absent). Collected data were subjected to analysis of variance. Data on insect counts were transformed using square root model $\sqrt{(X + 0.5)}$ prior analysis.

RESULTS

Table 1 shows insect species associated with rose plant on the field during the study. Five major insect pests belonging to two orders and five families were observed on the rose. The insect pests included: Grasshopper (*Zonocerus variegatus*), Mealybug (*Maconellicoccus hirsutus*), Rose Aphids (*Macrosiphum rosae*), Cotton stainer (*Dysdercus* spp) and Stink bug (*Nezera viridula*). Grasshopper observed on the field during the study were variegated with brown, greenish -yellow colours. *Zonocerus variegatus* (42.8%) were the most abundant on the field, followed by mealybugs (33.0%), while *Dysdercus* spp (5.2%) recorded the low pest population density (Fig.1). The occurrence of *Z. variegatus* and *M. hirsutus* were observed throughout the vegetative, flowering and post flowering stages of the plant, while *M. rosae*, *Dysdercus* spp and *N. viridula* were observed at flowering stage. Damage caused by grasshopper to the rose plant was defoliation of the leaves leaving behind ragged holes on them. *Maconellicoccus hirsutus* suck sap from the plant, they excrete sticky honeydew and wax, which reduces plant vigour and flower quality (Perring, 2018). *Macrosiphum rosae* cluster underneath the leaves where they pierce and suck cell sap from the plant. They produce honeydew which cause black fungal growth (sooty mold) on the leaves. This sooty mold interferes with plant photosynthetic activity resulting into stunting and poor development of the plant. *Dysdercus* spp caused damage to flower buds by sucking the sap and destroys the buds while stink bugs damage rose petals on blooming, they feed and disfigure blooms of buds and flowers making them unmarketable (Table 3).

DISCUSSION

Results of this study indicated that grasshopper (*Z. variegatus*), mealybug (*M. hirsutus*), aphids (*M. rosae*), cotton stainer (*Dysdercus* spp) and stink bug (*N. viridula*) were major insect pests that induced damage to rose plants causing plant tissue consumption and distortion in the physiological processes of the plant. This corroborates earlier reports by Rajkumar *et al*. (2004) and Chaudhari and Kumar, (2020 indicating similar trend of insects attack on rose plants regardless of location. Grasshoppers are polyphagous insects. They feed on many plant hosts including rose plants. High population of grasshopper on rose in the study may be as a result of palatability and suitability of the plant for consumption. Wisotsky *et al*. (2011) reported that insects have well developed taste receptor which they used in sampling food for suitability and consumption. The abundance of species on a host can also be due to choice made by female insects (Fitt, 1986). Akol *et al*., (2013) reported that female insects prefer to lay their eggs on hosts in which their offspring fare best. In this study, eggs of grasshoppers were found on the leaves of roses which most likely support the growth and development of the insect.

Insect-host relationship resulted into damage to the host as observed in this study. Damage to rose plants range from defoliation (grasshoppers), sap sucking (mealybugs), production of honeydew and sooty mold on leaves which affect photosynthesis (aphids) and damage to petals and flower buds (cotton stainers and stinkbugs).

CONCLUSION

Roses are important and highly demanding landscape plants grown for their beauty and as raw materials in agro and floriculture industry. Five major insect pests; grasshopper, mealybug, aphids, cotton stainers and stinkbug have been identified in the study. These insect pests reduced plant growth, flower growth, flower quality and aesthetic damage to the plant. The development and introduction of an effective management package is essential to keep the population of the insects low and remain under economic threshold.

Table 1: Profile of insect pests and their status on rose plants on the field

Common name	Scientific name	Order	Family	Status
Grasshopper	*Zonocerus variegatus*	Orthoptera	Pyrgomorphidae	Pest
Mealybug	*Maconellicoccus hirsutus*	Hemiptera	Pseudococcidae	Pest
Rose Aphids	*Macrosiphum rosae*	Hemiptera	Aphididae	Pest
Cotton stainer	*Dysdercus spp*	Hemiptera	Pyrrhocoridae	Pest
Stink bug	*Nezera viridula*	Hemiptera	Pentatomidae	Pest

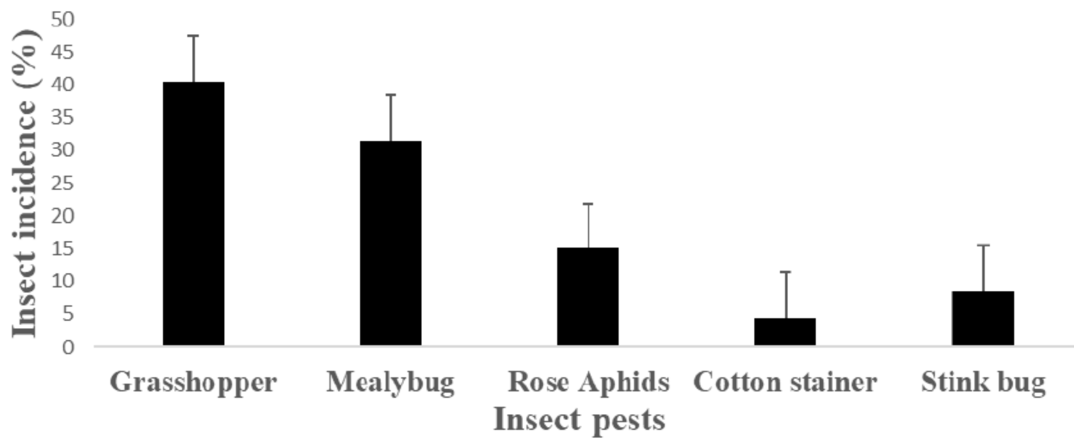

Fig. 1: Insect pests and incidence on rose plants in the field

Table 3: Rose insect pests, plant part damaged and nature of damage

Common name	Part damage	Nature of damage
Grasshopper	Leaf	Defoliation
Mealybug	Leaf, buds, flowers	Sap sucking
Rose Aphids	Leaf, buds, flowers	Sap sucking
Cotton stainer	flower buds	Sap sucking
Stink bug	flowers	chewing of petals

ABSTRACT
Mushroom is regarded as mother of all vegetables because of its roles in human nutritional supply with abundant number of essential vitamins, minerals and protein. However, there is dearth of information on what goes into its domestication, therefore this study assessed the availability and affordability of raw-materials for mushroom production in Ibadan metropolis with a view to encourage sustainable production for economic growth. Ibadan metropolis was purposively chosen based on the abundance of various institutions who are actively involved in the production of mushroom and presence of some trained farmers who are into the production. Information was elicited from 36 mushroom producers with the aid of structured questionnaire. Data were analysed using descriptive statistics such as frequencies and percentages. Findings revealed that 58.3% respondents rarely had materials for mushroom production whenever they intend to produce, 50% respondents cannot afford relevant materials needed for the production, while 30.5% respondents revealed that spawn production cost between 500-1,000 naira. Also, lack of capital and favourable environment are key factors contribution to no increase in mushroom production. It is therefore recommended that basic and necessary production materials be made available and accessible to producers at subsidized rates. In order to enhance production, credit support should be made available to producers at affordable interest rates.

***Keywords**: Mushroom production, availability of mushroom, production materials, affordability of mushroom production materials*

INTRODUCTION

Mushroom, a very nutritious horticultural crop that double as non-timber forest product is generated from lignocelluloses waste materials rich in crude fibre and protein. (Adedokun and Okomadu, 2017) The amount of protein in mushroom is double than any other vegetables. Hence, it is called vegetable protein. In fact, mushroom contains low fat, low calories and good vitamins (Jiao-Jiao *et al*., 2016) Mushroom is a source of extra ordinary power, virility and is used in the preparation of many continental dishes. It is a good source of protein, vitamins and minerals and contain about 85-95% water, 3% protein, 4% carbohydrates, 0.1% fats and 1% minerals and vitamin, this made mushroom to be regarded as game changer (Osuafor and Edeh, 2020).

Mushroom possesses multifunctional and medicinal properties; therefore, a culture of mushroom could be a source of additional income for the families on small scale farms with active participation of members (Osemwegie and Okhuoya, 2014). According to (Osuafor *et al.,* 2021), mushroom production is a useful way of earning income when climate change makes farming less reliable. In order to increase revenue, ensure food security and improve living conditions in the face of poor crop yields brought on by the effects of climate change, farmers can make an effort to grow protein-rich mushrooms. Mushroom is congenial for their flavour, economic and ecological values, and medicinal attributes for many years (Gupta *et al.,* 2018)

Mushroom can be cultivated easily in home yards because it requires a small space to grow thereby serve as means of creating employment, particularly for rural women and youths in order to improve their social status (Osemwegie and Okhuoya, 2014). The natural habitat of mushroom ranges from farm land, forest and newly cleared lands, pieces of wood found in several place. Naturally, the availability of mushroom is seasonal, depending on the species some may be available just at the onset of rains, others during the rains, some when the rains are winding up. By practicing mushroom production, farmers can contribute successfully and significantly to the economic development of the country (Stamets, 2020) It also provides additional work for the farmers during winter months when the farming schedule is light.

So, mushroom production plays a vital role on socio-economic development of those who are involved in the production (Zhang *et al*., 2014).

According to National Farmers Information Service (NAFIS, 2021), Nigeria produces 300 tonnes of mushrooms per year and has a market demand of 1200 tonnes, this means that many consumers of mushroom which include homes, hotels, and kitchens import from elsewhere, this implies that the supply within Nigeria does not meet up with the demand. In this case, there is market demand but insufficient supply within the country, hence the need to research on the availability and cost of raw-materials for the production of mushroom in the study areas.

MATERIALS AND METHOD

Study area

This study was carried out in Ibadan metropolis. Ibadan is the state capital of Oyo state Nigeria, It has a population of 3,720,643 people according to the ~~(~~2006~~)~~ census and it is the most populous city in Nigeria after Lagos and Kano.~~,~~ It is the largest city by geographical area with 128 km inland northeast of Lagos and 530 km southwest of Abuja, the federal capital, and is a prominent transit point between the coastal region and the areas in the hinterland of the country. The city covers a total area of 3,080 square kilometers (1,190 sq mi), the largest in Nigeria~~.~~ (Olanrewaju *et al.,* 2018). There are eleven local governments in Ibadan; the metropolitan area comprises five (5) urban local governments' areas in the city and six (6) semi urban local governments in the lesser city. The five urban local governments include; Ibadan-north, Ibadan North-east, Ibadan North-west, Ibadan South-east and Ibadan South-west while six semi-urban consists of Akinyele, Egbeda, Ido, Lagelu, Ona-ara and Oluyole (Olanrewaju *et al.,* 2018).

Sources and types of data

The study made use of primary data which were obtained through the use of structured questionnaire designed for generating data for the study area. The data collected from mushroom producers includes the following: demographic characteristics such as age, sex, household size, marital status and religion, availability and affordability of raw materials, types of mushroom cultivated and factors responsible for increase in production among others.

Sampling technique

The study made use of multistage sampling technique. The first stage was the purposive selection of Ibadan metropolis because of the high demand for fresh mushroom and mushroom products. The second stage involves the purposive selection of some organizations in Ibadan who are known to be the areas where mushrooms were been produced, these sites were also known for training and capacity building on mushroom production such as Forestry Research Institute of Nigeria (FRIN), National Horticultural Research Institute (NIHORT), ZARTECH, the Department of Crop Protection & Environmental Biology, and Department of Botany at University of Ibadan, Ibadan, Nigeria as well as the random selection of individual mushroom producers based on reference by the above named organizations. In all a total of thirty-six (36) respondents were sampled for the study.

Analytical technique

In order to achieve the set objectives for this study, data were analysed using descriptive statistics such as frequency and percentages.

RESULT AND DISCUSION

Socio-demographic characteristics of respondents

As observed from the results on Table 1, majority (61.1%) of the respondents were male, married (91.7%), within the age bracket 45-54 years (52.8%), are of the Christian religion (61.1%) and have between 1-10 years of experience in mushroom production. The implication of these results is that married people are more involved in mushroom production, this can be connected to the more responsibility attached to married people, they need extra income to cater for the wellbeing of their immediate family and other social responsibility. Also, young people were not showing interest in the production of mushroom in the study area, which may be as result of unavailability of social amenity to encourage young people into the farming system. Studies have shown that rural-urban migration by young people had leads to a shift in the roles of farming and collection of non-timber forest product such as mushroom to the hands of older people taking the lead in the collection of non-timber forest product (Hechat *et al.,* 2015*)*. On the years of experience, the result indicates that the low years of experience might have contributed to low production of mushroom in Ibadan metropolis.

Availability and affordability of mushroom raw materials

Results also revealed that, more than 50 percent of the respondents claim that they rarely had materials available for mushroom production (Table 2). This may be connected to lack of loans, incentives and credit facility to people engaging in farming activities couple with inflation ravaging most communities in the country According to the research work of Neelam *et. al,* (2013), important things to note before going into mushroom production include availability of materials needed for production including finance and ability to identify strategic area where mushrooms are been sold.

Results on Table 2 also revealed that 50.0% of the respondents believe that the necessary materials needed for production are affordable while the remaining half believe they are not. Additionally, oyster mushroom was the most cultivated in the study area thus affirming the result of Tolera and Abera (2017) that oyster mushroom are cultivated in different parts of the world. It also revealed in Table 2 that oyster mushroom was the most patronized (97.2%) mushroom by consumers.

Factors responsible for increased production

As shown in Table 3, more than 50 percent of the respondents affirmed that mushroom production increased within the last 2 years prior to the study and that market patronage was responsible for the increase. On the other hand, 63.9% arrogated the lack of increase in production to lack of capital and unfavourable environment (19.4%). Also majority do not make use of unskilled labour probably due to the technicality of mushroom production. Cost of producing spawn which is one of the key materials for mushroom production is between ₦500-1000 (30.5%) followed by ₦1501-2000.

Production method

Majority of the respondents affirmed that necessary materials needed to train people on mushroom production are not available and that such training cannot be done free of charge (Table 4). Also, a larger proportion of the sampled were satisfied with the reliability of the sterilization methods used in production and do not employ any special method during harvest. More than 80 percent cultivate mushroom on land especially in the garden (control environment), while only 11.1% picked their own from the forest.

CONCLUSION

Mushroom is an important horticultural and non-timber forest product which plays very important roles in improving the food and nutrition security of most developing countries such as Nigeria. Nigeria's sources of exchange and economic stability can be improved and achieved if proper attention is given to mushroom production. Findings from the study indicate that necessary materials needed for mushroom production are not readily available and affordable. Also lack of capital and favourable environment are key factors contribution to no increase in mushroom production. It is therefore recommended that basic and necessary production materials be made available and accessible to producers at subsidized rates. In order to enhance production, credit support should be made available to producers at affordable interest rates.

ABSTRACT
A study was conducted at the Headquarters of Cocoa Research Institute of Nigeria (CRIN) during the 2020/2021 dry season, with the aim of evaluating the effects of Arbuscular mycorrhizal inoculated soil and water regimes on root growth and dry matter biomass of three cashew biotypes in Ibadan, Nigeria. The study was designed as a Screen house experiment, consisting of a 3 x 3 x 2 factorial with 18 treatment combinations replicated three times, for a total of 54 experimental units, laid out in a completely randomized design (CRD). The factors included three cashew biotypes - Jumbo (C1), Medium (C2), and Madras (M3); 3 water regimes – 40% Field capacity (F1), 60% Field capacity (F2), and 80% Field capacity (F3) and 2 levels of Mycorrhiza - with Mycorrhiza (M1) and without Mycorrhiza (M0). Growth parameters such as plant height (cm), stem girth (cm), root length (cm), and dry matter biomass were collected and analyzed using ANOVA. The results indicated that Cashew biotypes responded differently to AMF inoculation, with Jumbo cashew inoculated with AMF showing a higher level of root colonization. Both negative and positive responses of the cashew biotypes were observed. The AMF inoculation significantly ($p > 0.05$) improved all the growth parameters considered, irrespective of the levels of water treatment. Jumbo cashew biotype (C1) inoculated with mycorrhizal (M1) at 80% field capacity produced the longest root (23cm) compared to others, followed closely by Jumbo biotype (C1) partially drought (F1) cashew seedlings with a root length of 22.00cm. Similarly, AMF inoculation, irrespective of rates of water applied, positively improved both fresh and dry matter accumulation of cashew biotypes throughout the periods of the experiment, with Jumbo biotypes inoculated with AMF inoculum at 80% field capacity. However, there was no significant difference between C1F1M1 and C1F3M1. C1F1M0 recorded the least dry matter yield. It is recommended that further research be directed towards exploring the potential of Arbuscular mycorrhizal in sustainable cashew production and other agricultural crops to enhance productivity. Such efforts would significantly contribute to the overall development of agriculture in the country. Notably, the pots that received AMF inoculation in conjunction with 80% field capacity (water treatment) exhibited the most significant response to the applied treatments ($p > 0.05$).

INTRODUCTION

Over 80% of the world's plant species have the ability to establish symbiotic relationships with Arbuscular Mycorrhizal Fungi (AMF) in their native habitats, as reported by Eom *et al.* (2000) and Parniske (2008). The association between AMF and plant roots has been linked to enhanced plant productivity, as demonstrated by Kaya *et al*. (2003). The colonization of plant roots by mycorrhizal organisms significantly increases the area available for nutrient uptake and drainage, leading to improved plant absorption. Previous studies on various crops have shown that mycorrhizal colonization results in a prolonged period of growth, as reported by Augé (2001). The presence of AMF can be observed in the early stages of plant development, as vesicles and spores resembling those of the Glomus species, as reported by Fulekar (2010). The first evidence of the superior growth of mycorrhizal plants compared to non-mycorrhizal plants was reported in Japan in the 1940s by Koide et al. (2014). In Europe, Mosse's study in 1957 demonstrated the beneficial interaction between Arbuscular mycorrhizal sporocarps of Endogone (Glomus) mosseae and apple seedlings and clonal leaf cuttings in autoclaved soil, as reported by Koide *et al*. (2004). The discovery and expression of AMF growth dates to the late nineteenth century, as reported by Brundrett (2004). AMF organisms obtain starch from plants, while plants benefit from mycorrhizal growth through nutrient supplementation, disease resistance, improved water relations, and reduced nutrient uptake.

These benefits have been demonstrated by numerous studies, including those by Augé (2001), Birhane *et al*. (2012), Bolandnazar *et al.* (2007), Kaya *et al.* (2003), and Rutto *et al.* (2002). Peterson *et al.* (2004) classified Arbuscular mycorrhizal organisms into six categories based on morphological characteristics and chemical investigations. Various species have been used for AMF identification, including hyphal traits, hyphae helper cells, spores, or spore carp intogeny, morphology, germination, spore separator protection, biochemical, sub-atomic, and physiological characteristics, as reported by Mukerji *et al*. (2002). When combined with mycorrhizal chemicals, almost all types of trapped roots show a yellow color indicative of disease (Bengum, 2019). Mycorrhizal fungi are present in any soil that support plant growth and help plants absorb water and nutrients. As a food source, plants provide sugars from their leaves to fungi. In addition, mycorrhizae can increase root surface area, allowing plants to absorb more water and nutrients from a larger volume of soil (Nadeem *et al.*, 2014). Furthermore, different mycorrhizal species respond differently depending on the plant species they are associated with (Ortas and Ostner, 2014). This is due to the wide variety of mycorrhizal fungal species that can alter the strength of plant-to-plant interactions and change the rate of plant growth. It is widely accepted that plants inoculated with mycorrhizal fungi have higher growth rates than control plants due to increased photosynthetic activity. The objective of this study therefore was to evaluate the effects of Arbuscular mycorrhizal inoculated soil and water regimes on root growth and dry matter biomass of three cashew biotypes in Ibadan, Nigeria.

MATERIALS AND METHODS

The study was conducted at the Headquarters of Cocoa Research Institute of Nigeria (CRIN), Kilometer 14, Ijebu – Ode Road, Onigambari, Adebayo, Idi Ayunre, Ibadan in Oluyole Local Government Area, Oyo state, Nigeria during the 2020/2021 dry season, with the aim of evaluating the effects of arbuscular mycorrhizal inoculated soil and water regimes on root growth and dry matter biomass of three cashew biotypes in Ibadan, Nigeria. The study was designed as a Screen house experiment, consisting of a 3 x 3 x 2 factorial with 18 treatment combinations replicated three times, for a total of 54 experimental units, laid out in a completely randomized design (CRD). The factors included three cashew biotypes - Jumbo (C1), Medium (C2) and Madras (M3); 3 water regimes – 40% Field capacity (F1), 60% Field capacity (F2) and 80% Field capacity (F3) and 2 levels of Mycorrhiza - with Mycorrhiza (M1) and without Mycorrhizal (M0). Ibadan is located at latitude 70 10’ N and longitude 030 52’ E. It is situated at an elevation of approximately 122 meters above sea level and is situated within the tropical rainforest region of Nigeria.

Planting of cashew seedlings

The topsoil utilized in this study was obtained from a Cashew plantation. It was air-dried and passed through a 10mm mesh sieve. Ten kilograms of the sieved soil were then filled into ten-liter plastic pots, watered to field capacity, and allowed to drain for 24 hours prior to planting Cashew seeds. The plastic pots were arranged on a raised concrete platform in a Screen house. The current season's Cashew seeds of Large, Medium, and Madras biotypes were planted individually in the pots. Two seeds were initially planted in each soil-filled punctured plastic pot, and later thinned to one seedling per pot. Prior to sowing the Cashew seeds, 50g of Arbuscular mycorrhizal was weighed and introduced halfway into the plastic container, mixed with soil, and watered immediately after sowing. Water treatments were applied at 40%, 60%, and 80% field capacity (F). Destructive sampling was carried out two months after treatment application to evaluate the effect of the mycorrhizal on fresh and dry shoot weight (g), leaf root weights (g), and root length (cm). This necessitated a doubling of 54 experimental units, thereby increasing the total experimental units from 54 to 108. The Cashew seedlings were monitored for four months at fortnight intervals for their growth parameters, which included plant height, girth, number of leaves, and branches. The growth parameters were measured using the following techniques: plant height was measured in centimetres using a meter rule from the plant base to the plant's terminal bud tip; visual inspection was used for the number of leaves and branches. Stem size was measured in centimetres using an advanced Vernier-Caliper 10cm above the ground level.

Agronomic practices carried out.

During the study period in the Screen house, watering was conducted biweekly with a three-day interval. Additionally, hand weeding and insecticide application were diligently executed in a timely manner.

Project termination and post-treatment soil sample collection

Upon completion of the experiment, the plants were harvested and subjected to a meticulous washing process with sterile water to eliminate any adherent soil particles. The various components of the plant, namely the roots, stem, and leaves, were segregated and packaged individually. The fresh weight of each component was measured and subsequently, the samples were subjected to oven drying at a temperature of 70 OC for a duration of 72 hours, following which their weight was determined. The oven-dried plant materials were then processed using a Glen Creston Mill equipped with a stainless-steel grinding chamber. The resulting materials were preserved for the determination of their nutrient contents in accordance with the procedures outlined by IITA (1979). Additionally, representative soil samples were collected from each experimental unit after thorough mixing of the soil in each pot. The soil samples were processed and analysed using the procedures prescribed by IITA (1979).

RESULTS AND DISCUSSION

Root length (cm) and growth biomass of cashew biotypes as influenced by Arbuscular mycorrhizal and water regimes. Despite the discernible treatment effects observed on the various cashew biotypes (C1F2M0; C1F3M0; C2F1M0 and C2F2M0) two months after treatment imposition with regards to the root length of the seedlings, the disparities were comparable and did not exhibit statistical significance ($p<0.05$) amongst themselves (Table 2). The Jumbo cashew biotype (C1) that was inoculated with mycorrhizal (M1) at 80% field capacity (F3) exhibited the longest root length (23cm) in comparison to the other biotypes. This was closely followed by the Jumbo biotype (C1) that was partially drought (F1) treated, with a root length of 22.00cm (Table 1). This result confirms the earlier observation of Kaya *et al.,* (2003) who reported that the association between AMF and plant roots is linked to increased plant productivity as Kaya et al., (2003). Similarly, the result of the present study agrees with the observations of Ying – *et al.,* (2014) and Campo *et al.,* (2020) who opined that inoculation with arbuscular mycorrhizal fungi significantly increased root projected area, surface area, volume, and total length, mainly in the range of 0 – 1 cm. However, the increase in length experienced by cashew seedlings may have been as a result of the colonization of the rhisozphere of the cashew seedlings by the AMF. However, the mean root difference was not statistically significant ($p < 0.05$). Cashew seedlings that were not inoculated with AMF, regardless of biotype, produced the least root length (8.00 cm). These trends persisted until the end of the experiment, which was 4 months after treatment imposition (4MAA).
Similar results were observed 4 months after treatment (4MAA), with the control producing the shortest roots and Jumbo cashew seedlings treated with mycorrhizal at 80% field capacity producing the longest roots (40.33cm) (Table 2). There were no significant differences observed in the root length values (15.00 and 15.17cm) of the medium cashew biotypes that were inoculated with Arbuscular mycorrhizal fungus at 40 and 80% field capacities (C2F1M1 and C2F2M1) respectively. However, these values were found to be significantly different ($p < 0.05$) when compared to the cashew biotypes that were not inoculated with mycorrhizal fungi and subjected to different water regimes at 2MAA as presented in Table 1. Moreover, the utilization of Arbuscular Mycorrhizal Fungi (AMF) inoculation exhibited a favorable impact on the fresh weight of roots and shoots, irrespective of the water application rate, as evidenced by Tables 1 and 2. Notably, the jumbo cashew (C1F3M1) that was subjected to AMF inoculum at the highest water regime (80% field capacity) demonstrated a significant improvement in both underground and above-ground fresh matter accumulation, in comparison to the other treatments applied. The control group exhibited the lowest fresh root and shoot weight (g/plant), respectively. The increase in weights (root and shoot) further confirms the work of Xue – Guang and Ming (2013) that, mycorrhizal plants exhibited significantly greater plant heights, stem diameters, leaf counts, and shoot masses (including leaf blades) in comparison to non - mycorrhizal plants. Additionally, the total masses of mycorrhizal plants were found to be considerably higher than those of non-mycorrhizal plants, they concluded.
Influence of Arbuscular mycorrhizal and water regimes on the dry root and shoot biomass of cashew biotypes. Throughout the experiment, the application of Arbuscular mychorrhizal in combination with three different field capacities and various water regimes had a significant impact on the accumulation of dry matter both underground and above ground in cashew biotypes (Tables 1 and 2). This result confirms the findings of Bengum *et al.,* (2022) who reported that introduction of Arbuscular mycorrhizal fungi (AMF) enhances the accumulation of dry matter and improves water moisture uptake, thereby resulting

in an overall improvement in crop performance. The Jumbo biotypes that received AMF inoculum at 80% field capacity demonstrated the most notable enhancement. Nonetheless, there was no discernible variation between C1F3M1 and C3F3M1 during the entire duration of the experiment ($p > 0.05$). At 2MAA and upon conclusion of the experiment, C1F1M0 exhibited the lowest dry matter yield (Tables 1 and 2). The Jumbo biotypes that were subjected to AMF inoculum at 80% field capacity manifested the most significant improvement. However, there was no statistically significant difference ($p < 0.05$) between C1F3M1 and C3F3M1 throughout the experimental periods. C1F1M0 recorded the least dry matter yield at 2MAA and at the conclusion of the experiment (Tables 1 and 2).

CONCLUSION

According to the findings of the current study, Arbuscular mycorrhizal fungi exhibit promising potential for enhancing seedling root development and promoting both below-ground and above-ground growth and dry matter accumulation. If utilized effectively, this could result in an overall increase in cashew production in the cashew-growing regions of Nigeria. Consequently, it is recommended that further research be conducted by scientists, particularly Agronomists in partnership with soil scientists and other stakeholders, to explore the prospects of this fungus in agricultural productivity.

ABSTRACT

In 16-days storage, this study assessed preservative effects of gum Arabic coating discretely and with cinnamon oil on fresh hot-pepper fruits, wherein microbial and colorimetric enumerations were monitored at 4 days intervals. Coatings significantly (p<0.05) achieved 30–70 % bacteria reductions from initial 7.3 x 10^4CFU/g, restraining rapid produce deterioration for ≥8<12 days; antifungal efficacies were exhibited through storage duration as yeasts and molds ranged 2.5 x 10^2 – 7.0 x 10^3CFU/g, within recommended 10^3–10^5 microbial limit for related food category. Brightness L (27–33) of preserved peppers gradually increased with ripening unto 8 days. Based on produce' variety, a (-3.14 – 9.11) and b (6.12 – 12.38) values were yellow on the colorimetric chart, without significant difference within treatments until two weeks storage. Gum Arabic without cinnamon oil ranked best across assessed visual and textural qualities, significantly different to other treatments. Applied coatings are effective in postharvest management of Capsicum fruits.

Keywords: *Peppers, Postharvest, Gum-Arabic, Cinnamon, Preservation*

INTRODUCTION

After tomatoes, the highly perishable Scotch Bonnet (*Capsicum chinense*) – a variety of chilli pepper ranks amongst important crops with about 18 t/ha yield in open fields (Barth *et al.,* 2009; Obayelu *et al.,* 2021; Ogungbemi, 2020). In the tropics of Sub-Saharan Africa, incurred losses in the postharvest value-chain of fresh produce, especially fruits and vegetables are in high (40–60 %) estimates (Obayelu *et al*., 2021) due to contributing pathological, physiological, ecological and mechanical factors such as microbial contaminants, prevailing environmental conditions (temperature and relative humidity), continued respiration of produce, and related gaseous interactions contribute to incidences of rapid quality deteriorations, safety and storability of these produce (FAO and CIRAD, 2021; Suchánková et al., 2015). In Nigeria and other developing nations, identified effective technologies with reduced temperature and increased relative humidity effectiveness for maintenance of quality during downstream value-chain are relatively unaffordable to smallholder farmers who are major producers of these fruits and vegetables (Obayelu et al., 2021; Oluwatobi, E. A., 2022). The adoption and utilization of Generally Regarded As Safe (GRAS) bio-polymeric materials (including Gum Arabic and essential oils) as edible coatings are recent interventions considered in the agricultural sector (Duguma, 2022). Thus, this study aims at preservation of scotch bonnet fruits with Gum Arabic–Cinnamon Oil edible coatings in related postharvest management.

MATERIALS AND METHODS

All materials were reliably sourced within Ilorin metropolis. Cinnamon bark was procured from Mandate market, while fresh Scotch Bonnet fruits were obtained at farmgate and transported early morning to NSPRI laboratory in surface-sterilized reusable plastic crates. The Scotch Bonnet fruits were sorted washed, surface sterilized by immersing in 0.01% hypochlorite solution for one minute, and air-dried.

Preparation and Application of Coatings: Cinnamon oil was extracted as described by Abubakar *et al.* (2014), while Gum Arabic coating was prepared according to Utami *et al*., (2014) with modifications. Ten grams (10 g) Gum Arabic was dissolved in 100 mL distilled water at 50 °C under continuous homogenization on a magnetic-stirrer hotplate for 60 minutes. Impurities were filtered off using muslin cloth, 2 mL glycerol was added as plasticizer to sustain potency and elasticity of coating mix, followed by addition of 3 mL cinnamon oil; this was tagged Coating A. Coating B with similar preparation lacked cinnamon essential oil. In three experimental lots: Treatment A (control) – fruits dipped in distilled water for 1-2 minutes; Treatment B – fruits dipped in Coating A; and Treatment C – fruits dipped in Coating B. Upon being air dried, all lots were assessed under same ambient storage conditions closely monitored with a data logger for 16 days, analytical monitoring was spaced 4 days.

Microbial Enumerations: Discrete samples initially diluted (1 mL aliquot) unto 10^{-6} dilutions were pour-plate inoculated for Bacteria and Fungi (yeast and mold) contaminants, enumerated using sterilized (121˚C, 15 psi, for 15 minutes in the autoclave) nutrient agar (FLUMEDIA, UK) and potato dextrose ager (HIMEDIA, India) appropriately; cultures were incubated at 35±2 ºC and 30±5 ºC for overnight 20±4 hrs. and 48±12 hrs. respectively. Colonies recorded were used for appropriated computation of microbial populace associated with the fruits and expressed as Colony Forming Unit per gram CFU/g (Fawole and Oso, 2007; FAO, 1997).

Color Measurements: Measurements on the epicarps were taken with a non-invasive colorimeter (FRU Color Reader, WR-10) of ShenZhen Wave Optoelectronics Technology Co. Ltd., China; and values presented as L (brightness), a (green to red) and b (yellow).

Organoleptic Assessment: Twenty panelists evaluated sensory attributes to infer consumer acceptance of the treated fruits as described by Fashanu *et al*. (2019).

Statistical analyses: Replicate data were subjected to Analysis of Variance (ANOVA) and tested for significant difference among treatments by New Duncan's Multiple Range F-Test (DMRT) at ($p<0.05$) using IBM SPSS software package version 26.0.0.

RESULTS AND DISCUSSIONS

The microbial populace enumerated from the three experimental lots of this study are presented in Figure 1. The recorded microbial loads of pepper fruits bulk (Day 0) distributed in lots exhibited an undulating pattern across treatments for the 16-days storage, this reflects microbial succession under supportive and unconducive environmental conditions for associated microbial diversity on the fruits. For Bacteria, similar to (Parveen et al., 2014), the proliferation of initial 7.3 x 10^4 CFU/g were 30–70 % reduced unto Day 8 evaluations, this infers influences of clean water dips (Treatment A), protective antimicrobial membranes of Gum Arabic and Cinnamon (Treatments B and C) to restrain rapid microbial deteriorations of produce and sustain marketable qualities for 72±12 hrs., which were best achieved in Treatment B (Day 4) and Treatment C (Day 8). Inclinations of bacteria loads by Day 12 unto Day 16 highlight the proliferation of less susceptible species to the coats and potency decline of in-place antimicrobial barriers, such that the extended shelf-life and quality retention against bacteria deteriorations of preserved scotch bonnet with Gum-Arabic and Cinnamon oil are optimally considered for 8 days. Recorded fungal contaminants relatively ranged 2.5 x 10^2 – 7.0 x 10^3 CFU/g with similar yeast and mold count of (Garuba et al., 2022; Ogungbemi, 2020), the antifungal efficacy of Treatments B and C were relatively inferred through the storage duration. The predominating yeasts by the 12th day of evaluations were significantly succeeded by associated molds.

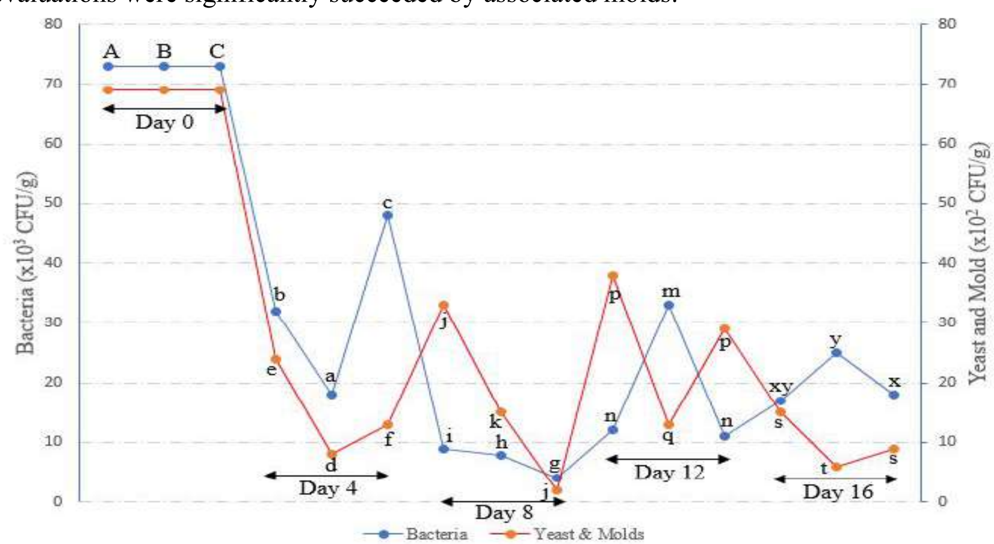

Figure 1: Microbial Enumeration of Pepper Fruits under Storage. A = Control; B = 10% Gum Arabic + 3 mL cinnamon oil; C=10% Gum Arabic; Lower-case alphabets (a – y) at markers are statistical comparison within A, B, C at each day of evaluation.

The color readings of evaluated *Capsicum* fruits are presented in Table 1 below. The brightness (27 – 33) of measured colors were observed to gradually increase unto the 8th day in storage, this considerably relate to the fruits' ripening characters within this duration. Recorded brightness were similar to (Díaz-Pérez et al., 2020). The fruits occupied the yellow region between green-red transition on the colorimetric charts, which relates to the varietal coloration of the *Capsicum* fruits used (-a to +a hemisphere), other varieties might highly tend towards red region (+a values) as reported by (Rahman et al., 2014). Despite non-significant difference ($p<0.05$) in recorded values, intensities of uncoated pepper fruits (Treatment A) were higher than the coated (Treatments B and C) till the 16th day; at which coloration (a, b) values of the coated peppers were significantly similar but different to the control; an effect of coating on the fruits' color is deduced.

Table 1: Color Measurements (L, a, b values) for Treated Scotch Bonnet under Storage

Sample	Day 0	Day 4	Day 8	Day 12	Day 16
L–values (brightness / intensity)					
A		$29.69^a±0.87$	$33.48^a±5.98$	$29.74^a±1.97$	$28.75^a±0.37$
B	$28.37^a±0.24$	$30.35^a±2.18$	$30.43^a±0.64$	$28.81^a±0.35$	$28.64^a±1.89$
C		$30.72^a±0.08$	$31.22^a±0.18$	$28.50^a±0.82$	$28.23^a±0.63$
a-values (green-red)					
A		$4.30^a±1.56$	$9.11^a±7.86$	$4.92^a±5.88$	$4.46^b±1.23$
B	$-3.14^a±0.26$	$5.30^a±1.80$	$5.90^a±2.89$	$-2.37^a±0.30$	$-1.17^a±0.11$
C		$6.48^a±0.59$	$8.15^a±1.05$	$2.31^a±2.93$	$0.94^a±0.35$
b–values (yellow)					
A		$9.03^a±0.76$	$12.38^a±6.38$	$8.23^a±1.95$	$7.69^b±0.40$
B	$6.12^a±0.67$	$10.05^a±2.30$	$10.36^a±0.10$	$7.17^a±0.68$	$6.50^a±0.16$
C		$10.70^a±0.07$	$9.66^a±1.03$	$6.92^a±0.39$	$6.19^a±0.07$

A = Control; B = 10% Gum Arabic + 3 mL cinnamon oil; C=10% Gum Arabic

The sensory qualities of the fruits evaluated are presented in Table 2 below. Appreciably, fruits coated with Gum Arabic without cinnamon oil constituents ranked best across assessed visual and texture qualities, significantly different to Treatments A and B. The panelists' preferences highlight significant shelf-life extension and retention of market qualities by applied coatings.

Table 2: Organoleptic attributes of Treated and Stored Scotch Bonnet

Sample	Aroma	Appearance	Colour	Firmness	Overall Acceptability
A	$2.10^a±0.10$	$1.90^a±0.18$	$2.20^a±0.20$	$2.40^a±0.16$	$2.30^a±0.15$
B	$2.10^a±0.23$	$2.00^a±0.21$	$2.50^a±0.17$	$2.30^a±0.26$	$2.90^b±0.10$
C	$3.50^b±0.17$	$3.50^b±0.17$	$4.00^b±0.21$	$3.30^b±0.15$	$3.80^c±0.13$

A = Control; B = 10% Gum Arabic + 3 mL cinnamon oil; C=10% Gum Arabic

CONCLUSION

The application of Gum Arabic and Cinnamon based edible coatings appreciably extended shelf-life and relatively retains qualities of preserved scotch bonnet peppers.

ABSTRACT

Field studies were conducted during 2018 and 2019 rainy seasons at Faculty of Agriculture Bayero University Kano (BUK) (Latitude 11° 58.861' N and Longitude 008° 25.155' E, Altitude 449 m above sea level) and at National Horticultural Research Institute (NIHORT) (Latitude 11^0 33^1 N and Longitude 8^0 23^1 E with Altitude of 481m above sea level) in the Sudan Savannah of Nigeria, to determine effects of spacing and weed control methods on the matrix correlation coefficient of sunflower production in Kano State. The experiment consisted of spacing (with three levels 30 x 75 cm, 60 x 75 cm and 75 x 75 cm) and eight weed control methods (as weedy check (T1), manual hoe weeding at 3 and 6 WAS (T2), pre emergence application of Tithonia plant extract followed by post emergence application of extract at 6 WAS (T3), pre emergence application of Tithonia followed by manual hoe weeding (T4), pre emergence application of Tithonia followed by post emergence application of post emergence Fluazipop (T5), pre emergence application of herbicide metolachlor followed by manual hoe weeding (T6) , pre emergence herbicides at planting (PEH) followed by post emergence application of herbicides Fluazipop (T7) and manual hoe weeding (MHW) followed by post emergence application of herbicides at 6 weeks (T8)). These were factorially combined in split plot design and replicated three times. Data were recorded on weed attributes, growth and yields character of sunflower. Results showed that the correlation coefficient between plant height, leaf area, weed dry weight and weed density were negative and non-significant. While the weed control efficiency and relative growth rate were highly significant and negatively correlated. The correlation coefficient between some selected weeds, growth characters and yield components of sunflower indicated negative and highly significant ($p \leq 0.01$) correlation between sunflower kernel yields and weed density. However, there was high negative and significant correlation between sunflower kernel yield and weed control efficiency.

Keywords: *Coefficient, correlation, herbicides, kernel, matrix, sunflower, weed, yield*

INTRODUCTION

Sunflower (*Helianthus annuus* L.) is the most successful cultivated species of the family *Asteraceae* (order *Asterales*), that includes over 70 species of shrubs (Anonymous, 2016). It is an important oilseed crop which ranks third after soybean and groundnut as source of edible oil in the world (Oyinlola *et al.*, 2010). The crop originated from North America (anonymous, 2016). It was likely to be the most "camp follower" Sunflower crop that is cultivated widely throughout the world (Groove *et al,* 2005). FAO (2010) reported that the current world area under sunflower cultivation was 22.3 million hectares, while seed production and average yield stood at 27.7 million tons and 1.2 ton per hectare respectively (Sani *et al.,* 2014). The major goal of growing sunflower is for its seed (achene) that contains oil (36- 52%) and protein (28– 32%) as reported by Rosa *et al.* (2009). It's a vegetable crop of economic importance that has a high oil content. It can be used as edible oil in form of margarine, salad dressing oil and cooking oil, it can also be used as snacks (Qahar *et al.,* 2010). The non-dehulled or partly dehulled sunflower meal can be used for ruminant animals, pigs and poultry feeds. Weeds significantly affect sunflower yield and reduce the quality and quantity of kernel during harvest. According to report loss due to weeds may reached up to 96 percent at the global level

MATERIAL AND METHODS

The experiments were conducted during the 2017/2018 and 2018/2019 rainy season at the Teaching and Research Farm of Bayero University, Kano, ($11^0$58N and $8^0$25E) and the Teaching and Research Farm of National Horticultural Research Institute NIHORT ((Latitude 11^0 33^1 N and Longitude 8^0 23^1 E with altitude of 481m above sea level) in the Sudan Savannah agroecology zone of Nigeria. The average rainy days of about 110 and annual rainfall of about 1033.3 maximum and minimum of 981.2.) At Bagauda in 2018 rainy season. The average rainfall of 500mm to 1000mm per annum was adequate for growing sunflower. The rainy days of 100 to 120 days can support sunflower production (Badu-Apraku *et al*., 2011), the area has an average temperature of $28^0 – 32^0$C and dry season of 6 to 9 months (Sowunmi and Akintola, 2010). Data were collected on growth parameters of sunflower, weeds and yield attributes. The data collected were subjected to the analysis of variance

RESULTS

Table 1 showed the matrix of the correlation coefficient between some selected weed characters, growth characters and yield components of sunflower in 2018 rainy season at Bagauda. The results indicated a negative and highly significant ($p \leq 0.01$) correlation between sunflower kernel yields, weed density. The correlation between sunflower kernel yield and weed control efficiency was negative but not significant. The correlation coefficient between sunflower kernel yields and weed dry weight was negative and highly significant. The correlation coefficient between sunflower kernel yields and weed cover score was negative and highly significant ($p \leq 0.01$). The correlation coefficient between weed density and number of leaf was negative and significant. The association between leaf area and weed density was negative and significant. The correlation coefficient between weed density and crop growth rate was negative and significant. There was positive significant correlation between weed density and relative growth rate of sunflower plants. The weed density was highly significant ($p \leq 0.01$) and negatively correlated with plant height. Relative growth rate was significant at ($p \leq 0.05$) and positively correlated with plant height. The association between number of leaves and lead area were highly significant at ($p \leq 0.01$) in relation with the plant height.

Table 2 showed the matrix of the correlation coefficient between some selected weeds, growth characters and yield components of sunflower in 2019 rainy season at Bagauda. There was negative correlation between sunflower kernel yield and weed density. The weed dry weight was negatively correlated with sunflower kernel yield and significant while weed control efficiency was highly significantly ($p \leq 0.01$) correlated with sunflower kernel yields. The association between sunflower kernel yield and weed cover score was negative and significantly correlated. The correlation coefficient between plant height and weed density was negative and non-significant. The correlation between leaf area and weed dry weight was negative but not significant, while the weed control efficiency and relative growth rate were highly significant and negatively correlated. The correlation coefficient between plant height and number of leaf were highly significant and positively correlated.

Table 3 showed the matrix of the correlation coefficient between some selected weeds, growth characters and yield components of sunflower in 2019 rainy season at BUK. The results indicated negative and highly significant ($p \leq 0.01$) correlation between sunflower kernel yields and weed density. There was highly negative and significant correlation between sunflower kernel yield and weed control efficiency. However weed dry weight was highly significant ($p \leq 0.01$) but negatively correlated with kernel yield per hectare. The number of leaf was not significantly correlated with sunflower kernel yield per hectare. Similarly plant height was negatively correlated with kernel yield per hectare and not significant. The correlation coefficient between plant height and weed cover score was highly significant ($p \leq 0.01$) and negatively correlated while number of leaf, was not significant and negatively correlated. The correlation coefficient between leaf area and crop growth rate was highly significant ($p \leq 0.01$) and negatively correlated.

Table 4 showed the matrix of the correlation coefficient between some selected weeds, growth characters and yield components of sunflower in 2019 rainy season at BUK. The results indicated positive and highly significant ($p \leq 0.01$) correlation between sunflower kernel yields sunflower and number of leaf. There was highly significant association between leaf area and crop growth rate. There was positive correlation between sunflower kernel yield and leaf area index highly and significantly ($p \leq 0.01$) correlated. The correlation coefficient between plant height and sunflower kernel yield was negative and not significant. The correlation coefficient between sunflower kernel yield and weed cover score was negative and highly correlated. The correlation coefficient between sunflower kernel yield and weed control efficiency was highly significant ($p \leq 0.01$) and negatively correlated. Also weed dry weight and sunflower kernel yield were highly significant and negatively correlated. The correlation coefficient between weed density and weed control efficiency were highly significant ($p \leq 0.01$) and positively correlated. The correlation between weed density and weed dry weight were significant and positively correlated. Weed cover score and weed control efficiency were significant ($p \leq 0.01$).

DISCUSSION

Matrix of Correlation Coefficients Analysis of Growth and Yield Characters of Sunflower

The results of correlation analysis of the experimental trial carried out showed that the negatives correlation between the sunflower kernels yield per hectare and weed attributes like weed density, weed dry weight, weed cover score and weed control efficiency during the periods of the experiments and combined this could be attributed to the fact that weed competes with sunflower for the environment resources required for the growth of the plant. This is in line with the findings of Nojavan, 2001 and Yaghobi and Yousefi, 2008 in which they reported that weed competes with sunflower for water, light and plant nutrient thereby reducing yield. Similar findings was reported by Gani and Shingu (2016) which indicated that, the grain yield of millet was negatively and highly significantly correlated with cumulative weed dry weight and weed density. The correlation coefficient analysis showed positive and significant correlation between sunflower kernel yield per hectare and growth parameters like plant height, leaf area, leaf area index, and crop growth rate this indicated the value and importance of these growth characters in determining the yield of sunflower. This agreed with reports by Gubta *et al*. (2007) who reported positive significant correlation of panicle weight and other yield attributes.

ABSTRACT
Most farmers use agro-chemicals in different ways to improve agricultural productivity however, it is essential to track the use of such agro-chemical. The study analyzes the use of agro-chemicals among vegetable farmers in Ibadan North west Local Government Area (IBNW LGA), Oyo State, Nigeria. Multi-stage sampling techniques was used. It involves purposive selection of one farmers' association in IBNW LGA, Oyo state followed by random selection of 40 farmers that came for the monthly meeting. Primary data was collected through questionnaire and analyzed using descriptive statistics. Majority (70.0%) of the respondents were male, 85.0% were married, 45.0% had tertiary education. Major vegetables planted by the respondents are Amarathus, Corchorus, Celocia, 67.5%, 65.0%, 42.5% respectively, tomato, okra, pepper with 22.5%, 20.0%, 12.5% respectively are the least of the fruity vegetables planted. The major agrochemicals used by the farmers are herbicides, fertilizer, insecticides, pesticides and fungicide, 67.5%, 57.5%, 50.0% and 12.5 respectively during farming operations. The study revealed that (77.5%) of the respondents got information on the use of agrochemicals from Agricultural Development Programmes, and research institute (57.5%) followed by other farmers and agrochemicals dealers with 50% and 7.5% respectively. The major constraints considered as severe on the use of agro-chemicals were high cost of agro-chemicals (87.5%), inadequate fund to purchase agrochemicals (85.0%), adulteration of agro-chemicals (67.5%) each were scored 1st, 2nd and 3rd respectively. Relevant agricultural stakeholders should link farmers with input agency and provide farmers with comprehensive training in safe use of agrochemicals.
Keywords: *Analysis, Utilization, Agro-chemicals, Vegetable farmers, Environment*

INTRODUCTION

Vegetables are the most important ingredients of human diets for the maintenance of good health and prevention of diseases (Funmilayo et al., 2016). Cultivation of vegetables is an excellent source of employment for both rural and urban dwellers as it takes place in many rural areas, towns and cities in the form of market and backyard gardening to supply fresh produce to urban markets. It thus, plays an important socio-economic role as well as in diversifying diets for improved nutrition (Ntow et al., 2006; Matthews, 2008). As vegetables are generally susceptible to a wide range of pests and diseases, production requires intensive effort in their management. The increased demand for food, particularly to feed the growing urban population in Nigeria has necessitated an expansion of agriculture and horticulture and consequently increase in use of synthetic agro-chemicals for production of high-value cash crops and vegetables (Jamala et al., 2013). However, these agro-chemicals are often applied indiscriminately and inappropriately, resulting in adverse environmental and health effects.

Agro-chemicals refers to the broad range of pesticides and insecticides including fertilizers, hormones, herbicides, fungicides, and other growth chemicals and concentrated stores of raw animal manure (cow dung and poultry droppings) (Ngowi1 et al., 2007). Globally, agro-chemicals are used as soil conditioners, acidifiers, nutrients and are also used to control diseases caused by bacteria, fungi, pests and viruses, enhancing agricultural productivity. These agro-chemicals to some extent proved harmful not only for humans but also pose a great danger to the environment. Fleisher (2006), reported that the use of synthetic fertilizers and pesticides in the developing countries has grown substantially during the past four decades. Government promotes the use of agro-chemicals in order to achieve national food security and improve the production of export crops.

The total exposure to chemicals is the sum of exposure during agro-chemicals storing, mixing, applying and disposing (Bhandari et al., 2020). These agro-chemicals are inhaled through different routes via; oral (through the mouth and digestive system), dermal (through the skin), occularly (through eyes) or by inhalation (through the nose and respiratory system. Scientific information on the agrochemical use and possible constraints to the use of agro-chemicals by vegetable farmers would provide insight for decision making on best ways of enhancing its use among vegetable farmers in the study area.

The specific objectives of this study were to: -

I. Identify the personal and entrepreneur characteristics of vegetable farmers in the study area;
II. Ascertain the farmers' knowledge of agro-chemicals application
III. Investigate constraints to use of agro-chemicals on vegetable productions.

METHODOLOGY

The study area was Ibadan Northwest local government area, Oyo State Nigeria, which belongs to the Yoruba ethnic group. The study was carried among Fadama Vegetable Farmers in Ibadan Northwest Local Government Area, Oyo State. A multistage sampling technique was used. The first stage was the selection of local government area which is Ibadan Northwest Local Government Area. The second stage was random selection of 40 Fadama Vegetable farmers from the selected local government. A total of forty (40) structured questionnaires were administered. The data collected were analyzed using descriptive statistics such as frequencies, percentages and mean scores were used to achieve objectives of the study.

RESULTS AND DISCUSSION

Personal and entrepreneur Characteristics of Respondents:

Table 1 shows that the respondents were within the mean age of 54.37 ± 9.42 meaning that farmers are still in their middle age and have the capabilities for the utilization of improved agricultural technologies such as agro-chemicals. This is in line with (Benedicta, 2010) who said younger people are relatively more open to risk taking and have longer planning horizon. Majority (70.0%) of the farmers were male, this could be that male farmers have more access to production resources and had the time to attend the monthly meeting of the farmer's organization because women are often time engaged in household chores and other activities. According to Onu (2006), activities of women farmers are faced with socio-cultural restrictions and sex plays significant role in having access to production resources such as agro-chemicals. Also, 85.0% of the respondent were married showing high sense of responsibilities and willingness to improve their standard of living. Most (45.0%) respondents had tertiary education while 37.5% had secondary education which means that an average number of the farmers could communicate well, 47.5% of the respondents had family size of (1-4), this could be as result of their high level education so that they can be able to provide for the family while (45.0%) of the respondents had 10-20 years of farming experience on vegetable production. The farm size of the respondents were within mean ratio 1.52 ± 1.04. Vegetable farmers operating on smaller farm holdings are placed at a disadvantaged position because of fragmentation (Idrisa et al., 2007). 60.0% of the respondents had contact with extension agents, the major vegetables planted by the respondents are *Amarathus, Corchorus, Celocia*, 67.5%. 65.0%, 42.5% respectively, tomato, okra, pepper with 22.5%, 20.0%, 12.5% respectively are the least of the fruity vegetables planted.

Knowledge on agro-chemical application

The result in table 2 revealed the major agrochemicals used by the respondent and their source of knowledge on agrochemical application. majority of the respondents identify pests attack on their vegetable before applying agro-chemicals. 82.5% were able to diagnose vegetable problem before applying agrochemicals, 95.0% of the farmers were able to read instructions on the use of agrochemicals. 67.5%, 57.5%, 50.0% and 12.5% of the respondents used herbicides, fertilizer, insecticides, pesticides and fungicide respectively during vegetable production. Hence, the use of herbicides, insecticides and pesticides among respondents is in accordance with the findings of Ngowi1 et al. (2007) who reported increased crop yield due to application of fertilizer. Fungicides was the least of agrochemicals used by the respondents, this could be as a result of farmers' inability and lack of technical know-how in identifying fungal infected plant in the locality or low incidence of fungal infection on the vegetable farms in the study area. The major pesticides used by the farmers are D.D Force (47.5%), Neem extract (37.5%) and Parac force (17.5%). 65.0% make use of inorganic fertilizer while 17.5% basically used organic (compost) fertilizers, and 42.5% of the famers apply their fertilizer weekly while 35.0% apply monthly. 72.5% of the respondents apply agrochemicals before pest infestation, Majority of the respondents got their recommendation on agrochemicals usage from ADPs and other farmers and friends 77.5% and 45.0% respectively, majority (85.0%) of the respondents use knapsack sprayer Also, 90.0% apply their agrochemical early morning using raincoat/safety clothes, nose mask and gloves, 77.5%,45.0%, 32.5% respectively while 57.5% leave their vegetable for 1-2 weeks after agrochemical application before harvest. (80.0%) of the farmers complain to expert when agrochemical is not effective, 97.5% have the knowledge/aware of the dangerous effect of agrochemical to people and the environment while 77.5% buried/burned their agrochemicals containers after use. Education has the capability of enhancing knowledge of the respondents. Majority of the respondents were literate with a good number of them having more than primary education. The high literacy level among the respondents could be responsible for the farmers' knowledge and awareness. Most (90.0%) respondents are aware and agreed that chemical residue can be identified in vegetable due to inappropriate use of chemical. Majority (57.5%) got information on use of agrochemicals from Agricultural Development Programmes (ADPs) and research institute (20.0%). This indicate that respondents got information on agro-chemicals usage mainly from ADPs and research institute due to the fact that the ADPs and research institute are mostly in touch directly with rural and grass root farmers in Nigeria.

Constraints to Utilization of Agro-chemicals among Respondents:

Table 3 shows the major constraints considered as severe on the use of agro-chemicals among the respondents as high cost of agro-chemicals (87.5%), inadequate fund to purchase agrochemicals (85.0%), adulteration of agro-chemicals (67.5%), high cost of personal protective materials (57.5%), ineffectiveness of agro-chemicals (52.5%), attracting a rank of 1st, 2nd, 3rd, 4th and 5th respectively

CONCLUSION AND RECOMMENDATION

The present study examined the analysis of the use of agrochemicals among Fadama Vegetable Farmers in Ibadan Northwest LGA, Nigeria. Pesticides such as insecticides and fertilizers are used by most farmers in the study area majorly to maximize productivity and pest attack reduction. Majority of the respondents were relatively young which result to their active participation on vegetable farming activities, and had 7 and above years of formal education, indicating that the respondents were literate and were able to read instructions for agrochemical use. Major challenges are high cost of agro-chemicals, inadequate funds and lack of training on the safe use of agro-chemicals. Based on the major findings of the study and the conclusions reached, the following recommendations were made

1. Creating awareness on safe use of agro-chemical should be promoted by both government and non-governmental organization.
2. Relevant agricultural stakeholders should link farmers with input agency and provide farmers with comprehensive training in agrochemical use.

A SURVEY ON COMMON ORNAMENTAL PLANT SPECIES AT SOME SELECTED HIGHER INSTITUTIONS IN EKITI STATE

Aluko M* and Oluwadare T.D
Department of Crop, Horticulture and Landscape Design, Ekiti State University, Ado-Ekiti, Nigeria

*Corresponding author: matthew.aluko@eksu.edu.ng +2348060263395

ABSTRACT
Humans are much more drawn to ornamental plants due to the aura of beauty and environmental enhancement they produce. It promotes learning, especially in educational institutions, by appealing to human comfort in a serene setting. In 2021, a survey was conducted on the grounds of some selected higher education institutions in Ekiti State, Nigeria by collecting, identifying, and describing some common ornamental plant species discovered on campus grounds. The various plant species were presented as original colour photographs and evaluated by determining their family, scientific, and English names which were classified according to their characteristics, propagation method, and uses (hedges, shading and indoor plants). This study identified and described twenty-seven (27) ornamental plant species from eighteen (18) families, including twelve (12) species of hedge plants, nine (9) species of shading plants, and six (6) species of indoor plants. Aside from aesthetic, ornamental plants serve as landscaping, windbreak, and shade provider.
Keywords: *Hedge plants, indoor plants, ornamental plants, plant species, shading plants.*

INTRODUCTION
Plants are the foundation of life and the ecosystem's primary producers; consequently, all other organisms depend on them for survival. However, some plants are aesthetically pleasing and are grown solely for aesthetic purposes; these plants are known as Ornamental Plants. These plants have aesthetic qualities that improve life quality (Akintoye, 2004). Historically, humans have utilized ornamentals as a class of plants. From the perspective of ethnobotany, the use of ornamental plants is a response to local botanical knowledge that guides diverse cultivation and consumption strategies in various cultural contexts (Hurrel, 2014). These plants include trees, shrubs, ground covers, turf grass or sod, bulbs and plant stock, and environmental horticulture, which provides crops typically grown outdoors and used primarily for landscaping purposes (Kolavalli and Whittaker, 2004). In addition to providing shelter and food for smaller organisms, they serve as the ecosystem's primary producers and tourist attraction (Onuegbu, 2005). In recent years, ornamental plant growth has increased across the nation as a common strategy to control unused and marginal land, which serves as a dumping ground for waste and other undesirable materials. An unplanned setting is unsightly, unhealthy, and undesirable (Oloyede, 2012).
Moreover, the use of woody plants in university campus planting arrangements plays a crucial role because these plants have both an educational value and an ecological function. Since the importance of growing ornamental plant species is becoming increasingly apparent, no special care is given to appropriately selecting and identifying plant species used as ornamentals for different purposes. Consequently, this survey was conducted to document and characterize the common ornamental plant species in Ekiti State institutions.

MATERIALS AND METHODS
Study Sites
The areas for this study are the Ekiti State University, Ado-Ekiti (7°44' N, 5°16' E), Federal Polytechnic, Ado-Ekiti **(**7°37' N, 5°24' E), both located at the central, the Federal University, Oye-Ekiti **(**7°49' N, 5°23' E) located at the north and Bamidele Olumilua University of Education, Science and Technology, Ikere-Ekiti (7°30' N and 5°03' E) located at the southern senatorial district area. These areas are within the tropical rainforest belt covering most of southwestern Nigeria with a West African monsoonal climate with a dry and wet season (Olujobi, 2013; Ogundele and Jegede, 2013).

Sampling techniques and Methods of identification used
The survey was conducted around these study sites in March 2021, involving collecting, identifying and describing various ornamental plant species commonly found around the study areas. The ornamental plants were identified, captured and snapped using a digital camera. A vial of this work was presented as

an original-coloured photograph described through consultation with gardeners' books, encyclopedias, and the internet. Pictures and illustrations, identification keys in botanical books and floras, i.e. dichotomous keys, matching in the herbarium, asking experts (inquiring about such species from experts in the field/ horticulturists), sourced from books, encyclopedias, and the internet were used to identify the plants in this study.

RESULTS AND DISCUSSION

This survey work was carried out by visually assessing some common ornamental plants species at some selected higher institutions in Ekiti State, Nigeria, which resulted in the collection, description and identification of 27 ornamental plant species belonging to 18 families distributed around the campuses (Figure 1). The results and observations made during the survey, along with each species' importance, were grouped into hedge plants (Table 1), shading plants (Table 2) and indoor plants (Table 3).

The survey showed that plants species of the family Euphorbiaceae were the most predominant, having four species, followed by the family Rubiaceae, Palmeae, Fabaceae, Commelinaceae and Combretaceae, with each family having two species, while the last family are Annonaceae, Nyctaginaceae, Malvaceae, Cupressaceae, Rutaceae, Strelitziaceae, Palmeae, Araucariaceae and Agavaceae around these campuses. Ornamental plants were authentically attractive to humans as a beauty to behold (Onuegbu, 2005) in agreement with landscape design technology (Kolavalli and Whittaker, 2004). The ornamental plants on the campuses were found to perform other purposes, such as landscaping, sites for visibility studies and research works, and relaxation point apart from their primary goal of beautification.

CONCLUSION

Ornamental plants are essential to human life, providing shade, indicating the walkways, serve as windbreaks and beauty around the higher institution campuses. Therefore, schools, offices, markets, and the religious centre should be sensitised on the importance of growing ornamental plants and encourage them to cultivate the habit of raising them.

Fig. 1: Some ornamental plants in some selected institutions in Ekiti State, Nigeria

Table 1: Most common hedge plant species identified at some established institutions in Ekiti State, Nigeria.

Family Name	Scientific Name	English Name	Common Name	Mode of propagation	Uses
Nyctaginaceae	*Bougainvillea spectabilis*	Bougainvillaea	Bougainvillaea	Stem cutting	Hedge plant and flowering climbers for covering trellises and spot plants.
Annonaceae	*Polyalthia longifolia*	Masquerade tree	Police tree	It is propagated by seed	Hedge plant also serves as a multipurpose plant
Malvaceae	*Rosa sinensis*	Hibiscus	Rose of china	Stem cutting	Hedge plant
Cupressaceae	*Thuja orientalis*	Orienta arborvitae	Thuja	Stem cutting	It is used as an avenue, spot and hedge plant
Rubiaceae	*Ixora duffi hybrid (Red)*	Jungle flame, dwarf Ixora	Double Ixora	Stem cutting	Hedge plant
Euphorbiaceae	*Cordiaeum variegatum (Gold dust)*	Gold dust croton	Croton	Stem cutting	It is used as a spot and hedge plant
Verbanaceae	*Duranta goldiana Linn.*	Duranta goldiana	Yellow bush	Stem cutting	Flowering/hedge plant
Rubiaceae	*Ixora javanica*	Jungle flame	Ixora nora (single ixora)	Stem cutting	Hegde plant
Rutaceae	*Murraya paniculata*	Orange jessamine	Murraya paniculata	Stem cutting	Hedge plant
Strelitziaceae	*Ravenala madagascariensis*	Traveller's palm			Hedge plant
Euphorbiaceae	*Cordiaum variegatum(Bravo)*	Codiaeum	Croton	Stem cutting	Hedge plant
Euphorbiaceae	Acalypha wilkesiana	copperleaf	Red acalypha	Stem cutting	Hedge plant

Table 2: Most common shading plant species identified at some selected higher institutions in Ekiti State, Nigeria.

Family Name	Scientific Name	English Name	Common Name	Mode of propagation	Uses
Combretaceae	*Terminalia catappa*	Umbrella tree	India Almond	Seed	It serves as a shade tree in landscaping
Combretaceae	*Terminalia mantaly*	Almond tree	French mantaly	It is propagated by seed	Shading or flowering tree
Palmae	*Roystonia regia*	Royal palm	Cuba royal palm	Seed	Avenue plant
Apocynaceae	*Plumeria rubra*	Temple tree	Frangipani	It is propagated by seed	Shade plant
Fabaceae	*Erythrina indica L.*	Variegated leave erythrina	India coral tree	Propagated by Seed	Shade plant
Cupressaceae	*Callitris rhomboidea*	Frenela or port Jackson pine	Oyster bay pine	Propagated by Seed	Shade
Pinaceae	*Pinus caribeae*	Honduras pine	Caribean pitch pine	Seed	Shade
Araucariaceae	*Araucaria* columnaris	Araucaria	Christmas tree	Propagated by seed	Shade
Fabaceae	*Delonix regia*	Flame of the jungle	Poiciana	Seed	Shading or flowering tree

Table 3: Most common indoor plant species identified at some selected institution campuses in Ekiti State, Nigeria.

Family	Scientific Name	Common Name	English Name	Mode of Propagation	Uses
Euphorbiaceae	*Euphorbia milli*	Euphorbia	Crown of thorns	Stem cutting	Potted plant
Moraceae	*Ficus benjamina*	Ficus (Variegated)	Weeping fig	Stem cutting	Potted plant
Commelinaceae	*Tradescantia spathacea*	Dwarf rheodiscolor	Moses-in-the-cradle	Plantlets	Potted plant
Cycadaceae	*Cycas revoluta*	Cycad palm	king's sago palm	It is propagated by seed	Indoor spot plant
Commelinaceae	*Tradescantia pallida*	Spiderwort	Purpleheart	Stem cutting	Potted plant
Agavaceae	*Cordyline terminalis*	T-1 plant	T-1 plant	Stem cutting	Potted plant

ASSESSING THE TRAINING NEEDS OF WOMEN FARMERS IN OYO STATE, NIGERIA: A CASE STUDY OF WOMEN FARMERS EMPOWERMENT INITIATIVE AND NATIONAL HORTICULTURAL RESEARCH INSTITUTE COLLABORATION

***Ajibade L. A., Adeoye, I. B., and Olajide-Taiwo F. B.**
National Horticultural Research Institute, Ibadan

Corresponding author: lukfal4real@gmail.com

ABSTRACT
A collaborative assessment was conducted to identify the training needs of women farmers in Oyo State, Nigeria. The study was carried out through a partnership between the Women Farmers Empowerment Initiative (WOFEI) and the National Horticultural Research Institute (NIHORT). The study aimed to identify the socio-economic profile of the respondents, evaluate the major crops cultivated by the farmers, and assess their areas of interest in horticultural production. A standardized closed-ended questionnaire was administered to 122 respondents, utilizing a descriptive research methodology. The study found that a significant proportion of the respondents (36%) were between the ages of 50-59 years, married (76.5%), reported having a family size of 6-8 (42.5%), and actively involved in agricultural activities as their main source of livelihood (93.3%). The horticultural crops of interest to the women farmers were found to be tomato (61.8%), jute mallow (58.4%), pepper (53.9%), okra (49.4%), amaranth (46.1%), and celosia (33.7%). Based on the findings, the study recommends developing targeted training programs that address the specific needs of women farmers, with a particular emphasis on improving their access to resources and enhancing their skills in horticultural production. This study represents a significant stride towards promoting gender parity and enhancing opportunities for women farmers in Nigeria
Keywords: *Women farmers, Collaboration, Horticultural crops, NIHORT, and WOFEI*

INTRODUCTION

Osabohien *et al.,* (2019) argue that the agriculture industry in Nigeria plays a significant role in terms of employment, engaging over 60% of the country's workforce. Additionally, it contributes 32.5% to the nation's gross domestic product (GDP) and serves as a source of cash through exports. The significance of skills development in rural areas is of paramount relevance, particularly because a substantial proportion, around 70%, of the global impoverished population is concentrated in these regions (Cicero *et al.,* 2021). According to Hassoun *et al.,* (2022), the enhancement of the agricultural sector through the cultivation of skills has the potential to contribute significantly to the attainment of the Sustainable Development Goals (SDGs). The acquisition of training and skills is crucial for both the agricultural and non-agricultural sectors, as it enables individuals to effectively address their livelihood requirements.

The inclusion of women in the agricultural industry is of utmost importance, as they make significant contributions to both global food security and economic development. Based on data provided by the Food and Agriculture Organisation (FAO), it is evident that women comprise approximately 43% of the agricultural workforce in developing nations (Olorunfemi *et al.,* 2016). According to Giroud & Huaman (2019), women agricultural practitioners encounter a multitude of constraints, encompassing restricted financial capital, availability of land, and educational prospects. Numerous studies have demonstrated that the empowerment of women in the agricultural sector can yield substantial enhancements in food security, productivity, and economic advancement. These goals can be attained through implementing interventions that encompass facilitating women farmers' access to loans, land, and various resources, with the provision of training and education programmes tailored to satisfy their individual requirements (Osabohien *et al.,* 2019). The promotion of gender equality in the agricultural sector is of utmost importance to effectively attain sustainable development goals and guarantee a more promising future for rural communities across the globe.

However, it is worth noting that there is a conspicuous lack of educational and training options accessible to this demographic, which has the potential to augment their skills and overall productivity Giroud & Huaman (2019). As a result, they rely on traditional agricultural practices that may demonstrate reduced levels of effectiveness and financial viability. Notwithstanding these constraints, Olorunfemi *et al.,*

(2016) posit that the government has implemented policies to promote gender parity and improve women's opportunities to get resources and services. Non-governmental organizations (NGOs) have also undertaken programmes to provide educational and training opportunities to women farmers, augmenting their agency, and addressing the challenges they face.

The aforementioned led to collaboration between the Women Farmers Empowerment Initiative (WOFEI) and the National Horticultural Research Institute (NIHORT) which took place intending to enhance the socio-economic conditions of women farmers in Oyo State, particularly in the Oke Ogun region. Collectively, their primary aim was to evaluate the training requirements of women farmers in the area and equip them with the essential competencies to augment their productivity and effectiveness. This collaborative effort represents a noteworthy stride in advancing gender equality and enhancing the prospects for female farmers in Nigeria.

Objectives of the Study

The overarching goal of this study was to ascertain the needs assessment of the women farmers in Oyo State. The specific objectives are to:

i. Identify the socio-economic components of the respondents
ii. Evaluate the major crops that are grown by the respondents
iii. Assess the respondents' horticultural crops of interest

MATERIALS AND METHOD

This study was conducted in Oke Ogun, a geographical area in the northern region of Oyo State, Nigeria, consisting of ten Local Government Areas (LGAs), including Saki West, Saki East, Atisbo, Iwajowa, Kajola, Irepo, Oorelope, Surulere, Itesiwaju, and Olorunsogo. Agriculture is the primary economic activity in the region, with community members engaged in the cultivation of crops such as yam, cassava, maize, groundnut, and vegetables, as well as livestock husbandry. Women's participation in small-scale enterprises and commercial activities has increased notably in the area. The study was conducted in three farm villages of Kajola Local Government Area: Ilero, Sepeteri, and Isemi-Ile. These locations were selected because they have a high concentration of WOFEI's women farmers who expressed a willingness to participate in the study. The research used a purposive sample method and a descriptive research methodology, administering a well-structured closed-ended questionnaire to 122 respondents in the farm villages of Kajola Local Government Area.

PRESENTATION OF FINDINGS

Socio-economic Characteristics of the Respondents

Table 1 indicates that the entirety (100.0%) of the participants in the study are residents of Oyo State. A significant proportion (36%) were the ages of 50-59 years, married (76.5%), and reported having a family size of 6-8 (42.5%). Most (41.6%) respondents possessed primary education while 23.6% had secondary education. A significant proportion (93.3%) of respondents reported being actively involved in agricultural activities as their main source of livelihood. Most (51.7%) respondents possessed farm sizes ranging from 1 to 4 acres. It is worth mentioning that a greater proportion (95.3%) of the respondents obtained their seed/seedlings from the open market, while 68.6% of them were affiliated with the Farmers Association

The Major Crops Cultivated by the Respondents

The findings presented in Table 2 reveal that the cultivation of cassava had the largest prevalence among the respondents, accounting for 75.3% of the respondents. Maize cultivation followed closely with 52.8%, while vegetable cultivation was reported by 22.5% of the respondents. In contrast, it was found that cashews, soybeans, fruit vegetables, watermelon, rice, okra, and cocoa had the lowest rates of cultivation among the respondents. The substantial proportion of respondents engaged in the cultivation of cassava can be ascribed to its significance as a fundamental agricultural commodity in Nigeria. The study by Ovharhe *et al.,* (2020) reveals that cassava holds a prominent position as a staple crop in Nigeria, mostly owing to its capacity to thrive in diverse soil conditions and its resistance to pests and diseases, while the substantial proportion of respondents engaged in maize cultivation can be credited to its significance as a vital means of sustenance and economic support for small-scale farmers in Nigeria. In the majority of instances, vegetable cultivation is commonly practised as an intercrop. This may be attributed to farmers' lack of trust in the profitability of vegetable production as a viable venture, coupled with a limited awareness of its potential for high profitability.

Table 2: The major crop(s) grown by the respondents (n=89)

	Yes/ (%)	No/ (%)
Cassava	67 (75.3)	22 (24.7)
Vegetable	20 (22.5)	69 (77.5)
Cashew	2 (2.2)	87 (97.8)

The Respondents' Horticultural Crops of Interest

Table 3 found that the horticultural crops with the largest percentage of interest to the respondents were tomato (61.8%), jute mallow (58.4%), pepper (53.9%), okra (49.4%), amaranth (46.1%), and celosia (33.7%). The cultivation of these crops in Nigeria is characterized by strong market demand and their significant nutritional value, which may account for the substantial proportion of respondents expressing interest in their cultivation. Additional crops that were reported to have high-interest rates include *Telfairia* ('Ugu') and garden egg, with 24.7% of respondents reporting favourable responses for each crop. However, respondents' lack of knowledge, training, and facilities likely prevented them from responding to questions bothering on interest in value addition.

Table 3: Respondents' horticultural crops area of interest (n=89)

Horticultural crops	*Area of Importance/Interest*		
	Production		Value Addition
	Yes/ (%)	No/ (%)	
Leafy Vegetables

CONCLUSION AND RECOMMENDATION

The results of the study indicate that women farmers have notable constraints in obtaining educational and training resources to build their capacity, resulting in a hindrance to their productivity and economic advantages. The partnership between WOFEI and NIHORT signifies a significant step towards promoting gender equality and improving the opportunities available to women engaged in farming activities in Nigeria.

To enhance the productivity and efficiency of women farmers:

1. It is recommended that training should be conducted in their horticultural crops of interest along the value chain to encourage involvement in horticultural crop production.
2. The partnership between WOFEI and NIHORT signifies a significant step towards enhancing vegetable production, gender parity, empowerment, and improving the opportunities available to women farmers in Nigeria, thus it should be embraced with passion and commitment by the collaborators for sustainable development.

INCIDENCE AND DISTRIBUTION OF CASSAVA (*Manihot esculentum* Crantz) VIRUS DISEASES IN EDO AND DELTA STATES, NIGERIA

Ahmad, H. A.,Kashina, B. D. and Adekunle, A. T.
Genetic Resource Unit, National Horticultural Research Institute (NIHORT) Ibadan Oyo State, Nigeria.

ABSTRACT
A survey was carried out in Edo and Delta States of Nigeria, to determine the incidence and distribution of cassava viral diseases. A total of 810 cassava leaf samples from visited fields were collected using quadrants and examined using Enzymes-linked immunosorbent assay (ELISA) tests for the detection of African cassava mosaic virus (ACMV), East African cassava mosaic virus (EACMV) and Cassava Brown Streak Virus (CBSV). Laboratory experiments were laid out in a complete randomized design replicated three times. Data obtained were analyzed using descriptive analysis and analysis of variance (ANOVA) while significantly different means were separated using Duncan's Multiple Range Test (DMRT) at 5 % level of probability. Symptoms of viral diseases were higher in Delta State. Edo South had the least percentage incidence of 2.45%. ELISA test revealed incidence of EACMV (78.89 %), ACMV (72.96 %) and CBSV (66.92 %).
Keywords: *Brown streak virus, Cassava mosaic virus, Incidence, Symptoms, Viral diseases*

INTRODUCTION

Cassava (*Manihot esculentum* Crantz) is a perennial shrub of the dicot family Euphorbiaceae (Leon, 1977). The genus *Manihot* is reported to have about 100 species but only *Manihot esculentum* Crantz is commercially cultivated (Benesi, 2005). Cassava is a drought tolerant shrub that is commercial propagated on a wide range of edaphic and climate conditions mostly by stem cuttings, although propagation by true seed occurs under natural condition and in breeding programmes, the root is the main storage organ, which result from secondary growth of the fibrous roots. All cassava organs except seeds contain cynogenic glycoside (CG) at varying quantity depending on the cultivar. Among food crops, cassava is ranked 12th in the world with Nigeria, Brazil, Thailand, Indonesia and Congo Democratic Republic producing over 70% of global cassava output (IITA, 2004). Nigeria is the largest Cassava producing country in the world with cassava being cultivated in all regions of the country however, with Benue and Kogi States in the North Central being the largest producers (IITA, 2004), It is used as a famine reservoir crop mainly for staple food and animal feed and also as a source of industrial raw material for local and refined starch, ethanol production for foreign exchange (IITA, 2003). Despite the immense importance of cassava, pests and diseases are the major constraints of cassava cultivation (Nweke *et al.,* 2002). The major diseases of cassava in Nigeria include Cassava Mosaic Disease (CMD), Cassava Bacterial Blight (CBB), Cassava Anthracnose Disease (CAD) and Cassava Root Rot (CRR) (Herren and Bennet, 1984).

MATERIALS AND METHODS

Experimental location

Samples used for the study were collected from three Senatorial districts each from Edo and Delta States of Nigeria. Laboratory analysis was carried out in the Virology laboratory of the Department of Crop Protection, Ahmadu Bello University (ABU) Zaria.

Surveyed Areas

Edo State Lies between Longitude 06^0 04^1 E 06^0 43^1 E, Latitude 05^0 44^1 N and 07^0 34^1 N. The climatic conditions are characterized by two distinct conditions of wet and dry seasons. The State experiences high rainfall and humidity (Ikhile and Aifesehi, 2011). Delta State lies roughly between longitudes 5Aº00 and 6Aº45E and latitude 5Aº 00 and 6Aº30 N it has total land area of 16, 842sq.km. Average rainfall is about 266.5 mm in the coastal areas and 1905 mm in the extreme north with the rainfall heaviest in July. Temperature increases from the south to the north (Osagie, 2002).

Survey and Sample Collections

Samples were collected from cassava farms in Edo and Delta States. For each senatorial district three cassava farms were selected within minimum distance of 1.55km and maximum distance of 10.55km consistence, two commercial farms five hectare and above and (2 – 5 ha) for subsistence farm. In each farm 5m x 5m dimension drowned 5 times, in 5 strategic locations in the farm. Total number of cassava plants and number of plants with symptoms in each quadrant were recorded. Nine symptomic and asymptomic leaf samples were collected randomly from each quadrant and three samples out of the nine were selected randomly for the laboratory analysis. Incidence of symptoms calculated using the formula below. The co-ordinates of farm locations and size of each farm were documented.

Disease incidence % $= \frac{Number\ of\ disease\ plants}{Total\ number\ of\ plant\ examine} \times 100$

Laboratory Analysis

Preparation of buffers: The buffers that were used in ELISA are (1) coating buffer (CB), (2) phosphate buffered saline (PBS) (3) PBS-Tween 20 (PBST) (4) sample extraction buffer (SEB), (5) conjugate buffer (6) substrate buffer (SB).

Serological procedures: The triple antibody sandwich formed of the enzyme-linked immunosorbent assay (TAS-ELISA). Polyclonal for serological diagnosis of (ACMV and EACV) while for the diagnosis of Cassava brown streak virus (CBSV) the Double antibody sandwich (DAS) Enzyme-linked immunosorbent assay (DAS-ELISA) was used. Results were assessed by (a) visual observation and (b) spectrophotometric measurement of absorbance at 405nanometer. Observance values twice those of the negative control were rated positive (Clark, and Adams 1977).

Data Analysis: The data collected were subjected to analysis of variance (ANOVA) using GenStart 2005 software. Mean separation was carried out using Duncan's Multiple Range Test (DMRT) of the same software.

RESULTS

Table 1 shows the farm location, characteristics and general observation for symptoms of viral diseases in Edo and Delta states. Farmers complied with the recommended plant population density of 10,000 plant/ha in Edo State. Plant population density was lower than the recommended rate Delta State7626 plants/ha. General observations for symptoms of viral diseases were higher in Delta State, severe in Delta North (57.45%), compared to Edo State, Edo South has the least percent incidence of 2.45%.

Table 2 show the disease incidence for ACMV, EACMV and CBSV were observed to occur at different levels in all farm locations in the study area (Table 2). In Edo State, ACMV had a highest incidence value of 90.4 followed by CBSV and EACMV (73.4 and 72.6) respectively. EACMV however had the highest disease incidence in Delta State (85.2) follow by CBSV and ACMV with incidence values of 60.4 and 55.5.

DISCUSSION

Enzyme-Linked Immunosorbent Assay (ELISA) was used to test the incidence of three important cassava viruses- ACMV EACMV CBSV in the senatorial districts of Edo and Delta States. In total, 810 samples from were analyzed. 78.89% were positive for EACMV, 72.96% for ACMV and 66.92% for CBSV. This is in agreement with IITA, (2000) which states that ACMV and EACMV occurs virtually throughout the cassava growing areas of Africa and that production losses due to CMD in Nigeria where estimated at 6.78-9.69 million metric tonne in 1998 when the total harvest for the country was 35.56 million tonne (Echendu *et al*, 2003). It implies that relying only on expression of CMD symptoms may often result in underestimating the CMD disease. While from this survey ELISA test of samples showed that EACMV and ACMV were widely distributed in the study area with 78.89, 72.96 mean, similar results were obtained in previous research study in 16 southern state of Nigeria including where ACMV and EACMV were widely distributed (Ogbe, *et al.,* 2006). The symptoms observed in the field include mosaic, chlorosis, yellow blotches, stunting, streak, stripe and reddening of leaves which is consistent with plant viral infections as described by (Calvert and Thresh, 2002a,b). The results of serological of samples from Edo and Delta States showed that ACMV, EACMV, CBSV, were detected in asymptomatic plant leaf samples. This finding was similar to the report of Ogbe, *et al.* (2006) that most samples from asymptomatic plants in Abia, Ebonyi, Enugu and Imo States were infected with either ACMV or EACMV and that the detection of (ACMV) and (EACMV) in asymptomatic plants is important information in the determination of (CMD) incidence. Survey farms were chosen within a minimum distance of 1.55km and maximum distance of 10.55km eighteen farms. Otim-Nape *et al*., (1997), Legg and Ogwal, (1998) estimated that a pandemic of CMD may exceed 20-30 km/annum. In all surveyed farm, cassava plant population per hectare were at range of 8000 -14000. This agree with the findings of Hahn *et al.,* (1979) who recommended that a plant population of 10,000-15,000 plants per hectares in general is economical and give a good yield of cassava.

CONCLUSION

Based on this survey work, all 18 cassava farms visited within the minimum distance of 1.55km and maximum distance of 10.55km in all the senatorial districts of Edo and Delta States of Nigeria has the three most important virus infecting cassava, out of 810 samples tested 78.89% were positive for EACMV, 72.96% for ACMV and CBSV 66.92%. High cassava plant density/ hectare could be one of the factors for the virus disease spread in these area. An epidemic of CMD and CBSD could occur in wide area of cassava production in Edo and Delta States of Nigeria.

ASSESSMENT OF FACTORS LIMITING PRODUCTION OF CITRUS AMONG SMALL HOLDER FARMERS IN BENUE STATE (USHONGO LOCAL GOVERNMENT AREA OF BENUE STATE, NIGERIA)

***Odoh, J. J, Muazu, Y.G, Idris, B.A, Yakub, A.M, Bala, H.U,Abdulrazak, K. B, Auwal, S. M**

*Corresponding author: Odohjosephjnr@gmail.com

ABSTRACT

The study assesses the factors limiting the production of citrus among small holder farmers in Benue State of Nigeria. Primary data was sought from 120 respondents using structured questionnaire. Data were analyzed using frequency and percentage. Result revealed that 67% male and 33% female were involved in citrus production in the study area, 75% were married with 42% having 7 and above years of farming experience and 42% of them having a farm size of 2 – 5 acres of land. 63% of the respondents make an annual income of around ₦ 51,000.00 - ₦ 100,000.00 and irrigation, pest and disease control, variety selection, fertilizer application and site selection were the farm management system being practiced by the respondents. Citrus plant was used for medical purpose using the leave majorly, prepared by boiling and administered orally. Lack of access to quality inputs such as fertilizers, pesticides and irrigation systems, poor soil fertility due to over-cultivation or inadequate use of fertilizer, low level of technical knowledge on best practices for citrus cultivation, lack of credit facilities and Inadequate infrastructure like roads linking the farms to the market were the challenges faced by the respondents in citrus production. The study concludes that males and female in their productive age are into citrus farming. The study recommends that government should provide quality inputs including fertilizers, pesticides, herbicides, credit facilities etc for farmers to utilize for their citrus cultivation. Also, training should be carried out on the farmers by extension service providers for a better knowledge and best practice of citrus cultivation.

Keywords: *variety, irrigation, inputs, credit and horticulture*

INTRODUCTION

Citrus was introduced in Nigeria by the Federal Department of Agriculture and Missionaries in the 1930s (Mbah *et. al.,* 2018). Nigeria is the 9th major Citrus producing country globally after Italy and the largest region in Africa (Food and Agriculture Organization, 2012). Citrus is one of the most important fruit crops grown all over the world. It is rich in Vitamin C (Ascorbic Acid) and Folic Acid as well as a good source of fiber. Citrus contain Potassium, Calcium, Thiamin, Niacin, Vitamin B6 (Pyrodoxine), Copper, Phosphorus and Magnesium (Chase, 2017). They are fat free, sodium free and cholesterol. About 930,000 tons of citrus fruits are produced annually in Nigeria from an average of estimated 3 million hectares of Land. Citrus is grown in the rainforest and Guinea Savannah; most of these farmlands are in the remote part of the country with poor roads and about 30-50% of these fruits getting spoilt before reaching to the final consumers in Urban Centers (Taiwo, 2015).

Citrus is one of the most important fruit crops grown all over the world. Citrus fruits are rich in vitamin C (ascorbic acid) and folic acid, as well as a good source of fiber. They are fact free, sodium free and cholesterol free. In addition, they contain potassium, calcium, foliate, thiamin, niacin, vitamin B6 (pyridoxine), phosphorus, magnesium and copper. In Nigeria, about 930,000 tons of citrus fruits are produced annually from an estimated hectrage of 3 million hectares of land. Citrus is grown in the rainforest and guinea savannah, most of these farmlands is in the remote part of the country with poor road networks. About 30-50% of these citrus fruits get spoilt on the way before getting to the final consumers in the urban centre (cities).

Commonly grown Citrus species belong to the family Rutaceae. Important species grown in Nigeria are Sweet Orange, Lemon, Lime, Grape fruit and Tangerine. Although there has been an improvement in Citrus fruit production in Nigeria over time, there are challenges that still persist in the industry in areas of production; harvesting, post harvesting activities; processing, marketing and storage are still preventing full exploitation of the best of Citrus production (Chase, 2017). Citrus is one of the most important fruit crops widely cultivated in Nigeria especially in North Central with Benue State in particular. Fortunately, the area of land under production is increasing, it is unfortunately at a low pace due to a number of constraints face by farmers on use of resources and production (Phat *et al.,* 2015).

Citrus contribute greatly to agricultural development in the country economy however faced with a lot of challenges in its development and maximization of potential by small holder's farmers (Attah *et al.,* 2018). Some of the limiting factors to citrus production are lack of capital, pest, diseases, soil fertility problems, scarcity of large quantities of high yielding varieties, scarcity of early maturing true –to-type planting materials, high cost of labour for farm operations, lack of information on the use of agro-chemicals, land tenure system, lack of farmers training and lack of market information (Owoeye, 2010).

Bhat*et al.* (2015) observed that most Citrus farmers are constrained by finance and credit facilities. It is a perennial that require constant management for continuous productivity and inadequate finance may hamper its production. Losses due to pests and diseases remain a major constraint (NIHORT, 2010). It is in line with this that this study seeks to assess the factors limiting the production of citrus among small holder farmers in Benue State of Nigeria.

The specific objectives of the study will be:

i. Describe the demographic characteristic of the citrus farmers in Benue State
ii. Determine information on farm management system in Benue State.
iii. Ascertain ethnobotany of citrus production in Benue State
iv. Identify challenges of Citrus production in Benue State

METHODOLOGY

The research will be conducted in Benue State, Nigeria. Benue State is delineated into three agricultural zones namely, Northern Zone (A), Eastern Zone (B) and Central Zone (C). The State has 23 Local Government Areas with Makurdi as the State Capital. It is located between Longitude 7^o 45' and 10^o 0' East and Latitude 6^o 25' and 8^o 8' North. It is bounded by five other states namely, Nasarawa State to the North, Taraba State to the East, Cross River State to the South, Kogi State to the West and Enugu State to the South-West. It occupies a landmass of 34,059 square kilometers and has a population of approximately 4,253,641 (NPC, 2016). Benue State is inhabited predominately by the Tiv, Idoma and Igede people with their major occupation been farming. It is the major source of food production in the nation with major crops grown as rice, Groundnut, Cassava, Sweet potato, Maize etc. and also raises livestock like, Sheep, Goat, Pig, Rabbit etc. (Mbah *et al.,* 2018).

The population of the study will consist of Citrus farmers in Ushongo Local Government of Benue State. Ushongo is located in Zone A area of the State. Ten (10) Council wards will purposively be selected because of their contribution to Citrus production. In each of the council wards selected, simple random sampling will be used to select twelve (12) respondents, making a total of 120 respondents. Primary data will be collected through the use of a well-structured Questionnaire. Descriptive statistics such as frequency and percentage will be used for data analysis.

RESULTS AND DISCUSSION

A total of 150 questionnaires were distributed to the respondents, however 120 were retrieved and since this number represent a good percentage of the total questionnaires distributed, the researcher decides to use it for the analysis of the study. From the Table 1, it was observed that majority of the respondents fall within the age limit of 20 – 30 years (42%) followed by those within 31 – 40 years (33%). This is closely followed by those within 41 – 50 years (21%) and lastly 4% for those within 51 years and above. It can therefore be concluded that young and more vibrant youths are into the farming of Citrus in Benue State. Majority of the farmers are male (67%) while 33% are female. This shows that there are more male farmers than females in Benue State. Also, majority of the respondents are married (75%), followed by single with 17% and lastly 8% separated. This can be attributed to the married ones having more responsibility to carter for their family than the others. Furthermore, majority of the respondents have secondary school certificate (50%) followed by those with primary certificate (29%). This is closely followed by those without any formal education with 13% and only 8% had tertiary certificate. It can be seen from hear that farmers in Benue State had a good educational background to practice agriculture effectively. On the household size, majority of the respondents had 7 and above number of households (46%), 37% for those with 6-7 numbers, 10% for those with 3-4 numbers and 7% for those with 1-2 numbers. Finally, on the years of farming experience, majority of the farmers (42%) had 7 years and above farming experience, 25% had between 5 – 6 years of farming experience, followed by those with

3-4 years of experience with 23% and lastly with 10% for those with 1-2years of experience. It can therefore be concluded that more farmers have more years of farming experience in Benue State.

From the Table 2, majority of the respondents (42%) have 2 – 5 acres small land size, 25% of them has 6-10acres of land, 18% has <1acre while 15% has >10acres of land. The majority of them having a small land size can be attributed to the fact that they are smallholders farmers. Majority of their sources of labour is family members with (50%) followed by Hired with 33%. Majority of the respondents (75%) said they have access to extension services while majority (67%) does not have access to credit facility. Also, majority does not have access to physical infrastructure however majority of them (83%_ have access to market. Majority of the respondents (63%) annual income ranges from ₦ 51,000.00 - ₦ 100,000.00 followed by those within ₦ 101,000.00 - ₦ 150,000.00 with 25%. The least of them 10% earned above or equal to ₦ 150,000.00. This can also be attributed to their small scale nature (smallholders). Also, from the table, it can be noticed that the farm management systembeing practiced in the area include irrigation, pest and disease control, variety selection, fertilizer application and site selection. This implies that farmers in the area adopted different management practices of citrus production to impact their productivity and profitability. This is in accordance with the finding of Dorji, Lakey, Chopel, Dorgi and Tamang, (2016) who opined that efforts should be made to select varieties needed and desired in the region,

Table 3 shows the ethnobotany of citrus fruit. This has to do with the scientific study of the traditional knowledge an customs of the people concerning plants and their medical, religious and other uses. In respect to this, it was observed from the table that majority of the respondents (92%) affirmed that orange has symbolic beliefs while only 8% said otherwise. All the respondents (100%) said orange plant is used for medical purposes. Majority of the respondents (46%) said orange is used for animal forage, beverages and medicine and the major part used for this purpose is the leave with 71% response. Also, boiling is the mode of preparation for medical use with 75% response rate and is administered orally (83%) and bathing in some cases (17%). This corresponds with the finding of Osunwole (2009) who reported that this species of plant are highly medicinal because they are used both for sustaining health and curing illness

Table 4, shows the challenges faced by farmers in citrus cultivation in Benue State. It can be seen that majority of the respondents (58%) agree that lack of access to quality inputs is the challenges faced by farmers, 32% strongly agree while 10% disagree. Also, majority of the respondents (63%) agree that poor soil fertility due to over-cultivation or inadequate use of fertilizer is the challenges faced by farmers, 25% strongly agree while 12% disagree. Majority of the respondents (50%) agree that low level of technical knowledge on best practices for growing citrus fruits is the challenges faced by farmers, 38% strongly agree,8% disagree while 4% strongly disagree. Majority of the respondents (46%) agree that inadequate infrastructure like roads is a challenge faced by farmers, 25% strongly agree, 17% disagree while 12% were undecided. This implies that citrus production by farmers in Benue is impeded by lack of infrastructures as well as knowledge of best practices. All this agrees with the finding of Mendelson and Williams (2014) who found that poor infrastructure is a major challenge faced by farmers in citrus production. More so, majority of the respondents (67%) agree that limited access to credit facilities is the challenges faced by farmers, 21% strongly agree, 10% disagree while 2% were undecided.This implied that citrus production by farmers in Benue is constrained by access to loan facilities. This agrees with the finding of Bhat, Jyoti, Manish and Rajinder (2015) who indicated that most farmers are constrained by credit facilities.

CONCLUSION AND RECOMMENDATIONS

From the findings of this study, it can be concluded that males and female in their productive age are into citrus farming. However, farmers in the area are into citrus management practices which include irrigation, pest and disease control, variety selection, fertilizer use and site selection. Despite this engagement, there is low level of productivity going by the annual income generation from the citrus production. This can be attributed to the small scale nature of the farmers in the area alongside the constraints being faced by the farmers. Thus, urgent attention is needed to address these challenges which include among others lack of access to quality inputs such as fertilizers, pesticides and irrigation systems, poor soil fertility due to over-cultivation or inadequate use of fertilizer, low level of technical knowledge on best practices for citrus cultivation, lack of credit facilities and Inadequate infrastructure like roads linking the farms to the market. This will to a large extent improve citrus production in Benue State of Nigeria. To this end, the study recommends the followings:

1. The government should provide quality inputs including fertilizers, pesticides, herbicides etc for farmers to utilize for their citrus cultivation.
2. Training should be carried out on the farmers by extension service providers for a better knowledge and best practice of citrus cultivation.
3. Credit facilities should be extended to farmers owing to their small scale production and limited resources for more productivity.
4. Finally, government should look into the issue of roads linking the farms to the urban market for easy accessibility to farm produce exchange as most of this rural areas lack this major facility.

ABSTRACT
This study was carried out in the green zone of the staff quarters old campus, Bayero university Kano in 2018. The study area located on the coordinate latitude 11^{0}58'11'N, longitude 8^{0}28'34''E. The staff quarters has a total quadrant of 51, in which 42 are full (10,000m^2) each, whereas 9 are third quarter's (7,500m^2). The total number of each species was recorded and the ecological parameter (frequency, relative frequency, abundance, relative abundance, density and relative density) of each species was calculated. Twenty seven quadrants were randomly selected. The results revealed that 387 horticultural tree plants species were recorded. However, Mangifera indica has the highest number of occurrences (19) out of 27 studied quadrant while Vitex doniana and Diospyrus mespiliformis were observed in only one quadrant. The conservation status of the species indicated that, 8 species(Adansonia digitata, Anona squamosa, Anarcadia occidentals, Carica papaya, Psidium guajava, Syzygium gynensis, Tamarindus indica and Taminalia mentali) are vulnerable (VU), 5 species (Citrus aurentifolia, Citrus cinensi, Diospyrus mestilifomis, zizipous moritiana and zizipous spinachristi) are threatened (T), 3 species (Balanite aegyptiaca, Mongifera indica and Moringa oliefera) are stable(S), while 2 species(Borassus eathiopum and vitex doniana) are at endangered (EN).
Keywords: *Species, Frequency, Density, Conservation and Horticulture*

INTRODUCTION

Most family of angiosperm is relatively represented in the savannah region of Nigeria. The genus of some families such as malvacea, Anacardiaceae and fabacea are widely available. Bayero University Kano, old campus with a land size of (893.700.68km^2) is regarded as the green zone of urban Kano. The level of plant trees cover in the green zone is fascinating to most visitors, these tree cover contribute to local weather condition that attract both human and other animal species populations. Conservation status of a species is an indicator of the likelihood of plant species continuing to survive either in the present day or the feature. Conservation status indicates weather the plant exists and how likely to become extinct in the near feature. Many factors are taken into account when assessing conservation status, not simply the number of individuals remaining but the overall increase or decrease in the population overtime, breeding success rates and known threaten (Milles, 2013).

Extensions occur when the motility (and emigration) rate is greater than the birth (and immigration) rate for sufficient long time that the population size reaches zero. When used in the context of the IUCN red list, a taxon is classified as vulnerable when facing a high risk of extinction in the wild in the immediate future (IUCN 2012). Endangerment is the exposure to risk when it comes to living organisms, and used in the context of 'endangered species', it generally means the risk of the species becoming extinct (Miller, 2013). A species is threatened when it is believed to be in danger of extinction. Status assessment in conservation has its roots in the late 1890s when researchers began to use population monitoring as mean to determine how populations of different species change overtime (stem *et al*., 2005). The international union of conservation of nature (IUCN) red list categories and criteria are widely used for its objective and authoritative system for assessing the global risk of extinction for species (mace *et al*., 1991). The red list introduce in 1994, is a list of species which has been evaluated against quantitative criteria to identify the extinction risk of species (Stuart *et al*., 2010). Currently, the IUCN red lists categories and criteria version 3.1 are widely used (IUCN, 2012). The aim of conservation status assessments is to provide information and analysis on the status, trend and threats to species in order to inform and catalyze action for biodiversity conservation (Possingham *et al*., 2002). The criteria have five categories of status namely extinction (EX), critically endangered (CR), endangered (EN), threatened (T) or vulnerable (VU). According to (Onyekwelu et al., 2007) relative density of species can be used to

categories plant into conservation statuses. If the relative density is less than 0.09 the species is said to be critically endangered (CR), if it's between 0.1 to 0.99 is endangered (EN), if the value is between 1 to 3 is threatened (T), if it's between 3 to 10 is vulnerable (VU) and if the value is greater than 10 the species is said to be stable. The economic benefit derives from this species cannot be under estimated. Tree plant species in general face extensive treat or pressure largely from humans for various reasons. No one is certain about the effect of human activities on distribution and density of horticultural tree species.
It's therefore necessary to study the number, density and other ecological parameter that can enable us to determine the current status and predict available data, the short term and along term status of this plant in the area in such a stable area. The objectives of the study were to survey and identification of selected horticultural tree species and to determine the frequency, density, abundance and other ecological parameters for the appropriate conservation strategies of horticultural trees in the study area.

MATERIAL AND METHODS

The study was carried out in the residential area of old campus Bayero University, Kano located on the coordinate latitude 11^{0}58'11'N, longitude 8^{0}28'34''E. Measuring tape, Ranging poles, Rope were used for measurement and data collection. Random sampling methods was used to select the study quadrants, the residential area where divided into different number of quadrant (10,000m^{2}) each. The area has a total quadrant of 51, in which 42 are full and 9 are third quarter's quadrant. Twenty seven quadrants were randomly selected. During this study the number of each species, occurrences of species were counted and recorded.

RESULT AND DISCUSSION

Table 1 shows the horticultural tree plant species present in the study area. Eighteen (18) species where recorded from difference families of the Fabaceae, Myrtaceae, Rutaceae and Rhamnaceae have two species while other families (Malvacea, Anonaceae, Zygophyllaceae, Ebenaceae, Moringaceae, Palmaceae, and Verbenaceae) has single species. Table 2 Shows the ecological parameters of the horticultural tree plant species in the study area. i .e the occurrences of the species, total number of each species, frequency, relative frequency, abundance, relative abundance, density, relative density and conservational status. The occurrence of species shows the number of quadrants in which the species is present out of 27 quadrants. From these studies the conservation statuses of the species are, 8 species are vulnerable, 5 are threatened, 3 are stable, while 2 are at endangered. *Mangifera indica* have the highest number of frequency and is more abundance, *Diospyrus mespiliformis* and *Borassus aethiopum* have lowest frequency and abundance. *Balanite aegyptiaca* and *Mangifera indica* has the highest relative density which shows they are stable while *Borassus aethiopum* have the lowest density. This work correspond with the work of (salami *et al., 2021*)

ABSTRACT
Electronic resources (e-resources) are materials in digital format and they are also known as online information resources. The study was conducted to examine the use of electronic resources (e-resources) for research purposes by scientists working in three distinct research institutes located in Ibadan, Oyo state, Nigeria: Cocoa Research Institute (CRIN), Forest Research Institute (FRIN), and National Horticultural Research Institute (NIHORT). More specifically, it examined number of published research articles, access to e-resources, use and contribution of e-resources to their research work. A total of 100 questionnaires were administered to elicit information from scientists, only 81 were filled returned and analyzed. The respondents were male (53) and female (28) The result reveals that in terms of scholarly output, a significant portion of scientists (58.7%) have published between 1 to 3 journal articles. Conversely, a mere 1.6% of scientists have achieved an impressive tally of over 16 journal publications. Similarly, the number of conference proceedings publications shows a similar trend, with 51.7% of scientists having 1 to 3 publications and only 5.2% with more than 16 conference proceedings publications. Notably, e-resource utilization was prevalent among the scientists, with 48.6% of respondents reporting daily use while 5.4% of scientists do not use e-resources, highlighting the widespread integration of digital resources into their research practices. Furthermore, scientists perceived e-resources as a valuable asset in their research activities. A significant 53.8% of respondents rated the contribution of e-resources to their research as "good," while 30.8% view it as "satisfactory." This underscores the integral role that e-resources play in enhancing the quality and efficiency of research conducted in these research institutes. The findings highlight the importance of digital resources in modern research and outline the need for continued investment in digital infrastructure and skill development among researchers to further harness the benefits of e-resources in scientific exploration.
Keywords: *Research Institutes, online information resources, scholarly output, utilization*

INTRODUCTION

In current information technology, electronic resources are essential research aids that complete print-based resources in any typical library. In terms of significance and usefulness, e-resources have surpassed print resources. The environment, resources, and services they offer users are always changing. In the current digital era, e-resources make up the majority of a library's collection. As a result, the objective of any collection of electronic resources is to offer users a focused, thorough, and rapid information dissemination service.

Literature Review

Numerous researches have been done to determine how users of agricultural scientist use online resources. The Essential Electronic Agricultural Library (TEEAL), Agricultural Online Literature (AGRICOLA), CAB Abstracts, International Information Systems for Agricultural Sciences and Technology (AGRIS), Current Agricultural Research Information System (CARIS), and Abstract on Tropical Agriculture (TROPAG) are a few noteworthy bibliographic databases relevant to African agricultural and food issues as reported by Azubike (1995) and Oduwole and Sowole (2006). According to a study by Bakkiaraj, Sathiyamurthy, and Esmail (2012), e-journals are the most widely utilized e-resources out of all the e-resources. They also discovered that the biggest obstacle to adopting the online services was a lack of IT expertise. Similar to this, Mtega, Wulystan, Dulle, Frankwell, Malekani, Andrew, and Chailla (2015) identified the e-resource sources used by the researchers and personnel in five out of Tanzania's seven agricultural zones. They also evaluated their degrees of information literacy and the variables impacting how they used online resources, and the results revealed that consumption of online resources from well-known agricultural databases remained low. The authors advocated for the development of electronic institutional repositories to increase access to research results by extension personnel, as well as improvements to ICT funding and infrastructure. This would establish a long-lasting connection between agricultural research and farming activities.

Objective of the study are to:

1. Examine the level of use of E – resource by scientists in three research institute
2. Find out the level of access to E-resources by scientists
3. To determine the contribution of E- resources to research work of scientist
4. Find out number of publications of scientists in Journals and proceedings
5. Find out areas of research interest of scientists.

METHODOLOGY

This study investigates the utilization of electronic resources (e-resources) for research purposes by scientists working in three distinct research institutes located in Ibadan, Nigeria: Cocoa Research Institute, Forest Research Institute, and National Horticultural Research Institute. A total of 100 questionnaires were administered to elicit information from scientists, only 81 were filled returned and analyzed. Descriptive statistics was used to analyze the data.

RESULT AND DISCUSSION

Area of research interests of scientists in CRIN, NIHORT, and FRIN (Fig.1), shows that 14.3% of the respondents had an interest in economics, 15.9% had an interest in crop physiology, 14.3% had an interest in soil fertility, 6.3% had an interest in technology, 1.6% had an interest in mushroom, 3.2% had interest in agrometeorology, 3.2% had interest in genetics, 6.3% had interest in food chemistry, 7.9% had in pathology, 3.2% had interest in extension, 4.8% had interest in agronomy, 1.6% had interest in breeding and biotechnology 6.3% had interest in environmental production management and 11.1% in agroforestry. Most of the scientists have their research interest in crop physiology, while there was a limited number of scientists who had research interest in the area of mushroom and breeding & biotechnology.

Majority of the scientists (58.7%) had just 1-3 journal publications, while there was a limited number of scientists (1.6%) who had above 16 journal publications (Figure 2). Few scientists (5.2%) had above 16 publications in conference proceedings which is the highest number of publications and the majority of the scientists (51.7%) had just 1-3 publications in conference proceedings (Figure 4). Figure 4, shows the graphical representation of the use of e-resources by scientists in CRIN, NIHORT, and FRIN. Most of the scientists (48.6%) make use of e-resources daily while a small number of scientists (5.4%) do not make use of e-resources . This shows a significant level of the use of e-resources by scientists in research institutes. The result in figure 5 indicates that 70.9% have access to E-resources in their institute while 29.1% do not have access to E-resources in their institute.

Electronic resources are helpful research tools that supplement traditional print library resources in addition to the benefits mentioned above (Mishra and Panda, 2022). The result in Figure 6 shows that there is a high level of contribution of e-resources on the research work of scientists as 53.8% of the respondents rated its contribution to their research work as good and 30.8% of the respondents rated its contribution to their research work as excellent.

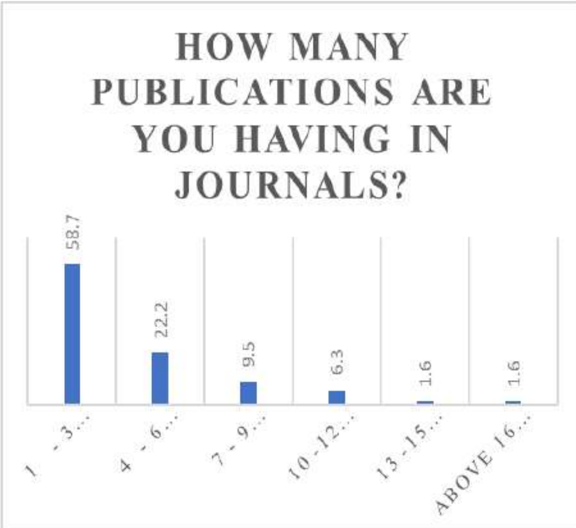

Figure 2: Publications of scientists in Journals

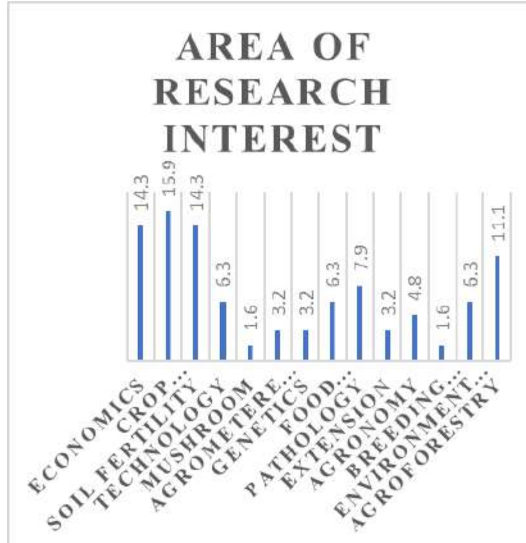

Figure 1: Area of Research interest of scientists

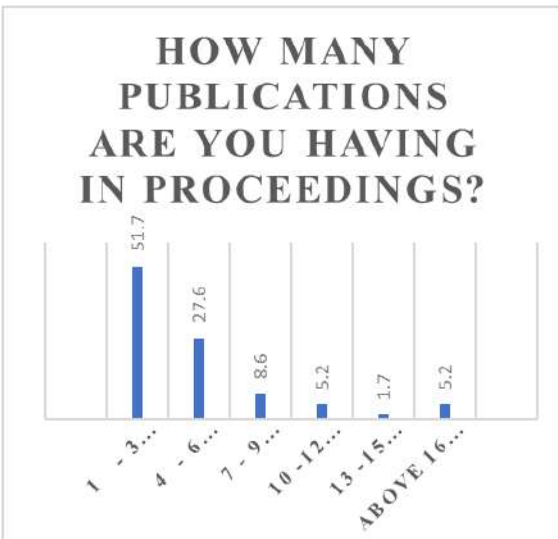

Figure 3: Publications of scientists

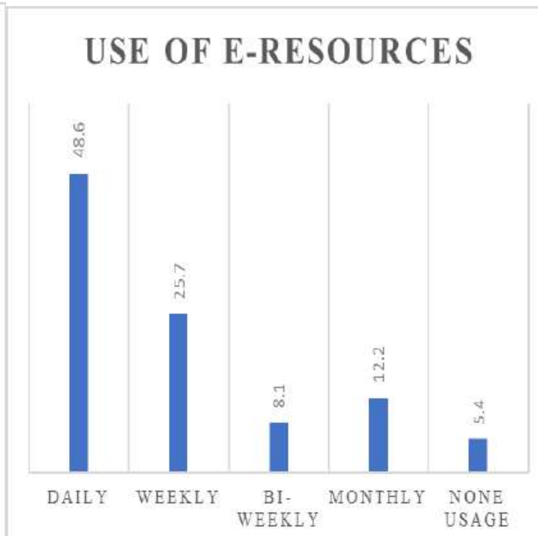

Figure 4: Use of e-resources in proceedings

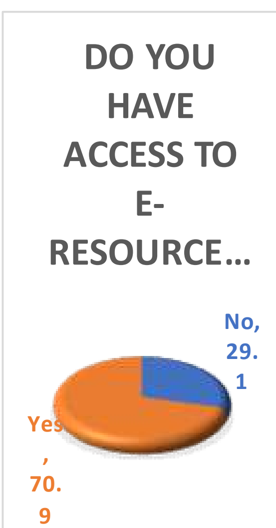

Figure 5: Access to E-resources

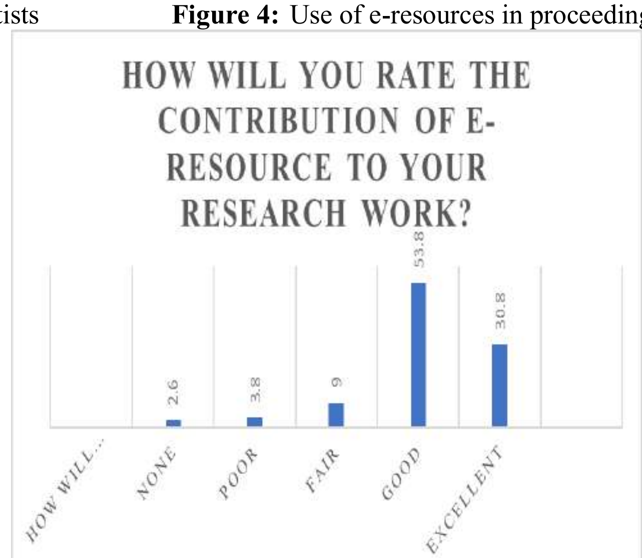

Figure 6: Contribution of e-resources to scientists' research work

CONCLUSION

The study revealed that use of E- resources has positive impact on the research work of scientists. Electronic information resources should therefore be easily accessible and reachable to agricultural scientists in research institutes. Access to quality information would improve the quality and effectiveness of the scientists' research activities. Hence, there should be provision of good institutional Information and Communication technology (ICT) infrastructure that support use of E- resources.

ABSTRACT
Five tomato varieties were evaluated to ascertain their level of resistance against tomato fruit borer Helicoverpa armigera Hubner (Lepidoptera: Noctuidae) under field conditions. The abundance of fruit borer larvae and their infestation, morphological characters and yield was determined. The tomato varieties vary in their leaf thickness, trichome density and rind thickness. Helicoverpa armigera larval population and fruit infestation among the varieties varied significantly. HORTITOM 1 variety was the least infested by fruit borer (5.4). Larval population ranged between 0.3 to 1.7 per plant). HORTITOM 1 was rated as moderately resistant while HORTITOM 2, HORTITOM 3 and Ibadan local was rated moderately susceptible (12, 15.6 and 16.2), Kerewa (22.2) was the most infested and ranked susceptible. Leaf thickness, trichomes density and rind thickness were the morphological traits accessed that confer different level of resistance. The study indicated that the varieties differed in their levels of resistance and this promising source of resistance may be incorporated in the integrated management of tomato fruit borer.

INTRODUCTION

Tomato *Lycopersicon esculentum* Mill is a major fruit vegetable in Nigeria. One of the major constraints of tomato production in Nigeria is insect pest infestation. The crop is devastated by the fruit borer *Helicoverpa armigera* Hubner (Lepidoptera: Noctuidae) which is noted as polyphagous pest and caused damage to over 181 cultivated and uncultivated plant species distributed in 45 families (Matthews, 1999). The *H. armigera* larvae damage tomato plants by feeding on buds, flowers and fruits. The newly hatched larvae bore into the fruit and feed inside. As a result, the fruits become unfit for human consumption. They are responsible for lowering the yield of tomato (Bhatt and Patel, 2001; Mehrvar, 2009). Proper variety selection and protection of tomato fruits from the attack of fruit borer is an important prerequisite for higher yield and quality of the crop. Management of fruit borer through insecticides is hazardous to human being and insecticides reduce insect predator and pollinator species in the field (Moser and Obrycki, 2009).

Plant morphological characteristics such as trichomes and thickness of the cuticle affect *H. armigera* larval movement and feeding rate (Shelomi *et al*., 2010; Amin *et al*., 2015). The biochemical contents and nutrients in the host plant affect survival, growth and reproduction of phytophagous insects (Browne and Raubenheimer, 2003). Thus the morphological traits and biochemical contents of the plants have important roles in varietal resistance. Cultivation of resistant variety is economical and safer, and it is the most important tool in integrated pest management (IPM). Reduction in insect pest infestation to an acceptable level with the use of resistant variety alone or in combination with other control measures has been reported (Ofuya *et al*., 2023). However, there has been lack of information regarding resistance in commercially available tomato varieties. The present study was undertaken with three varieties of tomato which were developed by National Horticultural Research Institute (NIHORT) to find out their level of resistance against *H. armigera* in the field conditions. The plant morphological characteristics associated with resistance, nitrogen content in the plant, and performances of yield and seed germination of the varieties were also assessed.

MATERIALS AND METHODS

The study was carried out in the experimental field of National Horticultural Research Institute, Ibadan from August 2021 to November 2022. The seeds of HORTITOM 1, HORTITOM 2 and HORTITOM 3 tomato varieties were collected from NIHORT gene bank, commonly grown Kerewa and Ibadan local varieties were used as check in the experiment.

Cultivation of tomato seeds

Seeds of the tomato varieties were sown separately in a nursery tray filled with cocopeat mixed with poultry manure. Seeds were sown on 31st August and the seed rate was 300 g ha^{-1}. Prior to sowing seeds were treated with Thiram to avoid damage from damping off disease. Seeds were sown at a depth of 2-3 cm and covered with a fine layer of cocopeat followed by light watering. The trays were arranged inside a screenhouse and covered with black nylon to maintain temperature and moisture. The nylon was removed immediately after germination had complete. During the last week in nursery, the seedlings were hardened by slightly exposing them to sunlight. The seedlings were cultivated in a randomized completely randomized design with a plot size of 3.0 × 2.0 m. Each variety was cultivated in three plots and there were 15 plots in this experiment. The spacing among the plots was 1.0 m. Seedlings were transplanted in rows three weeks after sowing. Each plot contained three rows and each row had 5 seedlings. The distance between two seedlings was 60 cm. The plants were supported by bamboo sticks to prevent lodging of tomato plant. A blanket application of N-P-K 15:10:10 fertilizer was applied two weeks after transplanting and no plant protection measure was applied in the field.

Screening against fruit borer

The entire experimental field was monitored every week to observe the abundance of fruit borer larvae and fruit infestation. To take count of fruit borer larvae, six plant from the middle of each plot was tagged for data collection at 20, 40 and 60 days after transplanting. The total number of healthy fruits and infested fruits of each variety were recorded at each harvesting stage. Fruits were categorized as healthy and infested based on the absence or presence of pod borer infestation. The damaged and undamaged fruits were harvested six times and percentage of fruit infestation was calculated on number basis. A rating system for fruit damage developed by Kashyap and Verma (1986) was adopted for estimating relative resistance/susceptibility.

Identification of plant morphological characters

Leaf thickness and trichomes population were observed on the terminal leaflet of the fifth leaf in four (4) plants per variety. From each leaflet 1 cm^2 section was taken from 1.5 cm above the base and 0.5 cm from each side of the main vein. Rind thickness was measured on the physiological mature fruits. Three fruits were randomly selected for each variety and from each fruit 1 cm^2 section, located at 0.5 cm from the calyx was taken. Leaf thickness and rind thickness were measured with an ocular micrometer (Carl Zeiss, Germany) at 10X amplification under a microscope (Carl Zeiss, Germany). Number of leaf trichomes was counted under the microscope. At each harvesting stage, data on fruit length, diameter and weight were taken from the healthy and infested fruits. Fruit length and diameter was measured with slide calliper and weight was taken with a digital balance (AG204, Mettler Toledo, Switzerland). The fruit yield recorded in each harvesting stage of a variety was pooled for the entire season and calculated in tons per hectare.

Data collection: The entomological data collection started at flowering stage and was monitored till fruiting. The five accessions were screened for their level of resistance and susceptibility to *H. armigera* infestation. The field was monitored for leaf and fruit damage at 6.00 am Nigeria time. Every larva captured was preserved in a well labelled insect vial containing 75% ethanol for proper identification in the laboratory. The damage rating was done according to the modified scale of Bitew MK 2018. Other insects encountered on the field was also recorded.

Statistical analysis

Data were analyzed by one-way analysis of variance (ANOVA) and the mean values were separated by Duncan multiple range test (DMRT). All the analyses were performed using SAS 2.0.

RESULTS AND DISCUSSION

The present study shows the responses of the screened tomato varieties to fruit borer infestation, there were significant differences in the number of fruit borer present on the tomato plant at different growing stages. HORTITOM 1 recorded the least *H. armigera* larvae (0.3±0.3a) as against other accessions. HORTITOM 2, HORTITOM 3 and Ibadan local were not significantly different in the population of larvae found feeding on the plant (1.3±0.3b, 1.2±0.1b and 1.3±0.3b). Karewa, one of the locally cultivated varieties was found to be significantly susceptible compared to other screened varieties (Table 1). Examining the percentage infestation of the varieties by fruit borer, HORTITOM 1 was less infested with about 5.4% infestation level which ranked it as moderately resistance. Same trend was observed on the population of larvae found boring the leaves and fruit (Table 1).. The screening grouped the varieties into three categories with Kerewa been the most susceptible (22.2%). Table 2 shows some distinct features that confers resistance on the tomato plant. Leaf thickness, trichome density and rind thickness of fruits. HORTITOM varieties were seen to have distinct morphological features, HORTITOM 1 tomato produced significant thicker leaves and significant number of primary trichomes respectively (1.18±0.04 and 5.7±0.3). In the present study, the screened tomato varieties differed in their leaf thickness, trichome density and rind thickness. Among the screened varieties, Kerewa, Ibadan local and HORTITOM 3 possessed lowest trichome density and rind thickness and comparatively lower leaf thickness and the varieties were classified as susceptible, moderately susceptible and moderately susceptible respectively. Tomato plants possess glandular and non-glandular trichomes which are considered as the most important pest resistance factor (Gurr and McGrath, 2001; McDowell et al., 2011; Zhang et al., 2020). There are reports that the presence, density and distribution of the trichome depend on the tomato genotype, organs/tissue, age and environmental conditions (Wilkens *et al*., 1996; Gurr and McGrath, 2001;). Rafiq *et al*. (2008) reported that plant characteristics are known to render the cultivars less suitable or unsuitable for the feeding, oviposition and development of insect pests. There were no differences in the thickness of leaves produced by Ibadan local (1.0±0.01) and Kerewa (1.0±0.03) which may make it attractive to the fruit borers. Trichome produced were significantly different from each other, this trichomes makes both leaves and fruits un- attractive to borers. All the *HORTITOM* varieties produced significant density of trichomes as compared with the local checks. The fruit rind thickness was also considered as a factor in the resistance study. Fruits produced by *HORTITOM 1*variety was seen to have thicker rind 0.73 mm and was significantly different from fruits of other varieties, where Ibadan local produced the least rind measurement 0.35mm.

In the present study, the tested varieties differed in their level of fruit infestation by fruit borer. That is why the varieties are classified as moderately resistant, moderately susceptible and susceptible. Significant healthy fruits were produced across all the tomato varieties in spite of *H. armigera* infestation. HORTITOM 1 produced more marketable fruits (34.4±3.4) with few infested fruits (2.9±0.7) and a 3.9 % yield loss. Marketable fruits from HORTITOM 2 and 3 were significantly different from each other with Kerewa producing the least marketable fruit (14.1±1.1) and unmarketable fruit (0.6±0.1) with a higher yield loss of 11.9 %. The total fruit yield was also significant across all varieties with HORTITOM 1 having the highest total yield (37.4±3.7) and Kerewa producing the least total yield (14.8±1.1). In the present study, the screened tomato varieties differed in their leaf thickness, trichome density and rind thickness. Among the screened varieties, Kerewa, Ibadan local and HORTITOM 3 possessed lowest trichome density and rind thickness and comparatively lower leaf thickness and the varieties were classified as susceptible, moderately susceptible and moderately susceptible respectively. Tomato plants possess glandular and non-glandular trichomes which are considered as the most important pest resistance factor (Gurr and McGrath, 2001;).

General Characteristics

HORTITOM 1: Pure line, indeterminate, rounded predominant fruit, red mature fruits, adapted to Sudan and Guinea Savannah agro-ecological zones, 75-82 days to maturity and good shelf-life.

HORTITOM 2: Pure line, intermediate, slightly flattened predominant fruit, orange mature fruit, adapted to Rainforest, Guinea and Sudan savannah, agro-ecological zones 80-87 days to maturity and medium shelf-life.

HORTITOM 3: Pure line, intermediate, high rounded predominant fruit, pink mature fruit, adapted to Rainforest agro-ecological zone, 79-85 days to maturity and good shelf-life.

Table 3: Effect of fruit borer infestation on the yield of different tomato varieties

Tomato varieties	Tomato fruit yield/ three plant			
	Marketable fruits	Infested yield	Total yield	Yield loss (%)
HORTITOM 1	34.4±3.4 a	2.9±0.7 b	37.4±3.7 a	3.9
HORTITOM 2	32.8±3.6 b	1.6±0.1 d	34.2±3.4 b	4.8
HORTITOM 3	27.6±2.6 c	4.2±0.2 a	31.8±2.7 c	9.2
Ibadan local	18.5±4.1d	2.4±0.4 c	20.9±4.3 d	10.8
Kerewa	14.1±1.1e	0.6±0.1 e	14.8±1.1 e	11.9

Data expressed as mean ±SE. Means within a column followed by same letter(s) are not significantly different by DMRT ($p \leq 0.05$).

CONCLUSION

It can be concluded that out of the tested varieties HORTITOM 1 tomato varieties was found to be moderately resistant while HORTITOM 2, HORTITOM 3 and Ibadan local were found to be moderately susceptible and Karewa was susceptible to *H. armigera* . Further work is needed to characterize the mechanisms of resistance in tomato varieties and also to determine the relationship between volatile organic compounds and the preference for each varieties.

ABSTRACT
Field trial was conducted at Federal College of Horticulture Dadin kowa Gombe State during 2022 wet season to determine the effect of manure source on growth and yield of two varieties of okra. The experiment consisted of two factors: variety (Kwadon and Chalawa) and the organic manure (Poultry, Sheep and Goat, Cow dung and the Control). The two factors and their levels gave 8 treatment combinations which were combined factorially and laid out in a randomized complete block design (RCBD) and were replicated three times. Data was collected on both growth and yield characters and were subjected to analysis of variance (ANOVA) using Genstat statistical package. The results indicated that different manure sources significantly (P<0.05) affected both growth and yield characters of okra. Based on these findings, application of poultry manure significantly increased both growth and yield characters of okra. Therefore, poultry manure should be adopted as source of organic manure in the production of okra.
Keywords: *Cow dung, Manure, Okra, Poultry, and Variety.*

INTRODUCTION

Okra (*Abelmoschus esculentus* L. Moench.) belongs to the family *Malvaceae* (Kumar *et al.*, 2010; Sorapong, 2012)). The crop was originated from Ethiopia in the 12th Century BC but is widely grown all over the world (Akande *et al.* 2010; Akanbi *et al.*, 2010). It is one of the most prominent and lucrative vegetables that can be used in fresh and canned forms (PROTA, 2010; Awe *et al.* 2011). Although an important vegetable crop, yields are usually lower in developing countries compared to developed countries (Olabode *et al.,* 2010; Sorapong, 2012). Okra contains proteins, carbohydrates, vitamin C and plays a vital role in human diet (Sorapong, 2012). Besides, the fruit contains a vegetable mucin that soothes the irritation of membranes of the intestinal tract. Okra has an alkaline reaction; it is good for elderly people because of high sodium content which is known to control certain diseases in the body such as ulcer, asthma, diabetes, and hypertension (Dilruba *et al.*, 2009; Sorapong, 2012).

Besides other factors such as rainfall, temperature, relative humidity, solar radiation, pests and diseases for lower yields and lack of proper fertilizer source are also responsible in reducing yields and quality of okra and other field crops (Kumar *et al.*, 2009; Ufere *et al.*, 2013). In addition, the use of inorganic manures in okra fields have been observed to cause the destruction of soil structure as well as widespread problems of soil acidification (Adilakshmi *et al.*, 2008 and Sorapong, 2012). Therefore, the study was conducted to determine the effects of organic manure source on growth and yield characters of okra in the study area.

MATERIALS AND METHODS

Site Characteristics

The experiment was conducted at Teaching and Research Farm of Federal College of Horticulture Dadinkowa, Gombe State. The area lies approximately 260 m above sea level is located between latitude 10°15' North and longitude 11°15' East. The climate of the area is semi-arid zone, which is characterized by a wet and dry season. October to March is the major dry season. The mean annual rainfall is 1,500mm and the mean temperature is 35°C. (URBDA,2015)

Treatments and Experimental Design

The experiment consisted of two factors: variety (Kwadon and Chalawa) and the organic manure (Poultry, Sheep and Goat, Cow dung and Control). The two factors and their levels gave 8 treatment combinations which were laid out in a randomized complete block design (RCBD) and was replicated three times. The land was first cleared and harrowed twice to obtain a fine tilth.Beds were marked out using a measuring tape, rope and pegs. Each plot measured 3 x 2m (6m^2) in size with 0.5m between the plots and 1m between replicates. Eight plots were obtained in a replicate, given a total of 24 plots. Before sowing the crop, soil samples were taken in a "Z" shape within the experimental area following the procedure of IFDC (2003) at a depth of 0-30cm using a tubular auger. The plants were sown at the rate of three to four seeds per holes at a spacing of 25x60cm Weeds were controlled at regular intervals after planting and insecticide was also applied to control insect pest. Data was collected on both growth and yield parameters. All the data collected were subjected to analysis of variance (ANOVA) using Genstat statistical package and least significant difference (LSD) was used where there was significant difference to separate the means.

RESULTS AND DISCUSSION

The results on Table 1 indicated that there was no significant difference between the varieties of okra regarding the data observed on plant height this might be related to the similarities existed between the two varieties used as reported by Usman *et a.l* (2020). On the other hand, the result is contrary to the findings of Tswanya *et al.,* (2017). Among the organic manure source used for the study there was significant difference where plant grown under poultry manure produced the tallest plant followed by Cow dung, Sheep and Goat and shortest plants were observed under Control. The results is accordance with the findings of many researcher such as Hussaini *et al.* (2010), Hamma and Ibrahim (2012), Adams *et al.* (2004), Enujeke and Egbuchua (2013), Tiamiyu *et al. (*2012) and Olaniyi *et al.* (2008) Olaniyi *et al.* (2008) who all reported that poultry manure seem to promote both growth and yield of okra.

The results on number of leaves of okra on two varieties of okra had indicated that there was no significant difference between the two varieties. The result is contrary to the findings of Tswanya *et al. (*2017) as earlier reported. The different sources of manure had indicated a significant respond where poultry manure produced the highest number of leaves followed by cow dung manure, sheep and goat while the fewer number of leaves was recorded under control plots. The result is accordance with the findings of Hussein *et al*., (2010). The stem girth of two varieties of okra had also indicated that there was no significant different between the two varieties. The result is contrary to the findings of Gudugi (2013) who assessed the effect of cow dung and variety on the growth of okra (*Abelmoschus esculentus* (L. Moench). Whereas the manure source indicated a significant respond among different sources used. Poultry manure produced the thickest plants followed by those fertilised with cow dung and the thinner plants where observed on plots that received no fertilizer (control). The results is in line with the findings of Viharmaa and Thayamini (2012) and Hamma and Ibrahim (2012) and Enujeke and Egbuchua (2013).

The result on number of pods of okra had indicated that there was no significant difference between the two varieties. Manure sources had indicated a significant different where poultry manure produced the highest number pods followed by cow dung manure, sheep and goat manure and the lease number was observed on plots that received no fertilizer (control). The results is accordance with the findings of Premshaker and Rajashree (2009) and that of Pandita *et al.* (2010) and Achieng *et al. (*2010).

The result on pods weight of two varieties of okra had indicated there was no significant difference between the two varieties. On the other hand, the manure sources had indicated a significant different. Poultry manure produced the heaviest pods followed by cow dung manure, sheep and goat manure and the lease was observed on control plots (0kg/ha). The results corroborate with the findings of Premshaker and Rajashree (2009), Islam *et al.* (2011) and Tiamiyu *et al.* (2012).

CONCLUSION

Based on the findings of the research, it could be concluded that, application of poultry manure significantly increased the growth and yield performance of okra compared to other nutrients source. Therefore, farmers in the study area should adopt poultry manure as source of organic manure in the production of okra.

ABSTRACT
This research examined how Nigeria's cash scarcity in 2023 affected tomato marketers in Ibadan metropolis. 36 people involved in the tomato value chain, including marketers, transporters, consumers, and input suppliers were surveyed. The marketers were specifically targeted and used for this study. The results showed that the cash crisis drove up tomato prices by an average of 31%, as reported by marketers. This price inflation was likely caused by consumers having less cash to spend, while sellers tried to protect their profits during the liquidity squeeze. Digital payments through bank apps, USSD codes, and POS machines became more common ways to pay when cash was scarce, while using cash-based ATMs and bank lobbies declined. It was recommended that ensuring that there is an adequate supply of new banknotes before withdrawing the old ones to avoid future cash shortages and associated economic disruptions.
Keywords: *cash-scarcity, tomato marketers, price inflation, currency designs, Ibadan Metropolis*

INTRODUCTION

In recent times, Nigeria has faced economic disruption due to cash shortages. As reported, the cash crunch started in late 2022 and has continued into 2023 (Emele Onu and Tolani Awere, 2023). This shortage was triggered largely by the naira redesign policy unveiled in October 2022 by the nation's Central Bank (Anthony Osae-Brown and Emele Onu 2022). The policy aimed to redesign some key banknotes while setting deposit deadlines and caps on withdrawals. However, the rollout faced challenges - inadequate supply of new notes as old ones were collected, contributing to the cash scarcity. Other drivers included hoarding, bank distress and foreign exchange constraints, as seen in prior shortages (Method, 2018). Consequently, limited cash circulation tended to inflate prices of essentials like food, impacting citizens. Overall, Nigeria's 2023 cash crunch caused economic and social hardship, stemming largely from central bank policies and their problematic implementation. Tomato is an essential crop in Nigeria, but with high perishability. Past studies indicate tomato prices are quite sensitive to distribution expenses and consumer liquidity (Katanga, Danwawu, and Musa, 2018). Given the 2023 cash crisis, tomato value chain actors - transporters, marketers, and consumers and input suppliers in major markets such as Ibadan - likely face severe challenges impacting tomato costs.

Prior academic work shows limited cash circulation amid economic turmoil often inflates food prices or even hyperinflation. Method (2018) documented Zimbabwe's 2016 cash shortage due to illiquidity and currency shortfalls dramatically spiked prices of basics like maize, soybeans, cooking oil. Gabriel (2006) also found significant price hikes during Ecuador's cash crisis despite official data showing low inflation. Experts suggest limited consumer purchasing power coupled with retailers protecting profits drive food inflation during cash shortages. This study examines the effect of cash scarcity on tomato marketers with a view to suggesting strategies to cushion the impact of restricted liquidity on tomato markers as key actors in the tomato value chain.

MATERIALS AND METHODS

The study was carried out in Ibadan Metropolis. Ibadan is the capital of Oyo State, the biggest City in Nigeria and sub-Sahara Africa. It has population of 2,550,593 (Nigeria population Census, 2006). The city is located on the Southern Western part of Nigeria, lying between latitude 70 and 90N of the equator, longitude 30E and 50E of Greenwich Meridian. Primary data was obtained using a structured questionnaire. The respondents were selected using a two-stage random sampling. The first stage involved the random selection of two local government areas in Ibadan metropolis, which are Ibadan North-West, and Akinyele LGAs. The second stage involved random selection of 36 respondents from the selected local governments. The Data collected were analyzed using Descriptive statistics.

RESULTS AND DISCUSSION

Table 1: Socioeconomic characteristics of the respondents

Variables	Category	Frequency	Percentage	Mean
Gender	Male	8	22.2	
	Female	28	77.8	
Marital status	Single	6	16.7	
	Married	28	77.8	
	Widowed	2	5.6	
Age (Years)	≤25	6	16.7	
	26-35	11	30.5	
	36-45	5	13.9	42.64
	46-55	5	13.9	
	>55	9	25.0	
Household size	1-5	20	55.6	
	6-10	8	22.2	6.86
	>10	8	22.2	
Educational level	No formal education	14	38.9	
	Primary education	5	13.9	
	Secondary education	11	30.6	
	Tertiary education	2	5.6	
	Others	4	11.1	

Source: Field Survey (2023)

The result revealed that most of the respondents were female (77.8%), this is because, higher number of marketers in Ibadan metropolis are female, married (77.8%) and within the age group of (26-35) years (30.5%). The average age of the respondents was 42.64 years indicating their activeness in trying to cope during the period of cash scarcity, most (55.6%) of the respondents had 1-5 members in the households with an average of 6.86 members and majority had no formal education.

Table 2: Effects of cash scarcity on the tomato price level increment among marketers in the study area

Price increase range	Frequency	Percentage
0.00 – 0.33	20	56.25
0.34 – 0.66	11	31.25
0.67 – 1.00	5	12.50
Total	36	100

Mean = 0.31
Source: Field Survey (2023)

The result revealed that majority of the marketers (56.25%) experience between 1 to 33% increases in price level of the tomato while the mean increment in tomato price is about 31% which is higher than the 23.75% food inflation rate that was reported by the National Bureau of Statistics in their consumer price Index report for December 2022 (NBS, 2023). This showed that period of cash scarcity rises the price of tomato, and this reduced the purchasing power of the consumer as their income is constant. According to conventional demand theory, increase in price of the tomato will reduce the demand for the tomato, causing the tomato demand to fall below supply and this will lead to increase in postharvest loss and level of food insecurity will increase. This in agreement with the study of Nigatu et al (2020) which find out that increase in price of agricultural commodity reduce the demand for it, tending it to have postharvest loss.

Table 3: Methods of transaction by the marketers during Cash scarcity

Methods	Frequency	Percentage
Transaction using Cash		
Yes	1	2.8
No	35	97.2
Transfer with conventional bank App		
Yes	14	38.9
No	22	61.1
Transfer with USSD		
Yes	17	47.2
No	19	52.8
Using online banking App (Opay, Kuda, PalmPay etc.)		
Yes	12	33.3
No	24	66.7
Using POS		
Yes	12	33.3
No	24	66.7
Using ATM		
Yes	5	13.9
No	31	86.1
Using Banking Hall		
Yes	2	5.6
No	34	94.4
Using neighbors' bank account		
Yes	11	30.6
No	25	69.4

Source: Field survey (2023)

The various methods adopted during the cash scarcity for transactions were conventional bank application which was used by (38.9%) of the respondents, (47.2%) transacted using the bank USSD code, (33.3%) of the respondents transacted using an online banking App like Opay, Kuda, PalmPay e.t.c. while (33.3%) represent those that transacted with POS, these may be due to their conversant with using the systems prior to the period of cash scarcity, (13.9% and 5.6%) transacted using ATM and Banking hall respectively, this is because, there was a limited supply of cash during the scarcity period from the banks directly to customers and (30.6%) transacted using their neighbors' bank account, this could be emanated from unstable network of banks during the period while people looks for an alternative banks with stable network.

CONCLUSION AND RECOMMENDATION

This study investigated how Nigeria's 2023 cash shortage affected tomato marketers in Ibadan metropolis. The findings revealed that marketers increased tomato prices by an average of 31% because of the cash scarcity. Transactions were also hampered by the lack of currency with actors relying more on digital payments such bank applications, USSD, and POS and less on ATMs and banking halls that only accepted cash. It is recommended that currency redesign be done in such a way that ensures that there is an adequate supply of new banknotes before withdrawing the old ones to avoid future cash shortages and associated economic hardships.

ABSTRACT
A screen house experiment was conducted at the National Horticultural Research Institute (NIHORT), Ibadan to assess the effects of sowing media on the vegetative growth parameters of Telfaria occidentalis. The experiment was laid out in a completely randomized design (CRD) with nine treatments replicated two times. The treatments were different sowing media T1: coco peat, T2: coco peat and topsoil (1:1), T3: spent mushroom compost, T4: spent mushroom compost and topsoil (1:1), T5: sawdust, T6: sawdust and topsoil (1:1), T7: rice husk, T8: rice husk and topsoil (1:1) and T9: sole topsoil (control). Each treatment had 10 seeds sowed in a nursery tray filled with medium. Data were collected on vine length, number of leaves, stem girth and root length. The result revealed that spent mushroom compost mixed with soil in a ratio of 1:1 competed favourably with coco peat which had the longest Telfaria occidentalis vine length of 100 cm and root length of 26.5 cm and the least was observed in rice husk treatment. Spent mushroom compost could therefore be recommended as effective media for raising Telfaria occidentalis in the nursery.
Keywords: *Growing media**,** Telfaria occidentalis, seedling growth, seed germination*

INTRODUCTION
Seed germination and seedling growth are critical stages in the plant's lifespan because it represents the transition from seed dormancy to a self-sustaining plant that is able to photosynthesize (Liaquat *et al*., 2020). The successful establishment of seedlings greatly depends on various environmental factors and the type of substrate of choice *Telfaria occidentalis*, commonly known as fluted pumpkin or "ugu" in West Africa, is a tropical vine of economic and nutritional significance. It is highly valued for its edible leaves and seeds, making it an essential crop for both subsistence and commercial farming (Eseyin *et al*., 2014). Compared to other tropical vegetables, it is a rich source of protein, iron, vitamins, micronutrients and minerals (Ajibade *et al*., 2006). Pre-germination of *Telfaria occidentalis* seed using different growing media is a major cultural practice in its production for enhanced seed germination, seedling quality and field establishment.
Growth media have been reported to have a significant effect on flowering plants and play a vital role in the rate of germination and many growth-related parameters such as plant height, number of leaves, leaf length, stem girth and yield, etc. (Vendrame *et al*., 2005). Baiyeri, 2006 opined that the quality of seedlings determines seedling establishment in the field and the overall crop productivity. The composition and physical properties of the growing medium influence water retention, nutrient availability, aeration, and root development, all of which have a profound impact on the overall performance of seedlings. The choice of suitable growing media is therefore essential for sustainable production of crops with this requirement.
The study therefore evaluates the influence of different growing media on seed germination and seedling growth of *Telfaria occidentalis* for enhanced field establishment and increased crop yield.

MATERIALS AND METHODS
The experiment was carried out at the experimental screen house of the National Horticultural Research Institute (NIHORT), Ibadan, located on latitudes 7° 40.534 N - 7° 41.069 N and longitudes 3° 84.716 N - 3° 85.294 E. The experimental treatments were arranged in a completely randomized design (CRD); T1: coco peat, T2: coco peat and topsoil (1:1), T3: spent mushroom compost, T4: spent mushroom compost and topsoil (1:1), T5: sawdust, T6: sawdust and topsoil (1:1), T7: rice husk, T8: rice husk and topsoil (1:1) and T9: sole topsoil (control). Ten seeds of *Telfaria occidentalis* were sown in a plastic nursery tray filled with the respective media and replicated two times. Plants were periodically and equally irrigated, but no additional nutrient elements were supplied throughout the nursery time. Data were observed on germination percentage and seedling growth parameters and subjected to analysis of variance (ANOVA) to compare the effects of the sowing media on the successful growth of *Telfaria occidentalis*. The differences between the means were compared, using the Least Significant Difference (LSD) at a 5% probability level.

RESULTS

The highest germination percentage of *Telfaria occidentalis* seeds was observed in coco peat treatment ten days after sowing; however, a similar trend was observed in coco peat and topsoil (1:1), spent mushroom compost, spent mushroom compost and topsoil and sawdust and topsoil. The lowest germination percentage was in the rice husk treatment (Figure 1). The longest *Telfaria occidentalis* vine length at four weeks after sowing was observed in coco peat treatment; however, it was not significantly different from the vine length in spent mushroom compost and top-soil; sawdust and topsoil treatments. The lowest vine length was observed in rice husk and topsoil treatment (Figure 2). A similar trend was observed in root length at the termination of the experiment (Table 1). The highest *Telfaria occidentalis* number of leaves was in rice husk and topsoil treatment and the least was observed in sawdust and topsoil.

DISCUSSION

The results show that seed germination and seedling growth parameters of *Telfaria occidentalis* were better in a coco peat growing medium. However, spent mushroom compost competed favourably well with it. The comparative performance of spent mushroom compost could be due to its characteristic composition of different types of agricultural waste, residual nutrients and leftover fungal mycelium (Jordan *et al*., 2008). Several studies have confirmed the use of spent mushroom compost as growing media for the seedlings of tomatoes, lettuce and other crops (Marques *et al*., 2014, Lopes *et al*., 2015). This study comforms with the work of Marques *et al*. 2014 on "Review of different types of media and their effects on tomato seedling production". They reported that the most economical treatment for seedling production is the traditional practicing media (soil sand and farmyard manure). In this study, spent mushroom compost could therefore be recommended as the most effective and economical medium for raising *Telfaria occidentalis* in the nursery for good field establishment and high yield.

ABSTRACT
Field experiment involving three levels of Chromolaena odorata mulch (CM) (0, 15 and 30 t/ha) and five rates of commercial organic fertilizer (OF) (0, 10, 15, 20 and 25 t ha^{-1}) was carried out at National Horticultural Research Institute, Ibadan. The experiment was a 3 x 5 factorial in a split plot design with three replicates. Ginger rhizomes were planted at a spacing of 20 cm x 25 cm. Bulk density ranged from 1.56 g cm^{-3} (30 t ha^{-1} CM) to 1.79 g cm^{-3} (0 t ha^{-1} CM) and 1.5 g/cm^{3} (25 t ha^{-1} OF) to 1.83 g cm^{-3} (0 t ha^{-1} OF). It also ranged from 1.58±0.01 g cm^{-3} (30 t ha^{-1} CM + 25 t/ha OF) to 1.78±0.01 g/cm^{3} (0 t/ha CM + 0 t/ha OF). Porosity ranged from 32.5% (0 t ha^{-1} CM) to 41.0% (30 t ha^{-1} CM) and 30.8% (0 t ha^{-1} OF) to 43.0% (25 t ha^{-1} OF) in the CM and OF treatments, respectively. The moisture content (MC) ranged from 1.60% (0 t ha^{-1} CM) to 9.30% (30 t ha^{-1} CM) and 1.40% (0 t ha^{-1} OF) to 9.4% (25 t ha^{-1} OF). In the combined treatments, porosity ranged from 33.0±0.4% (0 t ha^{-1} CM+0 t ha^{-1} OF) to 40.1±0.2% (30 t ha^{-1} CM + 25 t ha^{-1} OF). Rhizome yield ranged from 3.6 t ha^{-1} (0 t ha^{-1} CM) to 7.2 t ha^{-1} (30 t ha^{-1} CM) and 4.7 t ha^{-1} (0 t ha^{-1} OF) to 6.9 t ha^{-1} (25 t ha^{-1} OF). The effects of interaction of treatments on MC were not significantly different among the treatments. Rhizome yield was however significantly correlated with BD (r=-0.68), MC (r=0.74) and porosity (r=0.68). Combined applications of mulch at 30 t ha^{-1} and 25 t ha^{-1} of organic fertilizer was recommended for improved yield.
