Abstract

Vertical electrical sounding (VES) was carried out insouthern Paiko, north central Nigeria, using Abern Terrameter model SAS 4000. The study was carried out with a view of determining the subsurface layer parameters (resistivity, depth and thickness) which were employed in delineating the sites for building construction. A total of six transverses with ten VES stations along each traverse, having separation of 50 m apart were investigated. It has a maximum current electrode separation (AB/2) of 100 m. Three to four distinct geoelectric layers were observed namely; Top layer, weathered/fractured layer, and fresh basement. The observed frequencies in curve types include 21.6% of H, 0.6% of HA, 2.4% of K, 0.6% of A, 3.6% of KH, 6% of QA and 1.2% of HK. Eight VES stations were delineated for building site construction, having depths to bedrock varying between 0.63 m and 3.99 m.

Key words: Vertical electrical sounding, site, construction, resistivity, depth, geoelectric layer, bedrock, Abem Terrameter

Introduction

Paiko (the study area) is the headquarter of Paikoro local government area in Niger state, North Central, Nigeria. The population of Paiko is increasing rapidly as a result of people migrates from rural areas to urban towns to earn a living. As such, there is need for more estate development to accommodate the growing population of the area. However, in Nigeria Presently there are several cases of building collapse and cracking of walls as a result of poor foundation and lack of site investigation. There is need to search for the areas where the consolidated basement is shallow which can provide strong base for building construction. Therefore, the aim of this work is to applied geophysical method to determine sites where the fresh basement is intruded close to the surface that can support foundations to buildings. Presently, there is only one known geophysical survey conducted in the area (Dangana, 2007). Among several geophysical methods employed in determine depth to bedrock (electrical resistivity, gravity, seismic, magnetic, remote sensing, and electromagnetic), the electrical resistivity method is the most effective (Keareyet al., 2002). It is an effective and a reliable tool in slicing the earth into geoelectric layers. It has the advantage of non-destructive effect on the environment, cost effective, rapid and quick survey time and less ambiguity in interpretations of results when compared to other geophysical survey methods (Todd, 1980). The vertical electrical sounding (VES) technique provides information on the vertical variations in the resistivity of the ground with depth (Ariyo, 2005). It is used to solve a wide variety of problems, such as; determination of depth, thickness and boundary of aquifer (Asfahani, 2006; Bello & Makinde, 2007).

Geology of the Study Area

The study area is located within the north central Nigerian basement complex. It has an elevation of 304 m above sea level with population of about 736,133 people as at 2006 census.

It is bounded by latitudes 9°25'N and 9°27'N and longitudes 6° 37'E and 6° 39'E.Generally, the area mapped forms part of the Minna - granitic formation that consists of Metasediment' and metavolcanics. The Metasediment include quartzites, gneisses and the metavolcanics are mainly granites. Among the main rock groups are granites which occur at the central and northern parts of the area, while on the south and east, cobbles of quartzite are found especially along the channels and valley. However, the other bodies like pegmatites and quartz veins also occur within the major rock types (Figure 1). The rocks are mainly biotite –granites with medium to coarse grained, light colored rocks with some variation in biotite content. The mineral constituents are leucocratic to mesocratic. However, the biotite minerals are thread like and are arranged rough parallel streak, although some are disoriented in the groundmass. The feldspar minerals occur as fine to medium grained, though grains are cloudy as a result of alteration mostly along the twin planes, while the quartz minerals are constituents of the granitic rocks which show strong fracturing in the granitic rocks of the area (Ajibade, 1980).

The raining period runs from April to October with the highest amount of rainfall recorded in August while the average annual rainfall is between 1200mm-1300mm (Niger State Water and Sanitation Board, 2001). The mean annual temperature is between 22°C to 25°C. The period between November and February are marked with the NE trade wind called the harmattan, which often causes very poor visibility during this period.

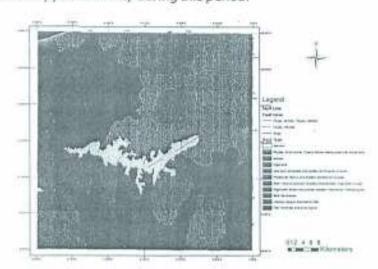

Figure 1: Geological Map of Paiko area (Modified after NGSA 2010)

Methodology

This research has utilized the electrical resistivity method in delineating the shallow consolidated basement of the study area. Sixty vertical electrical soundings were carried out using SAS 4000 model Terrameter and its accessories. The conventional Schlumberger array pattern with half electrode spacing (AB/2) varying from 1 m to a maximum of 100 m was adopted. The apparent resistivity was computed using equation 1

$$\rho_a = KR$$
 (1) Where

p_o is an apparent resistivity

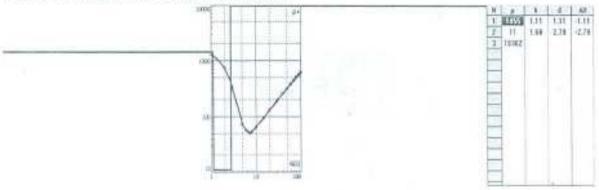

$$R = \frac{\Delta V}{I}$$
, is the earth resistance (2)

$$K = \Pi \left(\frac{\left(\frac{AB}{3} \right)^2 - \left(\frac{MN}{3} \right)^2}{MN} \right) \text{ is the geometric factor}$$
 (3)

The apparent resistivity values obtained from equation (1) were plotted against the half current electrode separation spacing using IPI2WIN software. From these plots, vertical electrical sounding curves were obtained (Figure 2) and qualitative deductions such as resistivity of the layers, the depth of each layer, the thickness of each layer, number of layers and curve types were made.

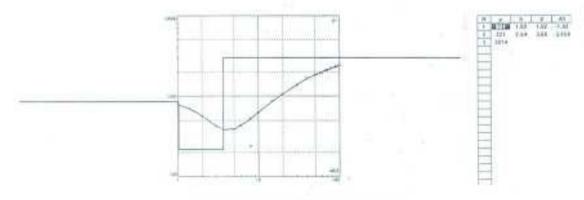

Analysis, Results and Discussion

The summary of the interpreted electrical resistivity survey is presented in Tables 1, 2, 3 and 4. Table 1 consists of VES stations A, toC, while table 2 comprised of VES stations D, to F, Tables 3 and 4 show the depth to consolidated basement. The geoelectric section (Figure 3 a-f) reveals that the area is characterized by 3 to 4 geoelectric subsurface layers. Six profiles with sixty VES stations were covered and their subsurface geoelectric sections were presented in Figure 3. From the figure, 3- layer type occurring more and are characterized by H curve type. Some are characterized by A and K curve types. The 3- layer geoelectric sections are generally made up of topsoil, weathered/fractured layer and fresh basement rock from top to the bottom with variable depths, thicknesses and resistivities. The 4- layer geoelectric sections are characterized by HA; QA, KH and HK curve types. The observed frequencies in curve types include 21.6% of H, 0.6% of HA, 2.4% of K, 0.6% of A, 3.6% of KH, 6% of QA and 1.2% of HK. The 4- layer geoelectric section is made up of topsoil, weathered layer, fractured layer and fresh basement rock. Generally, the topsoil of the area is made up of loose sand, gravels, sandy clay, laterite and clay. In a basement complex terrain, areas with fresh basement layer depth of 4 m and below are good for building construction.

Eight VES stations were delineated for building construction having depths to fresh basement varying between 0.63 m and 3.99 m, where consolidated basement is shallow (Table 5). In investigating the continuous variation of resistivity with depth, iso-resistivity map using Golden software (Surfer 11.0) version were obtained for the layers (Figure 4). It shows the color range corresponding to resistivity range of the earth materials. The iso-resistivity map of the first layer reveal that blue represent gravels, sky blue represent sand, green correspond to laterite and yellow represent alluvial deposits (Figure 4a).

The Iso-resistivity map of the second layer shows that blue color corresponds to clay and sky blue represent laterite (Figure 4b). Third layer iso-resistivity maps reveal that blue represent granite, sky blue represent gneiss, green correspond to igneous rock, yellow represent gabbros rock and red correspond to ultramafic rock (Figure 4c).

The depth to consolidated basement map shows the depth distribution within the area (figure 5). From the map, the area with black and blue coloration corresponds to depth range of 0 m to 8 m and therefore be the suitable areas suggested for building construction.

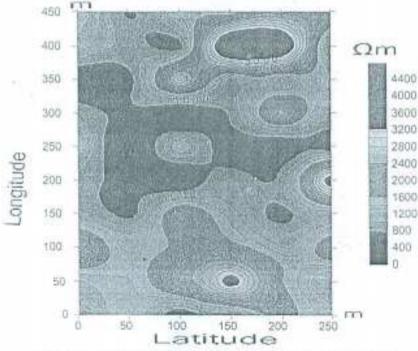

Figure 4 a: Iso-resistivity Map at First Layer

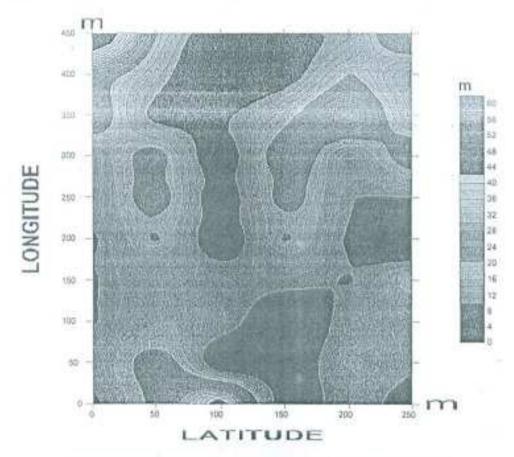

Figure 5: Depth to Basement Map of the Area

Conclusion

The use of various electrical resistivity parameters (resistivity of the layer, depth of the layer and thickness of the layer) were employed to determine the suitable site for building construction. Three to four distinct geoelectric layers were observed namely; Top layer, weathered layer, fractured layer, and fresh basement layer. The observed frequencies in curve types include 21.6% of H, 0.6% of HA, 2.4% of K, 0.6% of A, 3.6% of KH, 6% of QA and 1.2% of HK. Eight VES stations were delineated for building construction, having depths to fresh basement varying between 0.63 m and 3.99 m.Government and estate developers inPaiko are encouraged to make use of the results of this study for building construction site selection to reduce the problem of building collapse and cracking of walls. More research work in this area would contribute to solving the problemof collapse of building completely.
