Abstract

Geological or geophysical surveys must be tied-in to an existing Geographic Information System (GIS) platform and georeferencing of survey stations should be the acceptable norm. It is as a result of these facts that this work was designed in order that proper surveying, topographic, and GIS information for a defined fifteen square-kilometer (15km²) gridded area was executed. The objectives of this project are the creation of a detailed topographic map for the area of study so as to reduce ambiguities in future geoscientific studies at the study area, the implementation of georeferencing protocol at the area of study, the creation of a Geographic Information System (GIS) database for the area of study, and the creation of specific GIS layers for the area of study. These GIS layers define the outcrop, arboreal, economic resource, land use, as well as squatters' settlements profile of the area of study. The area selected for this study is located at the following co-ordinate grids: N09°30'25.20", E006°26'11.34"; N09°33'07.20", E006°26'11.34" and N09°30'25.20", E006°24'34.14"; N09°33'07.20", E006°24'34.14"; this area covers the portion of the Gidan Kwano Campus (GKC) where near-term, mid-term, and long-term facility expansion works are expected to be sited. Latitude, longitude, elevation (i.e. x, y, z) information using the Etrex hand-held Global Positioning System (GPS) units were collected every 100m along every N-S and E-W axes at the area of study, thus forming a grid of 1581 georeferenced stations of interest for the topographic map generation. X, y, z information-gathering sequence for the GIS layers was a non-gridded, spatial-oriented exercise. The site-specific topographic map for this project work was generated using the Golden Surfer 8 software. In addition, the ArcView GIS was used to create a six-layer Geographic Information System (GIS) for the area of study. The topographic map and GIS database can be considered as a suite of very important reference materials that can be assessed by researchers engaged in future surface and subsurface formation studies in the area of study.

Keywords: Topographic, georeferencing, GIS, geosciences, survey, latitude, longitude, elevation

1.0 INTRODUCTION

1.1 Need for the Study. It is now desirable, more than ever before, that geological or geophysical surveys must be tied in to an existing Geographic Information System (GIS) platform. Moreso, georeferencing of survey stations should be the acceptable norm and data analysis and presentation must be aided by tie-ins to the GIS database. It is as a result of these facts that this work was designed in order that proper surveying, topographic, and GIS information for a three-kilometre by five-kilometre (i.e. a fifteen square-kilometer) gridded area was generated.

1.2 Problem Statement. Geoscientific investigations must necessarily be tied-in to existing topographic maps and Geographic Information System (GIS) database of any area of study. Where no such information exist, result presentations are likely to be fraught with ambiguities.

1.3 Objectives of Study. The objectives of this study are the following:

- (i) The creation of a detailed topographic map for the area of study.
- (ii) The creation of a Geographic Information System (GIS) database for the area of study. This GIS database is made up of layers that define the outcrop, arboreal, economic resource, land use, and squatters' settlements profile of the area of study.

1.4 Justification of Study. According to the published literature (ABEM, 1999), any geoscientific survey must be tied-in to existing topographic, geologic, and suchlike (e.g. GIS) maps of the area of interest. Thus this project work has provided a platform by means of which these targets could be met.

1.5 Scope and Limitation of Study. The total extent of survey for this project work was 15km². Georeferenced data were collected at 100m intervals. Owing to financial and time constraints, only 15km² of the total 100km² landmass of the Gidan Kwano Campus could be covered.

1.6 Area of Study. The area of study is a 15km² areal extent within the Gidan Kwano Campus (GKC) of the Federal University of Technology, Minna, Nigeria. The GKC is about 10,650 hectares or 106.5 km² in size. The georeferenced indicators of the area of study are N09°30'25.20'', E006°26'11.34''; N09°33'07.20'', E006°26'11.34'' and N09°30'25.20'', E006°24'34.14''; N09°33'07.20'', E006°24'34.14''.

1.7 Basic Cartographic Concepts. Graph drawing and cartography interact when graphs that already have an embedding (i.e. geometric networks) have to be visualized. Examples of such networks are street, subway, river, or cable networks. Often it helps to visualize the underlying network for analyzing the quantity under consideration. For example, traffic on a road network can be visualized by drawing each road as a rectangle whose width is proportional to the amount of traffic in that road (Wolff, 2004).

One of the main problems in map production is a process called *generalization*. Given cartographic data that has been collected at large scale, this data must be simplified in order to produce maps at small scale. In order to obtain readable maps, detail must be reduced and spacing must be enlarged. Traditionally this has been done manually by cartographers, but increasingly semi-automated and even automated methods are in use, particularly in conjunction with Geographic Information Systems, GIS. The esthetic constraints that govern the process of drawing geometric networks can be seen as an example of generalization: usually vertices must keep a certain minimum distance and edges are restricted to polygonal lines that use few directions and have few bends. Note that general graph-drawing algorithms cannot be used ad hoc for drawing geometric networks since they do not respect the given embedding. A good drawing of a geometric network must reflect geometry in a certain way since a user typically has some intuitive notion of the underlying geometry, a *mental map* in other words. For example, the user of a metro system expects stations in the north to appear on the top of maps that depict the metro system. Thus the aim of drawing geometric networks is to find a good compromise between distorting geometry and maximizing aesthetics (Eades *et al.*, 1991).

1.8 Topographic Surveying. The term “topographic surveying” encompasses a broad range of surveying and mapping products, ranging from aerial mapping to ground and underground surveys (www.140.194.76.129.org). “Control surveying” is a survey which provides horizontal or vertical position data for the support or control of subordinate surveys or for mapping (www.140.194.76.129.org). Topographic surveys have been defined as follows: “A topographic map shows, through the use of suitable symbols, (1) the spatial characteristics of the earth’s surface, with such features as hills and valleys, vegetation and rivers, and (2) constructed features such as buildings, roads, canals, and cultivation. The distinguishing characteristic of a topographic map, as compared with other maps, is the representation of the terrain relief.”

1.9 Contouring Concept. According to Wikipedia (2011), a contour line (also *isoline* or *isarithm*) of a function of two variables is a curve along which the function has a constant value (also Courant et al., 1996). In cartography, a contour line (often just called a "contour") joins points of equal elevation (height) above a given level, such as mean sea level. A contour map is a map illustrated with contour lines, for example a topographic map, which thus shows valleys and hills, and the steepness of slopes. The contour interval of a contour map is the difference in elevation between successive contour lines (Tracy, 1907). More generally, a contour line for a function of two variables is a curve connecting points where the function has the same particular value. The gradient of the function is always perpendicular to the contour lines. When the lines are close together the magnitude of the gradient is large: the variation is steep. A level set is a generalization of a contour line for functions of any number of variables. Contour lines are curved or straight lines on a map describing the intersection of a real or hypothetical surface with one or more horizontal planes. The configuration of these contours allows map readers to infer relative gradient of a parameter and estimate that parameter at specific places. Contour lines may be either traced on a visible three-dimensional model of the surface, as when a photogrammetrist viewing a stereo-model plots elevation contours, or interpolated from estimated surface elevations, as when a computer program threads contours through a network of observation points of area centroids. In the latter case, the method of interpolation affects the reliability of individual isolines and their portrayal of slope, pits and peaks (Davis, 1986).

1.10 The Geographic Information System (GIS). According to Wikipedia (2010), Geographic Information System (GIS) represents a new paradigm for the organization of information and design information system, the essential aspect of which is use of the concept of location as the basis for the structuring of information system. The main advantage of using GIS is its ability to access and analyze spatially distributed data with respect to its actual spatial location overlaid on a base map of the area of coverage that allows analysis not possible with the other data base management systems. The main benefit of using the GIS is not merely the user friendly visual access and display, but also the spatial analysis capability and the applicability to apply standard GIS functionalities such as simultaneous access to several layers of data and the overlay of some, as well as the ability to interface with external programs and software for decision supper data management, and user specific functions. A Geographic Information System (GIS) or geospatial information system is a system designed to capture, store, manipulate, analyze, manage, and

present all types of geographically referenced data. In the simplest terms, GIS is the merging of cartography, statistical analysis, and database technology. A GIS can be thought of as a system — it digitally creates and "manipulates" spatial areas that may be jurisdictional, purpose or application-oriented for which a specific GIS is developed. Hence, a GIS developed for an application, jurisdiction, enterprise or purpose may not be necessarily interoperable or compatible with a GIS that has been developed for some other application, jurisdiction, enterprise, or purpose. What goes beyond a GIS is a spatial data infrastructure (SDI), a concept that has no such restrictive boundaries.

Therefore, in a general sense, the term describes any information system that integrates, stores, edits, analyzes, shares and displays geographic information for informing decision making. GIS applications are tools that allow users to create interactive queries (user-created searches), analyze spatial information, edit data, maps, and present the results of all these operations. Geographic information science is the science underlying the geographic concepts, applications and systems. In recent years computer tools such as geographic information systems (GIS) have become fundamental for environmental assessment, regional planning, ecosystem conservation and natural resource management. Also in developing countries there exists a growing interest in these tools, both in the public and private sector. GIS offer a wide range of possibilities in the fields of inventory making, planning and decision making. With GIS one can store and manage geographical data, integrate different types and analyze relations between data themes, perform spatial modeling, etc. The results are displayed visually on maps to help decision-makers better understand and solve problems.

GIS is an interdisciplinary tool. Therefore, it receives attention from various disciplines such as agricultural engineering, civil engineering, computer science, sociology, etc. This is positive in a way, for indeed it is necessary that all the involved disciplines become partners in the process of implementation of the GIS, on the other hand it also complicates the situation because each one of them tends to neglect the global picture. A sociologist does not worry about projection systems, an agricultural engineer does not see the need of a neatly structured database, a computer scientist does not understand the final goal of his new toy, and each one of them wants to have or to be himself "the" GIS specialist. Geographic Information System (GIS), Geographical Information System or Geospatial Information System is a system that captures, stores, analyze, manage, and

present data with reference to geographic location data. In the simplest terms, GIS is the merging of Cartography, statistical analysis and data base technology. GIS can be thought of as a system – it digitally creates and “manipulates” spatial areas that may be jurisdictional, purpose or application oriented, for which a specific GIS is developed. GIS (geographic information system) describes any information system that integrates, stores, edit, analyzes, shares and displays geographic information for informing decision making. GIS applications are tools that allow users to create interactive queries (user-created searches), analyze spatial information, edit data and present the result of all these operations. GIS (geographic information system) uses spatio – temporal (space – time) location as the key index variable for all other information. GIS can relate otherwise unrelated information by using location key index variable. The key is the location and / or extents in space – time. Any variable that can be located spatially, and increasingly also temporally, can be referenced using a GIS. Locations or extents in earth space – time may be recorded as date / time of occurrence and X, Y and Z co-ordinates representing; longitude, latitude and elevations (altitude) respectively. Related by accurate spatial information, an incredible verity of real world and projected past or future data can be analyzed, interpreted and represented to facilitate education and possible decision making. GIS accuracy depends upon source data, and how it is encoded to be data referenced. Land Surveyors have been able to provide a high level of positional accuracy utilizing the GPS derived positions. Also the high-resolution digital terrain and aerial imagery, the powerful computers, Web technology, are changing the quality, utility, and expectations of GIS to serve society on a grand scale, but nevertheless there are other source data that has an impact on the overall GIS accuracy like: paper maps that are not found to be very suitable to achieve the desired accuracy since the aging of maps affects their dimensional stability. In developing a Digital Topographic Data Base for a GIS, topographical maps are the main source of data. Aerial photography and satellite images are extra sources for collecting data and identifying attributes which can be mapped in layers over a location facsimile of scale. The scale of a map and geographical rendering area representation type are very important aspects since the information content depends mainly on the scale set and resulting locatability of the map's representations. In order to digitize a map, the map has to be checked within theoretical dimensions, and then scanned into a raster format, and resulting raster data has to be given a theoretical dimension by a rubber sheeting/warping technology process. Some maps were made many decades ago, where at that time the computer industry was not even in its perspective

establishments. This has led to historical reference maps without common norms. Map accuracy is a relative issue of minor importance in cartography. All maps are established for communication ends. Maps use a historically constrained technology of pen and paper to communicate a view of the world to their users. Cartographers feel little need to communicate information based on accuracy, for when the same map is digitized and input into a GIS, the mode of use often changes. The new uses extend well beyond a determined domain for which the original map was intended and designed. A quantitative analysis of maps brings accuracy issues into focus. The electronic and other equipment used to make measurements for GIS is far more precise than the machines of conventional map analysis (Wikipedia, 2010).

1.11 The GIS Layer. According to Wikipedia (2010), a Geographic Information System (GIS) is a tool for mapping and analyzing data. The ability to layer many features onto the same map and select or unselect as needed allows for a multitude of views and ease of interpreting data. More important, this allows for in depth scientific analysis and problem solving. When information, in digital form, is geographically referenced (meaning that the information is linked to specific places on the earth, using a system such as Latitude/Longitude) it can then be used as a map layer in GIS. Each map layer, or theme, thus consists of geographic, or spatial, data linked to descriptive, or tabular, information. The strength of GIS lies in its ability to create and organize these distinct map layers for different types of information, and then to overlay and combine layers as necessary to create maps and perform analyses.

1.12 Georeferencing Essentials. To georeference something means to define its existence in physical space. That is, establishing its location in terms of map projections or coordinate systems. The term is used both when establishing the relation between raster, vector images and coordinates but also when determining the spatial location of other geographical features. Examples would include establishing the correct position of an aerial photograph within a map or finding the geographical coordinates of a place name or street address. This procedure is thus imperative to data modeling in the field of geographic information systems (GIS) and other cartographic methods. When data from different sources need to be combined and then used in a GIS application, it becomes essential to have a common referencing system. This is brought about by using various georeferencing techniques. Most georeferencing tasks are undertaken either because

the user wants to produce a new map or because they want to link two or more different datasets together by virtue of the fact that they relate to the same geographic locations (Wikipedia, 2010).

1.12.1 Need for Georeferencing:

- (i) Georeferencing is crucial to making aerial and satellite imagery, usually raster images, useful for mapping as it explains how other data, such as the above GPS points, relate to the imagery.
- (ii) Very essential information may be contained in data or images that were produced at a different point of time. It may be desired either to combine or compare this data with that currently available. The latter can be used to analyze the changes in the features under study over a period of time.
- (iii) Different maps may use different projection systems. Georeferencing tools contain methods to combine and overlay these maps with minimum distortion.
- (iv) Using georeferencing methods, data obtained from surveying tools like handheld GPS may be given a point of reference from topographic maps already available.
- (v) It may be required to establish the relationship between social survey results which have been coded with postal codes or street addresses and other geographic areas such as census zones or other areas used in public administration or service planning (Wikipedia, 2010).

1.12.2 Method of Georeferencing: There are various GIS tools available that can transform image data to some geographic control framework, like ArcMap, PCI Geomatica, or ERDAS Imagine. One can georeference a set of points, lines, polygons, images, or 3D structures. For instance, a GPS device will record latitude and longitude coordinates for a given point of interest, effectively georeferencing this point. A georeference must be a unique identifier. In other words, there must be only one location for which a georeference acts as the reference. Images may be encoded using special GIS file formats or be accompanied by a world file. To georeference an image, one first needs to establish control points, input the known geographic coordinates of these control points, choose the coordinate system and other projection parameters and then minimize residuals. Residuals are the difference between the actual coordinates of the control points and the coordinates predicted by the geographic model created using the control points. They provide a method of determining the level of accuracy of the georeferencing process. In situations where

data have been collected and assigned to postal or area codes, it is usually necessary to convert these to geographic coordinates by use of a definitive directory or gazetteer file. Such gazetteers are often produced by census agencies, national mapping organizations or postal service providers. At their simplest, these may simply comprise a list of area codes or place names and another list of corresponding codes, names or coordinate locations. The range and purpose of the codes available is country-specific.

1.12.3 Latitudes and Longitudes: A geographic coordinate system is a coordinate system that enables every location on the Earth to be specified by a set of numbers. The coordinates are often chosen such that one of the numbers represents vertical position, and two or three of the numbers represent horizontal position. A common choice of coordinates is latitude, longitude and elevation. The geographic latitude (abbreviation: Lat., ϕ , or phi) of a point on the Earth's surface is the angle between the equatorial plane and a line that passes through that point and is normal to the surface of a reference ellipsoid which approximates the shape of the Earth. This line passes a few kilometres away from the center of the Earth except at the poles and the equator where it passes through Earth's center. Lines joining points of the same latitude trace circles on the surface of the Earth called parallels, as they are parallel to the equator and to each other. The North Pole is 90° N; the South Pole is 90° S. The 0° parallel of latitude is designated the equator, the fundamental plane of all geographic coordinate systems. The equator divides the globe into Northern and Southern Hemispheres. The longitude (abbreviation: Long., λ , or lambda) of a point on the Earth's surface is the angle east or west from a reference meridian to another meridian that passes through that point. All meridians are halves of great ellipses (often improperly called great circles), which converge at the north and south poles. A line passing near the Royal Observatory, Greenwich (near London in the UK) has been chosen as the international zero-longitude reference line, the Prime Meridian. Places to the east are in the eastern hemisphere, and places to the west are in the western hemisphere. The antipodal meridian of Greenwich is both 180°W and 180°E. The zero/zero point is located in the Gulf of Guinea about 625 km south of Tema, Ghana (Wikipedia, 2010) .

1.13 Concept of the Universal Traverse Mercator (UTM). The Universal Transverse Mercator (UTM) geographic coordinate system is a grid-based method of specifying locations on the surface of the Earth that is a practical application of a 2-dimensional Cartesian coordinate system. It is a horizontal position representation, i.e. it is used to identify locations on the earth

independently of vertical position, but differs from the traditional method of latitude and longitude in several respects. The UTM system is not a single map projection. The system instead employs a series of sixty zones, each of which is based on a specifically defined secant transverse Mercator projection. The Universal Transverse Mercator (UTM) coordinate systems use a metric-based Cartesian grid laid out on a conformal projected surface to locate positions on the surface of the Earth. The UTM system is not a single map projection but a series of map projections, one for each of sixty 6-degree bands of longitude.

The Universal Transverse Mercator coordinate system was developed by the United States Army Corps of Engineers in the 1940s. The system was based on an ellipsoidal model of Earth. For areas within the conterminous United States, the Clarke 1866 ellipsoid was used. For the remaining areas of Earth, including Hawaii, the International Ellipsoid was used. Currently, the world geodetic system 1984 (WGS84) ellipsoid is used as the underlying model of Earth in the UTM coordinate system. The transverse Mercator projection is a variant of the Mercator projection, which was originally developed by the Flemish geographer and cartographer Gerardus Mercator, in 1570. This projection is conformal, so that it preserves angles and approximates shape but invariably distorts distance and area. UTM involves non-linear scaling in both Easting and Northing to ensure the projected map of the ellipsoid is conformal. The UTM system divides the surface of Earth between 80°S and 84°N latitude into 60 zones, each 6° of longitude in width and centered over a meridian of longitude. Zone 1 is bounded by longitude 180° to 174° W and is centered on the 177th West meridian. Zone numbering increases in an eastward direction. Each of the 60 longitude zones in the UTM system is based on a transverse Mercator projection, which is capable of mapping a region of large north-south extent with a low amount of distortion. By using narrow zones of 6° (up to 800 km) in width, and reducing the scale factor along the central meridian by only 0.0004 to 0.9996 (a reduction of 1:2500), the amount of distortion is held below 1 part in 1,000 inside each zone. Distortion of scale increases to 1.0010 at the outer zone boundaries along the equator. In each zone, the scale factor of the central meridian reduces the diameter of the transverse cylinder to produce a secant projection with two standard lines, or lines of true scale, located approximately 180 km on either side of, and approximately parallel to, the central meridian ($\text{ArcCos } 0.9996 = 1.62^\circ$ at the Equator). The scale factor is less than 1 inside these lines and greater

than 1 outside of these lines, but the overall distortion of scale inside the entire zone is minimized (Wikipedia, 2010).

1.14 Economic Resources Concept. Economics might be defined as the study of how society allocates scarce resources (Conrad, 1999). The field of resource economics would then be the study of how society allocates scarce natural resources such as stocks of fish, stands of trees, fresh water, oil, and other naturally occurring resources. A distinction is sometimes made between resource and environmental economics, where the latter field is concerned with the way wastes are disposed of and the resulting quality of air, water, and soil serving as waste receptors (Aje, 1999). In addition, environmental economics is concerned with the conservation of natural environments and biodiversity. Natural resources are often categorized as being renewable or non-renewable. A renewable resource must display a significant rate of growth or renewal on a relevant economic time scale. An economic time scale is a time interval for which planning and management is meaningful (Edward, 2001). The notion of an economic time scale can make the classification of natural resources a bit tricky. A critical question in the allocation of natural resources is “How much of the resource should be harvested (extracted) today?” Finding the “best” allocation of natural resources over time can be regarded as a dynamic optimization problem. In such problems it is common to try to maximise some measure of net economic value, over some future horizon, subject to the dynamics of the harvested resource and any other relevant constraints. The solution to the dynamic optimisation of a natural resource would be a schedule or “time path” indicating the optimal amount to be harvested (extracted) in each period. The optimal rate of harvest or extraction in a particular period may be zero (Conrad, 1999). All natural resources and factors of production that have limited supply at any given price is an economic resource Data from member countries and existing statistical resources would allow the UNCRS to coordinate a global assessment of the quantity and types of emergency provisions required and an analysis of where they are required (UNDP, 2010).

1.15 Land Use Concept. A land ownership and use policy must recognize the fact that the very existence of some people rests on their having access to a piece of land and any attempt to wrest this from them would be strongly resisted. It is in this light that attempt is made to examine Nigerian experience on the land tenure and the land reform issues (Olayiwola and Adeleye, 2006). Human use of land has altered the structure and functioning of the ecosystem (Vitonset, 1997).

The most spatially and economically important human use of land globally includes cultivation in various ways, construction, reserves, protected lands and timber extraction. Recently settlements and sprawl development are becoming large active land use changes especially in the developing regions of the world (Turner et al, 1994). The pattern of land use can provide us insight into the factors that have caused the land cover to change. The urban population in Africa is growing faster than any other continent. It is predicted that by 2030 about 5 billion people, approximately the population size of the entire continent today will be in urban areas and that these figures will be absorbed by the urban areas of the less developed regions (United Nations Population Revision, 2001). The driving forces behind the rapid urbanization in Africa today are the combination of rural-urban migration and natural increase within the towns and cities themselves. Nigeria has been regarded as the most populous nation in Africa with a teeming population of over 130 million crowded over a land area of about 923,000 square kilometres. It has over a hundred cities with population that passes for urban centers. Nigerian cities, notably Lagos, Kano, and Ibadan are among the first one hundred largest cities in the world, which translates into pressures on land and thus high urban dynamics.

The concept of land use (i.e., the way a particular piece of land is utilized by humans and other living organisms), seems at first glance a simple and straightforward subject on the surface. Humans use land to build cities where they live (residential land) and work (commercial land). They use land for growing crops and raising livestock (agricultural land) for food. Forestland provides fuel for energy and lumber for building. Humans use land for play (recreational land) and set some of it aside as exclusive wildlife habitat (wilderness land). But no matter how land is used by humans and other living species, humans ultimately decide how land is used. Given the nature of humans, land use involves a complex interplay of environmental parameters, economic needs and often politics.

1.16 Arboreal Concept. Arboreal study is a dedication to a sustainable future for people and their trees. Arboreal specializes in tree management from the seed to the ancient living monument, individual specimens to entire wood lands. Arboreal describes anything referring to trees or something that is tree like (www.Uk.linkedin.co; www.Yourdictionary.com/arboreal). Trees are an important component of the natural landscape because of their prevention of erosion and the provision of a weather-sheltered ecosystem in and under their foliage. They also play an important

role in producing oxygen and reducing carbon dioxide in the atmosphere, as well as moderating ground temperatures. They are also elements in landscaping and agriculture, both for their aesthetic appeal and their orchard crops (such as apples). Wood from trees is a building material, as well as a primary energy source in many developing countries. A small group of trees growing together is called a grove or copse, and a landscape covered by a dense growth of trees is called a forest. Several biotopes are defined largely by the trees that inhabit them; examples are rainforest and taiga (see ecozones). A landscape of trees scattered or spaced across grassland (usually grazed or burned over periodically) is called a savanna. A forest of great age is called old growth forest or ancient woodland (in the UK). A young tree is called a sapling.

The parts of a tree are the roots, trunk(s), branches, twigs and leaves. Tree stems consist mainly of support and transport tissues (xylem and phloem). Wood consists of xylem cells, and bark is made of phloem and other tissues external to the vascular cambium. Trees may be grouped into exogenous and endogenous trees according to the way in which their stem diameter increases. Exogenous trees, which comprise the great majority of trees (all conifers and almost all broadleaf trees), grow by the addition of new wood outwards, immediately under the bark. Endogenous trees, mainly in the monocotyledons (e.g., palms and dragon trees), but also cacti, grow by addition of new material inwards. Trees with leaves range from being Deciduous to Evergreen. By analyzing the leaf arrangement and shape, a tree can be identified. As an exogenous tree grows, it creates growth rings as new wood is laid down concentrically over the old wood. In species growing in areas with seasonal climate changes, wood growth produced at different times of the year may be visible as alternating light and dark, or soft and hard, rings of wood. In temperate climates, and tropical climates with a single wet-dry season alternation, the growth rings are annual, each pair of light and dark rings being one year of growth; these are known as annual rings. In areas with two wet and dry seasons each year, there may be two pairs of light and dark rings each year; and in some (mainly semi-desert regions with irregular rainfall), there may be a new growth ring with each rainfall. In tropical rainforest regions, with constant year-round climate, growth is continuous and the growth rings are not visible nor is there a change in the wood texture. In species with annual rings, these rings can be counted to determine the age of the tree, and used to date cores or even wood taken from trees in the past, a practice known as the science of dendrochronology. Very few tropical trees can be accurately dated in this manner. Age determination is also impossible in endogenous trees. The roots of a tree are generally embedded in earth, providing anchorage for the

above-ground biomass and absorbing water and nutrients from the soil. However, while ground nutrients are essential to a tree's growth the majority of its biomass – over 90 percent – comes from carbon dioxide absorbed from the atmosphere (see photosynthesis). Above ground, the trunk gives height to the leaf-bearing branches, aiding in competition with other plant species for sunlight. In many trees, the arrangement of the branches optimizes exposure of the leaves to sunlight. Not all trees have all the plant organs or parts mentioned above. For example, most palm trees are not branched, the saguaro cactus of North America has no functional leaves, tree ferns do not produce bark, etc. Based on their general shape and size, all of these are nonetheless generally regarded as trees. A plant form that is similar to a tree, but generally having smaller, multiple trunks and/or branches that arise near the ground, is called a shrub. However, no precise differentiation between shrubs and trees is possible. Given their small size, bonsai plants would not technically be "trees", but one should not confuse reference to the form of a species with the size or shape of individual specimens. A spruce seedling does not fit the definition of a tree, but all spruces are trees.

1.17 Concept of Outcrops. An outcrop is a visible exposure of bedrock or ancient superficial deposits on the surface of the earth. Outcrops do not cover the majority of the earth's land surface because in most places the bedrock or superficial deposits are covered by a mantle of soil and vegetation and cannot be seen or examined closely. However in places where the overlying cover is removed through erosion or tectonic uplift, the rock may be exposed, or crop out. Such exposure will happen most frequently in areas where erosion is rapid and exceeds the weathering rate such as on steep hillsides, mountain ridges and tops, river banks, and tectonically active areas. Bedrock and superficial deposits may also be exposed at the earth's surface due to human excavations such as quarrying and building of transport routes. Outcrops allow direct observation and sampling of the bedrock in situ for geologic analysis and creating geologic maps. In situ measurements are critical for proper analysis of geological history and outcrops are therefore extremely important for understanding the geologic time scale of earth history. Some of the types of information that can only be obtained from bedrock outcrops, or through precise drilling and coring operations, are; structural geology features orientations (e.g. bedding planes, fold axes, foliation), depositional features orientations (e.g. paleo-current directions, grading, facies changes), pale magnetic orientations. Outcrops are also critically important for understanding fossil assemblages, paleo-environment, and evolution as they provide a record of relative changes within geologic strata.

Accurate description, mapping, and sampling for laboratory analysis of outcrops made possible all of the geologic sciences and the development of fundamental geologic laws such as: law of superposition, principle of original horizontality, principle of lateral continuity, and principle of faunal succession. Outcrops can therefore be considered the fundamental element of geologic science (Wikipedia, 2010).

1.18 Squatter Settlements Concept. In Nigeria, squatter settlements can be categorized into two main groups namely the illegally occupied settlements and the illegally developed settlements. Squatter settlement can either at first begin as a commercial or a residential enclave which at the latter stage would evolve into a settlement of mixed activities. Squatting activities on illegally occupied land is peculiar with government acquired lands. For reasons which include non-payment of compensation, project abandonments and change in government personnel, government often times do not put the acquired lands into use. Encroachment begins when the lands are put to agricultural uses by the former owners and their tenants. The problem is further compounded by the insatiable desires of the original land owning families (who own it before government acquisition) who pounce on this land and sell it to unsuspecting buyers. Other group of squatter settlements in this category includes those located on less desirable areas of the city such as wet land, refuse dump, over pipe lines and under high tension electricity transmission line. Illegally developed squatter settlements on the other hand, usually emerged at rural urban fringe as a result of land speculators buying agricultural land and laying it out without provision for adequate roads, facilities for health, education and recreation. The expectation is that government in the future would provide these basic infrastructures. In this circumstance, plots were bought, developed and occupied without necessary approval from Town Planning Authorities (Olanrewaju, 2001). According to Omirin (2003), most Nigerian cities are squalid, because majority is confined to marginal areas without services or infrastructure. In this wise, city dwellers are forced to provide inefficient solutions to their refuse disposal, water supply and other needs. Whatever the type of squatter settlement, the underlying causes is the same- the inaccessibility of developable land to the urban poor.

2.0 METHODOLOGY

The process of data acquisition for this study was accomplished in various stages discussed hence:

2.1 Co-ordinate Mapping. The combination compass-and-rope method enabled the survey party to maintain a straight course in any of the cardinal directions at the commencement of this project work. The use a hand-held Global Positioning System (GPS) units facilitated the determination of latitude and longitude values, as well as elevation values, at each of the stations of interest within the selected study area. The stations of interest are usually fixed at 100m intervals.

2.2 Projected Mapping. This is a fast and accurate method of locating the co-ordinates of stations at the 100m point intervals. Knowing the co-ordinates of any one station of interest, the co-ordinates of the remaining stations can be predicted using simple co-ordinate addition and subtraction based on the standard relationship expressed below:

$$100\text{m} \approx 3.24''$$

It is a generally accepted fact that latitude increases due north and decreases due south, whilst longitude increases due east and decreases due west. Thus adding $3.24''$ to a reference latitude value represents the next 100m spot along a constant longitude in a northerly direction. Subtracting $3.24''$ to a reference latitude value represents the next 100m spot along a constant longitude in a southerly direction. Adding $3.24''$ to a reference longitude value represents the next 100m spot along a constant latitude in an easterly direction. Subtracting $3.24''$ to a reference longitude value represents the next 100m spot along constant latitude in a westerly direction.

2.3 Dataset of Study:

2.3.1 Topographic (i.e. x, y, z) Dataset. At 100m spacing between stations of interest for the 15km^2 of the study area, there are 1581 survey points where latitude (x), longitude (y), and elevation (z) information were measured. The complete x, y, z plus their UTM equivalent dataset is presented in Appendix A.

2.3.2 Economic Resources Georeferenced Dataset. The x, y, z attributes of a recognized economic resource item (in this case the Shea butter tree) in the area of study is presented in Appendix B.

2.3.3 Land Use Georeferenced Dataset. The x, y, z attributes of recognized land use apportionement in the area of study is presented in Appendix C.

2.3.4 Arboreal Georeferenced Dataset: The x, y, z attributes of prominent arboreal resource item (i.e. trees greater 10m in height) in the area of study is presented in Appendix D.

2.3.5 Outcrops-on-Land Georeferenced Dataset. The x, y, z attributes of outcrops-on-land in the area of study is presented in Appendix E.

2.3.6 Outcrops-in-Stream-Channels Georeferenced Dataset. The x, y, z attributes of outcrops-in-stream-channels in the area of study is presented in Appendix F.

2.3.7 Squatter Settlements Georeferenced Dataset. The x, y, z attributes of squatter settlements in the area of study is presented in Appendix G.

3.0 DATA ANALYSIS AND RESULT PRESENTATION

3.1 Conversion of Latitude and Longitude to the Universal Traverse Mercator (UTM) System. The data collected from the field where all longitude and latitude representation, which in this case are in degree ($^{\circ}$), minute ($'$) and seconds ($''$). These data was acquired by means of the hand-held e-Trex Garmin GPS device. In using the TatukGIS coordinator calculator, the following properties were considered. The original datum was set as WGS 84 (World Geodetic System 1984) with the projection being Geodetic (unprojected) and the output projection being in UTM, the datum used was Minna, Nigeria Zone 32. The TatukGIS coordinate calculator was used in the data conversion in this study. By convention, the WGS 84 geoid describe Earth as an ellipsoid along North-South axis with an equatorial radius of $a = 6378.137\text{km}$ and an orbital eccentricity of $e = 0.0818192$. The resulting UTM values corresponding to the conventional latitude and longitude values are as shown in the various Appendices.

3.2 Production of Site-Specific Topographic Map. The site-specific topographic map for this project work was generated using the Golden Surfer 8 software. Initially, the Co-ordinate Calculator software was used to convert the 1581 georeferenced stations of interest of the 15km^2 area from their conventional latitude, longitude, elevation (x, y, z) attributes to their equivalent UTM attributes. These UTM values were exported to Golden Surfer 8. When in Golden Surfer 8 work mode, click on “Map” to show a dialogue, and then click on “Contour Map”, then “New

Contour Map.” Upon assessing the exported UTM dataset, the Golden Surfer 8 generates a topographic map of the designated study area. Fig.1 is the resulting contour map of the study area. The contour map of Fig.1 was produced at an interval of 10m. It is observed in Fig.1 that, overall, terrain elevation trends generally vary between 175m and 215m. The lower terrain elevations are observed in the southern portion of the map whilst the higher terrain elevations are observed in the northern portion of the map of Fig.1. Thus, elevation increases (i.e. topography becomes more steep) as one moves due north along the study area. This fact corroborates the observations of Adesoye (1986). Intense contour closures in the northeastern sector of Fig.1 are indicators of the presence of numerous depressions and prominences whereas the scattered contour signatures in the southerly portion of Fig.1 are indicators of flat lowlands. The twin contour closures between UTM 1054500 and 1055000 on the western edge of the survey area is a prominent stream channel that flows out of the study area. A prominent water hole can be seen at UTM 217500 in the deep south of the survey area. Another water hole is also observed at the northeast of the survey area.

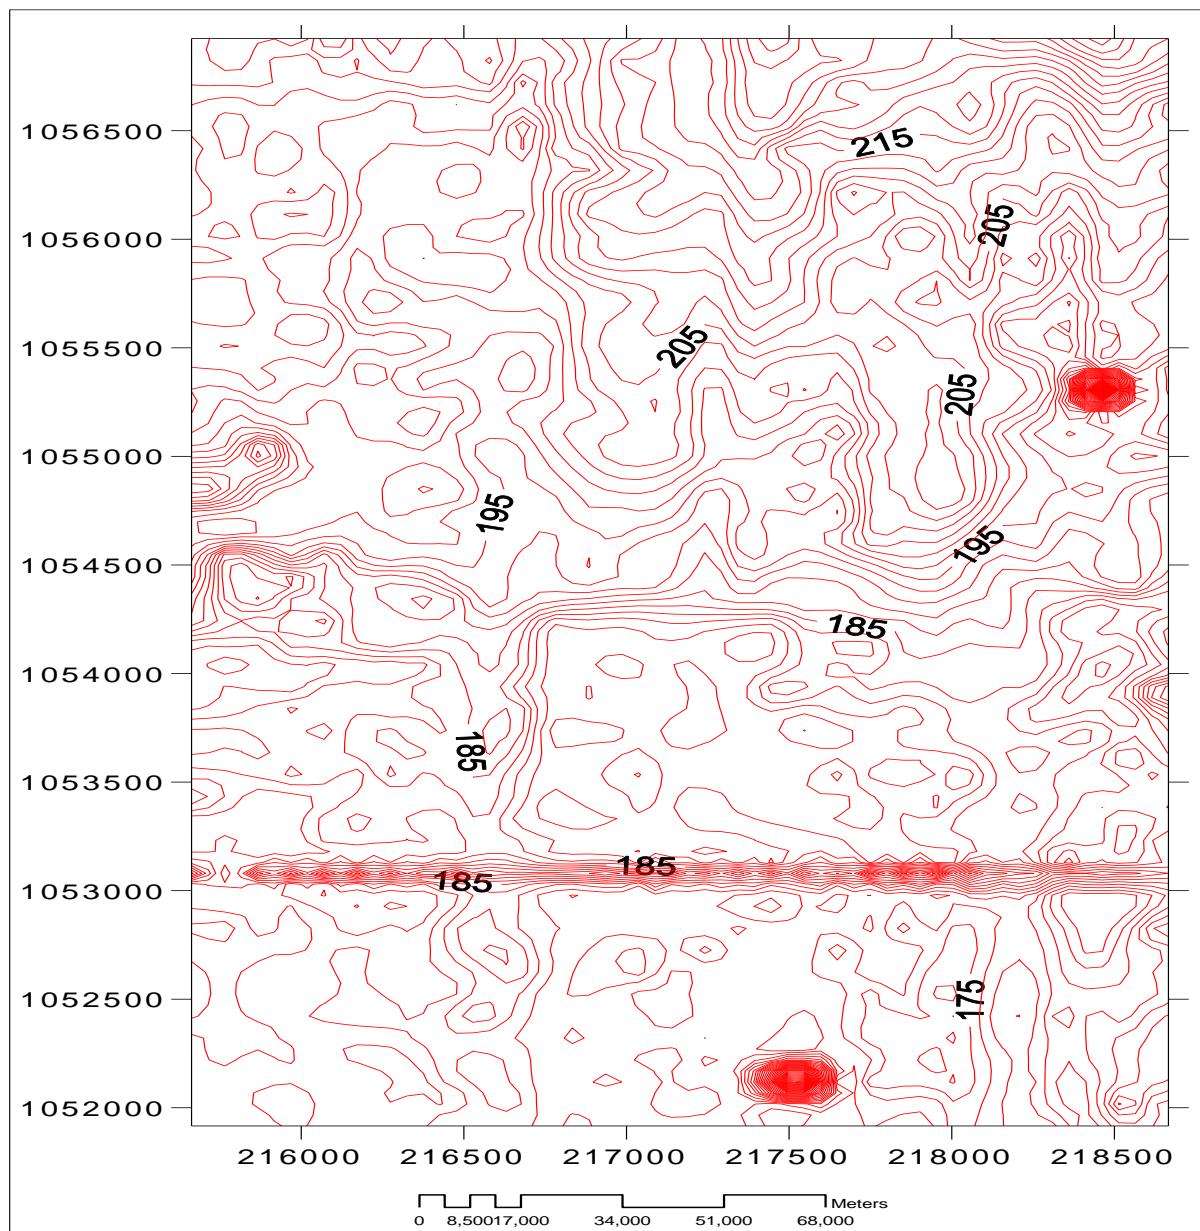

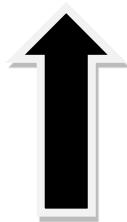

Fig.1. Topographic map of the 15km² area of study

3.3 Creation of a Geographic Information System (GIS) for the Area of Study. Initially, the database showing all the attributes of field data was created conventionally with a Management Information System (MIS) database application, Microsoft Excel. Later, the database was exported to the Arcview GIS platform. The GIS application has the potential of creating a database which shows the spatial information of any geographical locations on a digital map. The multiple field creation enables the GIS application to function with better user interphase coordination in terms of interactive abilities. After these fields were created in correspondence to each data point, then, the data was inputted into the database progressively such as to create a precise database showing the attributes of the spatial points located on the map. The various columns for the recording of the different attributes of these sources were created afterwards before the data were inputted into these fields. Fig.2 shows the composite GIS map of the area of study.

4.0 DISCUSSION, CONCLUSION AND RECOMMENDATION

4.1 Discussion. For the topographic map creation, data were acquired at 1,581 points of interest within the 15 km² gridded area. At 100m spacing between stations, this was considered sufficiently detailed for this study. An improvement over the “rope-and-compass” station-fixing process was the “projected mapping” approach incorporated during this study. Georeferencing economic resources, land use, arboreal, outcrops-on-land, outcrops-in-stream-channels, and squatter settlements information was not necessarily a function of the 100m station spacing. The major economic resource item identified in the area of study was the Shea butter tree and about 118 Shea butter trees were duly identified in the study area. Land use information in the area of study concerns the portions that were “active” farmlands (i.e. evidence of cultivation seen) and arboreal information concerns georeferencing trees that were at least 10m tall; about 131 trees were thus identified. Outcrops seen on land and in stream beds were considered important geological markers for subsequent detailed studies. For this study, squatter settlements were not

considered under the land use concept, so a separate information profile was created for it; about 17 different squatter settlements were identified in the area of study. All of the x,y,z dataset collected during the course of this exercise were converted to their corresponding UTM equivalent whilst production of the site-specific topographic map was aided by the Golden Surfer 8 software. The composite GIS map and the specific GIS layers of the study area were produced by use of the Arcview GIS software and the results are as shown in Figs1 to 8. In the ArcView GIS environment, distribution of the economic resource item identified for this study (i.e. the Shea butter tree) at the study area can be viewed by highlighting only the icon or legend corresponding to “Economic Resource (Shea butter tree)” as seen in Fig.3. It is also observed that all of the Shea butter trees identified during the course of this study were found at the northern portion of the study area. Fig.4 shows the enabled land use GIS layer map of the area of study whilst Figs 5 to 8 show the enabled arboreal GIS layer map of the area of study, the enabled outcrop-on-land/outcrops-in-stream-channels GIS layer map of the area of study, the enabled outcrops-in-stream-channels/outcrop-on-land GIS layer map of the area of study, and the enabled squatter settlements GIS layer map of the area of study.

4.2 Conclusion. The area identified as N09°30'25.20'', E006°26'11.34''; N09°33'07.20'', E006°26'11.34'' and N09°30'25.20'', E006°24'34.14''; N09°33'07.20'', E006°24'34.14'' at the Gidan Kwano Campus of the Federal University of Technology, Minna, can now be represented by the detailed topographic map of Fig.1. This map should form an integral component of the database of the Federal University of Technology’s Physical Planning and Development Unit (PPDU). Though the horizontal and vertical axes of Fig.1 are given in UTM values, the TatuukGIS coordinate calculator can be used to determine the corresponding x and y values at the appropriate locations on the map. Following on the heels of the creation of the topographic map for the study area, a composite GIS map made up of six different layers has now been created for the study area as can be seen in Fig.2. Figs 3 to 8 are for the different enabled layers. Overall, the Shea butter trees are scarce in the area of study; the good news is that they can be cultivated on a large scale. Agricultural activities are spread throughout the expanse of the study area, tall trees are scarce, and outcrops are scattered throughout. Seventeen different squatter settlements in the area of study indicate the density of illegal occupants in just 15km² of the total 100km² land area of the Gidan Kwano Campus of the Federal University of Technology, Minna.

4.3 Recommendation. Detailed topographic map creation for a 15km² area of the Gidan Kwano Campus of the Federal University of Technology, Minna, was only a pioneering effort in this regard. It is recommended that further and expanded studies targeting the whole of the Gidan Kwano Campus be carried out. As well as this requirement, a comprehensive and versatile GIS database for the whole of the Gidan Kwano Campus should be produced and archived.
